Patients and Methods: Fourteen consecutive unselected dyslipidemic patients, with previous adverse cardiovascular event (seven acute coronary syndrome, three stroke, two peripheral artery disease, one retinal occlusion, one sudden hypoacousia) and multiple comorbidities (six hypertensives, no diabetics), were treated daily with 2000 mg of nicotinic acid/40 mg Laropiprant and optimal statin therapy, in addition to cardiovascular medications according to current guidelines, for 6 months. The Clot Lysis Time (CLT) and the blood levels of triglycerides, HDL, LDL cholesterol and Lp(a), were determined before (T0) and after 6 months of treatment (T1). CLT was performed as lysis time of tissue factor-induced clots exposed to exogenous t-PA (Lisman et al., 2006); triglycerides, HDL, LDL levels were analyzed by chromogenic assays and Lp(a) by nephelometric measurement.
Results: The Clot lysis time (CLT) was significantly decreased after treatment (median (range) T0: 61 min (51–123.9) vs. T1: 56 min (44–76); $P < 0.05$). The average decrease of CLT was 11% (95%CI 4–18). The treatment reduced significantly the levels of triglycerides (median (range) T0: 98 mg/dL (65–201) vs. T1: 76 mg/dL [61–148]), LDL cholesterol (median (range) T0: 111 mg/dL (76–182) vs. T1: 90 mg/dL (54–118) $P < 0.05$) and Lp(a) (median (range) T0: 1155 mg/dL (560–1870) vs. T1: 677 mg/dL (202–1030) $P < 0.005$). As expected, HDL cholesterol levels significantly increased (median (range) T0: 53 mg/dL (33–96) vs. T1: 68 mg/dL (42–107);$P < 0.05$). The average decrease of concentration of triglycerides, LDL and Lp(a) was respectivly 27% (95% CI: 18–36%), 24% (95% CI: 16–32%), and 39% (95% CI: 26–51%) whereas the average increase of HDL cholesterol was 30% (95% CI: 11–50%).A significant correlation ($P < 0.05$) was found between CLT, triglyceride and LDL.
Conclusion: A treatment with nicotinic acid/laropiprant in patients with elevated levels of lipoprotein (a) may provide additional benefit on fibrinolysis.

PB 1.35-1

A fusion peptide binding to tissue factor pathway inhibitor (TFPI) inhibits both plasma- and platelet TFPI

Dockal M[1], Thomassen ST[2], Heinzmann A[2], Winckers K[2], Hartmann R[1], Hackeng TM[2], Rosing J[2] and Scheiflinger F[1]
[1]*Baxter Innovations GmbH, Vienna, Austria;* [2]*Maastricht University, Maastricht, The Netherlands*

Background: TFPI is a Kunitz-type protease inhibitor that inhibits both FXa and TF-FVIIa and which is an important physiological inhibitor of the extrinsic coagulation pathway. Plasma contains various truncated forms of TFPI, which are poor inhibitors of FXa and FVIIa, and full length TFPI (0.25–0.5 nM) which is the physiologically important form of TFPI. Platelets also contain full length TFPI which is released to plasma when the platelets become activated thus increasing the full length TFPI concentration in plasma 50–75%. Direct inhibition of TFPI in hemophilia models with blocking antibodies, aptamers or peptide inhibitors mitigates bleeding complications and may become an important approach in hemophilia treatment
Aims: To compare the effectivity by which a TFPI binding fusion peptide with TFPI antagonist activity inhibits the anticoagulant activity of plasma- and platelet TFPI in model systems and in plasma.
Methods: Platelets isolated from blood samples of different donors were activated with convulxin and spun down by centrifugation. The TFPI present in the supernatant was quantified with an ELISA and was taken as source of platelet TFPI. Recombinant TFPI, either glycosylated or non-glycosylated, was taken as source of plasma TFPI. The functional activities of plasma- and platelet TFPI and the effect of fusion peptide as TFPI antagonist thereon were compared in model systems (FXa and TF-FVIIa-catalysed FX activation) and in plasma (TF-triggered thrombin generation).
Results: Detailed kinetic analysis showed that platelet-derived TFPI and recombinant TFPI were equally potent inhibitors of TF-FVIIa-catalysed FX activation in models systems. The TFPI antagonistic fusion peptide blocked the anticoagulant activity of plasma- and platelet TFPI in the model system with similar IC50 values that were in the low nM range. Recombinant TFPI and platelet-derived TFPI also inhibited TF-triggered thrombin generation in TFPI-depleted plasma with identical activities and the anticoagulant activities of both forms of TFPI were blocked by TFPI antibodies as well as the TFPI antagonistic fusion peptide. The fusion peptide also enhanced thrombin generation in TFPI-depleted plasma reconstituted with platelets which is indicative of specific inhibition of platelet TFPI. Fusion peptide titrations of thrombin generation in platelet-poor plasma (PPP) and platelet-rich plasma (PRP) showed that the peptide enhanced thrombin generation in PPP 3–4 fold with a half maximal effective concentration (EC50) of 2 nM and in PRP 2-fold with an EC50 of 8 nM. Thrombin generation in PRP to which an inhibitory FVIII antibody was added to simulate PRP of a haemophilia patient was enhanced threefold by both the fusion peptide and TFPI antibodies.
Summary and Conclusions: Plasma- and platelet TFPI exhibit similar anticoagulant activities in the inhibition of TF-FVIIa catalysed FX activation in a model system and in the down-regulation of TF-triggered thrombin generation in plasma. A TFPI antagonistic fusion peptide enhances thrombin generation in PPP and PRP both in the absence and presence of inhibitory FVIII antibodies by blocking the anticoagulant activities of platelet- as well as plasma TFPI. Our observation supports the notion that targeting TFPI with TFPI inhibitors is a promising novel strategy to mitigate the bleeding risk of haemophilia patients.

PB 1.35-2

The incidence and impact of intracranial hemorrhages within a hemophilia and non-hemophilia population

Li-McLeod J, Xiong Y, Ito L and Epstein J
Baxter Healthcare Corporation, Westlake Village, CA, USA

Background: Intracranial hemorrhage (ICH), while rare, is a very serious complication of hemophilia. Understanding the incidence and outcomes of individuals with hemophilia who have had an ICH may help emphasize the importance of lowering ICH rates.
Aims: The objective of this analysis was to assess the incidence and outcomes of hemophilia patients who suffer an ICH compared to a non-hemophilia population to better understand the risk associated with ICH complications.
Methods: A retrospective, case-control analysis was undertaken using the *Truven Analytics Marketscan® Database*, which contains medical claims data from US commercial health plans representing approximately 130 million covered lives. Using data from years 2002–2011, male patients with ICD-9 diagnosis codes of 286.0 or 286.1 for hemophilia were selected and compared to a male only, random sample of non-hemophilia patients (excluded ICD-9 code 286.x). In addition to the incidence of ICH, inpatient visits, length of stay (LOS) and hospitalization costs were compared between the two groups. ICD-9 diagnosis codes 430, 431, and 432 were used to identify ICH.
Results: There were 11,267 persons with hemophilia in the database, of these 79% were Hemophilia A, 13% Hemophilia B, and 8% had codes for both hemophilia A and B. The non-hemophilia sample consisted of 103,620 individuals. Within the hemophilia sample, 217 (1.9%) had an ICH diagnosis, compared to 179 (0.2%) of the non-hemophilia sample ($P < 0.0001$). The mean age of patients with an ICH was 45.7 and 40.9 for the hemophilia and non-hemophilia population, respectively ($P < 0.05$). One hundred and forty (1.2%) patients in the hemophilia sample had an ICH inpatient visit with a median LOS of 7 days. In the non-hemophilia sample, 101 (0.1%) had an ICH inpatient visit with a median LOS of 6 days. The median (interquartile range) cost for an inpatient ICH visit among the hemophilia sample was $24,207 ($12,688–$68,728), while the median cost for the non-hemophilia sample was $19,255 ($11,804–$47,653).
Conclusions: These results indicate that individuals with hemophilia have approximately a 10-fold increased incidence of ICH compared to a non-hemophilia sample. This research also demonstrates the significant impact of ICH both in terms of hospital length of stay and cost. Given guidelines recommend ICH patients are treated with high-dose Factor concentrates for at least 10–14 days and are then placed on long-term prophylaxis, the hospitalization costs identified in this analysis do not reflect the full economic burden of ICH. Further research to better understand the long-term impact of ICH should be conducted to ensure that appropriate strategies are employed to lower the relative incidence of ICH in a hemophilia vs. non-hemophilia population.

PB 1.35-3

Variation in effect of DDAVP in mild haemophilia patients with an Asn637Ser mutation

Mauser-Bunschoten E, Franssen van de Putte DE, Fischer K, Van Galen KPM, Rosendaal G and Schutgens REG
UMCUtrecht, Utrecht, The Netherlands

Background: In mild haemophilia desmopressin acetate (1-deamino[8-Sarginine]-vasopressin, DDAVP) can be used for the treatment of bleedings. DDAVP increases FVIII and von Willebrand factor (VWF) 2–6 fold through endogenous release. Effect of DDAVP varies between patients and but it is suggested that it is dependent on the mutation causing haemophilia.

In our haemophilia centre a large cohort of patients with Asn637Ser (1910A>G) mutation causing mild haemophilia A is known. In individual patients the effect of intravenous DDAVP is routinely tested

Aim: To retrospectively investigate the variability in FVIII raise after DDAVP infusion in this cohort of patients.

Material and Methods: All male patients known with mutation Asn637Ser, and their relatives from maternal side suffering from mild haemophilia treated at the Van Creveldkliniek were included. Baseline characteristics including residual FVIII level, VWF level and blood group, FVIII raise after 30–60 min of intravenous infusion of 0.3 μg/kg, DDAVP age at test, were collected. DDAVP was infused in 20–30 min. When FVIII levels were measured at two time points between 30 and 60 min after end of infusion, the highest levels was used for analysis.

Results: In 77 patients with mild haemophilia caused by mutation Asn637Ser, a DDAVP test has been done, of which 68 could be analysed. The lowest baseline FVIII level varied greatly between 0.06 and 0.36 IU/dL, mean VWF was 0.101 IU/dL (IQR, 0.76–112). Forty-nine percent had blood group O, 23% A, 7% AB and 5% blood group B. Low VWF levels were associated with lower FVIII baseline levels. No effect of blood group on FVIII levels was found. The mean age at DDAVP test was 21.7 years (IQR 7–34). After DDAVP the mean level was 101.7 IU/dL (IQR 80–124)

The mean raise in FVIII levels was 0.78 IU/dL (IQR 57–98). Effect of DDAVP varied greatly from 2 to 10 fold increase of FVIII levels 30–60 min after end of infusion. Higher baseline FVIII was associated with a higher absolute raise in FVIII after DDAVP. After correction higher age appeared to have a positive effect on outcome, no effect of baseline VWF and blood group on outcome was seen.

Summary/Conclusion: In this group of patients with mild haemophilia caused by mutation Asn637Ser, baseline FVIII levels varied greatly. The effect of intravenous DDAVP varied between patients and was associated with baseline FVIII and age. Patients with higher baseline FVIII and older patients showed a better response to DDAVP

PB 1.35-4

Major surgery in haemophiliacs: Istanbul experience

Zulfikar B[1], Tuysuz G[2], Ozdemir N[2], Kilicoglu O[3], Aras N[4] and Taser O[5]

[1]Cerrahpasa Medical Faculty and Oncology Institute, Istanbul University; [2]Pediatric Hematology Department, Cerrahpasa Medical Faculty, Istanbul University; [3]Department of Orthopedics and Traumatology, Istanbul University; [4]Department of Urology, Istanbul University,; [5]The Haemophilia Society of Turkey, Istanbul, Turkey

Background: Surgery in patients with haemophilia can present a range of challenges to physicians.

Aim: To determine the perioperative management and outcome of heamophilia A and B patients during major surgical procedures.

Methods: Data pertaining to major surgeries from 1997 to 2012 at our center were retrospectively analysed. Patients with inhibitors were excluded from the study. All operations were elective and a plan for management of hemostasis was prepared for each patient.

Results: During this period 80 major surgeries were performed in 56 haemophiliacs (52 with haemophilia A and four with haemophilia B). Their median age was 29 years and range was 3 months–72 years. Most of the haemophiliacs (34/52 haemophilia A and 2/4 haemophilia B) had severe disease (Factor level < 1%). The majority of the surgeries were orthopedic procedures (n:64); there were eight urological and three neurosurgical procedures, three patients had adeno-tonsillectomy, one had abdominal abscess drainage and one had apendectomy. Eight orthopedic surgeries and one urologic surgery included two different operations at the same procudere. All patients were treated with intravenous bolus factor replacement therapy pre- and post-operatively. No severe life threating bleeding occured in any of the patients, 4% of the patients had mild bleeding after surgery. One severe haemophiliac developed post operative hematoma on related knee after total endoprosthesis of hip and left knee at post-operative 24th day while he was still on daily factor replacement treatment; the bleeding was controlled with extra factor infusion. Another haemophilia A patient (moderate) developed macroscopic haematuria after left kidney nephrolithiasis operation at 15th day of surgery but resolved in 2 days with an extra factor therapy. One severe haemophilia A patient who bled at the 7th day of left knee total endoprosthesis developed low responding inhibitor following operation. The bleeding was controlled with by-passing agents. One right knee prothesis insertion operation had a infection complication at the operation site which ended up with amputation of the affected leg. Another knee prothesis insertion operation was also infected and resulted with extraction of prothesis and arthrodesis of the affected ankle.

Conclusion: Our results showed good hemostasis plan with no major bleeding. Inhibitor development is currently the most severe complication in patients with haemophilia treated for surgical procedures. Three haemophiliacs developed inhibitors, two of them were low titer inhibitors, one haemophiliac needed long-term use of by-passing agents. The incidence of inhibitor development following intensive treatment for surgery was 5%. Wound infections are also an important problem after major surgeries, postoperative infection occured in two of our patients (2.5%) and resulted with amputation in one of them. Major surgical operations can be performed in haemophiliacs with a right hemostasis plan and the incidence of hemorrhage is low. Experienced physicians and centers have key role in operation of heamophiliacs and operations should be done without delay.

PB 1.35-5

What we can learn from real-life clinical experience data from a post authorization safety surveillance in PUPs treated with antihemophilic factor (recombinant), plasma/albumin free method in Japan

Taki M[1], Hanabusa H[2], Fukutake K[3], Matsushita T[4], Shima M[5], Shirahata A[6] and Pass A[7]

[1]St. Marianna University School of Medicine Yokohama City Seibu Hospital, Yokohama; [2]Ogikubo Hospital; [3]Tokyo Medical University, Tokyo; [4]Nagoya University Hospital, Nagoya; [5]Nara Medical University, Kashihara; [6]University of Occupational and Environmental Health Japan, Kitakyushu; [7]Baxter, Tokyo, Japan

Background: The treatment of young hemophilia A patients has been improved by the availability of safe FVIII products and the adoption of routine prophylaxis, but a major complication still remains the development of inhibitors to FVIII. Data on previously untreated patients (PUPs) is valuable in delineating the natural history of hemophilia treatment. The real-life clinical practice during the early treatment phase of hemophilia A in Japan has been documented by ADVATE (rAHF-PFM) PUPs study since 2007 under Japanese ordinance Good Post-Marketing Study Practice (GPSP).

Aims: To investigate safety ie, adverse events namely inhibitors, and efficacy in PUPs.

Methods: This prospective, multicenter, open-label, observational surveillance cohort study was initiated at 63 sites on February 2007 to investigate PUPs of any age and disease severity, with ≤ 3 exposure days (EDs) at study entry, who were prescribed rAHF-PFM. Data were collected every 6 months for over 2 years using the electronic data-capture system (EDC).

Results: As of 31 December 2012, data for 116 PUPs (0 ED:97, 1–3 EDs:19) out of 119 enrolled patients from 63 sites were available. Fifty eight (50%) of 116 patients had undergone a greater than two-year observation period. Eighteen patients dropped out within 2 years of observation (adverse events:7, lost to follow up:4, death:1, others:6). Seventy-four percent of patients had FVIII < 1%, 8% had 1 ≤ FVIII ≤ 2, 6% had FVIII > 2–5% and 12% had FVIII > 5%.

The median age at entry was 0.8 (range 0–81 years). All are Asian male. Forty-two percent of 116 patients had a family history of hemophilia and 8% had a family history of inhibitors. The median observation periods were 24.3 months. Fifty-eight percent had over 50 infusions (median: 80, 1–2092 infusions) on study.
The median age of diagnosis of hemophilia A was 0.33 in subjects who developed inhibitors (Inh) and 0.66 in subjects with no inhibitor (no Inh). The median age of first bleeds was 0.58 (Inh), 0.61 (no Inh) and the median age of severe bleeds was 0.37(Inh) and 1.13 (no Inh). The median age of first exposure to rAHF-PFM was 0.68 (Inh) and 0.88 (no Inh).
Ninety-four (81%) of 116 started on-demand and 57 (61%) of 94 moved to prophylaxis. At the worst efficacy evaluation during observation period, excellent/good rating was observed for 88.6% on prophylaxis and 90.7% on demand.
At the time of last report, 20 patients (17.24%, 95% CI: 10.86, 25.36) developed an inhibitor (seven high-, 13 low titer at inhibitor diagnosis). In nine of 20 inhibitors have disappeared. The adjusted odds ratio in risk of inhibitor development were family history of hemophilia: 0.91 (0.240–3.462), family history of inhibitors:12.518 (2.561–61.178), ICH:2.600 (0.684–9.887), severe bleeds: 2.040 (0.595–6.993), catheter insertion: < 0.001 (< 0.001–> 999.999), hemophilia severity:1.132 (0.194–6.589).
Conclusions: The safety profile of rAHF-PFM in Japanese PUPs appears consistent with previous reports with an inhibitor rate of 17.24% in this report. The adjusted odds ratio in inhibitor development was significantly higher in subjects with a family history of inhibitor.

PB 1.35-6
Costs and utilization of haemophilia A and B patients with and without inhibitors

Armstrong PE[1], Malone DC[1], Krishnon S[2] and Wessler J[3]
[1]Strategic Therapeutics, LLC, Tucson, AZ; [2]Biogen Idec, Weston, MA; [3]Naval Medical Center, Portsmouth, VA, USA

Background: Haemophilia is a costly disease resulting in bleeding complications, joint damage, and use of expensive factor therapies. Descriptive analysis of patient populations may provide valuable insight into the delivery of care and health resource utilization.
Aim: To evaluate the characteristics and health system costs among patients with haemophilia A and B with and without inhibitors over a 5 year period.
Methods: This was a retrospective, observational study utilizing medical and pharmacy electronic medical records and administrative encounters/claims data tracking US patients between 2006 through 2011 for up to 5 years. Patients with International Classification of Diseases, Ninth revision (ICD-9) diagnosis codes only for haemophilia (ICD-9 code 286.0 for haemophilia A (factor VIII deficiency) and 286.1 for haemophilia B [factor IX deficiency]) were identified. Eligible patients must have received clotting factors at least twice during the study period. Inhibitor patients were characterized by the utilization of one of two bypassing agents: activated prothrombin complex or factor VIIa on two or more distinct dates. Severity was classified as mild (5–40% normal factor activity), moderate (1–5% normal factor activity), or severe (< 1% normal factor activity). Research data was derived from an approved Naval Medical Center, Portsmouth, VA IRB NMCP.2012.0016 protocol.
Results: Overall, there were 160 haemophilia A patients and 54 haemophilia B patients identified. Of this group, seven were designated as inhibitor patients (five with haemophilia A and two with haemophilia B). The mean age (SD) in years was 2.6 (± 3.9), 8.6 (± 8.8), 11.2 (± 12.2) for patients with inhibitors, patients with haemophilia A without inhibitors, and patients with haemophilia B without inhibitors, respectively. Haemophilia A patients without inhibitors reported 65 (41.9%) as being severe, 19(12.3%) as moderate, and 71 (45.8%) as mild. Haemophilia B patients without inhibitors reported 9 (17.3%) as being severe, 1(14.3%) as moderate, and 2 (28.6%) as mild. All inhibitor patients had been hospitalized in the previous 5 years compared to 64 (41.3%) with haemophilia A without inhibitors and 22 (42.3%) with haemophilia B without inhibitors. The median aggregate cost per year (including factor and health resource use) was $325,780 for patients with inhibitors compared to $98,334 for haemophilia A patients without inhibitors and $23,265 for haemophilia B patients without inhibitors.
Summary/Conclusions: The results of this analysis suggest that while the frequency of inhibitors within the haemophilia cohort was low, there was a higher frequency of hospitalizations and the associated median aggregate costs per year are three-fold higher than those patients without inhibitors. In contrast, haemophilia B patients experience less severe disease and account for lower aggregate yearly costs compared to either patients with haemophilia A or patients with inhibitors.
The views expressed in this article are those of the authors and do not necessarily reflect the official policy or position of the Department of the Navy, Department of Defense, or the United States Government.

PB1.36 – Haemophilia A: Clinical – II

PB 1.36-1
Cognitive dysfunctions and cerebral microbleeds in adult patients with haemophilia A and B: the role of cardiovascular disease

Zanon E[1], Brandolin B[2], Manara R[3] and Amodio P[4]
[1]Haemophilia Center, 2Chair of Internal Medicine; [2]University Hospital of Padua; [3]Neuroradiology, Department of Neuroscience, University Hospital of Padua; [4]Department of Clinical and Experimental Medicine, University of Padua, Padua, Italy

Background: In children with haemophilia a decrease in intellectual function and in their face-spatial and motor skills was described. Moreover, a lack of language and language-related activities was reported. All these cognitive dysfunctions seemed to be related to previous cerebral microbleeds (CM). Studies that provide information about the cognitive condition of adult patients with haemophilia are lacking.
Aims: To measure the neuropsychological profile in a group of adult patients with haemophilia A and B; to verify the presence of asymptomatic CM; to identify some correlation between CM and cognitive dysfunctions; to assess the possible role of several contributing factors (i.e. severity of haemophilia, type of therapy, comorbidity) in determining cognitive dysfunctions.
Methods: After informed consent, 49 adult (age, 42 ± 15 years) patients with haemophilia A and B (31 severe and 18 mild), without inhibitors and consecutively evaluated at the Haemophilia Centre of Padua, were enrolled. Each patient underwent: (i) a 'Short Neuropsychological Test' assessing the following cognitive functions: learning, episodic memory, working memory, psychomotor speed, selective and divided attention, concentration, reasoning, and executive functions; (ii) a Nuclear Magnetic Resonance (NMR) of the brain to evaluate changes in signal intensity within the white matter on T2-weighted images, areas of brain atrophy, or haemorrhagic lesions. Results were standardised on a control group matched for age, sex, and cultural profile.
Results: Patients suffering from hemophilia A and B presented with a reduction of the overall cognitive performance (OCP), expressed by the Z-PSI index (−1.18 CI 95%: −1.34 and −0.03). In particular, the most compromised aspects were lack of both memory and verbal fluency. According to the OCP, no significant difference between severe and mild haemophilia was observed. Nevertheless, the score of the memory tests tended to be worse in severe haemophilia patients than in patients with mild haemophilia. The OCP was similar between

patients undergoing 'on demand' treatment and patients undergoing 'prophylactic' treatment (Z-PSI index -0.32 ± 0.48 vs. -0.13 ± 0.63; $P = 0.37$). According to risk factors for cerebrovascular disease, the OCP was significantly correlated with the presence of coronary artery disease ($P = 0.02$). As for NMR findings, available in 40 patients because nine of them refused to give informed consent, the presence of CM was associated with a worse OCP. Specifically, the CM episodes were inversely related to the OCP ($R = -0.32$ $P < 0.05$). CM was significantly associated with the presence of cerebrovascular risk factors (Fischer Test $P = 0.018$). Finally, patients undergoing 'prophylactic' treatment showed a better OCP than patients undergoing 'on demand' treatment.

Conclusions: In adult patients with hemophilia A and B a high prevalence of cognitive dysfunctions was observed. Moreover, a correlation between OCP reduction and CM was found. Hence, identifying each individual cerebrovascular risk in order to tailor the most adequate treatment to the needs of each patient is of crucial importance.

PB 1.36-2

Decreased FVIIIa stability of mild Hemophilia A mutation R527W explains discrepancy between two chromogenic method applications using different FX activation times

Bryngelhed P[1], Oldenburg J[2], Pavlova A[2], Hillarp A[3], Strandberg K[3] and Rosén S[1]

[1]Rossix, Molndal, Sweden; [2]University Clinic Bonn, Bonn, Germany; [3]University of Lund, Malmö, Sweden

Several mutations for mild Hemophilia A are reported to cause discrepant results between one-stage clotting methods: vs. two-stage clotting and chromogenic methods.

In an oligocenter study on plasmas from patients with mild Hemophilia A, two sites used the chromogenic Coatest SP4 FVIII kit, utilizing either 5 or 10 min FX activation times. There was an overall high agreement in results but the site using a 5 min FX activation time obtained significantly higher FVIII activities for ten samples, representing the five different mutations R527W, R531H, R531C, G479R, V663A.

Six of the ten samples were sourced from individuals with the R527W mutation and mean (SD) FVIII activities were 0.25 ($\pm$ 0.03) and 0.12 ($\pm$ 0.01) IU/mL when using 5 and 10 min FX activation times, respectively. Hence, a 5 min activation time resulted in about two-fold higher FVIII activities.

A study on FXa generation vs. time demonstrated that the time to reach a plateau level of FXa, indicating completely inactivated FVIIIa, on analysis of two R527W plasma samples was about half as compared to a normal reference plasma and a T295A plasma, the latter showing similar FVIII activity assignment at the two sites.

Using a 10 min FX activation time will therefore result in relatively more FXa being generated for normal plasma as compared to R527W plasmas and accordingly to a lower FVIII activity assignment of R527W plasmas.

FVIII:Ag was 0.75 ($\pm$ 0.09) IU/mL for the six R527W samples and hence within the normal range, whereas FVIII:Ag was 0.10 and 0.12 IU/mL for two T295A samples.

The R527W mutation is located in the A2 domain and a plausible explanation for the more labile R527W-FVIIIa is a faster dissociation of the A2 domain from FVIIIa. This has been shown by Pipe et al (Blood, 1999) to be the case for the R531H mutation. One R531H sample was included in this study, with assigned FVIII activity of 0.15 and 0.07 IU/mL when using 5 and 10 min activation times, respectively, and hence a similar two-fold difference in FVIII activity as for R527W.

Our results demonstrate that in patients referred for FVIII activity analysis as a follow-up from global screening or on suspicion of mild Hemophilia A due to the clinical phenotype, caution has to be made in interpreting FVIII activity results. In this study, FVIII activities were reported for the R527W mutation with two chromogenic method applications using 5 or 10 min FX activation times and for both applications the results were concordant with mild Hemophilia A. This may, however, not necessarily be the case for alternative methods.

PB 1.36-3

Clinical outcome of hemophilia patients undergoing major orthopedic surgery without pharmacological thromboprophylaxis

Brand B[1], Gerber B[1], Koch P[2] and Rinderknecht Graf S[3]

[1]University Hospital; [2]University of Zurich, Zurich; [3]Spital Buelach, Buelach, Switzerland

Background: Hemophilia patients are generally considered at low risk for venous thromboembolism. However, orthopedic surgery for hemophilic arthropathy exposes them to well established major risk factors for venous thrombosis due to the procedure itself, long immobilization, and factor replacement therapy. In contrast to non-hemophilia patients, pharmacological prevention of thromboembolism for hemophilia patients is not well studied nor standardized and largely depends on local practice. A multicenter European survey reported that 50% of centers are using anticoagulant prophylaxis. At our center, in agreement between orthopedic surgeon and hematologist, no pharmacological prevention of thromboembolism is given to patients undergoing orthopedic surgery.

Aims: The present study analyzes the safety and feasibility of this approach.

Methods: Retrospective analysis of all orthopedic operations performed in hemophilia patients of our center between 1978 and 2012. The study was approved by the local ethic committee, no patient informed consent was obtained as the retrospective study only involved anonymous patient record analysis.

Results: A total of 166 major orthopedic operations were performed in 47 patients. Forty-three (91.5%) had hemophilia A and 4 (8.5%) hemophilia B. Thirty-one (66%) patients suffered from severe, 14 (29.8%) from moderate and 2 (4.3%) from mild disease, respectively. One patient (2.1%) had a combined FVIII/Factor V deficiency. Median age was 44.9 years (IQR 34.9–55.0). Orthopedic interventions were divided into surgery of the lower extremity ($n = 138$, 83.1%%) and the upper extremity ($n = 21$, 12.7%%), for 7 (4.2%) data are missing. Follow-up information 9 weeks after surgery could be obtained for 124 operations (74.7%). No clinical signs of venous thromboembolism were observed in all cases. One (0.6%) intervention in a mild hemophiliac was complicated by a life-threatening perioperative myocardial infarction. Data on factor consumption was available for 101 interventions (60.3%) with a total dose per hospitalization of 45,000 IU (IQR 33,250–60,250) given to patients (mean body weight of 71.3 kg). Transfusions of red blood cells were needed in 12.3% of all interventions.

Conclusions: In this cohort of hemophilia patients undergoing orthopedic surgery without pharmacological prevention of thromboembolism followed over an overall period of 34 years, no symptomatic deep venous thrombosis or pulmonary embolism was observed. Prospective trials incorporating a systematic assessment for thrombosis are needed to confirm these encouraging data.

PB 1.36-4

Integrated analysis of safety data from 12 clinical interventional studies of a plasma- and albumin-free recombinant factor VIII (rAHF-PFM) in persons with hemophilia A (HemoA)

Shapiro AD[1], Romanov V[2], Silvati-Fidell L[2], Wong WY[2] and Schoenig-Diesing C[2]

[1]Indiana Thrombosis and Hemostasis Centre, Indianapolis, IN; [2]Baxter Healthcare, Westlake Village, CA, USA

Objectives: To update evaluation of the safety of rAHF-PFM by encompassing the results from 12 clinical interventional studies. rAHF-PFM is approved in the USA for perioperative management, control and prevention of bleeding episodes in both children and adults with HemoA. It is manufactured free of exogenous human or animal proteins using a non-hypersensitivity-inducing monoclonal antibody.

Methods: Four hundred and eighteen treated subjects (363 PTPs, 55 PUPs, all with baseline FVIII levels ≤ 2% of normal) from all Baxter Phase I–IV studies excluding PASS studies had a median age of 18.7 years (range: 0.07–72.3) who received at least one infusion of rAHF-PFM. Study analysis subsets comprised immune tolerance induction, PK assessments, prophylaxis, recovery, and surgical prophylaxis.

Results: The 418 subjects received a total of 122,281,528 IU of rAHF-PFM from 1276 lots in 63,188 infusions. 88.5% of subjects received their infusions as prophylaxis (82.8% of total infusions). Overall, subjects received a median of 97.0 exposure days (range: 1–709), with a median of 98 infusions per subject (range: 1–711) and a median of 118,778 IU (range: 467–1,572,194 IU) per subject. Three thousand three hundred and seventy-six adverse events (AEs) were reported in 314 of the 418 subjects (75.1%) with 106 events being serious. However, the majority of all AEs were non-serious (3270/3376) and judged by the investigator to be unrelated to IP (3283/3376). Only 93 AEs in 45 subjects (10.8%) were related to rAHF-PFM, with no predominant type or cases of recurrence in subsequent infusions. Of these, only Factor VIII inhibition, headache, and pyrexia were considered to be in the ADR Frequency Category of 'common'. Of 106 serious AEs (SAEs), that occurred in 69 subjects (16.5%): most commonly FVIII inhibition (4.1%), device-related infection (1.0%), or pyrexia (0.7%) were detected. Seventeen SAEs that were considered related to rAHF-PFM included the development of FVIII inhibitors in 16 PUPs (seven high-titer (> 5 BU), nine low-titer (≤ 5 BU), in 29% of PUPs) and 1 PTP (low titer). Eleven of the 16 PUPs with inhibitors underwent immune tolerance induction, with 72.7% success. Overall, the incidence of any FVIII inhibitor in PTPs was 0.4%, similar to reports of other FVIII products. No deaths and no cases of hypersensitivity related to rAHF-PFM occurred during the conduct of these studies.

Conclusions: The integrated safety analysis confirms previously demonstrated safety and tolerability in children and adults with moderately severe or severe HemoA in a wide variety of clinical settings, and reveals no new safety signals.

PB 1.36-5

Clinical study in children with severe haemophilia A investigating efficacy, immunogenicity, pharmacokinetics, and safety of human-cl rhFVIII

Klukowska A[1], Vdovin V[2], Szczepanski T[3], Jansen M[4], Knaub S[5] and Liesner R[6]

[1]Medical University of Warsaw, Warsaw, Poland; [2]Moscow Children's Hematology Centre, Moscow, Russian Federation; [3]Dept. of Paediatric Haematology and Oncology of Silesian Medical University, Zabrze, Poland; [4]Octapharma, Vienna, Austria; [5]Octapharma AG, Lachen, Switzerland; [6]Great Ormond Street Haemophilia Centre, London, UK

Background: Human-cl rhFVIII is the first recombinant factor VIII concentrate expressed in a human cell line (Human Embryonic Kidney 293F cells). Studies in previously treated adult and adolescent patients with severe haemophilia A demonstrated that Human-cl rhFVIII is bio-equivalent to a full length rFVIII concentrate and safe and effective in preventing and treating bleeding episodes (BE).

Aims: The objectives of this GCP study were to evaluate the pharmacokinetics (PK), efficacy, safety, and immunogenicity of Human-cl rhFVIII in previously treated children between 2 and 12 years of age.

Methods: First, all patients were to undergo an *in-vivo* recovery (IVR) investigation with Human-cl rhFVIII. In a subset of patients, also the PK of Human-cl rhFVIII was assessed in comparison to the patient's previously used FVIII product. After an injection of a nominal dose of 50 IU/kg, blood samples were collected up to 48 h for PK analysis and up to 2 h for IVR. IVR was repeated in all patients after 3 and 6 months. FVIII coagulant activity (FVIII:C) was measured by chromogenic substrate and one-stage clotting assay in a central laboratory. All patients were to be treated prophylactically with Human-cl rhFVIII every other day or three times weekly with 30–40 IU Human-cl rhFVIII per kg for 6 months. Human-cl rhFVIII was also to be used in case of breakthrough bleeds. Inhibitors were measured before, at defined time points during and at the end of the study by modified Nijmegen Bethesda assay in a central laboratory. Adverse events were recorded throughout the study.

Results: The study was approved by the Ethics Committee of each participating institution and informed consent/assent was obtained from the parents/legal guardians or patients, if applicable, prior to any trial-related activity. Fifty-nine patients (29: 2–5 years; 30: 6–12 years) were enrolled from 15 sites in Europe. Thirteen children of each age group participated in the comparative PK investigation. Mean PK parameters of Human-cl rhFVIII were similar to those of the previous FVIII product (20 full-length rFVIII, six plasma-derived FVIII), both for the chromogenic and the one-stage assay: AUC_{norm} 0.234 vs. 0.25 h IU/mL/[IU/kg]); IVR 1.61 vs. 1.59%/IU/kg; $T_{1/2}$ 12.5 vs. 13.1 h (one-stage assay). IVR remained stable throughout the study. There were a total of 129 BEs in 39/59 patients during the study, 108 of which were treated with Human-cl rhFVIII. The majority of treated BE were traumatic (60.2%) and minor (56.5%). The mean ± SD monthly rate of all types of BEs/patient was 0.34 ± 0.43 (spontaneous BEs: 0.12 ± 0.27; traumatic BEs: 0.19 ± 0.29). No patient discontinued the study because of an AE. There were no related serious and two possibly related AEs (mild headache, mild back pain) in two patients. No child developed an inhibitor.

Conclusion: The data indicate that Human-cl rhFVIII is efficacious and safe in preventing and treating BEs in previously treated children. The PK of Human-cl rhFVIII and the previous product were very similar to each other. A study in previously untreated patients was initiated.

PB 1.36-6

Evaluation of the hemostatic potentials in a mild hemophilia A with a novel factor VIII mutation Thr677Ile

Yada K, Nogami K, Kenichi O, Minami H and Shima M
Nara Medical University, Kashihara, Nara, Japan

Hemophilia A (HA) is classified by the factor (F)VIII activity (FVIII:C) as severe (FVIII:C < 1 IU/dL), moderate (1–5 IU/dL) and mild types (> 5 IU/dL). Some mild/moderate HA patients show the discrepancies in FVIII:C between a one-stage clotting assay and chromogenic assay. The patients with FVIII mutations such as Arg531Cys, Arg527Trp, Ser1791Pro and Leu1978Phe show the higher FVIII:C by one-stage assay than chromogenic assay. On the other hand, the mutations at Arg1639His and Arg1689His in the A3 domain of FVIII are known to show the higher FVIII:C by chromogenic assay than one-stage assay. We had a case of mild type HA associated with a Thr677Ile mutation in the A2 domain of FVIII, not enrolled in the HAMSTeRs database, hospitalized with iliopsoas muscular hemorrhage, exhibiting higher FVIII:C by one-stage assay (32 IU/dL) than chromogenic assay (18 IU/dL) and positive cross reacting materials (FVIII:Ag 92% in ELISA). To investigate the hemostatic potential in this case, the standard control plasmas constituted with FVIII-deficient plasma and serially diluted recombinant FVIII (final concentration 0.2–100 IU/dL) were prepared, and the thrombin generation test (TGT) and the clot waveform analyses (CWA) were performed. The parameters obtained (peak thrombin and time to peak thrombin) in the case by TGT were compared with those in standard plasmas. The respective parameter was 128 nM and 15 min, equivalent to FVIII:C 8–10 IU/dL in standard plasmas. Also, a parameter (min^2), acceleration rate of the clotting, in the case by CWA was equivalent to that of FVIII:C 5 IU/dL in standard samples. The haemostatic potential evaluated by TGT and CWA reflected the clinical phenotype, and was similar to FVIII:C measured by chromogenic assay rather than one-stage assay. To examine the mechanism(s) of the discrepancy of FVIII:C in this case between one-stage and chromogenic assays, the concentration of the aPTT reagent consisting of phospholipids (100 μg/mL) and ellagic acid (0.1 mM) used in one-stage clotting assay was varied. Dilution of aPTT reagent had little effect on FVIII:C in normal plasmas, whilst FVIII:C of the case was reduced by approximately 20% using the fourfold diluted aPTT reagent. The concentration of the phospholipids showed an inversed correlation with aPTT, but no significant difference was observed between in the normal and the case plasma. Surprisingly, the concentration of the ellagic acid also was inversely correlated with aPTT, but the rate of shortening of aPTT in the case plasma was approximately 1.3-fold greater than that in the normal plasma. Thus, the hemostatic potential in the case might be overestimated with the excess amounts of ellagic acids, and the combination of coagulation assays as TGT and CWA would be important to evaluate the clinical haemostatic potential of mild/moderate HA with discrepancy in FVIII:C.

PB1.37 – Haemophilia A: Clinical – III

PB 1.37-1

Molecular genetics of inherited bleeding disorders. External quality assessment identifies errors in genotyping and interpretation

Jennings I[1], Perry D[2], Goodeve AC[3], Cumming T[4], Hill M[5], Kitchen S[1], Woods T[1] and Walker I[1]
[1]UK NEQAS (Blood Coagulation), Sheffield; [2]Department of Haematology, Addenbrookes Hospital, Cambridge; [3]Sheffield Childrens NHS Foundation Trust, Sheffield; [4]Department of Haematology, Manchester Royal Infirmary, Manchester; [5]Nottingham University Hospitals, Nottingham, UK

Background: In the field of molecular genetics, investigation of the causative mutation in individuals and their families with haemophilia and other inherited bleeding disorders is common practice. The results of genotypes are unequivocal with no borderline values but failure to correctly identify a mutation or candidate mutation, or to misinterpret its significance, can have major implications for an individual, their family and offspring. Participation in an external quality assurance programme is a fundamental part of laboratory practice and in theU-Kis a requirement for laboratory accreditation. Experience from other genetic external quality assessment schemes has highlighted that errors may occur, both in the correct identification of mutations and in their subsequent interpretation.

Methods: An external quality assurance programme for the Molecular Genetics of Haemophilia was established in 1998 by UK NEQAS for Blood Coagulation. Preliminary exercises explored the ability of laboratories to identify the presence or absence of the *F8* intron 22 inversion mutation; subsequent exercises have included samples with point mutations in the *F8*, *F9* and *VWF* genes. In each exercise, participants are provided with a clinical scenario and are asked to carry out genotyping and associated interpretation in order to answer a clinical question. Numerical scores are assigned on anonymised reports by a panel of expert scientists and clinicians. In this way, the clerical accuracy, diagnostic capability with respect to genotyping, and interpretative ability of the centre is assessed.

Results: During the course of the 20 exercises to date there has been marked improvement in the quality and consistency of laboratory reports, prompted by advice and comments from the expert panel. Enhancements to reporting have included use of standard gene names and promotion of mutation nomenclature recommended by the Human Genome Variation Society. In the majority of exercises, the genotype failure rate of laboratories is low (~1%), although failure due to errors in the interpretation of data are more frequent (7%). However, an exercise in November 2011 revealed a failure rate of 4/22 (18%) in the genotypic detection of a *F8* intron 22 inversion mutation in an affected female. Three of these four failures were associated with long rangePCR methods. The material employed in this exercise was immortalised cell line material from the National Institute of Biological Standards and Controls (NIBSC, Potters Bar, UK). Investigations are ongoing into the reason for the unusually high failure rate in this exercise.

Conclusion: The scheme now has 26 participants primarily in the UK/Europe but also including a small number of laboratories outside of this geographical area. Given the large number and international distribution of laboratories performing genetic screening for inherited bleeding disorders it is likely that many centres do not participate in EQA, and thus fail to benefit from the improvement in diagnostic accuracy and reporting that such participation can bring.

PB 1.37-2

Efficient typing of copy number variations in HA and HB families with large deletion/insertion mutations using multiplex competitive amplification

Lu Y

Ruijin Hospital affiliated to Medical College of JiaoTong University, Shanghai, China

Background: Large deletion/insertion mutations are found in approximately 5% of patients with severe haemophilia. Though the patients with these kinds of mutations can be confirmed, carrier identification in affected families is indefinable by direct sequencing.
Aims: The aim of this study was to do the carrier and prenatal diagnosis in haemophilia families with the large deletion/insertion mutations using multiplex competitive amplification.
Methods: The APPT, PT, TT, Fg, FVIII:C, FIX:C were detected to make phenotypic diagnosis. LD-PCR and PCR were adopted for the screening of the intron 22 and 1 inversion respectively. The F8/F9 gene coding and boundary sequences were analyzed by direct sequencing. Seven STR sites related to F8/F9 gene were combined together to do the linkage analysis. The new CNV genotyping method, AccuCopy, based on multiplex competitive amplification of F8/F9 gene respectively was used to investigate eight HA families and three HB families with large deletion/insertion mutations.
Results: Laboratory tests indicated that all of the HA and HB patients had severe deficiency of related factors. Large deletions of exon 4, exon14, exons 2–9, exons 7–9, exons 2–6, exons 5–7 were confirmed in seven HA patients whose relative segments' copy number variations were zero respectively. One insertion of exons 11–12 was detected in one patient whose CNV of these segments was 2 while the normal male control's was 1. The carriers and prenatal diagnosis could be confirmed by the CNV detection of these segments with AccuCopy method. For the carrier, the CNV of the relative exons was 1, while the normal control female's CNV was 2. In the three HB families, it was failed to amplify the exons 1–6, exons 2–8 and exons 1–8 segments of the index respectively. The results of AccuCopy method manifested that the copy number variations of the relative exons were zero in all of the patients and one copy in their mothers who were female haemophila carriers respectively. The females who requested for the carriers detection were detected to have two copy numbers of the segments respectively. Furthermore, the linkage analysis results were coincident with the genetic analysis in these HA and HB famillies.
Conclusions: This report illustrated that multiplex competitive amplification method represented an efficient method to determine the carrier status and do the prenatal diagnosis in haemophilia families with large deletion/insertion mutations.

PB 1.37-3

Ongoing prospective rAHF-PFM immune tolerance induction registry (PAIR): success rates continue to support published literature

Shapiro AD[1], Khair K[2], Teitel J[3], Leony-Lasso I[4], Matovinovic E[4], Schoenig-Diesing CK[4] and Spotts G[4]

[1]Indiana Thrombosis and Hemostasis Centre, Indianapolis, IN, USA; [2]Great Ormond Street Hospital, London, UK; [3]St Michael's Hospital, Toronto, ON, Canada; [4]Baxter Healthcare, Westlake Village, CA, USA

Background: Prospective recombinant anti-hemophilic factor plasma/albumin free method (rAHF-PFM) Immune Tolerance Induction (ITI) Registry (PAIR) is a global, ongoing, non-interventional, post-authorization safety surveillance registry designed to collect treatment information on rAHF-PFM safety/effectiveness in ITI therapy. Several registries have reported ITI success rates ranging from 55% to 78% for rAHF-PFM and other products (Mariani, 2003; Hay, 2012).
Aims: To present interim results for patients who completed ITI at the time of data transfer on September 6, 2012. Specifically, to assess incidence of adverse events (AEs) related to rAHF-PFM during ITI therapy. Secondary objectives were to collect information on the incidence of central venous access device-related complications, and to evaluate success rates of ITI therapy.
Methods: Patients with hemophilia A of any severity and an inhibitor were eligible for study. Investigators determined dosing regimens and monitoring schedules. Maximum observation period for ITI was 33 months with a 12 month follow-up period.
Results: Enrollment took place from July, 2007 to April, 2011. Forty-four patients were enrolled from 10 countries. At the time of data transfer, 32/44 patients (72.7%) completed ITI therapy, 25 of which completed the 12 month follow-up. The following rAHF-PFM dosing regimens were administered for the full analysis set ($n = 44$): 4 (9.1%) patients received ≥ 200.4 IU/kg/day; 3 (6.8%) patients received 131–199 IU/kg/day, 26 (59.1%) patients received 90–130 IU/kg/day, and 11 (25%) patients received < 90 IU/kg/day. During the observation period, 262 AEs, excluding bleed events, occurred for all enrolled patients ($n = 44$). Of these, 52 (18%) AEs were serious and unrelated while 15 (7%) were considered non-serious and at least possibly related. None of the SAEs were considered related to the treatment. In the full analysis set, 294 bleeding episodes occurred. Central venous device complications were common: one patient was hospitalized, 10 experienced line infections, 10 had line insertions, five reported line malfunctions, four experienced line removal, and one patient reported pain following portacath bleed. While six patients withdrew prior to completing ITI therapy, 32 'completers' were categorized as follows: 14 patients had successful disappearance of inhibitor, seven achieved partial success, four were deemed successful by investigator, six were not anticipated to be successful within 33 months, and one patient reached the end of the study period at 33 months. Inhibitor titer level results for 28/32 completers were the following: 16 patients achieved negative titer levels, two experienced a high to low titer conversion, five failed to achieve negative titer, and five were unassessable due to missing titer data or discontinuation. After 12 months therapy, Kaplan–Meier estimate of success for achievement of first negative titer was 74.9% (asymptotic 95% CI: 56.7–89.8, $n = 32$) for the completer group. Kaplan Meier success rates were similar for the per-protocol (79.3%, CI 61.8–92.4%, $n = 27$) and lower in the full analysis set (61.1%, CI 45.6–76.9%, $n = 44$).
Summary/Conclusions: These interim results are consistent with previously reported PAIR analyses and with published data on rAHF-PFM and other commercially available FVIII products used in ITI (Mariani, 2003; Hay, 2012). PAIR continues to prospectively document rAHF-PFM safety and effectiveness in ITI and will contribute to understanding prognisticators of ITI success.

PB 1.37-4

Adherence to clotting factor treatment among patients with haemophilia A or B

Armstrong PE[1], Malone DC[1], Krishnon S[2] and Wessler J[3]

[1]Strategic Therapeutics, LLC, Tucson, AZ; [2]Biogen Idec, Weston, NS; [3]Naval Medical Center, Portsmouth, VA, USA

Background: Two limitations of conducting retrospective analyses related to outcomes and adherence for haemophilia patients include the fragmentation of care between home and hospital, and the inability to track episodic vs. prophylaxis treatment. However, such data are important for healthcare providers.
Aim: To evaluate adherence to clotting factor treatment and associated outcomes for patients with factor VIII or factor IX deficiencies using an integrated delivery system database for haemophilia patients.
Methods: This was a retrospective, observational study utilizing medical and pharmacy electronic medical records and administrative encounters/claims data tracking patients between 2006 through 2011

for up to 5 years. Patients with diagnosis codes for haemophilia (ICD-9 code 286.0 for haemophilia A and 286.1 for haemophilia B) were identified. Eligible patients must have received clotting factors at least twice during the study period. Severity was classified into mild (5–40% normal factor activity), moderate (1–5% normal factor activity), or severe (< 1% normal factor activity). Bleeding and complication rates were annualized over the study period. Medication adherence was assessed using prescription claims for clotting factors by examining sequential time periods of 180 days for each patient's continuous enrollment. Adherence within the time period was calculated using days supply for all clAims divided by 180 days. For each patient up to 10 observational windows were evaluated. Under the assumption that severe haemophilia patients should be treated continuously, patients were considered adherent within the time period if the ratio of days supply to observed days was 60% or greater. The approach was validated using haemophilia severity as a proxy. Research data was derived from an approved Naval Medical Center, Portsmouth, VA IRB NMCP.2012.0016 protocol.

Results: A total of 207 patients (74.9% and 25.1% haemophilia A and B, respectively) met the inclusion/exclusion criteria. The mean age (± SD) was 9.2 years (± 10.0). There were 101 (48.8%) mild, 32 (15.5%) moderate, and 74 (35.7%) severe haemophilia patients. The percentage of time periods where adherence to clotting factors was 60% or greater was 14% (SD = 28%) for patients with mild disease, 21% (SD = 32%) for moderate disease, and 51% (SD = 36%) for severe disease. Among patients with severe disease, 27 (36.5%) were adherent 30% of time periods or less, 22 (29.7%) adherent 31–70% of the time periods, and 25 (33.8%) were adherent between 71% and 100% of the time. Any bleeding episodes, joint bleeding episodes, and hospitalizations were uncommon events.

Summary/Conclusions: This analysis provides a novel approach for measuring adherence to clotting factor treatment through a retrospective database analysis. Adherence varied by severity. Among patients with severe disease, the majority (66.2%) were adherent < 70% of the time. The infrequent bleeding events and sample size limit analysis by severity. Future studies should explore the reasons for non-adherence and understand the implications as it relates to patient-reported breakthrough bleeding.

PB 1.37-5

P.I.S.A. – safety, immunogenicity and efficacy of a full length DNA rAHF-PMF in patients with hemophilia A in the Italian post-marketing surveillance study

Schino M[1], Rocino A[2], Santagostino E[3] and Mazzucconi MG[4]

[1]Baxter, Roma; [2]San Giovanni Bosco Hospital, Naples; [3]Ospedale Maggiore Policlinico, Milan; [4]Università La Sapienza, Rome, Italy

Background: Postmarketing surveillance studies of FVIII concentrates have been recommended [1], [2] to confirm the favorable efficacy and safety profiles of already approved medicines.

Aim of the Study: To assess safety, immunogenicity and efficacy of ADVATE (full length DNA rAHF-PMF) in Italian daily routine practice.

Patients and Methods: This was a retrospective-prospective, multicenter, 12-month observational study carried out in subjects with severe, moderately severe or moderate hemophilia A who gave informed consent. At enrollment, all subjects should have been treated with Advate for at least 6 months, according to any regimen determined by the physician and based on national SPC. Each subject has thus been retrospectively evaluated for this period of at least 6 months and prospectively observed for 12 months. The primary endpoints were incidence of non-serious and serious adverse events (AEs) at least possibly related to ADVATE, and incidence of high-titer, low-titer and transient inhibitor development during the course of ADVATE treatment. The main secondary endpoint was the overall assessment of the hemostatic efficacy for all bleeding episodes treated with ADVATE.

Results: During the period of surveillance, a total of 287 patients and 1452 bleeding episodes were treated with ADVATE. The median annualized bleeding rate (ABR) at baseline was 4 (IQ25–75 1–15). At the end of the period of surveillance the median ABR was 1.0 bleed year-1 (IQ25–75 0–5.2) for the entire cohort. The median ABR was the lowest for those continuously on prophylaxis (0 bleeds year-1, IQ25–75 0–2.7); higher median ABR was observed for subjects treated on-demand (5.4 bleeds year-1, IQ25–75 1–16.1)

At baseline nine subjects (3.2%) had FVIII inhibitors. The titer was < 1 BU in four subjects, between 1 and 5 in one subject, and > 5 in four subjects. Exclusion of subjects with a history of FVIII inhibitor (seven subjects) from this group yielded to an incidence of 2/276 (0.72%) patients at baseline who developed inhibitor during the previous 6 months retrospective phase. During the surveillance no new inhibitors developed in subjects without a history of inhibitors. A total of 40 AEs were observed in the 287 subjects treated with ADVATE during the period of surveillance. Three AEs were serious (retroperitoneal hematoma, cholecystitis and seizures). All AEs were deemed unrelated to the study drug by the investigators.

Conclusions: The results of this Italian surveillance confirm safety, efficacy and low immunogenicity of Advate in daily clinical practice.

PB 1.37-6

The influence of co-morbidities on annualised bleeding rates in patients with severe haemophilia A: experiences from the pivotal turoctocog alfa prophylaxis trial (guardianTM1)

Andreeva T[1], Suzuki T[2], Nielsen R[3], Andersen E[3] and Lindblom A[3]

[1]Republican Center for Hemophilia Treatment, St. Petersburg, Russian Federation; [2]Tokyo Medical University, Tokyo, Japan; [3]Novo Nordisk A/S, Søborg, Denmark

Background: Individual bleeding rates in patients with severe haemophilia A often show a high variability. This may be due to differences related to biological and behavioural patterns as well as differences in co-morbidities and regional treatment practice. Novo Nordisk has developed turoctocog alfa, a new recombinant FVIII with a truncated B domain. In the guardian™1 trial, 150 (24 adolescents and 126 adults) previously treated patients with severe haemophilia A were given prophylaxis with turoctocog alfa. This trial included patients from 15 countries across the world. Interestingly, a large variation between countries in the annualised bleeding rates was observed in spite of following the prophylactic dosing regimen specified in the protocol.

Aim: To investigate the potential influence of frequent co-morbidities on the annualised bleeding rate as a possible explanation of the variation between countries and patients.

Methods: Patients with severe haemophilia A (≤ 1% FVIII activity), aged from 12 years and above, with no history of inhibitors and with at least 150 exposure days to other FVIII products were included. Informed consent was obtained from all patients before any trial related activity and the trial protocol was approved by appropriate ethics committees or institutional review boards. The trial was conducted in accordance with the declaration of Helsinki and the principles of good clinical practice. At baseline, the patients' concomitant illnesses were recorded and a physical examination was performed. For each patient, we will assess two frequent co-morbidities, i.e. joints with haemophilic arthropathy and hepatitis C status. The association between these co-morbidities and individual annualised

bleeding rates during prophylaxis with turoctocog alfa will be investigated.
Results: A total of 499 treatment-requiring bleeds were reported by 105 patients, of which 389 were joint bleeds reported by 94 patients. The remaining 110 bleeds were non-joint bleeds reported by 51 patients, while 45 patients did not experience any bleeds during the trial. There was a large variation in the country-specific bleeding rates, and for some countries the rates were significantly different. The country-specific annualised bleeding rates ranged from 1.3 bleeds/patient/year (95% CI: 0.5–3.3) based on six bleeds in nine patients to 23.2 bleeds/patient/year (95% CI: 14.6–37.0) based on 58 bleeds in five patients. The association between each of the two frequent co-morbidities and the individual annualised bleeding rates will be explored graphically and statistically.
Conclusions: Several potential factors may have influenced the variation between countries in annualised bleeding rates. Here we will analyse the impact of two frequent co-morbidities as potential explanations for the observed variation in the country-specific bleeding rates.

PB1.38 – Haemophilia A: Clinical – IV

PB 1.38-1

The mechanism of action of prophylactic administration of recombinant factor VIIa may be explained by the presence of hemostatically active FVIIa in plasma throughout the time frame of prophylaxis

Schut AM[1], Hyseni A[2], Adelmeijer J[1], Meijers JC[3], De Groot PG[2] and Lisman T[1]

[1]University Medical Center Groningen, Groningen; [2]University Medical Center Utrecht, Utrecht; [3]Academic Medical Center Amsterdam, Amsterdam, The Netherlands

Background: Recombinant factor VIIa (rFVIIa) is registered for treatment of patients with inhibitor-complicated hemophilia A and B, in which it effectively treats bleeding episodes at a 90 μg/kg dose administration. Recently it has been shown that a prophylactic administration of 90 μg/kg rFVIIa once daily was successful in reducing the number of bleeding events. These results suggest that a single dose of rFVIIa has a pro-hemostatic effect of up to 24 h, which is difficult to explain given its half-life of ~2 h.
Aims: To assess potential mechanisms by which rFVIIa may exert a prolonged hemostatic effect, we analyzed FVIIa plasma levels and associated hemostatic activity of blood samples from non-bleeding pigs receiving a 90 μg/kg bolus administration of rFVIIa.
Material and Methods: Six adult pigs received a 90 μg/kg bolus administration of rFVIIa, and were followed up for 24 ($n = 3$) or 48 h ($n = 3$). Plasma was collected at baseline and at 5, 15, 30 min, 1, 2, 4, 6, 8, 12, 16, 24, and 48 h post-administration. Plasma FVIIa levels were measured using a commercially available FVIIa-specific clotting assay (STACLOT VIIa-rTF). Plasma haemostatic potential was estimated by a prothrombin time (PT) assay and thrombin generation assays (TGA) using calibrated automated thrombography.
Results: Plasma FVIIa levels reached their maximum at 5 min post-administration (30445.5 ± 1022.2 mU/mL [mean ± standard deviation]) and decreased to pre-administration levels over time with a half-life of 2 h. Elevated plasma FVIIa levels were detected up to 24 h post-administration (41.3 ± 14.1 mU/mL at 24 h vs. 7.5 ± 15.6 at baseline), although differences measured beyond 4 h did not reach statistical significance. Immediately after administration of rFVIIa, PT values decreased, and remained shortened compared to baseline until 48 h post-administration (10.0 ± 0.1 s at 48 h vs. 10.6 ± 0.5 at baseline, $P < 0.05$). In post-administration plasma samples, thrombin generation curves were altered compared to baseline, with the most profound effect in the lag time. These lag times were significantly shortened up to 12 h post-administration (1.9 ± 0.2 min vs. 2.4 ± 0.2 at baseline, $P < 0.05$), but only returned to pre-administration levels at 48 h.
Conclusions: Following administration of a 90 μg/kg bolus of rFVIIa to non-bleeding pigs, elevated plasma FVIIa levels remained detectable up to 24 h post-administration, despite a half-life of approximately 2 h. These low FVIIa levels are hemostatically active, as shown by shortened clotting times in PT and TGA assays. This, as yet unrecognized, prolonged pro-hemostatic effect of FVIIa may explain the prophylactic efficacy of a once daily rFVIIa treatment. We propose that only low plasma levels of FVIIa are required for prevention of bleeding, whereas much higher levels are needed for treatment of active bleeds.

PB 1.38-2

TF-initiated thrombin generation associates with bleeding phenotype in patients suffering from haemophilia A

Ninivaggi M[1], Dargaud Y[2], Van Oerle R[1], De Laat B[1], Hemker CH[1] and Lindhout T[1]

[1]CARIM, Maastricht University, Maastricht, The Netherlands; [2]Hopital Edouard Herriot, Lyon, France

Background: Although there have been improvements in the management of haemophilia A, there is no validated laboratory test that predicts bleeding tendency in patients suffering from severe haemophilia A. It is known that patients suffering from severe haemophilia A have a variable bleeding risk. Thrombin generation is increasingly recognized as a sensitive and reliable way to get an indication of a patients bleeding risk.
Aim: The aim of our study is to investigate whether thrombin generation is a method to get an indication of the bleeding risk in patients suffering from haemophilia A.
Methods: To investigate this we included 30 adult haemophilia A patients (FVIII ≤ 5 IU/dL). Patients were not on primary prophylaxis thereby not influencing coagulation measurements. Patients were assigned as bleeder when they had a Pettersson radiologic score between 3 and 4 with frequent spontaneous bleeding episodes. Factor VIII levels were determined via a recently published assay based on activation with FIXa and used thrombin generation as read out. Plasma samples were tested applying the Calibrated Automated Thrombograph method. Coagulation was initiated using 1pM of tissue factor (TF).
Results: From the 30 haemophilia A patients 21 patients were assigned as having a bleeding phenotype based on the Pettersson radiologic score. Using FIXa as initiator no difference was observed between bleeders and mild-bleeders ($P > 0.05$). When thrombin generation was initiated via 1 pM of TF, we observed a significant difference ($P < 0.001$) in ETP between bleeders and mild-bleeders (429 ± 163 vs. 787 ± 192 nM*min).
Conclusion: The endogenous thrombin potential (ETP) measured in low TF driven thrombin generation is a strong predictive thrombogram parameter of bleeding phenotype among patients with < 5 IU/dL FVIII.

PB 1.38-3

Thrombin generation assay by calibrated automated thrombogram (CAT): application to monitoring severe hemophilia A treatment

Vila V, Moret A, Cabrera N, España F, Martínez-Sales V and Aznar JA

Hospital Universitario y Politécnico La Fe, Valencia, Spain

Background: Severe hemophilia A (HA) has been traditionally considered when dosage of factor VIII (FVIII) measured by the one-stage clotting test is < 1 IU/dL. However, patients with FVIII < 1 IU/dL show an evident clinical heterogeneity. About 10–15% of patients classified as severe do not show a significant haemorrhagic incidence. This can be due to other procoagulant factors that compensate the FVIII deficiency. International guidelines for prophylaxis in severe HA recommend maintaining FVIII trough levels slightly above 1 IU/dL. The thrombin generation assay (TGA) is a global haemostatic technique capable of detecting the influence of small levels of coagulation and anticoagulation factors.

Aim: The aim of this study was to determine whether TGA can offer valuable information for proper monitoring of the prophylactic treatment in severe HA patients.

Methods: We included 103 samples of 44 severe HA patients with bleeding phenotype (more than two spontaneous hemarthrosis in the same joint in < 6 months) that were in prophylactic treatment biweekly. Blood samples were obtained every 3 months on the trough levels, 72 and 96 h after the last FVIII infusion. In our protocol the goal was to maintain the patient between 1.5 and 2 IU/dL of FVIII:C. Platelet-rich plasma (PRP) and platelet-poor plasma (PPP) were prepared for testing TGA and FVIII measurement. FVIII was quantified by one-step coagulation test (FVIII:C, IU/dL). TGA was measured by the calibrated automated thrombogram (CAT, Thrombinoscope BV) and three parameters were assessed: latency time (min), endogenous thrombin potential (ETP nMxmin) and peak height (nM Thrombin). All determinations were performed on frozen samples, as we have previously shown that freezing PRP not significantly affect TGA (Haemophilia. 2012 Nov 23. doi: 10.1111/hae.12044). Statistical comparisons were performed using the paired t test, and the bivariate correlations were analyzed by Pearson's test.

Results: TGA in PRP and PPP correlated significantly (for both peak height and ETP $r > 0.7$; $P < 0.01$). As expected, PRP showed higher thrombin generation than PPP (peak 78%; ETP 25% higher in PRP). However, there was no correlation between the number of platelets and the TGA (peak $R = 0.024$, $P = 0.541$). Overall, FVIII:C correlated significantly with the PRP-TGA peak height ($R = 0.77$, $P < 0.001$) and ETP ($R = 0.50$, $P < 0.001$) but there was no correlation with the latency time. When samples with FVIII:C < 1.5 IU/dL were analysed (22% samples), these correlations disappeared (peak $R = -0.317$, $P = 0.162$; ETP $R = -0.294$, $P = 0.221$). Meanwhile, samples with FVIII:C > 1.5 IU/dL maintained a good correlation (peak $R = 0.73$, $P < 0.001$; ETP $R = 0.34$, $P = 0.007$).

Conclusions: FVIII levels higher than 1.5 IU/dL correlate well with the TGA in PRP, especially with peak height, but lower levels do not have any significant correlation. The TGA as overall hemostatic test is especially useful when FVIII levels are very low, because this assay may detect small traces of haemostatic factors undetectable by one-step coagulation test. As prophylactic FVIII through levels may be at these low ranges (< 1.5 IU/dL), it would be helpful to implement the TG test for monitoring doses and frequency of these treatments.

PB 1.38-4

Patient reported outcomes in clinical hemophilia practice

Limperg PF, Peters M, Van Ommen H, Fijnvandraat KJ, Grootenhuis MA and Haverman L

Emma Children's Hospital AMC, Amsterdam, The Netherlands

Background: Children with congenital bleeding disorders may experience Health Related Quality of Life (HRQOL) problems. Two multicenter studies measuring the effect of electronic Patient Reported Outcomes (ePROs) in clinical pediatric practice pointed out that discussing HRQOL during consultation increases the psychosocial items discussed and the identification of emotional problems. It also increased the satisfaction of the pediatricians with their provided care.

Aims: The aim of this abstract is to describe the implementation of ePROs in pediatric hemophilia practice with the use of the KLIK website.

Methods: In September 2011, ePROs were introduced as part of the standard care for children at the Hemophilia Treatment Center AMC. Children (8–18 years) or their parents (if the child is < 7 years) with congenital bleeding disorders complete online HRQOL questionnaires (TNO-AZL Preschool children Quality of Life; TAPQoL or Pediatric Quality of Life Inventory; PedsQL) at the website www.hetklikt.nu before regular consultation. The answers are converted into a KLIK ePROfile, and discussed during consultation with the pediatric hematologist. Before multi-disciplinary consultations, patients also complete a behavioral problems questionnaire (Strengths and Difficulties Questionnaire; SDQ), which is discussed by a psychologist, and parents complete the distress thermometer (Distress Thermometer for Parents; DT-P), discussed by a social worker.

Results: So far, 106 children (out of 157 patients with congenital bleeding disorders; 70%) completed the online questionnaires and discussed the KLIK ePROfile during consultation. Children, parents and pediatric hematologists are positive about the use of the KLIK ePROfile. With the use of the internet, the KLIK ePROfile is easy to implement in clinical practice and helpful in facilitating communication about HRQOL. Moreover, KLIK helps to detect psychosocial problems at an early stage and to provide tailored interventions. Other Dutch Hemophilia Treatment Centers will start using the KLIK ePROfile in the near future.

Summary/Conclusions: The implementation of the KLIK ePROfile in daily clinical hemophilia practice appears to be feasible. To see an example of the KLIK ePROfile, log in as a doctor on www.hetklikt.nu with 'PRO' as username and 'KLIK' as password. The website is also available in English. On the website you can find an informative movie about KLIK.

PB 1.38-5

Adherence to prophylaxis in the Netherlands: a multicentre study

Schrijvers LH[1], Beijlevelt-van der Zande M[2], Peters M[2], Lock J[3], Cnossen MH[3], Schuurmans MJ[1] and Fischer K[1]

[1]UMC Utrecht, Utrecht; [2]AMC Amsterdam, Amsterdam; [3]EMC Rotterdam, Rotterdam, The Netherlands

Background: To prevent bleeding and joint damage in severe haemophilia and other congenital bleeding disorders, adherence to prophylactic treatment with clotting factor concentrates is of great importance. To be able to provide adequate support and to formulate recommendations for haemophilia care, studies with regard to adherence and the possible risk factors for non-adherence are of significance.

Aim: To assess adherence and to quantify deviations from the treatment schedule in patients with congenital bleeding disorders on prophylactic home treatment.

Methods: In three Dutch haemophilia treatment centres, semi-structured interviews were embedded in the routine consultation by

the haemophilia nurse. Interviews included questions on the timing of infusions and deviations from prescribed therapy over the last 2 weeks. High adherence was defined as a minimum of 90% adherence rate: no deviation from the prescribed schedule and skipping of prophylactic infusions no more than once per month. Parents who infuse their child and patients on self-infusion were analysed separately.

Results: In total, 243 patients were included (Utrecht $n = 186$, Amsterdam $n = 43$ and Rotterdam $n = 14$), comprising 71% of the total population on prophylaxis in these centres. Median age was 19.9 years (range 2.0–76.9), with 86% severe haemophilia A, 10% severe haemophilia B and 4% other bleeding disorders. Parents who infused their child ($n = 75$), deviated significantly less from prescribed treatment than the 168 patients who infused themselves (high adherence: 71% of the parents vs. 50% of the patients, $P < 0.01$). Skipping or forgetting an infusion was rare; parents skipped 1.2% infusions and patients 9.2% infusions. Both parents and patients were aware (93%) of the importance of infusing in the morning. However, 29% of the parents and 44% of the patients did not administer the clotting factor concentrate at this time point. Only 5.3% of patients changed the prophylactic dose on their own initiative.

Conclusion: In this study 50% of all patients on prophylactic home treatment demonstrated a high adherence, 71% of all parents. These results are slightly better than adherence rates reported in other chronic diseases. However, adherence rates decreased with increasing age. Both groups mainly deviated from prescribed therapy with regard to timing, instead of skipping infusions. Preferences and barriers for adherence to prophylactic therapy, as well as effects of non-adherence on bleeding and clotting factor consumption should be assessed to further improve haemophilia care.

Keywords: adherence, compliance, prophylaxis, haemophilia.

PB 1.38-6

Immuno-monitoring of patients with severe hemophilia A

Delignat S[1], Kreuz W[2], Escuriola C[2] and Lacroix-Desmazes S[1]
[1]Inserm, Paris, France; [2]HZRM – Haemophilia Centre Rhein Main, Frankfurt, Germany

Background: Immune tolerance induction (ITI) is the only available treatment that allows efficient eradication of FVIII inhibitors in patients with hemophilia A. ITI consists in the repeated administration of therapeutic FVIII. It is successful in 60–80% of the patients. However, ITI is complicated by the facts that it requires an extreme compliance of the patients and that the cost of treatment may reach more than 0.2 million euros/patient/year. It is thus essential to identify clinical and biological parameters that are associated with ITI success or failure. We initiated an immuno-monitoring study as a satellite study of the Observational Immune tolerance Induction (ObsITI) research program to follow immunological parameters in patients undergoing ITI.

Aim: To follow the evolution of CD4+ T cells and B cells during ITI in patients with hemophilia A.

Methods: Blood was collected from nine patients with severe hemophilia A (< 1% FVIII activity) before initiation of ITI, and 2 weeks, 4, 9, 12 and 18 months later. Percentages of different cell populations were quantitated by flow cytometry: naive (CD45RA) and memory (CD45RO) CD4+ T cells, $CD25^{low}$ and $CD25^{high}$ CD4+ T cells, and naive (IgD+IgM+) and memory (IgD−) B cells. The evolution of inhibitory titers, FVIII recovery and FVIII half-life were also measured to assess success/partial success/failure of ITI.

Results: Median age of patients at start of ITI was 5 years (range: 2–18). All patients received Octanate (Octapharma) for ITI. Seven patients had first intention ITI and two patients had third intention. Inhibitor was eliminated (< 0.6 BU) in 6 (67%) patients. Five patients had complete ITI success (inhibitor titre < 0.6 BU, FVIII IVR ≥ 80%, FVIII $t_{½} \geq 7$ h) after a median time of 7 months (range: 5–12), one ongoing patient has partial success and three patients failed ITI (two of whom were in third ITI course). No clear trend in evolution of naive or memory T and B cells was associated with ITI outcome. In particular, levels of memory B cells did not differ between patients with ITI success (three patients tested out of 5: 16%) and the two patients with ITI failure (10% and 25%). Likewise, increases in CD4+CD25+ T cells, that encompasses regulatory T cells, did not occur in all patients, and were found in some failure as well as ITI success patients.

Summary/Conclusion: Several parameters have been associated with ITI outcome or with the duration of treatment until ITI success. These parameters include the age of the patients at start of ITI, the high or low dose FVIII treatment, the recombinant or plasmatic origin of the FVIII used for ITI, and the properties of the FVIII inhibitor. Our results on the immuno-monitoring of a small cohort of severe hemophilia A patients before and during ITI does not confirm that patients with ITI success have higher levels of memory B cells, as compared to patients with partial success or failure. Likewise, we do not find that tolerance induction is associated with a consistently increase of CD4+CD25+ regulatory T cells.

PB1.39 – Haemophilia B – I

PB 1.39-1

Treatment of haemophilia B- comparison study of the *in vitro* activities of plasma derived and recombinant factor IX

Yu Y, Laffan MA and Millar CM
Imperial College London, London, UK

Background: Haemophilia B results from a deficiency of coagulation factor IX (FIX) and is treated effectively by either recombinant (r-FIX) or plasma derived (pd-FIX) although these have been noted to display some differences in behaviour. FIX is activated *in vivo* by both FXIa and tissue factor (TF)-FVIIa, however conventional APTT-based assays assess only activation by FXIa.

Aims: To examine the differences between pd-FIX and r-FIX concentrates in terms of their activities in thrombin generation and activation by different proteases.

Methods and Results: For equivalent labelled potency, FIX ELISA showed the antigen content of pd-FIX concentrate was ~1.6 fold greater than rFIX. Using calibrated automated thrombography (CAT), triggered by TF (1.5–5 pM) and 90 nM FIX antigen, the peak thrombin produced by r-FIX was > 1.5 fold that by pd-FIX. A similar but less marked difference was seen after contact activation. We noted that r-FIX stimulated significant thrombin generation in the absence of TF or contact; whereas, pd-FIX did not. Chromogenic FIXa assay demonstrated the presence of FIXa in r-FIX was ~10 fold that of pd-FIX at equal antigen concentrations, which may explain the above findings. Because we expect FIXa to be cleared rapidly following infusion, this may also explain the lower *in vivo* recovery observed for r-FIX. Next, we analysed the activation of the two FIX concentrates in a purified system. Over the first 10 min of activation, the amount of r-FIXa generated by FXIa was 1.53x that of pd-FIXa, whereas no difference in activation was observed when triggered by TF-FVIIa. No accumulation of FIXα was observed, suggesting the initial interaction and cleavage is limiting. To investigate the reason for the different activation rates we studied the effect of posttranslational modifications of FIX in the two preparations. The Km for Ca^{2+} was similar for pd- and r-FIX which suggests a lack of effect of the varying profiles of GLA domain γ-carboxylation between pd- and r-FIX as a cause of their distinct activation rates. Removal of N-linked glycans and terminal sialic acids in O-linked glycans by treatment of FIX with PNGase F and Neuraminidase respectively, did not alter the activation rate of pd- or r-FIX regardless of activation by FXIa or TF-FVIIa. This indicates that differences in glycosylation profile between pd- and r-FIX do not influence FIX activation. Furthermore, dephosphorylation of pd-FIX did not reduce the difference in activation rates between the two FIX concentrates.

Conclusions: The only remaining posttranslation difference is sulfation. More than 90% of pd-FIX is sulphated at tyrosine155, compared to < 15% in rFIX but it is not possible to manipulate this *in vitro*. Protein sulfation is important for protein-protein interaction and remains a possible explanation for the difference in pd- and r-FIX activation by FXIa. In conclusion, clear differences are observed between pd-FIX and r-FIX concentrates including the proportion of FIXa and the activation by FXIa. These may explain some of the discrepancies observed clinically and suggest that the APTT may not reflect their resultant *in vivo* properties.

PB 1.39-2

Restoration of coagulation factor IX function impaired by different splicing mutations by a unique exon-specific U1 small nuclear RNA (snRNA)

Balestra D[1], Cavallari N[1], Alanis EF[2], Dal Mas A[2], Rogalska ME[2], Bernardi F[1], Pagani F[2] and Pinotti M[1]

[1]University of Ferrara, Ferrara, Italy; [2]International Centre for Genetic Engineering and Biotechnology, Trieste, Italy

Background: Limitations of replacement therapy encourage research toward alternative strategies for coagulation deficiencies. The U1snRNA, the component of the spliceosomal U1snRNP with a key role in exon definition during the earliest pre-mRNA splicing step, represents an attractive molecule because of its ability to rescue splicing impaired by mutations, a frequent cause of coagulation factor disorders (~15%). Though an engineered U1snRNA, designed to restore complementarity to the mutated donor splice site, we have previously demonstrated in cellular models the rescue of coagulation factor VII mRNA splicing and protein function impaired by the IVS7+5G/A mutation.

Aims: To explore the ability of modified U1snRNAs to rescue different splicing mutations in coagulation factor IX (FIX) gene, and associated to moderate/severe Hemophilia B.

Methods: Creation of plasmids for the expression of splicing-competent FIX cDNA constructs and of modified U1snRNA in Human Embryonic Kidney (HEK293) cells. Evaluation of FIX mRNA (RT-PCR) and protein (ELISA. aPTT-based coagulation assays, Western Blotting) levels in conditioned medium.

Results: We investigated the aberrant splicing mechanisms caused by the IVS5-2A/T, IVS5-2A/C, IVS5-2A/G, IVS5-1G/T and IVS5+1G/A mutations at the donor splice site (5′ss) and by the IVS5-8T/G, IVS5-9T/G changes in the polypyrimidine tract of the acceptor splice site (3′ ss) of *F9* exon 5.

All mutations almost exclusively induced exon 5 skipping from the mature FIX mRNA, thus predicting the synthesis of a FIX variant lacking the EGF2. Studies at the protein level demonstrated that this deleted FIX variant was secreted with reduced efficiency as compared to FIXwt, and did not elicit any appreciable coagulant activity. Co-expression of these FIX minigenes with a U1snRNA designed to bind by complementarity to the normal FIX IVS5 5′ss (U1-FIXwt) was able to restore exon 5 inclusion in the presence of the 5′ss IVS5-2A/T, IVS5-2A/C and IVS5-2A/G mutations. Noticeably, the U1-FIXwt also corrected both the IVS5-8G and IVS5-9G at the 3′ss. Rescue of FIX mRNA splicing was paralleled by secretion of the full-length FIX with normal coagulant activity.

To improve specificity for *F9* gene we tested a panel of U1snRNAs, named Exon Specific U1snRNA (ExSpeU1), targeting non-conserved intronic sequences downstream of the 5′ss. Intriguingly, we found a gradient of rescue efficacy, which decreased with the distance from the 5′ss. The best ExSpeU1, targeting intronic positions +9 through +18, rescued exon 5 inclusion (from undetectable to 70–80%) in the presence of the mutations IVS5-2A/T, IVS5-2A/C and IVS5-2A/G at the 5′ss or of the IVS5-8G and IVS5-9G at the 3′ss, and resulted in remarkable increased secretion (~2–3 fold) of FIX molecules with procoagulant activity (from undetectable to ~100%).

Conclusions: These results demonstrate for the first time that a unique ExSpeU1 is able to restore gene expression impaired by different splicing mutants, and the extent of rescue of the procoagulant function, if achieved in patients, would be far beyond the therapeutic threshold. These data further highlight the therapeutic potential of the U1snRNA-mediated approach. Study to assess rescue of FIX expression in mouse models are underway.

PB 1.39-3

Improvement in health-related quality of life with recombinant factor IX prophylaxis in moderately-severe or severe hemophilia B patients: results from the BAX326 pivotal study

Windyga J[1], Lin VW[2], Epstein JD[2], Ito L[2], Xiong Y[2], Abbuehl BE[3] and Ramirez JH[4]

[1]Institute of Hematology and Transfusion Medicine, Warsaw, Poland; [2]Baxter BioScience, Westlake Village, CA, USA; [3]Baxter Innovations GmbH, Vienna, Austria; [4]Centro Medico Imbanaco, Cali, Colombia

Background: Health-related quality of life (HRQoL) benefits of prophylaxis have been largely drawn from the experiences of patients with hemophilia A. Clinical research has yet to establish the impact of prophylaxis on HRQoL in patients with hemophilia B.

Aim: To assess the impact of BAX326 (recombinant Factor IX) prophylaxis on HRQoL in adult patients with moderately-severe or severe hemophilia B who participated in the pivotal clinical trial.

Methods: A Phase I/III multicenter clinical trial prospectively evaluated the outcomes of patients with moderately severe ($1\% \leq$ FIX level $\leq 2\%$) or severe (FIX level < 1%) hemophilia B who were treated with BAX326 on-demand or prophylactically. Written informed consent was obtained from each participant and the study was approved by Independent Ethics Committee (IEC) of each participating institution. HRQoL data were collected from subjects aged ≥ 17 years using a generic HRQoL instrument, the Short Form-36v2 (SF-36). Baseline and 6 months follow-up HRQoL data in the prophylaxis arm were analyzed. Changes in HRQoL between baseline and follow-up in each of the SF-36 domains were tested for significance using paired t-tests. To further study the benefit of BAX326 prophylaxis, subgroup analysis was conducted to examine HRQoL changes among patients who had switched to BAX326 prophylaxis from either intermittent prophylaxis or on-demand treatment. Changes in SF-36 domain scores were compared to the previously established minimally important difference (MID) to determine clinically meaningful changes.

Results: Fifty-nine males participated in the prophylaxis arm of this study. Of these, 55 completed the SF-36. The median age for those who completed the SF-36 was 33.0 years. At Week 26, subjects reported statistically significant and clinically meaningful improvements in overall physical health-related quality of life, as measured by the Physical Component Score (PCS) (mean change = 2.6, $P = 0.018$), Bodily Pain (3.4, $P = 0.014$), and Role Physical domains (3.4, $P = 0.016$). Patients who switched to prophylaxis from intermittent prophylaxis or on-demand ($n = 42$) experienced more pronounced benefits, and reported statistically significant and clinical meaningful improvements not only in the PCS (3.21, $P = 0.014$), Bodily Pain (3.78, $P = 0.026$), Role Physical (4.43, $P = 0.008$), but also in the Vitality (3.72, $P = 0.04$), Social Functioning (5.06, $P = 0.002$), and General Health domains (3.4, $P = 0.009$).

Conclusions: Patients with hemophilia B experienced both statistically significant and clinically meaningful improvements in physical HRQoL after 6 months of BAX326 prophylaxis treatment. Furthermore, patients who switched to prophylaxis from intermittent prophylaxis or on-demand experienced not only larger improvements in physical HRQoL, but also statistically significant and clinical meaningful improvements in mental HRQoL.

PB 1.39-4

Complex gene rearrangement combining both large F9 gene duplication and exon 6 deletion in severe hemophilia B patients

Costa C[1], Fretigny M[2], Labalme A[3], Letourneau S[1], Schluth-Bolard C[4,5], Goossens M[1], Negrier C[2], Sanlaville D[4,5] and Vinciguerra C[2]

[1]APHP-CHU Henri Mondor, Creteil; [2]Hôpital Edouard Herriot; [3]Centre de Biologie Est, Bron, Lyon; [4]Université de Lyon 1, Centre de Biologie Est, Bron; [5]INSERM, U1028, CNRS, UMR52, Lyon, France

Background: Hemophilia B is an X-linked coagulation disorder caused by a wide range of mutations in the factor IX (*F9*) gene, mainly point mutations. Whole *F9* gene deletions and large *F9* gene deletions encompassing one or several exons are also reported and represent about 5% of the total defects. Identification of the causative mutation is not necessary for the diagnosis of the disease but is essential for genetic counselling.
Aim: Here, we report a complex rearrangement of *F9* gene associated with a same exon 6 deletion in severe non related hemophilia B families. Surprisingly, these families are originated from the same geographic region, Indian Ocean (La Reunion Island and Madagascar).
Methods: Exon 6 deletion was detected by PCR amplification in male patients and the breakpoint identified by Long Range-PCR and sequencing. Potential carriers in the families were further studied by either Multiplex Ligation Probe Assay (MLPA) and/or quantitative fluorescent multiplex-PCR (QFM-PCR) and array CGH for one family. These quantitative assays were also used to study the hemophilia patients.
Results: The breakpoints of the 6467 bp exon 6 deletion have been identified and are the same in all seven families c.[521–286_724-31497del]. The quantitative assays revealed a *F9* gene duplication encompassing all exons excepting exon 6, in three of seven of these families. Investigation by array CGH revealed that the duplication covers 514 kb and affects four other genes: *MCF2*, *ATP11C*, *MIR505* and *CXorf66*.
Conclusion: This is the first report of a complex *F9* gene rearrangement combining both gene duplication associated with deletion. The exon 6 deletion might be considered as causative event of hemophila B. Whether the duplication can be considered as deleterious or as a copy number polymorphim (CNP) is in discussion. Indeed, an Xq28 duplication has been recently reported in patients with intellectual disability without low factor VIII levels. A founder effect is suspected to have occurred in all these families bearing the same deletion. The genetic mechanism explaining this association is still unknown. This study suggests that a quantitative study should be realized in all patients with a deletion in *F9* gene to detect complex rearrangement, as shown in these families.
Acknowledgements: Thanks to the practitioners for addressing these families: P Lutz (Pédiatrie, Strasbourg), A Rafowciz (Centre de Traitement des Hémophiles Kremlin Bicêtre), F Cartault (Génétique Ile de La reunion).

PB 1.39-5

An amazing 10th century old mutation with a high prevalence in haemophilia B patients of the Rhone-Alpes region, France

Marmontel O[1], Fretigny M[2], Bouvagnet P[3], Pellechia D[2], Tailhefer H[2], Negrier C[4] and Vinciguerra C[4]

[1]Service d'Hématologie Biologique, Hôpital Edouard Herriot, Hospices Civils de L; [2]Hématologie biologique, Hôpital Edouard Herriot, Hospices Civils de Lyon; [3]EA 4173 Université Lyon 1, laboratoire Cardiogénétique, Hospices Civils de Lyon; [4]Hématologie biologique, EAM4174, Hôpital Edouard Herriot; Université Lyon 1, Lyon, France

Background: The g.30150G>A substitution in the exon 6 of the *F9* gene (p.Ala279Thr) is responsible for mild haemophilia B, a X-linked recessive bleeding disorder caused by a deficiency or a functional loss of blood coagulation factor IX. Whereas this missense mutation is observed in different geographical areas with a low prevalence (37 times/2891 *F9* mutations, 1.3%) as estimated from the Haemophilia B database, its prevalence is much higher in Rhône-Alpes region, France (50 times/209 *F9* mutations, 23.9%, $P < 10^{-80}$).
Aim of this Study: to understand the high prevalence of this p.Ala269Thr missense mutation in Rhône-Alpes.
Methods: Thirty four unrelated patients carrying the g.30150G>A substitution and 50 control individuals were studied. Four Single Nucleotide Polymorphisms (SNP) -*Xmn*I (rs438601), *Taq*I (rs398101), *Mnl*I (rs6048) and *Hha*I- and one insertion/deletion – *Dde*I – within or in the near vicinity of the *F9* were tested by restriction fragment length polymorphisms along with 5 short tandem repeats (poly(AC)) – DXS1061, DXS1211, DXS1192, DXS1232 and DXS984 -flanking the *F9* gene on a 3 cM genetic interval. ESTIAGE program was used to estimate the age of the most recent common ancestor of mutation carriers.
Results: all males carrying the g.30150G>A mutation had the same haplotype at the closest polymorphic markers. Moreover, this haplotype was totally absent from the 50 control DNA demonstrating a founder effect. Concerning the combination of alleles, the probability of not being due to a founder effect displayed by the ESTIAGE software was very low (10^-59). ESTIAGE estimated that the most recent common ancestor lived about 56 generations ago (range from 42 and 77 generations). With an average generation every 20–25 years, the mutation presumably appeared at about the Xth century.
Summary and Conclusions: Seventy one percent of mild haemophilia patients in the Rhône-Alpes have the g.30150G>A mutation. Interestingly, all are descendant of a common ancestor who lived approximately at the Xth century. Founder effect has already been described in haemophilia B but in this study, we used extragenic flanking poly (AC) repeats to enable an estimation of dating the most recent common ancestor. The very ancient appearance of this mutation is an unexpected observation based on the estimated lifetime of a mutation in X-linked recessive disease, which is usually much shorter. This observation suggests that the Rhône-Alpes founder mutation in the *F9* gene could give a fitness benefit to hemizygous male patients or/and to heterozygous female carriers. It is also possible that a mild haemophilia B does not impair reproductive fitness of male carriers.

PB 1.39-6

Superiority of the chromogenic assay specific for activated factor IX over the non-activated partial thromboplastine time (NAPTT) clotting assay in detecting FIXa in recombinant FIX preparations

Dockal M, Boehm E, Pilz J, Schrenk G, Varadi K and Scheiflinger F

Baxter Innovations GmbH, Vienna, Austria

Background: Due to the risk of thrombogenicity in hemophilia B patients, FIXa impurities in FIX concentrates should be minimal. Cur-

rently, two methods for detection of FIXa in rFIX preparations are available: a chromogenic assay specific for FIXa, and a one-stage clotting assay recommended by European Pharmacopeia (EP), which is sensitive to activated coagulation enzymes.
Aims: In this study we evaluated the suitability of a chromogenic FIXa and an NAPTT assay for measuring FIXa impurities in rFIX drug substance and drug product preparations.
Methods: We used a commercially available chromogenic FIXa assay in kit format (Rossix). FIXa activity was quantified specifically against an FIXa standard provided in the kit whose potency was assigned vs. a WHO International Standard for FIXa. FIXa was normalized for rFIX, which was tested by a standard clotting assay (APTT), and calculated as % FIXa (IU FIXa/IU FIX x 100). The NAPTT assay was performed as a one-stage clotting assay in human plasma by addition of phospholipids (tachostyptan, Baxter). Clotting was initiated with Ca^{2+} after addition of sample or buffer. The NAPTT assay readout was considered valid when meeting the criteria specified in EP (> 200 and < 350 s for the blank). Samples were measured undiluted and in serial dilutions ranging from 1:2 to 1:4096. The shortest NAPTT readout in seconds within this dilution series was related to the corresponding blank value for each sample by calculating a ratio.
Results: The FIXa content of 20 rFIX preparations with FIX-concentrations ranging from 50 to 3000 international units (IU) per mL (BAX326 drug substance and drug product, and licensed rFIX [Benefix, Pfizer]) was measured by chromogenic and NAPTT assay. NAPTT ratios ranged from 0.85 to 1.02, chromogenic results from 0.003% to 0.07% FIXa; values for each sample did not correlate. Preparations with the highest FIXa content did not have the lowest NAPTT ratios, as would have been expected, and vice versa.
Summary/Conclusions: A correlation between FIXa levels quantified by chromogenic assay and the ratios of sample to blank NAPTTs in rFIX drug substance and drug product preparations was not found over a broad range of FIX concentrations. The NAPTT assay was of limited use in determining the amount of FIXa in FIX products, therefore, the use of NAPTT only for product release would lead to possible release of batches with higher FIXa content.

PB1.40 – Heparin-Induced Thrombocytopenia: Clinical – I

PB 1.40-1

Evaluation of fondaparinux for the treatment of serotonin release assay positive heparin-induced thrombocytopenia

Bhatt SH[1] and Adra M[2]
[1]*Massachusetts College of Pharmacy and Health Sciences;* [2]*Beth Israel Deaconess Medical Center, Boston, MA, USA*

Background: Diagnosis and management of heparin-induced thrombocytopenia (HIT) remains challenging. The current standard of therapy involves rapid initiation of intravenous direct thrombin inhibitors (DTI) with transition to oral anticoagulation. Due to the coagulation assay interference and high cost of DTI therapy, alternative cost effective and clinically appropriate therapies have been explored for many years. Fondparinux represents a potential treatment option because of a clinical lack of cross reactivity to heparin-PF4 antibody and lack of coagulation assay interference. However, clinical experiences with fondaparinux, especially in serotonin-release assay (SRA) positive patients is limited and requires further research.
Aims: To evaluate the clinical outcomes of fondaparinux therapy in patients with SRA positive HIT.
Methods: The Beth Israel Deaconess Medical Center Institutional Review Board (IRB) approved this evaluation prior to initiation. Pharmacy and hospital databases were used to identify patients who received fondaparinux for a minimum of 24 h between January 2005 and December 2012. Data collection included patient demographics, admitting diagnosis, admitting medical or surgical service, comorbidities associated with elevated intrinsic coagulant activity (malignancy, hepatic diseases), recent surgical procedures, previous anticoagulant treatment, baseline platelet count, INR, hematocrit, hemoglobin, serum creatinine and calculated creatinine clearance(CLcr), and results of platelet-factor 4 (PF4)-Heparin dependent antibody and SRA tests. Medical charts and medication administration records were reviewed for dose and duration of fondaparinux therapy, time to platelet count recovery (i.e. Platelet count > 100,000 mm^3 or return to patient baseline), day of warfarin initiation, warfarin doses administered, duration of dual fondaparinux and warfarin therapy, and incidence of recurrent venous thromboembolism (VTE) at 6 months, and major bleeding.
Results: Thirteen patients with SRA positive HIT, who were treated with fondaparinux rather than DTI, were identified and evaluated. No patients experienced active thrombosis as part of the diagnosis of HIT. Mean age was 63 years old and 57% were female, and the mean CLcr was 72 mL/min. The most common admitting services were surgical, followed by medical. PF4 Antibody and SRA testing were performed in all patients. Fondaparinux was consistently dosed at 7.5 mg once daily, and the mean duration of therapy was 6 days. Patients were transitioned to warfarin, usually beginning on day 2. During the follow-up period, there were no cases of thrombotic complications, recurrent VTE at 6 months, or major bleeding.
Conclusion: Fondaparinux was safe and effective, although infrequent, in the management of SRA positive HIT at our institution. Further studies with larger patient populations are needed to confirm these findings.

PB 1.40-2

Recombinant thrombomodulin as an alternate anticoagulant in the long-term management of patients with heparin-induced thrombocytopenia. Laboratory validation

Fareed J[1], Walenga JM[1], Abro S[1], Hoppensteadt D[1], Syed D[1], Cunanan J[1], Wahi R[1] and Matsuo T[2]
[1]*Loyola University Medical Center, Maywood, IL, USA;* [2]*Hyogo Prefectural Hospital, Hyogog, Japan*

Introduction: Recomodulin® represents a recombinant form of human thrombomodulin, which has been used in Japan for the management of disseminated intravascular coagulation (Saito et al. Journal of Thrombosis and Haemostasis, 5: 31–41). This antithrombotic drug has also been tested in a clinical trial for the management of post-orthopedic surgical prophylaxis of DVT (Kearon, C et al. Journal of Thrombosis and Hemostasis, 3:962–968). Recomodulin produces its antithrombotic effects by multiple mechanisms, including the complexation with endogenous thrombin and mediating the conversion of protein C to activated protein C. It has been reported to have anti-inflammatory effects. At relatively low dosages, 0.3–0.45 mg/kg, this agent has been found to be effective in the management of post-surgical DVT. The structure and mechanism of action of this agent differed from heparins and can be used in the management of heparin-compromised patients. The purpose of this study was to determine if recomodulin cross-reacts with HIT antibodies in various settings.
Materials and Methods: Commercially available Recomodulin® was obtained in the lyophilized powder form from Asahi Kasei Pharma Corp. (Tokyo, Japan) and reconstituted in sterile saline to obtain 1 mg/mL solution. Working dilutions were prepared at 100, 10 and 1 μg/mL. The effect of recomodulin on HIT antibody mediated platelet aggregation was studied using platelet aggregometry. Platelet rich plasma preparations from normal donors (40) were supplemented at graded concentrations of 10, 1 and 0.1 μg/mL. The effect of HIT antibody was studied using individual and pooled HIT sera as a source of antibodies. Parallel positive controls were run using heparin at 10, 1 and 0.1 μg/mL. Saline served as a negative control. Recomodulin and heparin were incubated with whole blood and platelet factor 4 release was measured using an ELISA method.

Results: In a concentration range of 1–10 μg/mL, recomodulin did not facilitate HIT antibody mediated aggregation of platelets. In both the pooled and individual HIT sera studies, in contrast to recomodulin heparin mediated HIT antibody aggregation of platelets at 10 and 1 μg/mL in all PRP collected from various donors. At 0.1 μg/mL a slightly weaker aggregation response was observed in 30/40 donors' PRP. Incubation of heparin produced a measurable release of platelet factor 4 from platelets; whereas, recomodulin did not produce any release of PF4.
Discussion: These results suggest that recomodulin can be used as an alternate anticoagulant for the management of such heparin compromised patients as the heparin induced thrombocytopenia group. These studies also suggest that recomodulin does not interact with HIT antibodies and will not mediate platelet aggregation in HIT patients. Moreover, recomodulin does not release any platelet factor 4 and their subsequent complexation with heparin or heparin like substances. Since at relatively low dosages this agent has been found to be effective for extended prophylaxis of DVT, these studies indicate that recomodulin may be a useful option for the management of patients with heparin-induced thrombocytopenia.

PB 1.40-3

Variations in the prevalence of HIT antibodies during the period 2004–2012. Relevance to heparin contaminants

Bansal V[1], Hoppensteadt D[1], Jeske W[1], Walenga JM[1], Singh A[2] and Fareed J[1]

[1]Loyola University Medical Center, Maywood, IL; [2]Brigham and Women's Hospital, Boston, MA, USA

Introduction: The generation of anti-heparin platelet Factor 4 antibodies depends on several factors of which the quality of heparin in terms of its composition plays a major role. Heparins contaminated with other glycosaminoglycans and varying sources produce variable immunogenic responses. During the period of November 2007–April 2008 several batches of unfractionated heparin were recalled due to unexpected adverse reactions. These heparins were characterized to contain such contaminants as oversulfated chondroitin sulfate and high molecular weight dermatan sulfate. Other heparin-like glyocaminoglycans were also reportedly present in these preparations. Several centers also reported a high prevalence of heparin induced thrombocytopenia (HIT) during this time. In order to compare the prevalence of HIT antibodies in patients undergoing maintenance hemodialysis, plasma samples from different time periods were analyzed during the period spanning 2004–2012.
Materials and Methods: In conjunction with an ongoing program to investigate the prevalence of HIT antibody (HIT Ab) in ESRD, blood samples were collected from patients (n = 53–139) on maintenance dialysis were retrospectively analyzed for the presence of these antibodies during the period 2004–2013. Specified cut off levels were used to determine the positive and negative results. An ELISA method (GTI.Brookfield, WI) was used to quantitate the HIT antibodies.
Results: The prevalence of the HIT Ab during the period 2004–2011 was < 15% with the exception of 2007 where it was 35% and in 2008 it was 30%. A decreased prevalence was noted during the period 2009–2011 (13–15%). The samples collected in November 2012 showed an even lower prevalence (7%) of these antibodies. The antibody titers as quantified by optical density measurement were relatively higher during the year 2007 and 2008. Moreover, the subtyping of these antibodies in 2007 and 2008 showed a higher proportion of IgG subtype. Interestingly the platelet counts did not differ in the blood samples collected in different years. Similar trends were noted in the prevalence of HIT antibodies when other methods: to detect HIT antibodies were used.
Conclusions: The oversulfated glycosaminoglycans such as oversulfated chondroitin sulfate and other non-heparin GAG derivatives are most likely to contribute to this increased prevalence and seroconversion of HIT antibodies in 2007–2008. These observations suggest that heparin contaminants have contributed to the higher prevalence of HIT antibodies during the period 2007–2008. The improved quality measures resulting in more purified heparins after this recall have resulted in a decreased prevalence of these antibodies.

PB 1.40-4

Improving specificity for diagnosing heparin-induced thrombocytopenia through repeated testing

Vithanarachchi S, Saminaden L, Downey C, Toh CH and Dutt T

Royal Liverpool and Broadgreen Hospital Trust, Liverpool, UK

Background: Prompt recognition and appropriate treatment of heparin-induced thrombocytopenia (HIT) is required to reduce the risk of serious thrombotic events. Because of the challenges of clinical diagnosis, physicians rely heavily on laboratory testing. Investigation of HIT is common in patients undergoing cardio-pulmonary bypass surgery-due to frequent development of thrombocytopenia post-surgery on a Background: of heparin exposure. 2012 BCSH Guidelines suggest that a cut-off point for a positive test should be used when using an immunologic ELISA to look for HIT antibodies, rather than simply reporting a positive or negative.
Aim: This study looked at the pattern of HIT antibody requesting in a reference laboratory, and the trend of sequential quantitative results obtained using the ELISA immunoassay.
Method: This was a retrospective study of all HIT antibody requests received over the 12-month period December 2011–2012. Results were reported as a quantitative optical density (OD) value. An OD ≥ 1 was deemed a clear positive result, 0.7 to < 1 high negative and < 0.7 clear negative.
Results: Four hundred and fourteen requests were received over 12 months for total 238 patients. 255/414 (62%) requests came from the cardio-thoracic unit and cardiothoracic ITU. Repeat testing (next day) was noted in 86/238 (36%) patients, of which 80/86 (93%) were from cardiac patients. For this sub group, all 51/80 (64%) patients with an initial clear negative test result showed no increase in their OD > 1 with sequential testing. For patients with an initial high negative OD, 14/24 (58%) showed a progression in their OD to ≥ 1. This was statistically significant using Fishers Exact Probability test, $P < 0.001$.
Conclusion: Sequential testing for HIT is common in cardiac patients. Initial high negative OD values 0.7–1.0 have a significant chance of becoming clear positive with repeat testing. High negative ODs should be repeated and such a strategy incorporated into diagnostic algorithms to improve the specificity of the ELISA for the diagnosis of HIT.

PB 1.40-5

Further studies on the pro-inflammatory and thrombotic mediators in patients with suspected heparin-induced thrombocytopenia

Fareed J[1], Antovic J[2], Walenga JM[1], Prechel M[1], Jeske W[1], Hoppensteadt D[1] and Lewis B[1]

[1]Loyola University Medical Center, Maywood, IL, USA; [2]Karolinska Institute, Stockholm, Sweden

Background: Heparin-induced thrombocytopenia (HIT) represents a complex pathophysiologic syndrome in which inflammatory processes, thrombogenesis and vascular manifestations contribute to the morbidity and mortality outcomes. Inflammatory mediators including CD40L, adhesion molecules, tissue factor (TF), microparticles, and vonWillebrand factor (vWF) contribute to the pathogenesis. In addition, several other mediators of inflammation are generated which are not fully characterized at this time. This study was undertaken to

profile some of the mediators of inflammation and thrombogenesis along with the biomarker profiling using a mass spectrometric method.

Material and Methods: Forty (40) baseline samples from patients with suspected HIT were collected at theKarolinskaHospital, Stockholm, and frozen at −70 °C. The control represents plasma samples from 40 healthy normal males and females who have apparently never received heparin or related drugs. These samples were analyzed for HIT antibodies using two ELISA methods from GTI (Wisconsin, USA) and Hyphen (Paris, France). Serotonin release assay (SRA) was also carried out on all samples. vWF, TF antigen and functional microparticles quantitated by annexin trapping were measured by assays from Hyphen. CD40L, P-selectin and ICAM antigens were measured using assays from R&D Systems (Minnesota, USA). Protein chip array was carried out on a SELDI-TOF mass spectrometer (PCS 4000; BioRad, California, USA) employing a gold chip array in the molecular range of 3–150 kDa.

Results: Thirty-eight out of 40 patient samples were positive in the GTI and 37 out of 40 samples were positive in the Hyphen methods. Nineteen samples were positive in the SRA. None of the controls showed positive response in any of the HIT antigen assays or SRA. P-selectin levels were the same in patient and control groups. TF (16.8 ± 4.3 vs. 6.8 ± 3.2 pg/mL) and microparticles levels (25.2 ± 22.1 vs. 4.8 ± 3.8 nM) were higher in the HIT group. CD40L (135 ± 119 vs. 82 ± 48 ng/mL) and ICAM (416 ± 43 vs. 180 ± 20 ng/mL) levels were higher in the HIT group. vWF was increased in the HIT group (1.6 ± 1.0 vs. 0.7 ± 0.3 U/mL). In the SELDI-TOF analysis 32 out of 40 samples showed a unique peak at 11.6 kDa which was absent from the normal samples. Additional peaks at 15.1 and 15.8 kDa were also present in the HIT samples.

Conclusion: These studies further validate that both the inflammatory and hemostatic activation processes are involved in the mediation of the pathogenesis of HIT antibody associated complications. The increased levels of TF, microparticles, vWF, along with the up regulation of CD40L and ICAM may further augment the vascular manifestations. The presence of unique biomarkers also suggests protease dysregulation in this complicated syndrome and require additional characterization of these unique peaks. These studies also suggest that the heterogeneous group of HIT antibodies in this syndrome plays a central role in the regulation of inflammatory and hemostatic activation processes.

PB 1.40-6

Suspicion heparin induced thrombocytopenia in internal medicine: how appropriate are the prescriptions of anti-PF4 antibodies tests?

Reny J-L[1], Beauverd Y[2], Tessitore E[2], Boehlen F[2], Gerstel E[3], Nendaz M[2], Perrier A[2] and Reny J-L[1]

[1]Geneva University Hospital and Geneva Platelet Group, Thonex; [2]Geneva University Hospital; [3]Clinique de la colline, Geneva, Switzerland

Background: Predictive scores (4T's and HEP) to derive a probability for type II heparin induced thrombocytopenia (HIT) have been developed but their real impact in everyday practice is uncertain, particularly in internal medicine poly-morbid patients.

Aims: To describe the clinical management of patients suspected of HIT and evaluate to what extent the 4T's score and the HEP score might safely decrease anti-PF4 antibodies testing in internal medicine patients clinically suspected of type II heparin induced thrombocytopenia (HIT).

Methods: Internal medicine patients treated with unfractionated heparin (UFH), low molecular weight heparin (LMWH) or fondaparinux in whom anti-PF4 were assayed were included. Non inclusion criteria were absence of thrombocytopenia or fall of platelets count and transfer from another hospital.

Results: We included 74 patients over a 29-month period with a mean age of 68 ± 16 years. Twenty-five (34%) were transferred from the intensive care Unit. Forty-three (58%) were treated with UFH, 31 (42%) with LMWH and none with fondaparinux. Indication was thromboprophylaxis in 45 (61%) and therapeutic in 29 (39%). Eleven patients (15%) tested positive for antiPF4 and 4 (5.4%) had confirmed HIT. Clinicians documented the 4T's score in only 10 (14%) patients and the HEP score was never used. The retrospectively calculated 4T's score was < 4 in 54 patients (73%) who would not have needed antiPF4 testing. HEP score was < 2 also implying no antiPF4 testing was necessary in 34 patients (46%, $P < 0.0001$ compared to 4T's). Both scores had a sensitivity of 100% (no patient with a score below the cut-off had HIT). Specificity of 4Ts was 77% and that of HEP was 48%. Following anti-PF4 testing, clinicians stopped heparin in 48 patients (65%) among which 25 (34%) were switched to fondaparinux while the remaining had either a transient or definitive anticoagulant arrest. In three patients, a heparin-induced platelet aggregation (HIPA) test was performed (one despite a 4T's score < 4). At 3 months of follow-up none of the patients were readmitted for a HIT-related condition.

Conclusions: Validated and recommended scores for HIT were vastly underused in this internal medicine population while they could have avoided 73% of the requested antiPF4 tests (4T's) or 46% (HEP) and have a high sensitivity and safety using the appropriate cut-offs.

PB1.41 – Rare Bleeding Disorders – II

PB 1.41-1

Update on GGCX sequence variations causing combined deficiency of vitamin K-dependent coagulation factors (VKCFD) type 1 with a new case of compound heterozygosity

Lebreton A[1], Giansily-Blaizot M[2], Chambon F[1], Sapin AF[1], Aguilar-Martinez P[2], Charmes X[3], Marquès-Verdier A[1], Schved J-F[2] and Cunat S[2]

[1]CHU Clermont-Ferrand, Clermont-Ferrand; [2]CHU of Montpellier, Montpellier; [3]CH Aurillac, Aurillac, France

Background: Hereditary combined deficiency of vitamin K-dependent (VKD) coagulation factors is a rare autosomal recessive bleeding disorder, usually characterized by an early age of onset. Clinical symptoms of VKCFD vary mainly in accordance with pro-coagulant factors levels. VKCFD is genetically heterogeneous since VKCFD is caused by mutations in two distinct genes: the gene encoding for gamma glutamyl carboxylase (*GGCX*) and the gene encoding for the subunit 1 of vitamin K epoxide reductase complex (*VKORC1*). Both enzymes are involved in the vitamin K cycle and lead to post-translational modification of VKD factors to yield their biologically active form, which is an essential prerequisite for blood coagulation.

Aims: We have studied the genetic background of a full-term French male infant presenting a typical phenotype of VKCFD.

Methods: The infant, born with a forceps assistance showed retro-auricular haematomas and a cephalhematoma. He was referred to the Regional centre of bleeding disorders for clinical and biological exploration. After exclusion of acquired forms of the disorder, the two VKCFD related genes were studied using direct sequencing. *In silico* programs were applied to predict the functional significance of the variants. We finally summarized and presented an updated list of mutations associated with the phenotypic VKCFD1 background.

Results: The proband displayed an icterus having required extracorporeal phototherapy but did not show facial dysmorphy, organomegaly, nor infectious syndrome. No drug intake during pregnancy was reported. He is the first offspring of healthy non-consanguineous parents. The family history was negative for bleeding disorder.

Blood coagulation tests revealed a moderate deficiency of both VKD procoagulant factors and inhibitors. FV, VWF and FVIII levels were strictly in the normal range. A relative resistance to parenteral vitamin-K therapy led to explore genetical analysis for VKCFD.
Sequence analyses revealed a *GGCX* compound heterozygosity for a missense mutation of paternal inheritance p.Pro61Leu which is located in the first amino acid of the first transmembrane domain of GGCX, and for a frameshift mutation of maternal inheritance p.Tyr690Cysfs*39 in exon 14 which may give rise to a truncated protein. This was the eleventh case of VKCFD type 1 reported without PXE-like disorder associated, and the sixth involving a new compound heterozygosity.
Searches for Panther families and trees showed that Pro61 and Tyr690 are located in a highly conserved region. Interestingly, as predicted by JPred algorithm, both variants, if ever secreted, may impact the VKD protein site of interaction region of GGCX designed by Wu *et al*. (Blood 1997;89: 4058).
The follow-up of the child at 23 months of age displayed that the level of VKD coagulation factors returned to near-normal following treatment with 2 mg doses of vitamin K, three times a week, and there were no sign of skeletal abnormalities.
Summary/Conclusions: We identified a new *GGCX* compound heterozygosity (NP_000812.2: p.[Pro61Leu];[Tyr690Cysfs*39] associated with VKCFD1 in a French male infant. Functional impairment of the two variants was deduced from *in silico* studies. The collection of all genetically characterized VKCFD1 cases is also presented and could be useful for further genetic studies.

PB 1.41-2

Arg69Pro is a novel mutation in factor VII with defective binding to rabbit thromboplastin

Vinayagam S[1], Mellars G[1], Pie J[1], Thurlow P[1], Riddell A[1] and Gomez K[2]
[1]*Royal Free Hospital NHS Trust;* [2]*University College Medical School, London, UK*

Background and Aim: Heritable Factor VII (FVII) deficiency is a rare autosomal recessive disorder with highly variable phenotype. It is caused by mutations in the *F7* gene located at position 13q34. *F7* gene contains 9 exons (1a, 1b and 2–8) of 12.8 kbp that are translated into a 466 primary polypeptide. Many functional polymorphisms and mutations are described which can explain the variable phenotype. Therefore characterisation of the underlying molecular defect in these individuals facilitates diagnosis, informs clinical management and provides information about structure -function relationships in FVII.
Patients and Methods: Fifteen patients with reduced FVII levels were screened for mutations in the *F7* gene. Mutations were found in 13 patients. History were unknown for four cases. 6/9 patients had mild bleeding symptoms while 3/9 patients were asymptomatic and detected following incidental finding of a prolonged prothrombin time. Except for two siblings, cases were unrelated probands. The FVII:C assay was based on Quick's one stage clotting assay performed on the ACL 3000 coagulometer using Hemosil PT-Fibrinogen HS reagent (both from Instrumentation Laboratory, USA). Genomic DNA was amplified by PCR using M13 tailed primers (Eurofins MWG Synthesis, GmbH.) as previously described. The DNA was amplified in 35 cycles with denaturation at 96 °C (30 s), annealing at 67 °C (1 min) and extension at 72 °C (1 min). Amplicons were analysed by direct sequencing in AB3100 Avant Genetic analyser (Applied Biosystems, UK). Chromatograms were scanned for variations using the Staden package (http://staden.sourceforge.net/). Variants were modelled on the crystal structure of tissue factor (TF) complexed with FVIIa (PDB Id: 1DAN) using PyMOL (DeLano Scientific LLC).
Results: Mutations and polymorphisms were detected in 13 out of 15 patients all in the heterozygous state. One novel missense mutation p.Arg69Pro in exon 2 encoding the Gla domain of FVII molecular structure was found. This patient's FVII activity was discrepant with a markedly lower level of 7 IU/dL when assayed with rabbit thromboplastin compared with 44 IU/dL with human thromboplastin. The defective binding to rabbit thromboplastin has been described previously in patients with mutations in serine protease domain (p.Arg364Gln) and in EGF1 domain (p.Arg139Gln). Both the mutations, p.Arg139Gln and p.Arg364Gln are in the region that directly binds with TF and which explains the discrepancy. It is not clear how Arg69 might interact with TF as the resolved structure only contains the extracellular domain. It is likely that Arg69 disrupts interaction with the phospholipid component of the thromboplastin reagent which may then have a secondary effect on TF binding.
Other findings included four previously described missense mutations, two synonymous variations, two donor splice site and one nonsense mutation. Several polymorphisms were found with three being functional polymorphisms which is known to effect FVII levels namely g.73G>A, IVS7 and p.Arg413Gln.
Conclusion: A novel mutation identified and the effects on protein structure predicted. Previously described mutations found in these individuals may help in greater understanding of the clinical phenotype and for delivering the evidence based treatment and management choices.

PB 1.41-3

Influence of coagulation factor XIII on the severity of the skin affection and endothelial dysfunction in patients with progressive systemic sclerosis

Alesci SR[1], Dockhorn C[2], Wahle M[2] and Miesbach W[2]
[1]*IMD Gerinnungspraxis Mannheim, Mannheim;* [2]*Goethe University Hospital, Frankfurt, Germany*

Background and Aim: The postulated ability of factor XIII (FXIII) to influence the synthesis and resolution of collagen led to its usage in the treatment of progressive systemic sclerosis (PSS). Though an alleviation of the skin affection was described in the nineties, a further substitution therapy was given up due to the HIV epidemic. The fact safe FXIII concentrates are available today, allows us to reconsider the above-mentioned thesis.
Methods: After verification by the local ethical committee and with informed written consent, since March 2010 data from 142 patients could be collected. Blood clotting status, blood levels of disease-specific, acute phase and inflammation parameters (like VEGF, DLCO), medical results like the Modified Rodnan Skin Score (MRSS) and a Quality-of-Life-Questionnaire (Scleroderma Health Assessment Questionnaire) have been documented.
Results: Current interim results are presented. Fifty-seven patients (50 f, seven male) with PSS reflecting the broad spectrum of disease severity were included as well as 85 patients (60 f, 25 m) with rheumatic diseases without vascular involvement (R). The median age in both groups was alike (PSS: 52.5 ys R: 53.5). No correlation between FXIII and most of all examined parameters could be detected. Only in the group of patients with elevated FXIII (78% quantiles, $n = 16$) a not significant correlation ($P = 0.156$) to pulmonary arterial hypertension (PAP) was evident. A notable correlation was found between VWF:Ag and MRSS ($r = 0.66$, P: 0.036) as well as vWF:Ag and VEGF ($r = 0.52$, $P = 0.038$). Further, VEGF correlates with DLCO ($r = -0.62$, $P = 0.0558$).
Conclusion: The results of this interim analysis could give pointer of an influence of FXIII on endothelial damage and medical results, but could not yet confirm a significant correlation. Interestingly enough there were found a number of patients with elevated levels of FXIII in both groups (PSS>R). Considering these patients only, we could find an inverse correlation between FXIII and PAP, a severe complication in PSS.

PB 1.41-4

Intracranial hemorrhage (ICH) in Egyptian children with rare coagulation disorders: a single center experience

Abdelwahab M and Seif H

Cairo University Pediatric Hospital, Cairo, Egypt

Background: Rare Bleeding Disorders (RBDs) (such as afibrinogenemia, factors II, V, V+VIII, VII, X, XI and XIII deficiencies) represent 3–5% of all the inherited deficiencies of coagulation factors with ICH being the most serious complication. It is reported with a higher frequency in FVII, FXIII and FX deficiencies and a lower frequency in afibrinogenemia, FII, FV with overall prevalence ranging from 0% in FXI deficiency to 25% in FXIII deficiency.
In view of the rarity of these disorders, many questions remain unanswered making treatment of these life threatening episodes and subsequent prophylaxis a challenge because of the lack of experience and paucity of data on these disorders especially in children aim to prospectively collect data on children affected with RBDs who had CNS bleeding over a 7-year period, to establish incidence of recurrence, death rate, neurological sequences, efficacy of treatments and prognosis.
Methods: All patients with RBD were given instructions that in case of any head trauma or abnormal symptoms to immediately come for haematological consultation even if the child is well. All were subjected to a questionnaire to include all details of episode including triggering factors and replacement was started immediately according to the UKHCDO guidelines in rare coagulation disorders but in view of severe resource constraint. ICH was identified by clinical features, neurological examination and confirmed by computerized tomography scan of the brain. Neurosurgical consultation was done to identify those who could benefit from surgery. In children presenting initially with unexplained ICH, a full coagulation screen was done and patient was managed by hematologist.
Results: ICH occurred in 16/67 children (23.9%) of rare inherited coagulation disorders; 4 (25%) afibrinoginemia, 2 (12.5%) severe FV deficiency, 5 (31.3%) FX, three mild deficiency and two severe, 4 (25%) severe FVII Deficiency and one severe FXIII (7.7%) deficiency, a total of 36 episodes spontaneous in 83.3% and eight children having recurrent episodes. Their age ranged from 7 months to 10 years and 62.5% males whilst their age on intial presentation with ICH ranged from 1 month to 5.5 years (median: 5 months). ICH was the initial presenting symptom in 62.5%. All patients received replacement therapy with only six episodes (16.7%) requiring surgical evacuation. All children recovered their episodes of ICH but six developed neurocognitive deficit, two required shunt where one died postoperatively. Seven patients are on prophylaxis with three developing subsequent episodes whilst on prophylaxis. Intially patients presented with pallor, vomiting, fits, coma, high pitched cry but then subsequent episodes were usually of milder nature and patients outgrew the episodes as they became older . On CT scan, all had intracranial hemorrhage which was mainly subdural conclusion FX, FVII and FI deficiencies were associated with the highest prevalence with higher tendency of recurrence in those with FVII and X deficiencies. Surgical evacuation was not required in most patients and prognosis was usually good if the attacks were recognized within few hours of manifesting and replacement started immediately.

PB 1.41-5

Clinical and laboratory manifestation of bleeding diathesis in Noonan syndrome

Waespe N, Prader S, Kroiss S, Knirsch W, Albisetti M, Speer O and Schmugge M

University Children's Hospital, Zurich, Switzerland

Background: Noonan Syndrome (NS) is a relatively common genetic disorder with an estimated incidence of 1:1000 to 1:2500 live births. Several genetic mutations have been described in these patients leading to different phenotypical presentations. NS is associated with congenital heart defects, hearing loss, skin and facial abnormalities, and growth retardation. Bleeding symptoms and altered laboratory coagulation test results are described in 20–89% of affected patients. The most commonly cited coagulopathies are related to deficiencies of factors VIII, IX and XI, thrombocytopenia, von Willebrand factor deficiency and platelet function defects. The severity of clinical bleeding symptoms is variable.
Aim: To elucidate the incidence of clinical bleeding symptoms and its relation to normal and abnormal coagulation test results in patients with NS at our institution.
Method: Clinical features, bleeding history, blood smear and laboratory coagulation parameters were retrospectively reviewed in patients with NS at our institution. We evaluated the frequency of clinical bleeding symptoms with a questionnaire.
Result: Nineteen patients (seven female, 36.8%) with NS (genetically confirmed in 5, 26.3%) and a median age of 7.4 years (1.5–26.3 years) were included. In nine patients (47.4%) either a positive bleeding history (with a wide variety of bleeding symptoms) and/or abnormal laboratory test results (thrombocytopenia, von Willebrand disease, and abnormal platelet function test) were noted. Altered tests of haemostasis were present in most patients with bleeding symptoms.
Conclusion: The presence of various bleeding disorders within one syndrome is unusual but might be explained by the heterogeneity of several mutations on different genes described in NS. A standardized questionnaire, clinical assessment and laboratory evaluation of haemostasis can help characterize the pathophysiology of bleeding manifestations in NS. Due to the young age of patients at which invasive procedures are undertaken, the bleeding history can be unremarkable at initial presentation despite abnormal laboratory findings. As serious complications can arise and invasive procedures are frequent in these patients, a thorough evaluation of all patients with NS is highly recommended to ensure optimal management for surgery and other risk situations.

PB 1.41-6

Prospective data collection on patients with fibrinogen and factor XIII deficiencies: design of the PRO-RBDD project

Peyvandi F

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

The author is submitting the following abstract on behalf of PRO-RBDD project group.
Background: The cross-sectional project entitled 'Establishment of an European Network of the Rare Bleeding Disorders (EN-RBD)' funded in 2007 by the European Community was established to answer unmet questions on rare bleeding disorders (RBDs). The results of this project increased knowledge on frequency and distribution of each coagulation defect. The EN-RBD database enabled to explore the relationship between the laboratory phenotype and clinical severity of each deficiency, showing that only observed in fibrinogen, FX and FXIII deficiencies there is strong association between plasmatic factor levels and bleeding severity. The main limitation of this retrospective study was the lack of detailed data on the diagnosis setting and the chronology between diagnosis and bleeding episodes. Therefore there is still a gap in knowledge of annual incidence of either disorders and the bleeding manifestations as well as on what is the minimum coagulant activity level able to prevent spontaneous and trauma/surgery/pregnancy related bleeding and provide an adequate hemostasis.
Aims: To design a project to capture prospective data on patients with the most severe RBDs, fibrinogen and FXIII deficiencies being both conditions suffering from under-reporting.

Methods: A dedicated group consisting of specialists in the field and clinical epidemiologists have worked with informational technology team to implement the existing RBDD interactive web-base to include new variables for reaching the current objectives and to allow for data collection at sequential checkpoints (prospective design, PRO-RBDD).
Results: The new database captures data at specific time points for variables including: demographics, racial origin and family studies, genetic, laboratory studies, prophylaxis, bleeding/thrombotic manifestations and their sequelae, obstetric data, surgical bleeding and perioperative data, treatment efficacy and safety. A new section has been added to the database in order to allow prospective data entry. Over 3 years, there will be six data entry time points per patients (i.e. biannual update), although data will be collected also in any other non-scheduled visits. Seventeen participating centers from 10 countries (Germany, Greece, India, Iran, Italy, Pakistan, Serbia, Switzerland, Turkey, UK) have started the baseline data collection in January, which is performed at hospital/clinic. Follow-up visits will consist of initial screening contact by telephone, performed by experienced clinical study physicians/nurses, and personal check-up in case of report of (suspected) bleeding episodes or other medical events.
Conclusions: The PRO-RBDD collect prospective data on patients with the two most severe RBDs, fibrinogen and FXIII deficiencies. Once data will be available for these two disorders, hopefully the same model will be extended to different disorders. This endeavor shall provide essential information on the course and optimal management of these orphan diseases. Moreover the prospective cohort design will allow to define appropriate surrogate end-points to adequately evaluate treatments and particularly the design of new clinical trials and the creation of guidelines for standardized therapeutic approaches.

PB1.42 – von Willebrand disease: Clinical – I

PB 1.42-1

Iatrogenic bleeding is the presenting symptom in children with moderate or severe von Willebrand disease – from the WiN study

Sanders YV[1], Fijnvandraat KJ[2], Mauser-Bunschoten E[3], Van Der Bom JG[4], De Meris J[5], Eikenboom HCJ[6], Laros-van Gorkom BAP[7], Tamminga R[8], Cnossen MH[9] and Leebeek FWG[1]

[1]Erasmus University Medical Center Rotterdam, Rotterdam; [2]Emma Children's Hospital, Academic Medical Center, Amsterdam; [3]Van Creveldkliniek/UMCU, Utrecht; [4]Leiden University Medical Center & Sanquin Research, Leiden; [5]Netherlands Hemophilia Society, Badhoevedorp; [6]Leiden University Medical Center, Leiden; [7]Radboud University Nijmegen Medical Centre, Nijmegen; [8]University Medical Center Groningen, Groningen; [9]Erasmus University Medical Center/ Sophia Children's Hospital, Rotterdam, The Netherlands

Background: von Willebrand Disease (VWD), the most common inherited bleeding disorder, is caused by reduced levels or activity of von Willebrand factor (VWF). Clinical expression of VWD in children may differ from adults. Currently limited information is available on the bleeding phenotype in children with VWD.
Aims: To evaluate the occurrence and severity of various bleeding symptoms in a large cohort of children with different types of VWD and to compare it with bleeding symptoms in adults with VWD.
Methods: We included 140 children with type 1 (n = 70), 2 (n = 51) and 3 (n = 19) VWD and 664 adults (≥ 16 years old) with type 1 (n = 389), 2 (n = 247) and 3 (n = 28) VWD in a nation-wide cross-sectional study among patients with moderate and severe VWD, defined as VWF levels ≤ 30 U/dL (Willebrand in the Netherlands – WiN study). Informed consent and ethical approval was obtained. Bleeding severity was determined using the validated adult Tosetto Bleeding Score (BS) with the extension of additional pediatric-specific bleeding symptoms (umbilical stump bleeding, cephalohematoma, post-circumcision bleedings, post-venipuncture bleeding and macroscopic hematuria) (*Bowman et al, JTH 2009*).
Results: Median age was 7 years in children (range 0–16 years) and 45 years in adults (range 16–85 years). In children median BS was 5.5 (IQR 2.0–9.0). When pediatric-specific bleeding symptoms were included it was 6.0 (IQR 2.0–10.0). In adults the BS was significantly higher with a median BS of 11.0 (IQR 6.3–17.0) ($P < 0.001$). The most frequent bleedings in children were: cutaneous, minor wounds, tooth extraction and menorrhagia. Compared with adults with VWD, children had significantly less bleeding from minor wounds, oral cavity and gastro-intestinal tract, bleeding after surgery and tooth extraction, muscle hematoma and hemarthrosis ($P < 0.05$). Pediatric-specific bleeding symptoms were reported in 41 children (14/140; 29%), occurring in 12 (12/19; 63%) type 3 VWD, 17 (17/51; 33%) type 2 VWD and 12 (12/70; 17%) type 1 VWD patients ($P < 0.001$). Thirteen patients reported more than one pediatric-specific bleeding symptom. The most observed pediatric-specific bleeding symptoms were: post-vaccination bleeding (24/140; 17%), post-venipuncture bleeding (17/140; 12%), post-circumcision bleeding (5/140; 4%) and cephalohematoma (5/140; 4%). Eight of 31 index cases (26%) had a pediatric-specific bleeding symptom as presenting symptom. A iatrogenic bleeding was the presenting symptom in almost half of the index cases (n = 13/31; 42%). These iatrogenic bleeding symptoms were cephalohematoma after vacuum extraction (1/31; 3%), umbilical stump bleeding (1/31; 3%), post-surgery (5/31; 14%), post-circumcision (1/31; 3%) and post-vaccination bleeding (5/31; 16%).
Summary/Conclusion: A large proportion of children with VWD reported pediatric-specific bleeding symptoms. Iatrogenic bleeding is the presenting symptom of VWD in almost half the index case patients.

PB 1.42-2

Prenatal diagnosis in severe von Willebrand disease using intron 40 markers of VWF gene and phenotypic assays

Shetty SD, Ghosh K and Kasatkar P

National Institute of Immunohaematology, Mumbai, India

Background: von Willebrand disease (VWD) is the common hereditary coagulation abnormality arising from deficiency of von Willebrand factor (VWF), a multifunctional, multimeric protein that is required for platelet adhesion and carrier of Factor VIII. Type 3 is the predominant subtype (60%) followed by (19%) type 2 and (18%) type 1 reported at our center. Diagnosis, genetic counseling, carrier and antenatal diagnosis play an important role in the comprehensive management of these cases. Genetic diagnosis in VWD by direct mutation detection is a complex and laborious procedure due to large gene size, high heterogeneity of mutations and 97% homology to a pseudogene in chromosome 22.
Aim: To offer genetic diagnosis to affected severe VWD families using intron 40 markers in VWF gene and by phenotypic assays.
Methods: Sixteen families with severe VWD were referred for antenatal diagnosis. Chorionic villus sampling was done in 10–12th week of gestation and cordocentesis was done between 18th and 19th week of gestation. PCR amplifications of VWF1, VWF2 and VWF3 markers (entire VNTR amplified and digested using AluI restriction enzyme) of intron 40 followed by polyacrylamide gel electrophoresis reveals several alleles. Phenotypic assays included FVIII:C, FIX:C and von Willebrand factor antigen (VWF:Ag) assays.
Results: Antenatal diagnosis was offered by intron 40 VNTR analysis in 12 VWD families by chorionic villus sampling. Four families were offered the diagnosis by cord blood sampling. In two of these families,

none of the VNTR markers were informative, while two were referred late during pregnancy; so cordocentesis was done by phenotypic analysis. Among the 16 fetuses three were found to be affected and 13 unaffected.

Conclusion: Antenatal diagnosis could successfully be offered in all the sixteen VWD families referred using both genotypic and phenotypic investigations. RFLP analysis with the aid of intragenic markers is a simple accurate method for genetic diagnosis of severe VWD families, when both the parents are informative. Phenotypic assays are still not obsolete techniques for prenatal diagnosis of VWD and other bleeding disorders, wherein the genes are large and mutations are highly heterogeneous.

PB 1.42-3

Vicenza bleeding score is correlated with postoperative bleeding and blood transfusion requirement in total knee replacement operation

Chinthammitr Y, Srisawat S, Ruchutrakool T, Suwannawiboon B, Chareancholvanich K, Udomkiat P, Soontarinka S, Nakkinkun Y and Binhama T

Siriraj Hospital, Bangkok, Thailand

Background: The Vicenza bleeding score is a validated research tool to discriminate between healthy subjects and those with von Willebrand disease. Standard preoperative bleeding assessment comprises history taking and physical examination whereas blood test is usually performed in the operation with a high bleeding risk. Whether Vicenza bleeding score is predictive for postoperative bleeding and postoperative blood transfusion requirement is not known.

Aims: To study the correlation of bleeding score and postoperative bleeding and blood transfusion requirement in total knee replacement operation.

Methods: Prospective study has been performed from 1 March 2012 to 31 January 2013. A total of 270 patients admitted for total knee replacement operation due to osteoarthritis of knee had been interviewed with bleeding score questionnaire. The amount of postoperative bleeding and blood transfusion given in hospital were recorded. Other collected data included preoperative CBC, coagulogram, creatinine, medication and underlying disease.

Results: Of the 270 patients (230 females, 40 males), the median age is 70 years old (range 46–90). There is no perioperative thromboprophylaxis. All patients received perioperative tranexamic acid injection. The median (range) of bleeding score are −1 (−3 to 9) in women and −1 (−2 to 4) in men, respectively. The mean + SD amount of postoperative bleeding is 424.8 + 267.1 mL. High bleeding score more than zero (score > 1) is statistically significantly associated with higher amount of postoperative bleeding (median 375 vs. 485 mL, $P = 0.01$ (Mann–Whitney *U*-test)). Postoperative blood transfusion requirement is significantly associated with both bleeding score ($P = 0.004$), preoperative hematocrit level ($P < 0.001$, (Mann–Whitney *U* test)), and amount of postoperative bleeding ($P < 0.001$, (Mann–Whitney *U* test)). Bleeding score is not associated with preoperative hematocrit level ($P = 0.119$). The amount of postoperative bleeding is not associated with preoperative hemoglobin level, platelet level, creatinine clearance level, medication and any underlying disease. There is no symptomatic venous thromboembolism during admission.

Conclusion: High Vicenza Bleeding score more than zero (score > 1) is associated with postoperative bleeding and blood transfusion requirement in total knee replacement operation.

PB 1.42-4

Screening for type 2 von Willebrand disease in the pediatric population

Shafi R[1], Soundar EP[1], Teruya J[2], Srivaths LV[2] and Hui SKR[2]

[1]Baylor College of Medicine; [2]Texas Children's Hospital, Houston, TX, USA

Background: Diagnosis of Type 2 VWD can often be challenging. von Willebrand Factor (VWF) panel, especially VWF activity to VWF antigen ratio (VWF: RCo/Ag) is used as an initial screening tool for Type 2 VWD often followed by a confirmatory multimer analysis. Commonly, VWF: RCo/Ag of < 0.5–0.7 cut-off is used by pediatricians to select patients for multimer analysis. However, such a cut-off is established by adult studies and no pediatric specific range has been suggested thus far.

Aim: Our aim was to determine a cut-off point for VWF: RCo/Ag that best discriminates pediatric patients as suspicious for Type 2 VWD prompting multimer analysis vs. having type 1 VWD.

Methods: We performed a retrospective chart review of 300 children with VWF panels and multimer analysis seen at our tertiary referral hospital from 2009 to 2012. Patients without multimer analysis were excluded from the study population. A receiver operating characteristic (ROC) analysis was done to determine the optimal VWF: RCo/Ag cut-off value that identifies patients with ratio below the cut-off value as suspicious for Type 2 VWD prompting multimer analysis.

Results: Out of 300 patients (median age 14 years; range 11 months–20 years), 230 (77%) were female, of which 150 (50%) had menorrhagia at presentation. Fifty eight patients (19%) experienced epistaxis, four presented with intracranial bleed, 12 showed easy bruisabilty, six each showed post-operative bleeding and other symptoms such as hematochezia and hemoptysis while four had bleeding after dental extraction. Thirty one (10%) patients did not report bleeding symptoms at presentation and in 22 patients (7%), bleeding symptoms were not documented.

Twenty one patients out of 300 had abnormal multimer analysis of which 18 results were suggestive of Type 2 or acquired VWD and the remaining three were suggestive of artifact and/or inconsistent with Type 2 VWD.

At a cut-off value of 0.70 for VWF:RCo/Ag ratio, the sensitivity to detect possible type 2 VWD was 83% with a positive predictive value of 90%, specificity of 45% and a negative predictive value (NPV) of 98%. When the cut-off value was increased to 0.80, the sensitivity increased to 100%, but the specificity decreased to 25%. These results were essentially similar in a subset of female patients with menorrhagia. At a cut-off value of 0.70, the chance of missing a true positive patient was 17%. This contrasts with a 39% (< 0.6 cut-off) and 72% (< 0.5 cut-off) chance of missing a true positive patient with the currently employed cut-off values used by clinicians in determining the need for multimer analysis.

Summary/Conclusion: The current recommended VWF: RCo/Ag ratio below which multimer analysis is performed can be as low as 0.5. However, our study showed that VWF: RCo/Ag ratio of 0.7 is the optimal cut-off for screening children for abnormal multimers to detect Type 2 VWD. This is the first study to validate the role of VWF: RCo/Ag ratio as a screening tool for Type 2 VWD in the pediatric setting.

PB 1.42-5

von Willebrand factor genotyping for validation of type 2N von Willebrand disease subtitle: the relation between genotype and phenotype in von Willebrand disease type 2N

Mancini T, Van Haren B, Schoormans S, Hofste T, Diekstra A, Laros-van Gorkom BAP, Brons P, Hoefsloot L and Van Heerde WL

Radboud University Medical Centre, Nijmegen, The Netherlands

Introduction: von Willebrand disease (VWD) type 2N is characterized by a defective binding of Factor VIII to the von Willebrand factor (VWF) resulting in lowered plasma factor VIII level and a clinical phenotype mimicking mild hemophilia A. Several mutations in the factor VIII binding site on von Willebrand factor have been reported, which were confirmed by the VWF – factor VIII binding assay (BC). This study aims to examine the effect of genotype on clinical phenotype in a cohort of VWD-2N patients.

Methods: In a retrospective study, results of genetic screening in the VWF molecule from 173 patients were analyzed. Patients with at least one 2N mutation were included in this study. Clinical phenotype including bleeding scores (BS) were obtained and analyzed using independent T tests and Mann–Witney *U* tests.

Results: Forty-three VWD-2N patients were included. Median age was 40 years. Six patients were homozygous, 37 patients were heterozygous. Eighteen patients had a secondary mutation outside the FVIII binding domain. Four different 2N mutations were reported. A strong correlation was observed between FVIII and VWF-FVIII binding capacity (slope = 0.735, $P = 0.000$). Typically affected 2N patients, defined as having a VWF-FVIII BC < 20%, were compared with heterozygous carriers (with a VWF-FVIIIBC > 20%). Significant differences were found in FVIII level ($P < 0.001$), VWF-ristocetin activity ($P = 0.048$) and VWF-antigen levels ($P = 0.003$). Median BS was 7 in typical 2N patients compared to 1 in carriers. There was an inverse correlation between vWF-FVIII:BC and BS (slope = −0.450, $P = 0.016$). Hemarthrosis (31%), muscle hematoma's (22%), and postpartum hemorrhage (60%) were only reported in typical affected patients but not in the group of type 2N carriers.

Conclusions: VWD type 2N patients form a heterogeneous group. Carriers of VWD 2N have an insignificant BS unlike typically affected patients. Bleeding symptoms of affected patients are comparable to mild hemophilia A. Classical Hemophilia A symptoms are absent in heterozygous carriers. We suggest genotyping as a powerfully tool in the diagnostics and sub classification of type 2 VWD.

PB 1.42-6

Safety and efficacy of a von Willebrand factor/factor VIII concentrate (Wilate®): a single centre experience

Batty P[1], Chen YH[2], Platton SJ[1], Bowles L[1], Hart DP[2] and Pasi J[2]

[1]Royal London Hospital; [2]Barts and the London School of Medicine and Dentistry, QMUL, London, UK

Background: von Willebrand disease (VWD) is a highly heterogeneous bleeding disorder characterised by a defect in primary haemostasis. The majority of patients with severe disease will require treatment with a VWF containing concentrate in the event of bleeding or surgery. A new VWF/fVIII concentrate (Wilate®) has been available for usage in the United Kingdom. This concentrate has dual viral inactivation (SD and Permaheat) and provides a physiological ratio of VWF:fVIII (1:1). We present a large cohort of usage of this concentrate in an adult population.

Aims: Retrospective review of indications for Wilate® over 5 years (2007–2012) at a large haemophilia treatment centre. The primary outcome measure was efficacy for the treatment of bleeding and usage in the peri-operative period.

Methods: Clinical and laboratory data of all patients issued with Wilate® during the study period were reviewed.

Results: One thousand two hundred and eighty-seven evaluable doses of Wilate® were issued to 46 patients (25 male/21 female). Median age was 42.5 years (18–83). Eleven patients had type 1 disease, 26 patients had type 2 disease, eight patients type 3 disease and one patient acquired vWS. One hundred and twelve infusions were issued for surgery over 63 treatment episodes. Median number of infusions used peri-operatively was 1 (1–13), with a median dose prior to surgery of 3600 Units (1800–7200), corresponding to 42.6 U/kg (11.8–117.5). In patients receiving more than one dose the median follow up dose was 2250 Units (1800–4500) equivalent to 26.5 U/kg (17.9–68.2). Efficacy was rated as being excellent or good in 94%, fair in 6% and poor in 0%. Two hundred and forty-six doses were issued for the treatment of 39 hospital treated bleeding events. The median number of infusions received per bleeding episode was 2 (1–92). The median dose used was 2700 Units (900–8100) corresponding to 38.5 U/kg (11.8–95.7). Efficacy was rated as being excellent or good in 97%, moderate in 3% and poor in 0%. One treatment episode (type 3 VWD) required 92 inpatient treatments for haematuria due to underlying bladder pathology and subsequent prophylaxis. Thirty-nine infusions were issued for other indications such as delivery and single dose prophylaxis. Six patients were on home therapy programmes using 890 infusions. Of these patients, two switched from an alternative VWF/fVIII containing product. Similar efficacy was seen for Wilate® in comparison to the 6 month period on prophylaxis prior to switching. Six adverse events (0.005% of all infusions) were documented. This included four hypersensitivity reactions requiring medical treatment and subsequent product switching. No thrombotic or infective complications were described in the study period. There were no treatment failures. No demonstrable accumulation of FVIII was seen in patients receiving treatment for > 3 days.

Conclusions: A retrospective review of 1287 doses of Wilate® shows safe and well tolerated usage covering a wide range of indications. Within this study period efficacy was excellent or good in 94% or greater of all treatment episodes. In patients treated with repeat doses of Wilate® no accumulation of FVIII occurred.

PB1.43 – Von Willebrand Disease: Clinical – II

PB 1.43-1

von Willebrand disease patients with associated risk factor(s) of venous thromboembolism: efficacy and safety of a von Willebrand factor product with a low factor VIII content

Goudemand J[1], Borel-Derlon A[2], Federici AB[3], Chatelanaz C[4], Henriet C[4], Jaffry A[4], Bridey F[4] and Group TS[5]

[1]University of Lille, Lille; [2]Hemophilia Center, Caen, France; [3]University of Milan, Milano, Italy; [4]LFB, Les Ulis; [5]France

Background: The main objective of von Willebrand Disease (VWD) treatment is the control of bleeds with normalization of von Willebrand factor (VWF). Because VWF is the carrier of factor VIII (FVIII), exogenous added to endogenous FVIII may cause very high levels of FVIII coagulant activity after repeated infusions (FVIII:C). Multiple clinical risk factors as well as biomarkers have been identified as predictive of venous thromboembolism. These risk factors include patient-related factors e.g. advanced age, obesity, inherited thrombophilia and medical condition-associated factors e.g. surgery, immobility, pregnancy/puerperum or cancer. High plasma levels of FVIII:C are confirmed as a risk factor for VTE.

Aims: To present the efficacy and safety of WILFACTIN (VWF with low FVIII content) in different clinical settings in a large cohort of VWD patients with risk factors of VTE.

Methods: Data from four clinical studies and one post-marketing survey, carried out between 1999 and 2009, were pooled.

Results: Across clinical studies, data displays mainly three sets of patients:

- Elderly patients ($n = 21$) between 65 and 85 years old (1 type 3, 16 type 2, 4 type 1 VWD) were treated with WILFACTIN for 42 bleeds, 31 surgeries including six major risk orthopaedic procedures. Four patients were on long-term prophylaxis initiated for recurrent gastrointestinal bleeds for more than 2 years. Treatment was judged by investigators as 'excellent/good' in 90.9% of the 11 bleeding episodes and in 100% of the 26 surgical procedures for which the efficacy information was available. A 'moderate' response was observed for one bleed. The prophylaxis regimen (mean dose: 37 IU/kg 2.2 times per week) was successful in all patients; the annual number of bleeds was 1.2 (range 0–2.8).
- Obese patients ($n = 14$), including one elderly, had BMI > 30 kg/m^2. The body weight ranged from 82 to 135 kg (mean 99) at time of therapy. There were three patients with type 3 VWD, 8 type 2, 3 type 1; 86% were female. Coexisting thrombotic risk factors included surgery (13) or caesarean section (5). Efficacy was rated as excellent/good in all procedures (11) and major bleeds (5) in 11 patients treated for more than 3 days. No bleeding occurred in the elderly patient on long-term prophylaxis.
- Pregnant women ($n = 22$), including four obese patients, were treated for vaginal (9), caesarean (15) deliveries, or therapeutic abortion by caesarean (1). A 28–103 IU/kg/day dosage was used with a median of 374 (range 103–1114) IU/kg per procedure over a 9.0 (range 1–18) days therapy. Results showed that 95% of episodes (22 with available data) were treated successfully. No relevant safety information was reported in either mother or newborn.

No thrombotic events occurred in all these patients with risk factors for thrombosis.

Conclusion: The results obtained from the analyses of several clinical studies clearly show that WILFACTIN, a VWF concentrate almost devoid of FVIII, can be used frequently and intensively also in VWD patients with older age and/or with relatively high risk of thrombosis. Therefore, WILFACTIN should be always considered by haematologists among the available VWF products useful for VWD with those phenotypes.

PB 1.43-2

Validation of a new panel of automated chemiluminescence assays for von Willebrand factor antigen and activity in the screening for von Willebrand disease

Verfaillie C and Devreese K

Ghent University Hospital, Gent, Belgium

Background: von Willebrand disease (VWD) is one of the most common inherited bleeding disorders and its diagnosis largely depends on the results of von Willebrand factor (VWF) antigen and activity. Although used as a surrogate for the classical ristocetin cofactor activity (VWF:RCo), current latex immunoassays measure indirectly the VWF activity and do not reflect binding of VWF to GPIba or collagen. Recently, a new automated VWF:RCo assay on Acustar was developed. The HemosIL AcuStar VWF:RCo assay is a ristocetin-dependent, platelet-free chemiluminescent immunoassay. Recombinant GPIbα (rGPIbα) is coated on magnetic particles through a highly specific monoclonal antibody. VWF present in the test sample binds to the rGPIbα in the presence of ristocetin.

Aims: The assay panel on AcuStar combines the analysis of VWF:Rco with a new antigen (VWF:Ag) test. In this study, both chemiluminescence tests (HemosIL VWF:Ag and VWF:RCo) were evaluated.

Methods: Imprecision, limit of detection and linearity were evaluated. Method comparison with the currently used VWF:Ag latex assay, VWF activity (VWF:Act) and VWF:RCo by aggregometry was performed and diagnostic performance of the new test panel was examined by analyzing 61 patient plasma samples. As the new assays are calibrated against the current WHO-standard, the international standard was analyzed as well.

Results: The imprecision was 7% and the LOD was 0.2% for both assays. Dilution series showed a large linearity for both HemosIL VWF:Ag (0–300%) and VWF:RCo (0–200%) and method comparison studies revealed good agreement with the currently used VWD panel. The results of the WHO-standard were in accordance with the expectations. The new panel showed adequate diagnostic performance: diagnostic sensitivity was 100% and diagnostic specificity 82% compared to the VWF:Ag latex assay and VWF:RCo by aggregometry. In addition, the new HemosIL Acustar VWF:Ag and HemosIL Acustar VWF:RCo are more sensitive for VWD than the currently used assays.

Conclusions: The HemoSIL Acustar VWF:RCo demonstrated adequate diagnostic performance, improved precision (also in the lower range), a good sensitivity to low VWF activity and a large linearity. Furthermore this test can be considered as a true VWF ristocetin cofactor activity assay independent of the variability present in human platelets. The VWF:Ag test showed equally good performance and a lower LOD compared to the VWF:Ag latex assay. This new VWD test panel has adequate laboratory characteristics and allows fully automated and simultaneous analysis of the VWF:Ag and VWF:RCo.

PB 1.43-3

Analysis of factor VIII:c/VWF:Ag ratio in the Brno-von Willebrand disease study

Vangenechten I[1], Smejkal P[2], Zapletal O[2], Bouddount F[1], Zavrelova J[2], Blatny J[2], Penka M[2], Michiels JJ[1] and Gadisseur A[1]

[1]Antwerp University Hospital, Edegem, Belgium; [2]University Hospital Brno, Brno, Czech Republic

von Willebrand Disease (VWD) is an autosomally inherited bleeding disorder caused by a quantitative or qualitative defect of von Willebrand factor (VWF). VWF is important for platelet adhesion to collagen, platelet aggregation, and for binding to Factor VIII through the D'/D3 domain. FVIII degrades rapidly when not bound to VWF. Generally, except for type 2N patients, FVIII:c values mirror those for VWF:Ag.

In the Brno-VWD study blood was collected from 205 patients representing 95 families with suspected VWD. FVIII:c, VWF:Ag, VWF:RCo, VWF:CB, VWFpp, VWF-FVIII binding (if indicated), VWF multimers and molecular analysis were performed in all patients.

Within the Brno-VWD study we performed a separate analysis of the results for FVIII:c in this group of VWD patients. There were no type 2N patients in the Brno-VWD cohort

Mean FVIII:c/VWF:Ag ratio in the whole cohort van 1.13 (CI_{95} 1.04–1.21) with a statistically significant difference between patients with type 1 VWD (mean 1.31, CI_{95} 1.18–1.45) and type 2 patients (mean 0.91, CI_{95} 0.82–1.02). Two thirds of the patients had a ratio between 0.5 and 1.5. High ratios > 1.5 were found in 40/205 patients (19.5%) and 27/95 families in which sofar 10 mutations have been found (molecular analysis ongoing), mainly type 1 and some type 2A/IIE. Low FVIII:c/VWF:Ag ratios < 0.5 were found in 19/205 patients (9.3%) and 13/95 families in which sofar 6 mutations have been found (molecular analysis ongoing), mainly type 2A, 2A/IIE and 2M, with only 3 type 1 patients which are all compound heterozygous for the type 1 mutation p.P812Rfs (X31) together with the type 2N mutation p.R854Q .

Although the majority of VWD patients have FVIII:c/VWF:Ag ratios between 0.5 and 1.5, around one third may present with either very low or very high ratios. A FVIII:c/VWF:Ag ratio < 0.5 does not always lead to the diagnosis of a type 2N VWD but may be present in other type 2 mutations. High ratios are mostly seen in type 1 VWD.

PB 1.43-4

Efficacy and safety of Wilate® following an en masse switch for patients with inherited von Willebrand disease

O'Connell M, Singleton E, Byrne MB, Ryan K, White B and O'Donnell J

The National Centre for Hereditary Coagulation Disorders, Dublin, Ireland

Background: Wilate is an albumin-free, high purity, double virus inactivated concentrate of von Willebrand Factor (VWF) and factor VIII (FVIII). Previous clinical trials have reported high levels of Wilate efficacy in the treatment of acute bleeding episodes and surgical procedures. A National Tender process in Ireland in 2010 resulted in the introduction of Wilate as the treatment of choice for patients with von Willebrand disease (VWD) who fail to respond to DDAVP.

Aims: This study aimed to assess the efficacy and safety of Wilate for the treatment of unselected Irish patients with VWD following an en masse switch in treatment product.

Method: A retrospective review of the clinical records of all patients treated with Wilate between September 2011 and September 2012 was undertaken. The following datasets were reviewed: demographics, VWD diagnosis, treatment indication, haemostatic efficacy, adverse events and laboratory data including pre and post FVIII, VWF antigen (VWF:Ag) and Ristocetin co-factor activity (VWF:Ricof) levels.

Results: Wilate was used on 39 occasions in 28 patients with the following subtypes of VWD: Type 1 (n = 14), Type 2 (n = 11), Type 3 (n = 2) and acquired VWD (n = 1). Of 29 invasive procedures, six were major surgeries, eight were minor surgeries and 15 were invasive dental procedures. The median (range) of Wilate doses used were 49 IU/kg (40–53.1 IU/kg) for major surgery, 42.5 IU/kg (28–53.1 IU/kg) for minor surgery and 30 IU/kg (20–43 IU/kg) for dental procedures. Wilate was used to treat acute bleeding on five occasions and to prevent postpartum bleeding on two occasions. One patient with acquired VWD received Wilate on three occasions to treat acute bleeding. Wilate doses ranged from 24 to 50 IU/kg to treat acute bleeds with higher doses used to treat the patient with acquired VWD (48–75 IU/kg). Haemostatic efficacy was rated as excellent or good in 28/29 surgical procedures and in all episodes of acute bleeding. Three mild adverse events were noted including dry cough, an anxiety reaction and an urticarial reaction with hoarseness. Post infusion, laboratory analysis demonstrated that the FVIII and VWF:Ag levels were in the normal range for all patients. The VWF:Ricof was < 0.5 IU/mL in five patients who received doses of Wilate of < 30 IU/kg. It was notable that the VWF:Ricof levels in all patients were significantly less than the VWF:Ag levels. No accumulation of FVIII was noted in patients receiving repeated doses but two patients with type 2A VWD required increasing doses of Wilate post-op due to sub-therapeutic VWF:Ricof levels. Importantly, no new clinically significant VWF inhibitors were identified following this en masse switch in treatment product.

Conclusion: Wilate has been found to be clinically effective with a satisfactory safety profile, following an en masse switch in Ireland. Of note, a significant number of patients with types 1 and 2 VWD have been treated which adds to the limited clinical data previously published on the use of Wilate in these subtypes. Our findings suggest that optimal laboratory assays and target levels for monitoring patient response following Wilate administration requires further evaluation.

PB 1.43-5

Biologic response to desmopressin is there predictable in patients from the same family?

Rugeri L, Meunier S, Gierczynski M, Garcia A, Lienhart A, Dargaud Y, Ffrench P, Chevalier Y and Negrier C

Hopital E.Herriot, Lyon, France

The use of desmopressin (DDAVP) has been largely recommended in the treatment of the von Willebrand Disease (VWD). As the DDAVP biologic response is dependant of the type and the severity of the VWD, its assessment contribute to verify its efficacy before surgery and also contribute to classify the subtype of VWD. Previous studies have shown that in type 2A and 2N only, the genotype could be helpful to predict the individual response. And in patients with severe type 1, a variability of the response could be observed despite the same type of mutation.

The aim of the study was to evaluate if an identical response to DDAVP could systematically be observed in all members from the same family, in order to know if a test have to be always performed.

Methods: We have retrospectively analyzed the biologic response to DDAVP in 87 patients with VWD from 37 families, referred to our centre between January 2003 and December 2012. Intravenous infusions of 0.3 μg/kg body weight DDAVP was given in all patients. Venous blood was withdrawn at baseline and at 0.5 or 1, 2 and 4 h after the infusion ended.

Biologic response to DDAVP was analyzed at time 0.5 or T1 h (T1H) and at time 4 h (T4H). Patients with VWF: RCo and FVIII:C higher than 50 IU/dL was defined as complete responders. Patients with VWF: RCo and FVIII:C lower than 50 IU/dL but increased at least three-fold was defined as partial responders, and if neither criterion obtained as non responders.

Results: Biologic response was evaluated in 58 members of 25 families with Type 1 VWD and 29 patients (12 families) with Type 2 (16 with type 2A, 4 with type 2B (New York), 4 type 2M and 5 unclassified), including 50 children (aged 2–16 years). The mean age was 18 ± 15 (mean SD) years.

In Type 1, 98% of patients had a complete response at T1H and 93% at T4H. At T1H, one patient with severe type 1 (1.7%) had no response, in discrepancy with the complete response observed in the other member of family.

At T4H, an absence of response was observed in four patients (69%) from four families, in discrepancy with the results of the others members.

In Type 2, 65% of patients had a complete response at T1H and only 45% at T4H.

At T1H, among the 10 patients (who had partial or no response), two patients with type 2A had discrepant partial response with the complete responses observed in the other members of the family.

At T4H, a discrepant additional response was observed in a family with type 2M VWD.

Conclusion: Within a family who present a moderate type 1 VWD, the biologic response to DDAVP is identical between the members and thereby the test could probably be delayed or cancelled in other members especially in children. As expected the lower rate of response and its variability in type 2, must to lead us to systematically perform a test in each members.

PB 1.43-6

Low-dose ristocetin induced platelet aggregation. Which dose is low enough?

Frontroth JP, Hepner MD, Pieroni G, Annetta ES, Sciuccati GB, Feliu Torres AS and Bonduel M

Hospital de Pediatria Dr. JP Garrahan, Ciudad Autonomade Buenos Aires, Argentina

Low-dose ristocetin induced platelet aggregation (RIPA) is used to characterize Type 2B (VWD2B) and platelet-type (PT-VWD) von Willebrand disease variants, evidenced by an enhanced aggregation. A 0.5 mg/mL dose is classically applied but recent studies indicate that some VWD2B patients may need up to 0.80 mg/mL of ristocetin to evidence this behavior.

The aim of this study is to evaluate the effect of different doses of ristocetin on platelet-rich-plasmas (PRP) of healthy individuals and to determine the dose to be used in the screening diagnosis of variants with enhanced response to low doses of this agonist.

One hundred and fifteen normal PRPs of healthy individuals (median age 33 year old; range: 19–65, 65 blood group O and 50 blood group non-O) were analyzed testing RIPA at different doses of ristocetin from 1.00 to 0.40 mg/mL. All assays were performed using the same batch of ristocetin in order to avoid batch-to-batch variations. Maximal percent aggregation was measured. All individuals had no history of bleeding symptoms or drug use or thrombocytopenia. Twenty out of 65 (30.8%) of the blood group O and 19/50 (38.0%) of the blood group non-O individuals presented > 30% maximal aggregation at 0.80 mg/mL. Four out of 65 (6.2%) of the group O and 10/50 (20.0%) of the non-O group individuals presented > 30% maximal aggregation at 0.70 mg/mL. No individual presented RIPA at doses of 0.60 to 0.40 mg/mL. We found that a percentage of normal individuals had aggregation at doses > 0.7 mg/mL of ristocetin.

Different responses to the ristocetin doses were observed in healthy individuals according to their blood group. It is necessary to establish a local normal reference range for RIPA and the lowest dose of ristocetin able to differentiate enhanced PRP aggregation, in order to avoid under or over-diagnosis of VWD2B and PT-VWD variants.

PB 1.44-1

Alterations in aberrant and alternative endothelial splicing of von Willebrand factor under high laminar shear stress

Hawke LK[1], Poon M-C[2], Scully M-F[3] and James PD[1]

[1]Queen's University, Kingston, ON; [2]University of Calgary, Calgary, AB; [3]Memorial University, Saint John's, NF, Canada

Background: von Willebrand factor (VWF) mutations have been identified which affect splicing leading to von Willebrand disease (VWD). Although alterations in splicing are not always pathogenic, no alternative splice variants have been described for VWF thus far. Shear stress is an important environmental factor contributing to endothelial cell phenotype, altering many cellular processes, including the expression of transcription factors.

Aim: To investigate the effect of shear stress on the production of aberrant and alternative VWF splice variants in blood outgrowth endothelial cells (BOEC) from type 1 VWD patients and normal controls using an *in vitro* flow system.

Methods: BOEC were derived from two type 1 VWD patients; one with the consensus splice site mutation, c.5842+1G>C, and one with the putative exonic splicing mutation, c.3538G>A, as well as three normal controls. Platelet and BOEC-derived mRNAs were reverse transcribed and sequenced to identify VWF transcripts which were quantified by qRT-PCR. Additionally, BOEC were subjected to high laminar shear stress (30–50 dynes/cm^2) for 48 h and the ratios of the transcripts were compared to those from BOEC grown under static conditions.

Results: Three VWF transcripts were identified from heterozygous c.5842+1G>C BOEC: wildtype, in-frame exons 33–34 skipped, and exon 33 skipped, comprising 50%, 28%, and 22% of the patient's VWF mRNA respectively. The exon 33 skipped transcript was transcribed from the patient's wildtype allele, and represented 13% of VWF mRNA in normal BOEC and platelets, suggesting it was produced by alternative splicing. Under high laminar shear stress patient and normal BOEC significantly up-regulated this alternative transcript 2.6 fold; exon 33 was skipped in 68% of the patient's ($P < 0.05$) and 34% of normals' ($P < 0.005$) VWF mRNA. The proportion of the double exon skipping transcript relative to wildtype remained comparable regardless of shear stress. Therefore, the up-regulation of the alternative transcript shifted the patient's total VWF transcript composition to 22% wildtype, 68% exon 33 skipping, and 10% exons 33–34 skipping.

Four in-frame VWF transcripts were identified in the heterozygous c.3538G>A BOEC grown under static conditions: wildtype (2%), exon 23 skipped (22%), exon 26 skipped (64%), and exons 23 and 26 skipped (11%). The patient's platelet VWF RNA exhibited these transcripts in the same ratios. RNA from statically cultured normal BOEC contained exon 23 skipped or exon 26 skipped VWF transcripts at levels between 15% and 25%. Exposure to high laminar shear stress increased wildtype expression making the exon 23 skipped transcript negligible and decreasing the exon 26 skipped transcript to 3% in normal ($P < 0.05$). This shift was also observed in the patient BOEC under high laminar flow where expression of the exons 23/26 skipped transcript was also abolished under high laminar shear, producing a modified patient VWF population of 93% wildtype and 7% exon 26 skipped ($P < 0.0001$).

Conclusions: This study identified three potential alternative VWF splicing variants and found VWF mRNA in platelets is similar to that from static BOEC. Additionally this study highlights the influence of laminar shear stress on the regulation of VWF alternative and aberrant splicing and expression.

PB 1.44-2

Potential thiol isomerase activity of conserved CXXC motifs in D3, D4 and C1 domains of von Willebrand factor

Shapiro SE, Laffan MA and McKinnon TAJ

Centre for Haematology, Imperial College London, London, UK

Background: A CXXC motif constitutes the active site of thiol isomerases. VWF propeptide contains two CGLC motifs. Whilst the isomerase activity of the propeptide has not been demonstrated directly, there is indirect evidence that these motifs are active in the Golgi, promoting interchain disulphide bonds to form multimers. We noted that VWF contains 14 other CXXC sites, three of which are similar to these motifs in the propeptide (^{994}CGLC in D3, ^{2085}CGIC in D4 and ^{2304}CGLC in C1). Because the -XX- residues are important in determining thiol isomerase activity, we chose these three for further study. In silico analysis showed that they are conserved across domains and species. We postulated that these motifs might either be important for the intracellular synthesis of VWF or in the extracellular promotion of thiol-disulphide exchange suggested to meditate VWF lateral self-association.

Aims: To examine whether the conserved CG (L/I)C motifs in D3, D4 and C1 possess thiol isomerase activity by expressing recombinant mutants and studying their structure and function.

Methods: Two complementary types of full-length VWF mutants were made:

1. D2 replacement mutants. The D2 domain (thiol isomerase activity essential for mutlimerisation) was replaced by either the D3 or D4 domain.
2. Glycine insertion mutants. Each motif was modified by insertion of a glycine (to form CXGXC), which is known to disrupt thiol isomerase activity, creating the mutants GlyD2, GlyD3, GlyD4, GlyC1. Additionally GlyD3 was made in the D'D3 fragment of VWF. The constructs were expressed in HEK293T or HEK293 cells.

Results: Neither of the D2 domain replacement mutants secreted.

GlyD4 and GlyC1 secreted and showed similar expression levels, collagen binding activity, and multimer pattern to wild-type (wt) recombinant VWF. However they both showed a relative increase in free thiols compared to wt VWF. When perfused over collagen, GlyD4 and GlyC1 showed similar platelet capture to wt over a range of shear (800–3000/s).

GlyD2 and GlyD3 were retained intracellularly, although a small amount of GlyD2 was secreted which was largely dimeric.

Wt D'D3 expressed as a monomer, detected in both media and lysate. Interestingly whilst GlyD3 in D'D3 did not secrete, the lysate contained higher order oligomers which were reduced to monomers by β-mercaptoethanol. The multimers were more marked when the intracellular pH was elevated by monensin or ammonium chloride. Co-expression with wt D'D3 did not rescue the secretion of GlyD3 in D'D3.

Summary: These data demonstrate that neither D3 nor D4 can substitute for the D2 domain. Whilst disrupting CG (L/I)C motifs in D4 and C1 resulted in increased free thiols, the integrity of these motifs is not essential for secretion, normal multimer structure, static collagen binding activity or platelet binding. Conservation of D3-CGLC is essential for secretion, suggesting that it has a critical intracellular role. The higher order oligomers in the lysate of GlyD3 in D'D3 is compatible with D3-CGLC regulating aberrant disulphide bond formation in the endoplasmic reticulum. A similar role has previously been reported for the CGLC motif in the D3 domain of submaxillary porcine mucin.

PB 1.44-3

An evaluation of the age-related quantitative and qualitative pathophysiology of von Willebrand factor

Albánez S, Michels A, Sponagle K, Grabell J, James PD and Lillicrap D

Queen's University, Kingston, ON, Canada

Background: Plasma levels of von Willebrand factor (VWF) are influenced by a variety of both genetic and environmental factors. Several studies have shown that VWF levels increase with age, but the mechanisms mediating these age-related changes are unknown.
Aim: To determine the changes in VWF during aging in healthy humans and mice, and to begin to characterize the underlying mechanisms.
Methods: VWF antigen (VWF:Ag), VWF propeptide (VWFpp), Factor VIII (FVIII:C), ADAMTS13 activity, platelet count, Ristocetin cofactor (VWF:RCo) and total carbonyl content were measured in three normal human populations comprised of 172 individuals; 52 young (7 ± 5 years), 42 middle-aged (41 ± 6 years) and 78 old individuals (70 ± 7 years), similar in gender and ABO blood type. Additionally, we measured murine VWF:Ag, VWFpp, FVIII:C and ADAMTS13 activity in a minimum of 10 normal C57BL/6 mice at 9-, 55- and 97-weeks of age, as well as in young and old ADAMTS13 KO and VWF KOs (9- and $\geq$ 55-weeks). Infusions with 200 U/kg of recombinant or plasma-derived murine VWF were performed in young and old VWF KO mice to evaluate VWF clearance.
Results: VWF levels increased progressively with age in humans and mice ($P < 0.0001$), and no difference was observed with gender ($P = 0.55$). VWF levels were positively correlated with increased FVIII:C and reduced ADAMTS13 activity in the human population ($P < 0.0001$). VWFpp levels were only increased in the old human population ($P < 0.0001$), while no difference was observed in mice throughout aging ($P = 0.83$). Therefore, the VWFpp/VWF:Ag ratio decreased progressively with age in both humans and mice ($P < 0.0001$), suggesting a reduction in VWF clearance. Although no difference was observed in the clearance of recombinant mouse VWF in young and old mice ($P = 0.95$), VWF glycan composition may be a key determinant in this process as initial studies following murine pd-VWF infusions have shown marked prolongation of the VWF half-life. In the human population, a significant difference was observed in the increase in VWF levels with age in individuals with blood types A and B, compared to type O subjects ($P < 0.005$). In type O subjects, VWF levels increased minimally with age. ADAMTS13 was not associated with the increase in VWF levels, as similar levels were observed in ADAMTS13 KO mice compared to age-matched normal mice ($P = 0.40$). However, a decrease in ADAMTS13 activity with age and the aforementioned increase in VWF levels were both positively correlated with a decrease in platelet count in humans ($P < 0.05$). VWF levels were also correlated with an increase in VWF:RCo ($P < 0.0001$), however, there was no difference in the VWF:RCo/VWF:Ag ratio between the three populations ($P = 0.49$). Although no correlation was observed between VWF and total protein carbonyl levels ($P = 0.17$), higher carbonyl levels were observed in older individuals ($P < 0.0005$), suggesting that oxidative stress could contribute to altered processing and function of VWF in later life.
Summary/Conclusions: Our findings suggest that the age-related increase in VWF levels occurs progressively due, at least in part, to reduced clearance from plasma, possibly mediated through VWF glycan content. The results also show that there is enhanced VWF activity and secretion in later life.

PB 1.44-4

High-resolution, functional mapping by phage display of VWF residues required for platelet binding

Yee A, Dai M, Meng F and Ginsburg D

University of Michigan, Ann Arbor, MI, USA

Background: Binding of von Willbrand factor (VWF) via its A1 domain to the platelet receptor, GPIb, initiates platelet-VWF interaction. This interaction is influenced by the residues in and around the A1 domain, particularly the cysteines (C1272 and C1458) responsible for forming the intramolecular disulfide loop within the A1 domain.
Aims: To define a minimal VWF fragment required for optimal platelet binding and to test the effect of the C1272-C1458 disulfide bond on platelet binding.
Methods: M13 filamentous phage libraries constructed with random VWF cDNA fragments (400–100 bp or 300–1000 bp) were composed of 8.6×10^5–2.7×10^6 independent clones. Accounting for VWF content (3/4), frame (1/3 at the 5′ and 3′ ends), orientation (1/2), and the fraction of VWF fragments large enough to encompass C1272 and C1458, these libraries were expected to display 754–2073 independent peptide fragments of the A1 domain. Phage clones were also constructed to display either a wild type VWF A1 fragment, a mutant VWF A1 fragment in which the C1272-C1458 disulfide bond was disrupted by alanine substitutions (C1272/1458A), or a wild type VWF A3 fragment. Phage libraries or phage clones screened against formalin-fixed platelets were subsequently analyzed by Sanger or high-throughput DNA sequencing.
Results: Following a single-round screen in the presence of botrocetin, DNA sequencing of randomly selected phage clones revealed a significant enrichment of VWF fragments containing the A1 domain (7/24, $P < 10^{-16}$). Surveying larger sample sizes of phage clones (~1x10^5) by high-throughput DNA sequencing resulted in ~1.24×10^7–1.35×10^7 reads. Applying *in silico* filtration for VWF cDNA and for correct orientation and reading frame at the VWF-phage cDNA junctions identified a minimal, overlapping VWF segment spanning V1252-C1458 (> 9-fold enrichment over pre-screened phage) and found no evidence for VWF segments outside the A1 domain. No specific VWF fragments were enriched in the absence of botrocetin. All enriched VWF fragments encompassed C1272 and C1458, consistent with a requirement for formation of this intramolecular disulfide bond to confer an optimal A1 domain structure for platelet binding. Further analyses of a mutant VWF A1 fragment (C1272/1458A) vs. a wild type VWF A1 fragment by competitive screening against platelets in the presence of excess VWF A3 fragment confirmed this observation. Formation of the C1272-C1458 intramolecular disulfide bond in *E. coli* was verified by western blotting.
Summary: These results demonstrate the utility of phage display for functionally mapping VWF residues with high resolution and confirm the importance of the C1272-C1458 intramolecular disulfide bond in VWF-platelet interaction.

PB 1.44-5

Investigation of the effect of CLEC4M on plasma von Willebrand factor level in the general population

Mufti A[1], Lillicrap D[2], Peake IR[1], Goodeve AC[1] and Hampshire D[1]

[1]Sheffield University, Sheffield, UK; [2]Queen's University, ON, Canada

Background: von Willebrand factor (VWF) is a large multimeric plasma glycoprotein with an important role in haemostasis. VWF levels vary considerably (between 50 and 200 IU/dL in 95% of the

general population) with low levels associated with von Willebrand disease (VWD) while high levels are associated with increased risk of thrombosis, stroke and myocardial infarction. Several factors have been associated with VWF plasma level including ABO blood group, age, and genetic variations in *VWF* and other novel genetic loci identified by the CHARGE genome wide association study. These include *CLEC4M* which is expressed in liver endothelial cells and lymph nodes and encodes L-SIGN, a transmembrane receptor involved in pathogen adhesion and recognition, which binds glycosylated products. The *CLEC4M* intronic single nucleotide variant (SNV; rs868875, c.631+73A>G) and a 23 amino acid variable number tandem repeat (VNTR; ranging from 4 to 9 repeats in size) have both been reported to be significantly associated with VWF plasma level in the general population and type 1 VWD patients respectively.

Aim: To further investigate the contribution of *CLEC4M* genetic variation on VWF plasma level in the general population.

Methods: *In silico* prediction tools were used to identify SNVs in strong linkage disequilibrium (LD) with c.631+73A>G (Haploview v4.2) and to assess the effect of *CLEC4M* SNV on splicing (NetGene2 and NNSPLICE v0.9). SNVs were genotyped in healthy controls (HC) from the MCMDM-1VWD study, for whom extensive phenotypic data (including VWF:Ag level and ABO blood group genotype) was available. The VNTR was genotyped on an ABI 3730 and the size of the amplified product containing the repeat determined using Peak Scanner v1.0. The association of the SNVs and the VNTR with VWF level was investigated using Mann–Whitney and Kruskal–Wallis tests.

Results: c.631+73A>G was not predicted to influence *CLEC4M* splicing or L-SIGN expression. However, SNV rs2277998 (c.718G>A) in exon 5, in perfect LD with c.631+73A>G, altered an amino acid (p.Asp240Asn) present on the outer surface of the L-SIGN receptor suggesting a possible influence on ligand binding sensitivity. c.718G>A accounted for ~5% variation in VWF level in 921 genotyped HC with the non-reference allele associated with higher plasma levels (GG: 93.0 IU/dL; GA: 96.0 IU/dL; AA: 98.0 IU/dL; $P > 0.05$). The VNTR also accounted for ~5% variation in plasma level in 928 genotyped HC when divided into small/small (4–6/4–6; 95.5 IU/dL), small/large (4–6/7–9; 97.0 IU/dL) and large/large (7–9/7–9; 101.5 IU/dL) repeats ($P > 0.05$). These observations between c.718G>A and the VNTR with VWF level while failing to reach significance remained after correcting for ABO blood group. c.718G>A and the VNTR demonstrate ~74% LD.

Conclusion: Both the VNTR and SNV in CLEC4M may account for ~5% variation in VWF plasma level within the general population. LD between both variants may indicate a combined influence.

PB 1.44-6

Comparative pharmacokinetic analysis of 1200/500 IU vWF/FVIII and 900/800 IU vWF/FVIII concentrate in patient with type 3 vWillebrand disease

Nagy A, Reger B, Toth O and Losonczy H

University of Pecs, Pecs, Hungary

Background: von Willebrand disease (vWD) is the most frequently inherited bleeding disorder, its incidence is of 1–2%. Type 3 is the most serious form of vWD with an autosom recessive inheritance, having a FVIII activity of < 1–2%. These patients have a haemophilia type bleeding tendency with joint bleeds. Our type 3 vWD patient was a 46 year old caucasian male scheduled for an elective hip prosthesis surgery. The baseline level of his Factor VIII procoagulant activity (FVIII:C) and vWF Ristocetin cofactor activity (vWF:RCo) were 3% and < 1% respectively.

Aim: For the determination of a proper dose of perioperative bleeding prophylaxis dose, we compared the pharmakokinetics (PK) of two plasma-derived coagulation factor concentrates composed of coaglation factor VIII (FVIII) and von Willebrand factor (vWF). Concentrate A contains FVIII/vWF in 1: 2,4, whereas concentrate B in 1:1 ratio, similar to that of normal plasma.

Methods: Simplate II bleeding time, FVIII:C and vWF:RCo activities were followed for 72 h. Baseline, then post bolus determinations were done at 15, 30, 60 min, respectively thereafter each hour untill 12, then at 24, 48 and 72 h. The wash-out period was 15 days between the administration the two concentrates.

Results: The calculated vWF:RCo activity for achieving 100% was 97 U/kg, i.e. 3492 IU from concentrate A and B as well. The measured peak vWF:RCo activity at 30 min after bolus infusion was 103% (recovery: 103%) in the case of concetrate A and 117% (recovery:117%) in concentrate B. The calculated activity of FVIII in the case of concentrate A was 41.6%, in concenrate B 109%. The measured FVIII activity was 40% (recovery: 95.45%) in the case of concentrate A and 98% (recovery: 89%) in the concentrate B. The half-time life of concentrates was the following: with concentrate A of vWF:RCo was 13 h that of FVIII was 44 h. For concentrate B the half-life of vWF:RCo was 10.5 h and that of FVIII was 48 h.

Conclusion: At both concentrates the recovery and the half-life (vWF:RCo, FVIII) was sufficient, similar and long enough, respectively. At concentrate B with higher FVIII level and higher peak activity, the half-life was the same as with concentrate A, having lower FVIII level. Both concetrates can be administered safely in the treatment of type 3 vWD. The pharmacokinetic examination is useful and advised at the planning of a personalized treatment strategy.

Does anticoagulant treatment duration vary by the risk of venous thromboembolism recurrence in clinical practice?

Kaatz S[1], Fu AC[2], AbuDagga A[2], LaMori JL[3], Bookhart BK[3], Damaraju CV[4], Tan H[2], Schein J[3] and Nutescu E[5]

[1]Hurley Medical Center, Flint, MI; [2]HealthCore Inc., Wilmington, DE; [3]Janssen Scientific Affairs, LLC, Raritan, NJ; [4]Janssen Research & Development, LLC, Raritan, NJ; [5]University of Illinois Hospital & Health Sciences System, Chicago, IL, USA

Background: Although the American College of Chest Physicians (ACCP) guidelines on venous thromboembolism (VTE) treatment provide recommendations for anticoagulant treatment duration based on patient-specific risk factors, it is unclear how well these recommendations are adopted in clinical practice.

Aims: This retrospective observational study examined whether anticoagulant treatment duration varies by risk of VTE recurrence among patients with a first observed VTE.

Methods: Data from the HealthCore Integrated Research Database, a commercial health plan database representing 45 million US members, were used. Study patients were identified by a first observed VTE event between June 2007 and September 2011; all patients were naïve to anticoagulants (including warfarin, low molecular weight heparin, unfractionated heparin, and fondaparinux). The index date was the date of the first observed VTE event. Patients who filled ≥ 1 anticoagulant within 7 days of the index event, were ≥ 18 years old, and had ≥ 12 months pre- and post-index health plan eligibility were included. Patients with a prior VTE event, atrial fibrillation, mechanical valve replacements, or rivaroxaban or dabigatran use were excluded. Based on the 8th ACCP guidelines (current at the time of this study), VTE patients were categorized into three risk categories for anticoagulant treatment duration: provoked VTE (secondary to a transient risk factor); VTE associated with active cancer (cancer-related); and unprovoked VTE. Anticoagulant treatment duration was defined as the period from initiation to discontinuation of anticoagulant treatment, based on prescription fills with an allowable gap of 90 days or an INR test of every 42 days. Kaplan–Meier curves and Cox proportional hazards models were performed to evaluate how VTE recurrence risk categories were associated with anticoagulation duration, while

controlling for baseline characteristics and bleeding risks (recent major bleeding, creatinine levels > 1.2 mg/dL, anemia, cancer, clinically overt pulmonary embolism, and age > 75 years).

Results: A total of 2002 patients were identified (52.3% males, mean age 57 ± 15 years), including: 21.4% provoked, 16.4% cancer-related, and 62.1% unprovoked VTE. The average anticoagulant treatment duration was 306 ± 269 days (mean follow-up period: 734 ± 245 days). A total of 20.2%, 22.0%, and 24.9% of patients discontinued anticoagulant therapy within 90, 180, and 365 days, respectively. Patients with provoked, cancer-related, and unprovoked VTE had anticoagulant treatment durations of: 266 ± 243, 309 ± 277, and 319 ± 275 days, respectively. After adjusting for demographics and clinical characteristics, provoked and cancer-related VTE patients were 30% (95% CI: 12–52%, $P < 0.001$) and 35% (95% CI: 6–71%, $P = 0.037$) more likely to discontinue anticoagulants than were unprovoked VTE patients, respectively. No differences were observed between provoked and cancer-related VTE patients.

Summary/Conclusion: The observed anticoagulation duration for VTE in clinical practice may not be concordant with guidelines, which recommend a longer duration of anticoagulant treatment for cancer-related and unprovoked VTE and a shorter duration for provoked VTE. While patients with unprovoked VTE had the longest treatment duration, the average length of therapy was only about 2 months longer compared with provoked VTE. Moreover, cancer-related VTE did not have a discernibly longer treatment duration than provoked VTE. Further studies are needed to explore potential reasons.

PB 1.45-2

Differential stimulation of fibrinolysis by vitamin K-antagonists alone and associated with low-molecular-weight heparin

Colucci M[1], Galasso R[1], Incampo F[1], Carrieri C[1], Marino R[2], Ettorre CP[2] and Semeraro N[1]

[1]University of Bari; [2]Policlinico, Bari, Italy

Background and Aim: Treatment with Vitamin K antagonists (VKA) has been shown to reduce fibrinolytic resistance of blood and plasma clots through the inhibition of thrombin-mediated TAFI activation. Because low-molecular weight heparin (LMWH) is co-administered with VKA during initiation of anticoagulant treatment, we evaluated the impact of LMWH and VKA combination on fibrinolytic resistance.

Patients and Methods: Three different groups were studied: (i) patients on stable warfarin treatment for more than 1 month ($n = 35$);(ii) patients starting oral anticoagulant therapy, who were evaluated both during the co-administration of enoxaparin and warfarin and 3–10 days after the withdrawal of enoxaparin ($n = 30$); 3) healthy subjects ($n = 15$). In patient groups, only the samples with an INR > 2 were considered. The resistance of tissue factor-induced clots to t-PA-induced fibrinolysis was evaluated in blood and plasma by thromboelastography (TEG) and turbidimetry, respectively. Results were expressed as fibrinolysis time.

Results: In healthy subjects, the median fibrinolysis time of blood clots (TEG) was 42 min [IQR: 36–58]. Patients on VKA only displayed a significantly shorter fibrinolysis time ($P < 0.001$), regardless of whether they were in group 1 (32 min [27–37]) or group 2 (32 min [26–39]). In patients receiving VKA and enoxaparin, fibrinolysis time amounted to 24 min [14–29] and was significantly shorter than the values recorded in the same patients after enoxaparin withdrawal and in patients on stable warfarin ($P < 0.005$). INR values were similar in all patient groups (2.7 [2.4–3.1]). Moreover, there were no differences in red blood cells, hematocrit, leucocytes and platelets. Concerning other TEG parameters, the clotting time (R) was slightly longer under dual anticoagulant treatment as compared to VKA only (8.8 min [7.3–12.2] vs. 7.6 min [6.0–8.9], $P = 0.03$) whereas the maximal amplitude was visibly smaller (22.5 mm [8.3–34] vs. 34.7 mm [27–42], $P = 0.0003$), suggesting that co-administration of enoxaparin markedly reduced clot strength. Thrombin generation assay in platelet-poor plasma showed that dual anticoagulation had no effect on lag time as compared to VKA only (7.0 min [6.3–9.8] vs. 7.3 min [5.4–9.9]) but reduced both the thrombin peak (22.4 nM [5.7–42] vs. 69 nM [41–101], $P < 0.0001$) and ETP (442 nM*min [35–590] vs. 559 nM*min [439–727], $P = 0.01$). Rather surprisingly, fibrinolysis time of plasma clots, at variance with blood clots, was similar in patients receiving enoxaparin+VKA and VKA only (47 min [44–56] vs. 56 min [46–66], $P = 0.08$). Most likely, thrombin generation in these groups was below the threshold concentration required to activate anti-fibrinolytic amounts of TAFI, as suggested by the fact that PTCI, a specific inhibitor of TAFIa, did not shorten the fibrinolysis time in either group.

Conclusions: These data show that the co-administration of LMWH in patients under VKA treatment has a marked effect on the fibrinolytic resistance of blood but not plasma clots, suggesting a cell-mediated mechanism. Further studies are warranted to assess the clinical implications of these findings.

PB 1.45-3

Evaluation and introduction of direct thrombin inhibitor assay to assess dabigatran anticoagulant effect in patients undergoing direct current cardioversion

Needham J, Lewis H, Lock J, Brookes C and Rangarajan S

Hampshire Hospitals NHS Foundation Trust, Basingstoke, UK

Background: Oral direct thrombin inhibitors (DTI) are now increasingly being used in clinical practice as anticoagulant of choice in reducing thrombotic risk. Whilst outcome of clinical trials negates requirement for regular monitoring in there are clinical situations where assessment of DTI anticoagulant activity is required to ensure adequate anticoagulation and assessment in bleeding complications. Traditionally patients undergoing direct current cardiversion (DCCV) would require warfarin prior to procedure to reduce the risks of thrombo-embolism, however this is associated with need for monitoring and frequent cancellation of DCCV if not in range. The use of dabigatran following risk assessment offers advantages over warfarin both in procedure scheduling and monitoring removal. Patients were prescribed a standard dose of dabigatran150 mg bd unless contraindicated.

Aims: To evaluate and establish a quantitative assay for measuring the anti-IIa activity of the DTI dabigatran and to assess the presence of an anticoagulant effect in patients, prior to undergoing DCCV.

Methods: Biophen DTI chromogenic assay (DTIChr) and the Hemoclot Thrombin Inhibitors clotting assay (DTICt – Hyphen BioMed) for dabigatran were established and optimised on the Destiny Max coagulation analyser (Stago). Citrated samples ($n = 28$) were collected as part of routine pre-operative assessment from dabigatran patients prior to undergoing DCCV. Activated partial thromboplastin time (APTT) using TriniCLOT aPTT HS (Stago) and thrombin time (TT) using TriniCLOT thrombin time (Stago) were performed. Plasma was frozen and DTI assays were performed in batches. Samples were collected randomly prior to DCCV which commenced 4–6 h post last dose of dabigatran provided prolongation of TT and APTT.

Results: There was good correlation between the APTT and DTIChr $r = 0.92$ ($r^2 = 0.84$) and DTICt $r = 0.90$ ($r^2 = 0.80$) and between the DTIChr and DTICt $r = 0.97$ ($r^2 = 0.95$) although DTICt gave lower results (median = 0.19 and 0.09 respectively) there was no statically significant difference $P = 0.21$. The TT was over sensitive with 'no clot' detected above levels of 0.03 μg/mL. The DTIChr had greater sensitivity to both low and high levels of dabigatran compared to the DTICt. Within the patient group lowest level detectable was 0.03 μg/mL by DTIChr, APTT and TT, however TT at this level was > 180s. The APTT below 0.03 μg/mL gave a normal clotting time. Dabigatran concentration in patient group ranged from 0.0 to 0.52 μg/mL with

mean 0.16 μg/mL. At time of testing based on PETRO trial data for maximum and trough levels of dabigatran 90.5% by DTIChr and 81.0% by DTICt were in the range 0.03–0.44 μg/mL with corresponding APTT and TT times.

Summary/Conclusions: APTT prolongation demonstrated a dose response in patients that had detectable levels of dabigatran by the DTIChr and would provide a rapid test for anticoagulant effect. TT can also be used but is oversensitive. The DTIChr offers improved sensitivity for quantifying dabigatran effect over a wide dose range. To minimise cancelling DCCV, testing prior to day of procedure 4–6 h post dose would potentially identify patients with no anticoagulant effect and establish a dabigatran dose range for procedure.

PB 1.45-4

Outcome of patients treated with plasma or prothrombin complex concentrates for warfarin related intracerebral hemorrhage

Majeed A[1], Meijer K[2], Larrazabal R[3], Arnberg F[1], Roberts RS[3] and Schulman S[3]

[1]Karolinska Institutet, Stockholm, Sweden; [2]University Medical Center, Groningen, The Netherlands; [3]HGH, McMaster University, Hamilton, ON, Canada

Background: Prothrombin complex concentrates (PCC) can rapidly normalize prolonged prothrombin time, induced by vitamin K antagonists (VKA). It is unclear whether this rapid reversal of VKA coagulopathy would lead to improved survival compared to transfusion of plasma in patients with warfarin-related intracerebral hemorrhage.

Aims: To investigate whether the use of PCC improves the outcome of patients with warfarin-related intracerebral hemorrhage as compared to plasma.

Methods: We conducted a retrospective study at three centers in as many countries (Canada, The Netherlands and Sweden). We included consecutive patients with warfarin-related intracerebral hemorrhage treated either with plasma (mainly in Canada) or PCC (The Netherlands and Sweden) for the reversal of the anticoagulant effect of warfarin between 2002 and 2010. Data on age, sex, indication for anticoagulation, concomitant antiplatelet therapy, diabetes, and international normalized ratio (INR) on admission were collected. The volume of intracerebral hematoma was calculated from the first computed tomography (CT) scan. Bleeding localization, intraventricular hematoma extension and surgical evacuation were also documented. The unadjusted and adjusted odds ratio for 30-day all cause mortality in both treatment groups was calculated using logistic regression.

Results: Patients who received plasma ($N = 35$) had a significantly higher prevalence of diabetes, more concomitant use of antiplatelet therapy, and more frequent intraventricular hemorrhage on the initial CT scans as compared to patients who received PCC ($N = 100$). The median INR on admission was 3.0 (interquartile range 2.4–3.9) The volume of intracerebral hematoma was larger in the group treated with a median of 4 units of plasma compared to the group treated with a median of 1750 units PCC (hematoma, median 37.1 vs. 22.9 cm^3; $P = 0.063$). The unadjusted odds ratio for all-cause 30-day mortality in the PCC group was 0.40 (95% confidence interval, 0.18–0.87; $P = 0.021$) compared to the plasma group. After adjusting for the hematoma volume, bleeding localization and age, the effect of PCC on mortality became non-significant.

Conclusion: Treatment with PCC for warfarin reversal in patients with intracerebral hemorrhage does not seem to reduce the 30-day all cause mortality compared to plasma. Further studies are needed to clarify whether certain subsets of patients might benefit from warfarin reversal with PCC.

Keywords: warfarin, intracerebral hemorrhage, prothrombin complex concentrates, plasma.

PB 1.45-5

Therapeutic concentrations of dabigatran inhibit factor XIa

Kluft C[1], Van Leuven K[1], Laterveer R[1] and Burggraaf J[2]

[1]Good Biomarker Sciences; [2]Centre of Human Drug Research, Leiden, The Netherlands

Background: As the thrombin inhibitor dabigatran inhibits APTT (two-fold increase at 250 ng/mL dabigatran) stronger than it inhibits PT (two-fold increase at 465 ng/mL dabigatran), we suspected additional effects to thrombin, particularly on enzymes of the intrinsic coagulation pathway.

Aims: Therefore we evaluated possible pleiotropic effects of dabigatran *in vitro*.

Methods: Purified enzymes were purchased and measured on their advised chromogenic substrate. A factor Xa generation assay using plasma was developed, excluding thrombin participation by adding excess hirudin. The test was started with micronized silica and calcium/lipids. Thrombin generation was done with the TGA-RCH® from Technoclone.

Results: Inhibition tests with purified enzymes of the intrinsic coagulation pathway using chromogenic substrates showed that dabigatran only significantly inhibited factor XIa and not factor XIIa, kallikrein or factor IXa. The inhibition of factor XIa (Ki = 1400 ng/mL) was well above the therapeutic range of dabigatran. We subsequently utilized the Xa-generation test using contact activation of whole plasma for factor XIa generation to investigate more of its physiological roles such as reciprocal activation of factor XII, while in complex with HMW-kininogen. The chromogenic test excluded thrombin involvement by excess hirudin, and this was confirmed by benchmarking the test with prothrombin deficient plasma. The Xa-generation test showed a Xa peak which was confirmed by using factor X- and factor IX-deficient plasma, showing inhibition by rivaroxaban, and the production of a similar Xa peak when purified factor IXa was used as starter.

Addition of dabigatran showed a dose dependent shift in time to peak and in peak level with an IC50 for peak height of 450 ng/mL. Reducing factor XI level by mixing depleted plasma with normal plasma showed a delayed and lower factor Xa peak with IC50 at 10% factor XI. When using the thrombin generation test, dabigatran (IC50: 420 ng/mL) caused significant peak reduction, while this could not be achieved with hirudin and bivalirudin at comparable concentrations.

Summary/Conclusion: Dabigatran in therapeutic concentrations showed *in vitro* significant inhibition of factor XIa in factor Xa generation with an IC50 for FXI inhibition equivalent to 10% residual factor XI function. This inhibition is similar to peak reduction in the TGT test confirming inhibition potency of around 400–450 ng/mL dabigatran. Although the inhibition of factor XIa *in vitro* may not represent the actual inhibition in the clinic, the additional effect of therapeutic concentrations of dabigatran on factor XIa may be physiologically relevant. This may regard efficacy and bleeding as observed in patients with factor XI deficiency and should be investigated further.

PB 1.45-6

Assessment of dabigatran activity using the activated clotting time assay with concomitant heparin *in vitro*: comparison of two different point of care tests

Van Ryn J, Schurer J and Clemens A

Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany

Background: Intraprocedural anticoagulation (AC) in patients receiving dabigatran or warfarin is achieved using unfractionated heparin (UFH), with or without discontinuation of the oral anticoagulant. The level of AC during procedures such as catheter ablation or angioplasty is usually monitored using activated clotting time (ACT). These assays

have been validated for use with heparins, however, it is unknown if the combination of dabigatran and heparin has additive effects on clotting time as shown by these assays.
Aims: The purpose of this study was to determine whether there is an interaction between dabigatran and unfractionated heparin (UFH) in ACT assays as measured by commonly used PoC systems.
Methods: Human whole blood (no anticoagulant) from healthy volunteers ($n = 4$) was obtained and increasing concentrations of heparin (UFH, 0.5–2 U/mL, ratiopharm®), dabigatran (125–500 ng/mL) or a combination was added. Samples were immediately tested in Hemochron Signature Elite®, Hemochron Response® or i-Stat® Point of Care (PoC) systems, using both kaolin and celite ACT assays. Assay results were obtained in seconds, and additive effects of known amounts of heparin and dabigatran were compared to each alone.
Results: Baseline clotting ranged between 115 and 122 s for kaolin tests and 124–125 s for celite-based tests. There was a concentration-dependent increase in all PoC assays with increasing concentrations of dabigatran and UFH alone, with i-Stat kaolin assay showing the greatest sensitivity to dabigatran (ratio of 3.8 and 5.1 over baseline, respectively, for 500 ng/mL dabigatran and 2 U/mL UFH). When dabigatran and UFH were combined in whole blood, measured increases were similar to the calculated additive effect when each was measured alone. At the lower concentration of UFH (0.5 U/mL), dabigatran activity tended to be slightly overestimated. At 1 and 2 U/mL UFH, this effect was no longer seen.
Conclusions: This study shows there is minimal interaction between UFH and dabigatran *in vitro* in these PoC assays. These results suggest that additive AC activity can be measured via ACT in dabigatran-treated patients given UFH, i.e. during intraprocedural AC. However PoC test results with concomitant warfarin and UFH treatment may respond differently than dabigatran and UFH. Particularly if dabigatran is stopped before the intervention, more UFH may be required to achieve a similar level of AC than in warfarin-treated patients due to the shorter half life of dabigatran.

PB 1.46-1

Oral and parenteral antithrombotic agents differentially inhibit tissue factor mediated generation of thrombin in prothrombin complex concentrates

Fareed J, Kahn D, Hoppensteadt D, Jeske W, Walenga JM and DeChristopher PH
Loyola University Medical Center, Maywood, IL, USA

Introduction: Several parenteral (hirudin, angiomax, argatroban) and oral antithrombin agents (ximelagatran and dabigatran) have been developed for various clinical indications. While the parenteral agents do not require any endogenous activation, the oral agents do require activation. Both groups of these agents inhibit thrombin at varying intensities. However their effects on the generation of thrombin are not fully explored. All of these agents have been reported to be weaker inhibitors of thrombin generation. The purpose of this investigation was to differentiate between the parenteral and oral thrombin inhibitors in biochemically defined systems.
Materials: Hirudin, Angiomax and bivalirudin were obtained from commercial sources. The active form of dabigatran exetilate was obtained from Selleckchem (Houston, TX) whereas the melatagran was of synthetic origin. All agents were reconstituted at 100 μg/mL. Cofact brand of prothrombin complex concentrate (PCC) was purchased from Biotest (Drerich, Germany) and reconstituted to 10 U/mL. Recombiplastin was purchased from Instrumentation Laboratory. The PCC was supplemented with recombiplastin and the generated thrombin and other cleavage products were evaluated using a SELDI-TOF mass spectrometer method and immunoblotting techniques using anti-bovine thrombin antibodies. To investigate the effects of various thrombin inhibitors, each agent was added to the PCC prior to the recombiplastin activation at graded concentrations of 20, 200 and 2000 ng/mL. Saline was used as a control. The reaction was stopped at 15 min with the addition of EDTA and the mass spectrometeric profile was carried out using the gold chip in the molecular weight range of 3.0–150 kDa. Western blot analysis was carried out to determine the generation of thrombin and activation products.
Results: The native Cofact showed a single distinct band at 71 kDa representing prothrombin whereas upon activation with recombiplastin the 71kDa peak disappeared and a prominent peak at 36 kDa representing thrombin appeared. Parenteral thrombin inhibitors did not inhibit the generation of thrombin at any concentration. Similarly, dabigatran and melagatran failed to inhibit the generation of thrombin, however in addition to the thrombin peak (36 kDa) an additional peak at 50 kDa was generated representing prethrombin. The western blot analysis was consistent with the SELDI-TOF analysis. An additional biomarker peak in activated Cofact at 12.6 kDa was generated and was absent from the native Cofact. This peak was also present in all of the parenteral and oral thrombin inhibitors supplemented mixtures.
Conclusion: These studies demonstrate that upon activation with TF, PCCs such as the Cofact can be activated into thrombin and other activation products. Furthermore, the oral thrombin inhibitors differ from the parenteral thrombin inhibitors and result in the generation of prethrombin along with thrombin. Thus besides being a weaker inhibitor of thrombin generation, dabigatran and melagatran facilitate the formation of prethrombin. This differentiation between the parenteral and oral thrombin inhibitors may impact on the safety and efficacy of these agents in the management of anticoagulation.

PB 1.46-2

Evaluation of edoxaban in Japanese patients with severe renal impairment undergoing lower-limb orthopedic surgery

Fuji T[1], Fujita S[2], Abe Y[3], Tachibana S[4] and Kawai Y[5]
[1]Osaka Koseinenkin Hospital, Osaka; [2]Takarazuka Daiichi Hospital, Takarazuka; [3]Kumamoto Chuo Hospital, Kumamoto; [4]Mishuku Hospital; [5]International University of Health and Welfare, Tokyo, Japan

Background: There are limited therapeutic options in Japan for prevention of venous thromboembolism (VTE) in patients with severe renal impairment (SRI; creatinine clearance [CL_{CR}] ≥ 15–< 30 mL/min) undergoing lower-limb orthopedic surgery (LLOS) such as total knee arthroplasty (TKA), total hip arthroplasty (THA) and hip fracture surgery (HFS). Edoxaban, an oral direct factor Xa inhibitor, is approved in Japan for VTE prevention in patients undergoing LLOS (TKA, THA, HFS), but contraindicated in those with SRI.
Aims: Compare the safety and pharmacokinetics of edoxaban 15 mg in Japanese patients with SRI with that of edoxaban 30 mg in patients with mild renal impairment (MiRI; CL_{CR} ≥ 50–≤ 80 mL/min) and of fondaparinux 1.5 mg in patients with SRI (CL_{CR} ≥ 20 to < 30 mL/min) undergoing LLOS.
Methods: Patients ≥ 20 years of age undergoing unilateral LLOS with SRI or MiRI were enrolled in this open-label study. Patients undergoing or planning to undergo hemodialysis, at risk for bleeding or VTE, receiving antithrombotic therapy, evidence of hepatic dysfunction or unable to take oral medication were excluded. Patients with CL_{CR} ≥ 20 to < 30 mL/min were randomized to edoxaban 15 mg or fondaparinux 1.5 mg once-daily (QD). All patients with CL_{CR} ≥ 15–< 20 mL/min received edoxaban 15 mg. Patients with MiRI received edoxaban 30 mg. Treatments were administered for 11–14 days. Blood samples for measurement of plasma drug concentrations and determination of prothrombin time (PT) were collected on treatment Day 7 and treatment completion day at pre-dose, 1–3 and 4–8 h post-dose. Safety endpoints included incidence of major bleeding, clinically

relevant non-major (CRNM) bleeding, any bleeding event, and adverse events (AEs).

Results: Of 80 patients enrolled, 29 received edoxaban 15 mg, 21 fondaparinux 1.5 mg, and 30 edoxaban 30 mg; 74 completed the study (45 SRI and 29 MiRI). Most patients were female (91%). Mean age was 88, 86, and 78 years, mean body weight was 43, 46, and 55 kg, and median CL_{CR} was 26.15, 26.17, and 62.71 mL/min, for edoxaban 15 mg, fondaparinux 1.5 mg, and edoxaban 30 mg, respectively. On Day 7, plasma concentrations of edoxaban and PT ratios overlapped between the SRI and MiRI groups. Any bleeding event occurred in 6 (20.7%), 8 (40.0%), and 10 (33.3%) patients in the edoxaban 15 mg, fondaparinux 1.5 mg, and edoxaban 30 mg groups, respectively. No major bleeding events occurred in any treatment group. CRNM bleeding occurred in 1 (3.4%), 1 (5.0%), and 2 (6.7%) patients in the edoxaban 15 mg, fondaparinux 1.5 mg, and edoxaban 30 mg groups, respectively. The incidence and nature of adverse events other than bleeding events was comparable among the treatment groups. No serious AE was considered related to study drug and the majority occurred after completion of treatment.

Summary/Conclusions: These results suggest that edoxaban 15 mg QD appears to be safe and may be a therapeutic option in Japanese patients with SRI undergoing LLOS.

PB 1.46-3

Clinical profile of patients with low quality of oral anticoagulation in regular medical care

Coldewey M[1], Keller K[1], Hendelmeier M[1], Prochaska J[1], Sebastian G[2], Lamparter H[1], Ullmann A[1], Walter U[1], Munzel T[1] and Wild P[1]

[1]University Medical Center of Mainz; [2]German Center for Cardiovascular Research, Mainz, Germany

Background: Vitamin-K antagonists (VKA) are frequently used to prevent or treat thromboembolism. Thereby the time in therapeutic range of anticoagulation is a marker of quality of anticoagulation.

Aims: We investigated the clinical profile of patients with low quality of anticoagulation with vitamin-K antagonists.

Methods: In the observational, multi-center thrombEVAL-trial, patients treated with VKA in regular medical care for at least 4 months were eligible. The clinical status was recorded and quality of therapy assessed by the individual time in therapeutic range (TTR), excluding phase of initiation. Data were obtained by a clinical visit, from medical reports and anticoagulation pass. Subjects with adequate documentation of INR measurements were included into analysis.

Results: The sample (N = 892) was split into subgroups with low quality (N = 298) and normal or high quality (N = 594) of OAC by the lowest vs. the two upper tertiles of TTR. The cutoff for TTR was 56.7%. There was no difference in indications for OAC in both groups. Subjects with low quality were older at initiation of therapy (66.03 vs. 64.24 years, P = 0.048) and had shorter measurement intervals (14.8 vs. 17.5 days, P = 0.0033). They had more diabetes and less frequently a positive family history of MI or stroke. Diabetes was independently associated with low quality (OR 1.15 [1.1, 2.0], P = 0.012) in a logistic regression model adjusted for all classical risk factors. The Charlson comorbidity index was significantly higher in patients with low quality than in all others (3.5 ± 2.8 vs. 2.8 ± 2.5, P = 0.00036). Low quality was independently associated with chronic kidney disease (OR 1.5 [1.1, 2.2], P = 0.014), heart failure (OR 1.4 [1.0, 1.9], P = 0.031), and COPD (OR 1.4 [1.0, 2.0], P = 0.047). In this survivor cohort, bleeding events were more often reported in low quality (Rate ratio 1.32 [1.08, 1.61], P = 0.00058), whereas no difference was present in thromboembolic events (P = 0.42).

Conclusion: For clinical practice, lower quality of oral anticoagulation should be considered in patients with diabetes and a larger number of comorbidities, especially chronic kidney disease, heart failure and COPD.

PB 1.46-4

Low intensity and good-controlled anticoagulant therapy can prevent thromboembolism but cannot reduce bleeding in AF patients with both hemodialysis and mechanical valve replacement

Murasaki KM, Shimatani Y, Uetsuka Y and Nobuhisa H

Tokyo Women's Medical University, Tokyo, Japan

Background: The prevalence of atrial fibrillation (AF) in end-stage renal failure is high, with an increased risk of thromboembolism and bleeding. However, there is little evidence that assess the real risk/benefit of anticoagulation in patients with severe renal impairment. Nevertheless there is an AF population that is required life-long anticoagulation due to mechanical heart-valve replacement. However, patients on hemodialysis (HD) may not derive the same benefit from warfarin as the general population. There might be a prompt answer to anticoagulant therapy in AF patients with end-stage renal failure for now.

Aims: The aim of this study is to clarify whether low intensity anticoagulant therapy and good controlled anticoagulant therapy can prevent thrombotic and reduce bleeding events in AF patients with both hemodialysis and mechanical valve replacement.

Methods: To evaluate the risk of thromboembolic events (TEs) and ISTH major bleeding events (BEs) of Japanese patients on Hemodialysis (HD), 22 consecutive AF patients on HD underwent mechanical valve replacement operations were evaluated. From the same institute mechanical valve replacement of 550 patients, we randomly sampled a control non HD group of 44 patients, frequency matched to the cases by age, sex, other risk factors and calendar year. A nested case-control analysis assessed the risk of these events. Target PT-INR was set 1.5–2.5 according to Japanese guidelines for high risk of bleeding.

Results: Patients were followed up for a mean of 6.6 years. TTR for HD group was 76.8% and non-HD group was 78.2%. There were four TEs and nine BEs (ICH1, GI bleeding 8) in HD group. There was no significant association between TEs (2.0, 95% CI 0.30–13.3) between both groups. However, compared with non HD patients, patients with HD had a significantly increased risk of bleeding (risk ratio 4.0, 95% CI 1.10–14.50). The five-year survival of HD group was 66%. This rate is superior to those of generall hemodialysis patients in Japan.

Conclusion: In this well-controlled and low anticoagulant intensity, AF patients with HD have similar risk for TEs, but have significantly increased risk of BEs compared with non-HD patients. HD group have a good life expectancy compared with general hemodialysis patients without heart valve replacement.

Close and careful anticoagulant control should be needed in order to avoid thromboembolism and bleeding in patients with end-stage renal failure and mechanical valve replacement.

PB 1.46-5

Increased anticoagulant response to drugs targeting thrombin, but not to drugs targeting FXa, in plasma from patients with cirrhosis

Potze W, Arshad F, Adelmeijer J, Blokzijl H, Van Den Berg AP, Porte RJ and Lisman T

UMCG, Groningen, The Netherlands

Background: Chronic liver disease was previously considered as the prototype of acquired coagulopathy responsible for bleeding because of a decreased number and function of platelets, decreased synthesis of coagulation factors by the diseased liver, and hyperfibrinolysis. Recently, laboratory studies and clinical observations have provided evidence for a rebalanced hemostatic status in patients with chronic liver disease due to a concomitant decline in pro- and antihemostatic proteins. However, this balance can be easily tipped over to a hypercoagulable or a hypocoagulable state with the risk of both bleeding complications and clinical thrombotic events. In fact, treatment and

prevention for thrombotic complications is frequently required. Nevertheless, patients with liver disease are often withheld from anticoagulant therapy, because of the perceived bleeding diathesis and as a result of the limited clinical experience the anticoagulant of choice for the various indications is still not known. A recent study demonstrated an increased anticoagulant response to low molecular weight heparin in plasma from patients with cirrhosis. This potentially increased response of cirrhotic patients to anticoagulant drugs may require dose adjustments to prevent unwanted bleeding complications.

Aims: Here we evaluated the *in vitro* effect of clinically approved anticoagulant drugs in plasma from cirrhotic patients at different stages of liver disease.

Methods: We studied the anticoagulant potency of antithrombotic drugs by performing thrombin generation tests (Calibrated Automated Thrombinography) in the presence of thrombomodulin, which allows the evaluation of the balance between pro- and anticoagulant factors in plasma. Thirty patients with cirrhosis (10 with mild, 10 with moderate, and 10 with severe disease) and 30 healthy controls were studied. The study was approved by the local medical ethical committee (METc 2012/122 Nl40435.042.12) and informed consent was obtained from all subjects. Thrombin generation was determined before and after addition of unfractionated heparin (0.1 U/mL), low molecular weight heparin (0.2 U/mL), fondaparinux (0.5 μg/mL), dabigatran (300 ng/mL), and rivaroxaban (25 ng/mL).

Results: We observed an increased anticoagulant response in plasma from cirrhotic patients to anticoagulants targeting thrombin. The endogenous thrombin potential was reduced by 85.7 ± 8.5% by heparin in patients, and a 79.6 ± 10.8% reduction was observed in controls ($P = 0.038$). Addition of dabigatran led to a much more pronounced reduction in peak thrombin generation in patients compared to controls (69.6 ± 26.6% reduction in patients vs. −3.3 ± 27.8% reduction in controls, $P < 0.0001$). The enhanced effects of both drugs on thrombin generation were proportional to the severity of disease. In contrast, a similar anticoagulant response to low molecular weight heparin and even a reduced response to fondaparinux and rivaroxaban, which exclusively target factor Xa, was observed in plasma from cirrhotic patients as compared to control plasma.

Conclusions: We observed an increased anticoagulant response to drugs targeting thrombin in plasma from patients with cirrhosis. Furthermore, in contrast to a recently published study, we observed no increased response to drugs targeting factor Xa. These results may imply that drugs targeting factor Xa are the drugs of choice for prevention and treatment of thrombotic complications in cirrhotic patients.

PB 1.46-6

Risk factors for suboptimal efficacy of 3-factor prothrombin complex concentrates in emergency reversal of anticoagulation with vitamin K antagonists in patients with major bleeding

Dentali F[1], Imberti D[2], Tamborini Permunian E[3], Croci E[4] and Ageno W[3]

[1]University of Insubria, Varese; [2]Hospital of Piacenza, Piacenza; [3]Insubria University, Varese; [4]Piacenza Hospital, Piacenza, Italy

Background: Three-factor prothrombin complex concentrates (PCC) are commonly used for reversal of international normalized ratio (INR) in patients who are bleeding or require emergency surgery. However, there is little information regarding the optimal dosing strategy for achieving adequate INR reversal.

Aim of the Study: To investigate potential risk factors for suboptimal efficacy of 3-factor prothrombin complex concentrates in emergency reversal of anticoagulation with vitamin K antagonists in patients with major bleeding.

Methods: Patients receiving VKAs and suffering from acute major bleeding were eligible for this study if their international normalized ratio (INR) was higher than or equal to 2.0. Stratified 35–50 IU/kg PCC doses were infused based on initial INR. Patients may also be treated with intravenous infusion of vitamin K. INR was controlled within 30 min from the infusion of PCC. Characteristics of patients who had an adequate INR reversal (INR ≤ 1.5) and inadequate INR reversal were compared.

Results: One hundred and seventy-three patients (mean age 77.46 years, range 34–97 years, 100 males) were included in the study. Main indication for anticoagulation was atrial fibrillation. Mean INR at the time of inclusion was 3.74 (range 2.01–12.80). After PCC administration the mean INR was reduced to 1.51 (range 0.94–3.96), 163 (94.2%) had the INR a < 2.00 and 109 patients (63.0%) had the INR < 1.5. Intravenous vitamin K was used in 147 patients. At the univariate analysis INR value at the time of inclusion, use of intravenous vitamin K, major bleeding site and cause of bleeding were associated with rate of success in the INR reversal. At multivariate analysis only high baseline INR values (> 3.74) (OR 3.78, 95% CI 1.71, 8.32) and the non-use of intravenous vitamin K (OR 2.98, 95% CI 1.22, 7.33) were significantly associated with a suboptimal INR reversal (INR > 1.5).

Conclusion: our study confirms a general efficacy of 3-factors PCC in correcting INR in patients treated with VKAs with a major bleeding complication. Use of intravenous vitamin K increases the efficacy of PCCs Conversely in patients with a high INR 3-factors, PCC seems to have a suboptimal efficacy in correcting supratherapeutic INR. Future studies are necessary to evaluate the best treatment of this subgroup of patients.

PB 1.47-1

Patients with atrial fibrillation undergoing PCI and subsequent triple therapy with aspirin, clopidogrel and VKA – results from a single center retrospective study

Kaiser M, Hehrlein C, Bode C and Ahrens I

Heart Center Freiburg University, Freiburg, Germany

Background and Aims: Patients with atrial fibrillation (AF) are of increased risk for stroke and systemic embolism and often have concomitant coronary artery disease (CAD). In many of these patients bleeding risk correlates with the risk of stroke according to the CHA_2DS_2VASc and HASBLED score systems. Current clinical practice in patients with AF and CAD undergoing percutaneous coronary interventions (PCI) with stent implantation involves dual antiplatelet therapy and the continuation of oral anticoagulation. Although generally perceived as a high bleeding risk population, there is uncertainty about the bleeding rates in these patients. Furthermore the necessity and duration of triple therapy are currently the topic of an intensive debate. We analyzed subsequent patients treated with PCI and stent followed by triple therapy who were admitted to a university hospital medical center (2000 until 2011).

Methods: The fulltext inpatient and cathlab database including discharge summaries and cathlab reports were screened for the key words PCI, Stent, Aspirin, Clopidogrel, and Phenprocouomon (Marcumar). We identified 88 patients that received aspirin, clopidogrel and oral anticoagulation with phenprocoumon for at least 4 weeks following stent implantation and for whom follow up within the inpatient database was available. CHA_2DS_2VASc and HASBLED scores were calculated on the basis of the current patient diagnosis at the time of the index PCI. Major bleeding events were defined as gastrointestinal, pulmonary, retroperitoneal, intracerebral, intraocular or intraarticular bleeding.

Results: Out of the 88 patients, 72% received triple therapy because of AF and 28% received triple therapy for other reasons (including markedly reduced ejection fraction, left ventricular thrombus and pulmonary embolism). Fifty-five percent of all patients had persistent and 17% had intermittent AF at the time of the index PCI. The mean CHA_2DS_2VASc and HASBLED scores of the patients receiving triple

therapy were 3.3 and 2.7 respectively. Forty-four percent of the patients had a reduced renal function (GFR < 60 mL/min). The mean duration of triple therapy was 17.3 weeks. During this period there was no stent thrombosis or target vessel revascularization in the observed population. Major bleeding occurred in 9.1% of all patients, while gastrointestinal bleedings were the most frequent bleeding events (5.7%) of all patients on triple therapy followed by pulmonary bleedings (3.4%). No intracerebral bleedings were observed in the studied population.

Conclusion: Triple therapy consisting of dual antiplatelet therapy with aspirin and clopidogrel and oral anticoagulation with phenprocoumon is associated with an elevated risk for major bleeding events. In a real-world retrospective analysis of patients treated with PCI and stent followed by triple therapy for at least 4 weeks in a university hospital medical center, we observed major bleeding events with a frequency of 9.1% with gastrointestinal (GI) bleedings representing the majority of all bleeding events. These data are in line with reports of other groups and generate the hypothesis that GI-bleedings are the major obstacle associated with triple therapy. Future multicenter clinical studies on triple therapy vs. clopidogrel + oral anticoagulant are needed to define the optimal medical therapy for patients on oral anticoagulants undergoing PCI and stent implantation.

PB 1.47-2

Vitamin K antagonists (VKA) for stroke prevention in atrial fibrillation (AF) in very elderly naïve patients

Granziera S, Bertozzo G, Marigo L, Petruzzellis F, Rossi K, Infante T, Pletti S, Nante G, Manzato E and Pengo V
University of Padua, Padua, Italy

Background: Prevalence of atrial fibrillation AF increases with age. Similarly, the incidence of thromboembolism is higher among elderly with AF compared with younger patients. Although VKA strongly reduce stroke in AF, they are underused in the elderly and this mainly depends on the fear of bleeding. In an observational study Hylek et al. found a rate of major bleedings significantly higher in patients ≥ 80 years compared with patients ≤ 80 in the first year of treatment (13.1 vs. 4.7 per 100 patient-years). On the other hand, in a large prospective study with a mean follow up of 2.3 years Poli et al. found a rate of bleeding among patients ≥ 80 years old, followed by a specifically trained centre, of 1.87 per 100 patient-years. Guidelines suggest anticoagulation treatment in elderly patients with AF but they are discontinuously applied by clinicians.

Aims: The aim of this study was to analyse the outcomes in terms of major bleeding, thromboembolic events and deaths in a cohort of very elderly (≥ 85 years) naïve patients starting VKA for stroke prevention in AF.

Methods: This is a retrospective observational study. Electronic records of patients referred to our anticoagulation clinic between 2007 and 2012 were analysed. Major bleedings were considered according to ISTH definition. Ischemic events were classified as stroke or peripheral embolism. Thromboembolic risk profile was ascertained by CHADS2 score. Cardiovascular and non cardiovascular deaths were also registered.

Results: During a mean follow up of 2.25 years, 55 major bleedings occurred in 356 studied patients (7.0%pt-yrs). INR at the time of bleeding was above 3.0 in 20 pts (36.4%). Seven patients were on VKA and antiplatelet therapy (12.7%). Seventeen of 55 major bleedings (2.4%pt-years) were intracranial bleedings and 11 (1.4%pt-years) were fatal. There was no correlation between major bleedings and the CHADS2 score as well as among its single components. Moreover no relation between gender and major bleedings was found. Systemic thromboembolic events were 19 (2.4%pt-years; 16 were stroke and three were peripheral embolism). The INR at the time of thromboembolic events was below 2.0 in 7 pts −36.8% (below 1.5 in 1 pt −5.2%). The mean CHADS2 score in the cohort was 2.67. Seventy-four patients (20.8%) died during follow up and among these 42 (56.7%) were cardiovascular deaths.

Conclusions: According to our data the rate of major bleeding is high over 85 years of age in patients treated with VKA for stroke prevention in AF. There is no relationship between analyzed risk factors and major bleeding. A close monitoring of anticoagulation is suggested.

PB 1.47-3

Determination of dabigatran and rivaroxaban in serum samples from patients on treatment

Du S[1], Krämer S[1], Weiss C[2], Krämer R[3] and Harenberg J[1]
[1]Clinical Pharmacology; [2]Biometry and Statistics, Mannheim; [3]Institute Inorganic Chemistry, Heidelberg, Germany

Background: Coagulation analysis and determination of the effects of anticoagulants is currently performed from plasma samples. Determinations of the concentration of anticoagulants from serum samples are made using specific and laborious methods such as various chromatographic or mass spectrometry techniques. These methods are not suitable for rapid determinations required in clinical routine for patient care. We have developed specific and sensitive method to determine new oral anticoagulants (NOAC) in serum and urine namely oral thrombin inhibitors (international patent application No. PCT/EP2012/002540) and factor Xa inhibitors (international patent PCT/WO2012/069139A1). Serum samples have several advantages over citrated plasma samples regarding reduced pre-analytical errors. They are taken almost always from patients, can be stored for longer time periods and frozen if clinical conditions may require later testing for specific parameters.

Aim: We have compared the concentration of plasma and serum samples of patients on treatment with 10 mg rivaroxaban od and 110 or 150 mg dabigatran od to identify the feasibility of the determination of the NOACs from serum samples for clinical routine.

Methods: In a prospective study we analysed 120 serum and plasma samples from patients with atrial fibrillation during therapy with 110 or 150 mg dabigatran bid. Samples were taken 2–4 h after intake of the medication. In another prospective study patients (n = 150) received 10 mg rivaroxaban od. Before and 4–6 days after initiation of therapy plasma and serum samples were taken in the morning 12 h after intake of the anticoagulant. Both studies were accepted by the local ethics committee and patients gave written informed consent prior to participation. The methods for determination of the concentration of dabigatran and rivaroxaban used purified human thrombin and factor Xa as enzymes and substrates 2238 for the thrombin assay and S2222 for the factor Xa assay. The methods for detection of dabigatran and rivaroxaban are described in the patents.

Results: Dabigatran and rivaroxaban were purified from commercially available Pradaxa® and Xarelto®, respectively. The purity of the compounds was characterized by analytical methods and was quantified in plasma samples using the thrombin specific S2238 and factor Xa specific S2222 chromogenic substrate assays. The concentrations of dabigatran and rivaroxaban were read from dilution curves from pooled plasma samples spiked with defined amounts of the purified of the NOACs. In controls concentrations of dabigatran in plasma and serum were 15 + 5 ng/mL and 21 + 12 ng/mL, and of rivaroxaban 15 + 12 and 18 + 17 ng/mL, respectively. During therapy concentration of dabigatran were 163 + 116 and 120 + 102 ng/mL, and or rivaroxaban 67 + 41 and 82 + 40 ng/mL, respectively. The correlations between plasma and serum concentrations were r = 0.5 for dabigatran and r = 0.6 for rivaroxaban.

Conclusion: The study demonstrates the feasibility of the determination of NOACs from serum samples. Dabigatran and rivaroxaban can be determined specifically in serum samples as in plasma samples using the described method. This is of advantage in specific clinical situation when plasma samples are not available or if later testing may be required.

PB 1.47-4

Assessment of cross-reactivity in three different fecal occult blood test systems with dabigatran and dabigatran etexilate: identification of useful test methods for gastrointestinal bleeding

Goss AM[1], Van Ryn J[2], Schurer J[2] and Clemens A[2]

[1]*Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, USA;* [2]*Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany*

Background: Anticoagulant therapy can elevate the risk of gastrointestinal (GI) bleeding and may affect its management. Fecal occult blood tests (FOBT) are non-invasive, widely-used tests that can aid in detecting early and thus treatable stages of GI lesions or bleeding in patients on these therapies. The literature suggests that use of anticoagulants does not diminish the positive predictive value of FOBT, however a potential limitation and concern of these tests is the possibility for drug interactions with test components which may lead to false positives. Dabigatran is a new oral, reversible, direct thrombin inhibitor currently approved for stroke prevention in patients with atrial fibrillation. Dabigatran etexilate (DE) is the prodrug of the active ingredient dabigatran, and is converted by non-specific esterases in plasma and liver to dabigatran. Approximately 6.5% of DE in Pradaxa® is bioavailable and absorbed in the gut with the remaining 93.5% eliminated in the feces.

Aims: The purpose of this study was to investigate any potential cross-reactivity of dabigatran, DE or Pradaxa® with three commonly-used commercial fecal occult blood tests (FOBTs) with different detection methods.

Methods: Common methods of detection in FOBTs used worldwide include guaiac oxidation in hemoccult tests, immunochromatographic methods (membrane strip precoated with hemoglobin antibody), or the benzamidine method (heme in hemoglobin induces a blue/green color change). Examples of each method were tested. The Hemoccult II® SENSA® (Beckman Coulter Inc.), EZ DETECT (Biomerica Inc.), and BioNexia® Hb/Hp Complex Professionell (FROST Diagnostika GmbH) FOBT were were used for this study and all tests were conducted according to manufacturer's protocol. DE, dabigatran or the contents of a single Pradaxa® capsule were suspended in a 0.5% cellulose solution. Vehicle solution was used as negative control and human blood used as a positive control.

Results: Isolated human blood samples generated positive results in all three FOBTs as expected, whereas vehicle solution did not. Exposure to DE, dabigatran or Pradaxa® suspensions did not result in positive readouts with any detection method of the tested FOBTs.

Conclusions: These studies show that the prodrug DE and its active drug form dabigatran, as well as any further excipients in the Pradaxa® formulation do not cross-react with a set of commonly-used fecal occult blood tests. This supports the usefulness of these three tests in dabigatran etexilate-treated patients.

PB 1.47-5

Low molecular weight heparin monitoring

Testa S, Paoletti O, Bassi L, Cancellieri E, Cogrossi A, Damiolini E, Zambelli S and Zimmermann A

Haemostasis and Thrombosis Center-A.O. Istituti Ospitalieri, Cremona, Italy

Background: Anti-Xa activity (aXa) can be used as biological marker of low molecular weight heparins (LMWHs). LMWH prophylactic and therapeutic ranges have been defined for a large part of molecules and aXa commercial tests are currently available. Because of clinical trials have been conducted without any laboratory monitoring, aXa testing is not routinely recommended and debates are ongoing about clinical utility of laboratory testing. Anyhow, because aXa could be indicated in selected clinical conditions at risk of drug accumulation such as renal disease, over-underweight, prolonged therapy, pregnancy, our local guidelines follow this indication.

Aims: The aim of this study was to describe the prevalence of aXa levels out of range, both in prophylaxis and therapeutic regimens, in patients treated with enoxaparin during hospitalization in two medical and one surgical division of our hospital.

Methods: We prospectively monitored aXa activity in 373 consecutive patients during year 2011. Two hundred and fifty-two determinations were performed on patients treated with therapeutic regimen, while 121 were on patients on prophylaxis. Blood samples were collected after 4 h from the last LMWH injection, in patient treated at least from 2 days. Anti-Xa activity was measured on fresh plasma, by Stago Rotachrom heparin kit chromogenic assay (Diagnostica Stago) on magneto-mechanical instrument (STA-R Roche,Basel). The following protocol of dose adjustement is on use in our hospital: dose/kg standard posology as recommended by international guidelines, but reduced posology by 30% in patients with renal impairement (creatinine clearance < 30 mL/min) and in patients obese, underweight and elderly (age > 80y). We considered the following ranges for enoxaparin: prophylactic range = 0.20–0.49UI/mL, therapeutic range = 0.5–1.0 UI/mL.

Results: aXa out of range were 38% and 34% of the total therapeutic and prophylactic regimen, respectively. Mean creatinine level was = 1.16 ± 0.25 mg/dL in standard group and 2.46 ± 0.42 mg/dL. We analyzed separately results obtained in patients on adjusted doses compared with standard regimen, both in therapeutic and prophylactic regimen. One hundred and seventy-eight patients treated with therapeutic dose in standard regimen and 74 patients in adjusted protocol showed 41.6% and 29.6% out of range respectively. Considering prophylaxis we found 39.6% out of range in 91 patients in standard prophylaxis and 16.7% out of range in 30 patients in adjusted dose.

Conclusions: Confirming recent studies, also our experience show high frequency out of range both in prophylaxis and in therapeutic regimen. LMWH adjusted doses resulted more frequently in recommended range. Anti-Xa activity can easily be performed in a routine coagulation laboratory and could guide LMWH dose adjustment avoiding potentially dangerous out of range in special populations.

PB 1.47-6

Surgical safety threshold in patient under long term Rivaroxaban treatment: is quick PT suitable?

Dierge L, Fosse E, Alewaeters A, Chevalier C, Govaerts D and Cauchie PH

CHU de Charleroi, Montigny-le-Tilleul, Belgium

Aims: The oral direct factor Xa (FXa) inhibitor Rivaroxaban has been developed for treatment and prophylaxis of thrombo-embolic disorders. Most conventional coagulation tests, and especially some Prothrombin Time (PT) assays, are affected by Rivaroxaban. The purpose of this study is to evaluate if the new proposed safety threshold (GIHP, http://site.geht.org/site/Pratiques-Professionnelles/Nouveaux-anticoagulants-oraux/Propositions-du-GIHP-NACO-et-Urgences-decembre-2012_96_810.html) for urgent surgery may be adequately estimated with our thromboplastins (STA-NEOPLASTINER, Stago and Owren's PT, MediRox).

Methods: Rivaroxaban was spiked at increasing concentrations into normal human PPP from five healthy volunteers. Two Prothrombin Times (Quick PT, STA NEOPLASTINE R, Stago and Owren PT, Owren's PT, MediRox), activated partial thromboplastin time (aPTT) (PTT-A, Stago and Actin FS, Siemens), thrombin time (TT – Thrombin10, Stago), were measured. Tests were performed on a STA-R (Stago) and responsiveness to Rivaroxaban was assessed. PT and aPTT were also evaluated on selected Rivaroxaban treated patients and correlated extemporaneously with their Rivaroxaban concentrations (Liquid anti-Xa® Stago).

Results: Rivaroxaban prolonged Quick and Owren PT in a concentration-dependent way with increased inter-variability at high concentra-

tions levels. Our Quick PT assay was more sensitive compared to the Owren PT assay. In addition, Neo-R demonstrated a high sensitivity to Rivaroxaban. aPTT was also prolonged in a concentration-dependent manner but this test seemed less sensitive than PT. Similar results were observed on *ex-vivo* samples. Individual variability did not allow the use of PT to estimate Rivaroxaban concentration. With our reagents, these preliminary results indicate that a PT > 80% (as proposed by GIHP) ensures a Rivaroxaban level lower than 30 ng/mL. However, with this cut off, about eight patients out of 10 will be inadequately postponed.

Conclusions: Despite the use of a high sensitive Quick PT reagent to Rivaroxaban, the individual variability does not allow an estimation of the anticoagulant concentration. Particularly, in front of an urgent surgical procedure, too many patients would be delayed. Therefore, in case of an abnormal PT, a specific test is required for this purpose.

Association between CYP2C9, VKORC1 and CYP4F2 genetic variants in anticoagulation related outcomes during initiation period in acenocoumarol therapy

Cerezo-Manchado JJ[1], Gonzalez-Conejero R[2], Ana isabel A[2], Constatino M[2], Perez-Andreu V[1], Nuria GB[2], Jose P[2], Vicente V[2] and Vanessa R[2]

[1]*Centro Regional de Hemodonación, Hospital Morales Meseguer;* [2]*Centro Regional de Hemodonación, Hospital Morales Meseguer, UMU, IMIB, Murcia, Spain*

Background: Acenocoumarol (AC) is a widespread used anticoagulant with a high inter-personal variability in required dose to achieve a stable INR. Thus, it needs careful clinical management to balance the risks of over-anticoagulation and bleeding with those of under-anticoagulation and thrombosis. Such adjustment mainly depends on both clinical and genetic factors (SNPs). There is an abundant evidence of the role of certain SNPs on the pharmacogenetics of AC. The strongest SNPs are *CYP2C9* isoforms and −1639G>A change of *VKORC1*. Recently, the influence of rs2108622 in *CYP4F2* gene in AC dose has been described as slighter but significant. Despite the relevance of these SNPs on the dose required to achieve a stable anticoagulation has been deeply studied, the relationship between these SNPs and other outcomes has not been well defined in the first stages of AC therapy.

Aims: We evaluated the influence of *VKORC1*, *CYP2C9* and *CYP4F2* SNPs in time to over-coagulation and time to achieve stable dosage in our population.

Methods: Characteristics of our primary cohort has been described previously[1]. We performed a retrospective study with patients who had started therapy from 1995 to 2009 and that are being controlled at our Unit. The primary outcomes considered for 2 first months of therapy were: time to stable dosage and time to first INR>4. Statistical analyses were done using SPSS 16.0 (SPSS Inc., Chicago, IL). All statistical tests were two-sided and a $P \leq 0.05$ was considered statistically significant.

Results: A total of 973 patients were enrolled. The relationship between genetic and clinical factors with INR>4 was evaluated by Cox regression model: age, body surface area, antiplatelet therapy, *CYP2C9, VKORC1,* and *CYP4F2* SNPs were statistically significant (univariate analysis, all $P < 0.15$). However, in the multivariate analysis only *CYP2C9, VKORC1,* and *CYP4F2* SNPs remained significant: CYP2C9 3* carriers and *VKORC1* −1639AA patients had a higher risk to over-anticoagulation (HR 1.19, CI95% 1.06–1.34 and HR 1.37, CI95% 1.21–1.54, respectively). Interestingly, in this model *CYP4F2* TT subjects had a low risk to suffer an INR>4 (HR 0.87, CI 95% 0.77–0.99, $P = 0.037$). Time to stable dosage was also evaluated using a Cox regression model where only *VKORC1* SNPs remained significant. Thus, *VKORC1* −1639AA patients spent less days to achieve stable dosage (HR 1.38, CI95% 1.01–1.90, $P = 0.045$).

Summary: Our data show that the main determinants in required dose to achieve a stable INR, *VKORC1* and *CYP2C9* SNPs, have a significant impact on the risk of overdosing in the 8 first weeks of AC therapy. Moreover, we show for first time that *CYP4F2* SNPs, with a slighter weight on AC stable dose, is also influencing the INR overshooting at early stages of therapy. These findings suggest that these four polymorphisms should be included in pharmacogenetic algorithms to guide the first weeks of AC therapy.

The effect of dabigatran on the activated partial thromboplastin time and thrombin time as determined by the hemoclot thrombin inhibitor assay in patient plasma samples

Hapgood G, Butler J, Malan E, Chunilal S and Tran H

Monash Medical Centre, Melbourne, Vic., Australia

Background: Dabigatran is an oral direct thrombin inhibitor available for stroke prevention in non-valvular atrial fibrillation. Although dabigatran does not require routine laboratory monitoring, an assessment of its anticoagulant effect in certain clinical settings, such as urgent surgery or bleeding is desirable. To date, our understanding of the effect of dabigatran on coagulation assays is based on the analysis of dabigatran-spiked plasma.

Aim: We examined the relationship between dabigatran levels, as determined by the hemoclot thrombin inhibitor assay (HTI) (Hyphen Biomed, France), and the activated partial thromboplastin time (aPTT) and the thrombin time (TT) using patient plasma samples.

Methods: Seventy five samples from 47 patients receiving dabigatran were analysed. Thirty-three patients were assessed for dose-appropriateness, seven patients required urgent surgery/procedure, including three requiring neurosurgery, and seven patients presented with bleeding. These were random plasma samples taken from mainly inpatients and some outpatients. The HTI assay was established to measure dabigatran concentration using three lyophilised dabigatran calibrators (ranging from 30 to 480 ng/mL) to establish a standard curve ($R^2 = 0.995$). aPTTs were performed using our local TriniCLOT aPTT S reagent (Trinity Biotech). We assessed three additional aPTT reagents: aPTT SP (Instrumentation Laboratory), aPTT SS (Instrumentation Laboratory) and Actin FS (Siemens).

Results: Our local aPTT demonstrated a modest correlation with the dabigatran level ($r = 0.80$, $R^2 = 0.645$) with the aPTT range of 46–54 s corresponding to the therapeutic dabigatran level of 90–180 ng/mL. An aPTT of ≥ 64 s correlated with a supra-therapeutic dabigatran level of ≥ 300 ng/mL. The correlation became less reliable at high concentrations. A dabigatran level of 10 ng/mL correlated with an aPTT of 36 s (our reference range 22–32 s). The aPTT reagents differed in their sensitivity to dabigatran with different values obtained across the therapeutic range. The aPTT range for a therapeutic dabigatran level (90–180 ng/mL) and R^2 for additional aPTT reagents was: aPTT SP 61–71 s, 0.505; aPTT SS 51–60 s, 0.663; and aPTT FS 54–64, 0.636. The TT was extremely sensitive to the presence of dabigatran. A dabigatran level of 60 ng/mL resulted in a TT of greater than our reportable limit (> 300 s). The withholding of dabigatran until normalisation of the TT was associated with favourable outcomes in the three patients requiring neurosurgery. Conversely, supra-therapeutic levels were not associated with excessive bleeding in three patients requiring urgent surgery or a procedure. The inability to reverse dabigatran contributed to the one fatality in our series.

Conclusion: The aPTT demonstrated a modest correlation with the dabigatran level, as determined by the HTI assay. In our lab, an aPTT of between 46 and 54 s corresponds to the therapeutic range of dabigatran. aPTT reagents differ in their reactivity to the presence of dabigatran, thus making it difficult to compare values between laboratories

and to make recommendations regarding monitoring. The TT is useful to exclude the presence of dabigatran. The aPTT and TT provide complementary information to assess the presence of dabigatran in guiding peri-procedural management and bleeding scenarios. This data represents our 'real-world' experience of monitoring the anticoagulant effect of dabigatran in patient samples.

PB 1.48-3

Personalised clopidogrel therapy by teststrip-based CYP2C19 genotyping

Oberkanins C, Puehringer H and Rauscher B
ViennaLab Diagnostics, Vienna, Austria

Background: Clopidogrel (Plavix[TRADEMARK]) is widely prescribed to reduce recurrent ischaemic complications in patients with acute coronary syndromes and/or post-percutaneous interventions. High interindividual variations in and non-responsiveness to clopidogrel-induced platelet inhibition often complicate the treatment. Genetic polymorphisms in the *CYP2C19* gene, which encodes the principle enzyme responsible for the bioactivation of this prodrug, lead to reduced enzyme activity and reduced levels of clopidogrel's active metabolite. Patients carrying defective *CYP2C19* variants have a higher risk for major adverse cardiovascular events than noncarriers, whereas individuals with increased enzyme activity are more at-risk for developing bleeding.
Methods: A genetic test (StripAssay) was developed for the detection of the *CYP2C19* loss-of-function alleles **2, *3, *4, *5, *6, *7* and **8*, as well as for the gain-of-function allele **17*. The StripAssay is based on multiplex PCR, followed by reverse-hybridisation of biotin-labeled amplification products to a parallel array of allele-specific oligonucleotides immobilised on membrane teststrips.
Results: Genotyping for functionally enhanced (*17) or defective (*2–*8) *CYP2C19* variants allow the classification of patients into ultra-rapid, extensive and poor metabolisers for clopidogrel. Favourable properties, such as the rapid DNA extraction protocol, ready-to-use reagents and teststrips, as well as the potential for automation of the hybridisation/detection step, make the StripAssay convenient and easy to perform within < 6 h.
Conclusion: A simple and reliable diagnostic tool was developed for predicting the response of patients to clopidogrel treatment. The CYP2C19 StripAssay will assist clinicians to achieve a more individualised antiplatelet therapy.

PB 1.48-4

A novel synthetic heparin antagonist neutralizes the anticoagulant actions of branded and generic enoxaparins in the whole blood clotting assay used during interventional cardiology

Iqbal O[1], Hoppensteadt D[1], Lewis B[1], Khan H[1], Walenga JM[1], Scott R[2] and Fareed J[1]
[1]Loyola University Medical Center, Maywood, IL; [2]Polymedix, Inc., Radnor, PA, USA

Introduction: Heparin and low molecular weight heparins (LMWHs) are commonly used in the management of cardiovascular disorders and interventions. LMWHs, such as enoxaparin, are also used intravenously in the management of cardiovascular patients. Delparentag (PMX 60056, Heptagonist; Polymedix, Radner, PA) is a synthetic LMWH neutralizing agent, which has been shown to also neutralize LMWHs, such as enoxaparin. During interventional cardiology and surgery, the anticoagulant effects of heparin and related drugs are usually monitored using whole blood celite Activated clotting time (ACT) and similar tests. LMWHs produce relatively weaker anticoagulant effects on this test, however, are capable of prolonging this test proportional to the concentration. Recently, generic versions of enoxaparin have also been introduced. In the US there are two generic products available, namely Sandoz enoxaparin (SE) and Watson enoxaparin (WE). The purpose of this study is to compare the neutralization effect of the Delparentag with protamine sulfate (PS) on enoxaparin supplemented whole blood.
Materials and Methods: Four individual batches of SE and three individual batches of WE, along with four batches of branded enoxaparin (BE) were commercially obtained. The whole blood anticoagulant effects of each of these agents were measured using celite ACT at a fixed concentration. Whole blood samples from healthy volunteers were supplemented with each of these drugs at 25 μg/mL. To determine the neutralization profile, equigravimetric amounts of either Delparentag or PS were added to individual tubes (n = 4–7). The results were compiled in terms of cumulative means of the different batches for the native, enoxaparin supplemented and enoxaparin supplemented with both PS and Delparentag.
Results: The baseline ACT values in the native whole blood ranged from 124 to 164 s in the different groups. Supplementation of enoxaparin at 25 μg/mL resulted in a prolongation of celite ACT, resulting in a clotting time of 219–265 s. No significant differences were noted between the generic and BE preparations. Supplementation of Delparentag at 25 μg/mL to each of these different enoxaparin supplemented whole blood resulted in the neutralization of the anticoagulant effects, resulting in a decrease in the clotting times in the range of 137–174 s. While some differences in the batches of BE, SE and WE were noted, these were not significantly different. Overall, the cumulative neutralization of the ACT by Delparentag was comparable for each group of enoxaparins. Similarly, in the neutralization studies with PS, comparable results were observed in all groups. The relative neutralization of the anticoagulant effects of both agents were comparable, resulting in 80–95% neutralization of the anticoagulant effects of enoxaparin.
Conclusions: These studies suggest that both generic and branded versions of commercial enoxaparins produce comparable anticoagulant effects in native whole blood, which can be monitored using celite ACT. At 25 μg/mL, all agents produced a > 200 s prolongation of the celite ACT in comparison to the control (< 140 s). Although minor batch-to-batch differences existed among the generic and branded enoxaparins, the cumulative means were comparable. The relative neutralization of the anticoagulant effects of enoxaparin by both PS and Delparentag was comparable, resulting in > 80% neutralization of these effects.

PB 1.48-5

Antidotal effects of non-specific reversal agents on anticoagulant-induced inhibition of thrombin generation

Pillitteri D, Pilgrimm-Thorp AK, Krause M, Scholz T and Kirchmaier C
Deutsche klinik für Diagnostik, Wiesbaden, Germany

Introduction: Reversal of pharmacologic anticoagulation is an issue that arises when an anticoagulated patient has a major bleeding or when an emergency surgery needs immediate correction of coagulation. However, the new oral anticoagulants (NOAC) Rivaroxaban (anti-FXa) and Dabigatran (anti-FIIa) lack specific antidotes and only limited data is available regarding the antidotal effect of non-specific haemostatic agents.
In this *ex vivo* study reversal of anticoagulant activity after the administration of either 20 mg Rivaroxaban or 150 mg Dabigatran was tested *in vitro* using two different PCC (Beriplex, Cofact), aPCC (FEIBA; factor eight inhibitor bypassing activity) or rFVIIa (NovoSeven) at various concentrations.
Method: Ten healthy subjects were first randomized to receive either 20 mg Rivaroxaban or 150 mg Dabigatran in one oral dose.

Citrated venous blood was taken right before (T0) and 2 h after administration (T2) of either Dabigatran or Rivaroxaban. The potential of four haemostatic agents to reverse the anticoagulant effect of the NOACs was evaluated:

Beriplex: 0.25; 0.5; 1; 2 U/mL
Cofact: 0.25; 0.5; 1; 2 U/mL
FEIBA: 0.25; 0.5; 1; 2 U/mL
NovoSeven: 1.25; 2.5; 5; 10 μg/mL

Thrombin generation was the primarily applied assay, along with the parameters aPTT, PT, thrombin time, Rivaroxaban- and Dabigatran levels and Ecarin time. Parameters of interest concerning the thrombin generation assay (TGA) were ETP, *Peak* and Lag time. Thrombin generation in platelet poor plasma was initiated by adding 1 pM tissue factor and 4 μM phospholipids.

Results: Two hours after administration (T2), Rivaroxaban showed remarkable inhibitory effects on the investigated TGA parameters ETP, Peak and Lag time, with a more pronounced inhibitory effect on the Peak. In contrast, Dabigatran at T2 only showed a slight effect on ETP and no effect on the Peak whereas LT was significantly prolonged.

Rivaroxaban-induced inhibition of ETP and Peak were reversed by FEIBA in a concentration dependent manner with an over-correction for the two highest concentrations (1 and 2 U/mL). Cofact and rFVIIa restored ETP dose-dependently and both reached baseline T0 at their highest concentrations. Compared to FEIBA, rFVIIa and Cofact only had a slight but dose-dependent effect on the Peak. Interestingly, the other PCC, Beriplex, did not show any reversal effects on ETP and Peak.

Regarding Rivaroxaban-prolonged LT all concentrations of rFVIIa and FEIBA were responsible for a significant LT-reduction close to baseline, whereas both PCCs did not correct prolonged LT.

Regarding Dabigatran, all doses of rFVIIa, Cofact and FEIBA reduced the LT, with a more pronounced and dose-dependent effect of Cofact and FEIBA. For Beriplex only a slight reduction in LT was observed.

Conclusion: FEIBA and rFVIIa showed significant reversal of anticoagulant activity already at low therapeutic concentrations for both anticoagulants in TGA. Surprisingly, regarding both investigated PCCs, only Cofact showed an antidotal effect on TGA parameters, especially in higher therapeutic concentrations. Considering that the main difference between the two PCCs is that Beriplex contains small amounts of heparin and Cofact does not, it is conceivable that this may explain the observed differences in TGA. Further clinical validation is needed.

PB 1.48-6

D-dimers levels evolution during heparin therapy of patients with cerebral venous thrombosis

Tardy B[1], Chalayer E[1], Piot M[2], Chapelle C[2], Garnier P[3] and Tardy-Poncet B[1]

[1]Inserm CIE3; [2]EA 3065; [3]CHU Nord, Saint Etienne, France

Background: Heparin therapy is widely used as the first line treatment in patients with cerebral vein thrombosis (CVT). However, near 20% of patients presented poor outcome (deaths or major handicaps) during the first weeks of heparin therapy. The aim of this prospective study was to evaluate the evolution of D-dimers levels during the first 2 weeks of anticoagulant treatment.

Methods: All consecutive patients with CVT, admitted in our ICU before heparin treatment initiation, were included in this prospective study. Patients with duration of their symptoms more than 2 weeks before admission, or related to a cancer, an infectious disease or a recent neurosurgery, were not included. All patients were treated with therapeutic doses of UFH for a minimum of 5 days. The heparin dose was adjusted so that the initial APTT was at least doubled. Then, oral anticoagulants (OA) were initiated (INR values between 2 and 3) for a 3–6 month period. Plasma D-dimers levels were evaluated for each patient on admission and then each days during heparin therapy until the biological efficiency of the treatment with oral anticoagulant alone. Outcome assessment: Patients were clinically assessed daily by a clinician unaware of the results of D-dimer test. In case of clinical worsening during the two first weeks of anticoagulant therapy, CT scan or MRI had to be performed. D-Dimers were compared from day 1 to day 14 between the presence or the absence of: a lesion, an aggravation, an infection, more than two sinuses, an hemorrhage, a coma and an epilepsy. The coefficients of equation of the curves of D-dimers evolution were compared between groups using a student's t-test.

Results: Thirty-one patients were included (25 women and six men, mean age: 37.2). The median D-Ddimers levels (Q1-Q3) were, on admission, 1327 ng/mL (836–2410) and at day 417 ng/mL (141–1852). During the two first weeks of anticoagulation therapy, eight patients presented a clinical worsened course related with a thrombosis extension (three patients), a new intracerebral hemorrhage (three patients) or an isolated increase of brain edema (two patients). In patients (n = 17) with initial hemorraghic or ischemic intracerebral lesions, D-dimer levels at day 0 were significantly higher than those (n = 14) without lesions (median: 1885 vs. 955; P = 0.04). The coefficients of equation of the curves of D-dimers evolutions were not statistically different between patients with neurological aggravation and patients without aggravation. No significant difference was also observed between patients with initial coma or epilepsy and patients without coma or epilepsy, between patients with more than two thrombosed sinuses and patients with less two thrombosed sinuses and between patients with brain hemorrhagic complication and patients without hemorrhagic complication.

Conclusion: The evolution of D-dimers levels I patients with CVT is not correlated with the clinical evolution of patients.

Short-term prognosis of intracranial haemorrhage in patients on oral anticoagulant and antiplatelet drug: the VAIP study

Squizzato A[1], Melchio R[2], Sironi A[1], Girando AV[2], Dentali F[1], Fenoglio LM[2] and Pomero F[2]

[1]University of Insubria, Varese; [2]Cuneo Hospital, Cuneo, Italy

Background: Intracranial hemorrhage (ICH) is the most serious and feared complication of oral vitamin K antagonists (VKAs) and antiplatelet drugs. Despite medical and surgical approach are promptly conducted, a very high rate of mortality and severe disability has been reported in case of VKA-related intracerebral bleeding. Only few data are available on the clinical course of other sites of antithrombotic drug-related ICH, on the efficacy of available treatments and on prognostic risk factors.

Aims: To investigate determinants of short-term prognosis of antithrombotic drug-related ICH.

Methods: The Vka- and Antiplatelet drug-related Ich Prognosis (VAIP) is designed as a retrospective study. Consecutive adult patients with an ICH objectively documented by neuroimaging (cerebral computed tomography or magnetic resonance), occurring during treatment with VKA (warfarin or acenocoumarol), defined by an international normalized ratio (INR) of 1.5 or more, or with an antiplatelet drug (aspirin, ticlopidine, or clopidogrel) at the time of hospital admission, were included. Patients were identified by searching the administrative database of the Cuneo hospital, Piedmont Region, Italy, from 2005 to 2010. As a control group, we randomly selected patients with ICH not on treatment with VKAs or antiplatelet drugs and admitted in the same hospital during the same period.

Results: Overall, 451 patients were included: 75 on VKA, 96 on antiplatelet drug, and 280 as a control group. Patients on VKA were, in comparison with the control group, older (77.7 vs. 72.9 years old; $P < 0.05$), more likely to have a subdural haematoma (49.3% vs. 30%; $P < 0.05$) and less likely an intracerebral haemorrhage (45.3% vs.

66.4%; $P < 0.05$), at higher risk of death during hospital stay (33.3% vs. 22.1%; $P < 0.05$). Patients on antiplatelet drug were, in comparison with the control group, older (77.3 vs. 72.9 years old; $P < 0.05$) with a greater proportion aged more than 80 years (44.8% vs. 32.1%; $P < 0.05$), with a worst Glasgow Come Scale (GCS) at admission (< 8%, 10.4% vs. 26.8%; $P < 0.05$) and a modified Rankin scale at discharged (4–6, 50.0% vs. 37.9%; $P < 0.05$). At the multivariate Cox regression analysis, independent predictors of in-hospital death for ICH were: age > 80 years (HR 2.3, 95% CI 1.5–3.5), GCS < 8 (HR 7.8, 95% CI 5.0–12.1), treatment with VKAs (HR 2.0, 95% CI 1.2–3.4), and treatment with antiplatelet drug (HR 1.8, 95% CI 1.05–3.0); surgical treatment is an independent predictor of survival (HR 0.5, 95% CI 0.3–0.96). Independent predictors of combined outcome in-hospital mortality and disability, defined as modified Rankin scale 4–6, were: age > 80 years (HR 2.1, 95% CI 1.6–2.8), GCS < 8 (HR 3.0, 95% CI 2.2–4.0), and treatment with antiplatelet drug (HR 1.5, 95% CI 1.1–2.1); surgical treatment is an independent predictor of good outcome (HR 0.7, 95% CI 0.5–0.97).

Conclusions: Our data suggest that both VKAs and antiplatelet drugs worsen short-term prognosis of ICH and that a prompt surgical treatment is life saving, in particular for patients with a subdural haematoma.

PB 1.49-2

Risk factors for death and thromboembolic complications in patients with major or clinically relevant non-major bleeding while on oral anticoagulant treatment

Franco L[1], Becattini C[1], Masotti L[2], Sbrojavacca R[3], Nitti C[4], Cappelli R[5] and Agnelli G[1]

[1]Internal and Cardiovascular Medicine-Stroke Unit, University of Perugia, Perugia; [2]Internal Medicine, Cecina Hospital, Cecina; [3]Emergency Medicine, Ospedale Santa Maria della Misericordia, Udine, Udine; [4]Medicina d'Urgenza, Ospedali Riuniti Umberto I, Lancisi, Salesi, Ancona, Ancona; [5]Internal Medicine, University of Siena, Siena, Italy

Background: The incidence of major bleeding (MB) complications is about 3% per-year during oral anticoagulant treatment. Optimal management strategies and their effect on thromboembolic complications remain unclear.

Methods: CLIMBING is an Italian, prospective, observational, cohort study including patients on oral anticoagulant therapy admitted to the Emergency Department for MB or clinically relevant non-major bleeding (CRNMB). The aim of the study was to evaluate the clinical management and outcome of MB or CRNMB. MB was defined according to ISTH criteria. The primary endpoint of the study is death or major thromboembolic complications (acute coronary syndrome, ischemic stroke, systemic cardioembolism, pulmonary embolism). The secondary endpoint is bleeding-related or treatment-related adverse events and recurrent bleeding during hospitalization.

Results: As for January 1st 2013, 202 patients were included in the study, 161 with MB (79%). Both previous bleeding (53.6% vs. 13.6%, $P < 0.001$) and HASBLED score ≥ 3 (65.8% vs. 42.8%, $P < 0.001$) were more common in patients referred for CRNMB than for MB. No association was found between clinical presentation as MB or CRNMB respect to age, gender, indication for anticoagulation, INR at admission, ongoing antiplatelet therapy or recent trauma. Fresh frozen plasma (FFP) or prothrombin complex concentrates (PCCs) were used only in patients suffering MB.

Among patients with MB, previous intracranial hemorrhage (ICH) was more common in patients admitted for ICH (7% vs. 0%, $P = 0.05$) while HASBLED score ≥ 3 (53.7% vs. 37.4%, $P < 0.05$) was more common in patients with non-ICH-MB. FFP was used in similar proportions of patients with and without ICH while PCCs was more commonly used in patients with ICH (49.5% vs. 25.9%, P 0.004). In-hospital death occurred in 34 patients with and in seven patients without ICH (31.8% vs. 12.9%, $P = 0.01$) and rebleeding in 12 and eight patients, respectively (16.6% vs. 11.4%, P = ns). ICH (OR 3.09, 95% CI 1.26–7.61, $P = 0.01$) but not HASBLED score ≥ 3 (OR 0.93, 95%CI 0.44–1.97) nor any of the HASBLED components was an independent risk factors for death. During hospitalization, an acute coronary syndrome occurred in four patients (all non-ICH), ischemic stroke in three patients (all ICH), pulmonary embolism in two patients (both ICH). No significant difference was observed in the incidence of thromboembolic complications between patients receiving and those not receiving PCCs (three out of 67, 4.5% vs. six out of 94, 6.4%, P = ns).

Among patients with ICH, age (83 ± 6 vs. 77 ± 9, $P < 0.001$), Glasgow Coma Scale at admission (9 ± 4 vs. 14 ± 2, $P < 0.001$) and parenchymal localization of ICH (44.1% vs. 16.3%, $P = 0.004$) were associated with death, while no association was observed between gender, hypertension, renal failure, previous ICH, INR at admission, the use of PCC or FFP and death.

Conclusions: Among patients with MB while on oral anticoagulant treatment, the risk for death is substantial in those with ICH and is not associated with HASBLED score. The incidence of thromboembolic complications during hospitalization seems not to be associated with PCCs use.

PB 1.49-3

The synthetic pentasaccharide fondaparinux attenuates myocardial ischemia-reperfusion injury in rat via STAT-3

Guillou S, Moussa W, Tamareille S, Lamon D, Prunier D, Prunier F and Macchi L

Université d'Angers, EA 3860, Angers, France

Background: Acute myocardial infarction is a leading cause of death worldwide. Although highly beneficial, reperfusion of myocardium is associated with reperfusion injury. Pharmacologic inhibition of factor Xa has been shown to attenuate ischemia-reperfusion (I/R) injury but the cellular mechanism is poorly understood.

Aims: To determine the role of blood in fondaparinux (FDX)-induced cardioprotection and the involvement of RISK and SAFE pathways, two major survival signalling cascades commonly associated with protection against I/R injury.

Methods: We investigated the ability of FDX to prevent I/R injury *in vivo*, in a model of transient coronary ligation, and *ex vivo* in a model of crystalloid-perfused isolated-heart. In the *in vivo* model, 40-min of myocardial ischemia was followed by 120-min of reperfusion. FDX (10 mg/kg) was injected intraperitoneally 10-min before reperfusion. In the isolated-heart model, FDX (0.1 mg/mL) was administrated in the recirculating buffer. In both models, infarct size was assessed after 120-min of reperfusion. Myocardial tissues were collected at 15- and 30-min reperfusion for western-blots analysis.

Results: *In vivo*, FDX decreased infarct size by 29% (44.28% vs. 61.98% in FDX-treated rats and controls respectively, $P < 0.05$). FDX induced a significant phosphorylation of STAT-3 and GSK3β as compared with controls. Addition of AG490, an inhibitor of JAK/STAT pathway before I/R prevented the phosphorylation of STAT-3 and GSK3β and abolished the FDX-induced cardioprotection. On the contrary, FDX had no effect on infarct size and hemodynamic parameters in the isolated-heart model.

Conclusion: FDX decreased I/R injury *in vivo* but not in a crystalloid-perfused isolated-heart. The protective effect was mediated through the phosphorylation of STAT-3. In our experimental conditions, FDX needed whole blood to be protective but its beneficial effect was not directly related to anticoagulant effect but to the activation of the SAFE pathway.

PB 1.49-4

A pharmacodynamic comparison of otamixaban and bivalirudin in primates

Jeske W, Walenga JM, Escalante V, McGeehan E, Khan H, Fareed J and Bakhos M
Loyola University Medical Center, Maywood, IL, USA

Background: Preventing blood clots is important in the treatment of myocardial infarction and unstable angina. Research on new anticoagulants continues to develop safer and/or more effective drugs. It is not yet clear whether there is an advantage in terms of safety (less bleeding) or effectiveness (less clotting) to inhibiting factor (F) Xa rather than thrombin in such patients.
Aims: The purpose of this study was to compare the pharmacodynamic relationships for bivalirudin (direct thrombin inhibitor; The Medicines Company) and otamixaban (direct FXa inhibitor; Sanofi-Aventis Paris) following iv administration to primates.
Materials and Methods: Following anesthesia, primates (*Macaca mulatta*; $n = 8$) were administered bivalirudin (0.185, 0.375 or 0.75 mg/kg) or otamixaban (0.05, 0.1 and 0.2 mg/kg) intravenously with a 1 week washout period between treatments. Blood samples were collected over a 60 min period. Celite ACT (Hemochron) and tissue factor activated thromboelastography (Haemonetics TEG) were assessed using fresh whole blood. Plasma aliquots were used for clotting (PT, aPTT, Heptest), amidolytic (anti-Xa, anti-IIa) and fluorogenic (thrombin generation; Technoclone) assays. Area under the curve values were determined by trapezoidal approximation (SigmaPlot 12; Systat Software). Differences between treatment regimens (drug/dose) for all study endpoints were tested for significance by two-way analysis of variance (SigmaPlot 12); P-values ≤ 0.05 were considered significant.
Results: Using anticoagulant monitoring tests, otamixaban and bivalirudin were both cleared rapidly from the circulation, with the drug effect in most assays gone by the 30 min. Comparable prolongations of the ACT could be achieved 5 min following administration of otamixaban (278.1 $\pm$ 19.1 s) or bivalirudin (270.3 $\pm$ 8.2 s), although otamixaban was more potent, producing this effect at a dose of 0.2 vs. 0.75 mg/kg for bivalirudin. Dose-dependent increases in clotting time could be measured by aPTT and Heptest for both drugs. PT, however, was only prolonged by bivalirudin. Using assays to analyze the mechanism of the anticoagulant action of these two types of drugs, in the tissue factor supplemented TEG assay, bivalirudin prolonged the clotting time (R-time), reduced the rate of clot formation (angle) and decreased clot strength (maximal amplitude). In contrast, otamixaban produced different effects on these parameters suggesting differential mechanisms for modulating clot formation dynamics. In a fibrinokinetic clot formation assay, bivalirudin completely inhibited clot formation, while otamixaban did not. Furthermore, otamixaban more effectively inhibited thrombin generation than did bivalirudin, and otamixaban more effectively inhibited thromboplastin-induced platelet activation.
Conclusions: The anticoagulant effects of otamixaban and bivalirudin exhibit comparable plasma time courses which can be effectively monitored by the ACT suggesting that otamixaban may be useful in surgical or interventional indications. However, the observed differences in the effect of these two types of drugs on the dynamics of clot formation, thrombin generation inhibition and platelet activation inhibition reveals a different balance among the inhibitory effects on the various hemostatic parameters, suggesting that otamixaban may have superior safety and/or efficacy advantages over bivalirudin. The mechanistic differences between the thrombin inhibitor and the FXa inhibitor warrant further investigation to determine how they translate into clinical outcomes in patients undergoing interventional procedures.

PB 1.49-5

Evaluation of the new DG-Chrom Anti-Xa kit from Grifols for detection and quantification of new oral anti-Xa anticoagulants

Ambros R, Montanini V and Civit G
Grifols, Parets del Vallès, Spain

Background: A new chromogenic kit for the detection and quantification of anti-Xa activity (DG-Chrom Anti-Xa) was evaluated by Grifols. This kit will offer an assay capable to detect and quantify anti-Xa activity of the new oral anticoagulants.
Aims: The aim of this study is to evaluate the preliminary performance of this new kit with Rivaroxaban in a wide range of concentrations.
Methods: The study was performed in the optical coagulometer Q Hemostasis Analyser (Grifols).
Linearity of the calibration curve was analyzed using two different sets of commercial Rivaroxaban calibrators. A precision study was performed using three commercial controls containing three different concentrations of Rivaroxaban during five different days. The accuracy of the concentration determination was also tested.
Results: Linearity was found acceptable in the range of 0.0–433.3 ng/mL showing correlation coefficients higher than 0.99 using log-lin axis transformations. Linearity was found acceptable in the range of 0.0–145.6 ng/mL showing correlation coefficients higher than 0.99 using lin-lin axis transformations. Precision results showed appropriate coefficients of variation (CV) of 5.6% for the high control, 7.9% for the medium control and 10.2% for the low control Accuracy was found acceptable showing the following% of bias, 2.5% for high control, 4.3% for medium control and 1.3% for low control.
Conclusion: DG-Chrom Anti-Xa, a new chromogenic kit for detection and quantification of new oral anti-Xa anticoagulants, was found acceptable in terms of linearity, precision and accuracy with a wide range of concentrations of Rivaroxaban tested in Q Hemostasis Analyzer.

PB 1.49-6

Can high quality vitamin K-antagonist treatment be further improved?

Skov J, Bladbjerg E-M and Jespersen J
University of Southern Denmark, Esbjerg, Denmark

Background: The safety and efficacy of vitamin K-antagonist treatment depend on the clinical setting, and specialized anticoagulant clinics using computer-assisted dosage have been shown to provide treatment of high quality. To achieve further improvements, a focus on specific groups of patients seems necessary. In example, patients with venous thrombotic disorders (VTE) have been shown to be particularly vulnerable to the thrombotic complications of under-anticoagulation in a large multicenter study.
Aims: We investigated whether three groups of potentially vulnerable patients were prone to unstable responses to anticoagulant treatment. These were patients with VTE, patients with variant alleles of the *CYP2C9* and *VKORC1* genes and young patients.
Methods: Consecutive patients ($n = 308$, 67% men, median age 67 years) from a nurse-managed anticoagulant clinic at a Danish hospital were interviewed about health-related behaviour and socio-demographics at baseline and followed for 1 year. The majority of the patients had received anticoagulant therapy for more than 1 year, and the most common indications were atrial fibrillation ($n = 180$) and VTE ($n = 83$). Most of the patients were on warfarin ($n = 300$). The patients received standard care provided by the clinic, except that the longest accepted interval between INR measurements was 4 weeks (usually, intervals of 6 weeks are accepted). Information about clinical variables was found in DAWN, the dosage-assisting software used in the clinic. Time in therapeutic range of INR (TTR) was calculated by Rosendaals method.

Results: The mean TTR during the follow-up period (307 patient-years) was 73.9% and seven patients experienced a total of eight clinical events; two thrombotic (one stroke, one transient ischemic attack) and six hemorrhagic, none of which were fatal. There were no differences in TTR or time spent below therapeutic range among the different indications for anticoagulant therapy. Patients heterozygous for the common *VKORC1* rs9934438 polymorphism had a slightly, but significantly reduced TTR of 71.8% ($n = 154$, $P = 0.04$), while the six patients with two variant alleles of *CYP2C9* (*2/*3 or *3/*3) had a substantially reduced TTR of 60.5% ($P = 0.03$). The 34 patients below 50 years had a significantly lower TTR compared with the remaining patients (67.4% vs. 74.7%, $P = 0.01$). The young patients had a higher score on the perceived stress scale at baseline (mean score 15.5 vs. 8, $P < 0.01$) and were more likely to report their general health as 'poor' or 'fair' than the older patients (46% vs. 24%, $P = 0.01$).
Conclusions: Since the number of clinical events was too low for statistical analysis, the surrogate marker TTR was used to assess quality of treatment among different groups of patients. The results did not indicate that patients with VTE were at particular risk of unstable anticoagulation, and only a small minority of patients had a clinically relevant reduction in TTR due to genetic polymorphisms. Interestingly, the youngest patients had both lower TTR and higher levels of perceived stress, and therefore constitute a relevant and easily identifiable target group for increased attention and support from the clinical staff at anticoagulant clinics.

Association of D-dimer levels with all-cause mortality in a healthy adult population: findings from the MOLI-SANI study

Iacoviello L, Di Castelnuovo A, De Curtis A, Costanzo S, Persichillo MR, Olivieri M, Zito F, Donati MB and De Gaetano G
Catholic University, Campobasso, Italy

Background: Elevated D-dimer levels are reportedly associated with higher risk of total mortality in patients with different diseases. We investigated if a similar association could be found in a large apparently healthy population.
Methods: Seventeen thousand three hundred and fifty-nine (47% men, age ≥ 35) individuals free of clinically recognized cardiovascular and cancer disease, for whom baseline D-dimer was available, were studied within the MOLI-SANI cohort, randomly recruited from the general adult population of the Molise region, Italy. The cohort was followed for a median of 4.2 years (73,807 person-years). D-dimer was measured on fresh citrated plasma by an automated latex-enhanced immunoassay (HemosIL-IL, Milan). Hazard ratios (HRs) were calculated using three Cox-proportional hazard models (Table 1).
Results: Two hundred and eighty deaths could be recorded. When modeled as a continuous variable, D-dimer at baseline showed a non-linear association with mortality, whose incidence increased only in the upper quartile of the distribution (D-dimer ≥ 221 ng/mL). Thus, the group of individuals with D-dimer < 221 ng/mL (75% of the population) acted as the reference group, while the remaining individuals were subdivided in tertiles that were compared with the former group. Multivariable HRs for mortality were 1.06, 1.45 and 1.97, respectively (P for trend < 0.0001) across the three categories of increasing D-dimer. The association was slightly attenuated, but still highly significant (P for trend 0.0002), after further adjustment for white blood cell count and C-reactive protein.
Conclusions: Elevated D-dimer levels were independently associated with increased risk of death for any cause in an apparently healthy adult population.

PB 1.50-2

Phosphatidylserine exposure on platelets'surface upon binding to rigid fibrin scaffold

Brzoska T[1], Suzuki Y[1], Mogami H[2], Sano H[1] and Urano T[1]
[1]Hamamatsu University School of Medicine; [2]Hamamatsu University, Hamamatsu, Japan

Background: An adequate surface exposure of phosphatidylserine (PS) on the platelet outer membrane leaflet promotes thrombin formation by providing a catalytic membrane surface for vitamin-K dependent coagulation factors. Difficulties to evoke PS exposure on platelet surface in fluid-phase suggest the requirement of additional stimuli. Recently, by employing intra-vital confocal microscopy, we demonstrated that platelets expose PS and fibrin accumulate only in the center of the thrombus but not in its periphery.
Aim: To address the question how exposure of platelet anionic phospholipids is regulated within the thrombus, an *in-vitro* experiment has been designed.
Methods: Confocal Laser Scanning Microscopy was employed to study the PS exposure on the platelet surface incorporated into fibrin network.
Results: Almost all platelets exposed PS after treatment with tissue factor, thrombin or ionomycin, and platelet PS exposure was strictly dependent on the sustained intracellular calcium concentration $[Ca^{2+}]_i$. Argatroban abrogated fibrin network formation in all samples, however, platelet PS exposure was inhibited only in tissue factor- and thrombin-treated samples but not in ionomycin-treated samples. FK633, an $\alpha_{IIb}\beta_3$ antagonist, and cytochalasin B impaired platelet binding to the fibrin scaffold and significantly reduced PS exposure evoked by thrombin. Gly-Pro-Arg-Pro amide abrogated not only fibrin network formation, but also PS exposure on platelets without suppressing platelet binding to fibrin/fibrinogen.
Conclusions: Our data confirm that PS exposure evoked by TF or thrombin is $[Ca^{2+}]_i$ dependent and precisely regulated by time- and space-dependent mechanisms. Integrin outside-in signals generated by platelet binding to a rigid fibrin network, and resulting in generation of mechanical foci through this binding, appear to be essential for modulation of anionic phospholipids' exposure. Such regulation of platelet PS exposure may play an important physiological role in the control of hemostasis.

PB 1.50-3

The effect of tissue factor pathway inhibitor (TFPI) on thrombin generation and post-operative bleeding in patients undergoing surgery requiring cardiopulmonary bypass

Percy CL[1], Hartmann R[2], Panholzer E[2], Kolm A[2], Mehta D[3], Balachandran S[3], Hall JE[1], Dockal M[2], Scheiflinger F[2] and Collins PW[1]
[1]Cardiff School of Medicine, Cardiff, UK; [2]Baxter Innovations GmbH, Orth an der Donau, Austria; [3]University Hospital of Wales, Cardiff, UK

Background: TFPI is an important inhibitor of the initiation phase of coagulation. Its release is stimulated by heparin. Therefore it may play a role in determining bleeding in patients undergoing surgery requiring the use of cardiopulmonary bypass
Aim: To measure TFPI concentrations before and after cardiopulmonary bypass, correlate these with thrombin generation and investigate the effect of inhibiting TFPI as a potential therapeutic target.
Methods: One hundred and two patients undergoing valve surgery, surgery on the thoracic aorta or undergoing coronary bypass grafting plus another procedure, were recruited. Informed consent was obtained and the study received approval from the local research ethics committee. Blood samples were collected into 3.2% citrate (for

TFPI measurement) and 3.2% citrate with 20 μg/mL Corn Trypsin Inhibitor (for thrombin generation experiments), in the anaesthetic room before heparin was given, and then in the operating theatre 30 min after reversal of heparin. An ELISA was used to quantify full-length and total TFPI using an anti-c-terminus and anti-KD2 antibody respectively. Thrombin generation experiments were performed by calibrated automated thrombography using Thrombinoscope PPP Low trigger reagents. Thrombin generation was measured in the presence and absence of a polyclonal anti-TFPI antibody (AF2974, R&D Systems, Abingdon, UK) at a concentration of 100 nM. Post-operatively patients were observed for evidence of bleeding for 24 h. Abnormal bleeding was defined as drain loss of more than 1 L at 24 h, more than 200 mL/h for two consecutive hours, more than 2 mL/kg/h for two consecutive hours in the first 6 h, the need for haemostatic treatment or the need to return to theatre for bleeding. SPSS software was used to analyse the data.

Results: Compared to pre-cardiopulmonary bypass samples the median full-length TFPI concentration was lower in the post-cardiopulmonary bypass samples (20.4 vs. 16.6 ng/mL, $P < 0.001$). In contrast, median total TFPI levels increased (55.7 vs. 112.4 ng/mL, $P < 0.001$). There was no observed difference in either full-length or total TFPI levels in those who bled excessively compared to those who did not. Thrombin generation was also reduced in the post-cardiopulmonary bypass samples compared to those pre-surgery (median ETP 530.3 nM/min pre vs. 108.5 nM/min post, $P < 0.001$; peak thrombin 42.7 nM pre vs. 5.4 nM post, $P < 0.001$). There was a weak inverse correlation between full-length TFPI concentration and thrombin generation. Addition of AF2974 resulted in a significant increase in thrombin generation parameters in both pre and post-cardiopulmonary bypass samples (ETP 1352.3 nM pre, peak thrombin 245.5 nM pre $P < 0.001$; ETP 1045 nM post, peak thrombin 223.8 nM post, $P < 0.001$) the change being greatest in the post-surgery samples.

Conclusions: Post-cardiopulmonary bypass full-length TFPI is lower than pre-surgery whilst total TFPI is increased. Measurement of TFPI at the time points chosen does not correlate with observed bleeding. Inhibition of TFPI significantly enhances thrombin generation and may be a therapeutic target in patients suffering from excess bleeding.

PB 1.50-4

Safety and effectiveness of anti inhibitor coagulation complex (AICC) in routine clinical management: a post-authorization safety study (PASS)

Novack A[1], Romanov V[1], Pirck M[2] and Numerof RP[1]

[1]*Baxter Healthcare Corporation, Bioscience, Westlake Village, CA, USA;* [2]*Baxter Innovations GmbH, Bioscience, Vienna, Austria*

Background: Hemophilia patients with inhibitors present a treatment challenge due to an increased risk of difficult-to-treat bleeds. Activated prothrombin complex concentrate, AICC [FEIBA NF], has been a key therapeutic option for the prevention and management of bleedings in patients with inhibitors for over three decades. FEIBA NF has been approved in more than 60 countries with a prophylaxis indication in more than 40 countries. Launched in 2008, FEIBA NF is essentially the same as the previous formulation of FEIBA (VH) but with an additional viral removal step (35 nm nano-filtration) added during the final stages of manufacturing.

Aims: FEIBA NF PASS is a prospective open-label, observational surveillance program that documents the adverse events (AEs) and hemostatic effectiveness associated with FEIBA NF use in routine practice. Data collection includes dosage of FEIBA NF (total dose, number of infusions) required for prophylaxis or bleed resolution, infusion rates, physician rated efficacy assessment, bleed type and location, incidence of non-serious and serious adverse events related and unrelated to FEIBA NF, and anamnestic response.

Methods: An electronic data collection system is utilized to monitor the safety and effectiveness of FEIBA NF in subjects for 12 ± 2 months. Standard quality of life assessment tools (SF-36, Peds-QL and EQ-5D) are used at time of enrollment and at the end of the observation period. Furthermore, the surveillance will attempt to identify best practices in managing hemophiliacs with inhibitors on regular FEIBA prophylaxis. All patients gave informed consent and the study was conducted according to the Declaration of Helsinki and its amendments.

Results: As of January 2013, 44 study sites in 10 countries have been initiated and eighty five patients have been enrolled. Sixty two patients have completed a 1 year study period. Enrollment has closed in the UK, France, Germany, Spain, Belgium, Sweden, Poland, Italy, and the United States but is still ongoing in Canada. At enrollment, 86% of patients have been diagnosed with congenital hemophilia A, 13% with acquired hemophilia A and 1% with congenital hemophilia B. At screening, 41 subjects were prescribed regular prophylaxis and 39 were prescribed on-demand treatment for bleeding episodes. Subject profiles highlighting bleeding episodes and treatments over the study period were created for every patient and representative graphs were generated. Three related serious adverse events (haemarthrosis, catheter related infection, and thrombophlebitis superficial) have been reported, all associated with on demand treatment.

Summary: The development of inhibitors is the most serious complications in the treatment of hemophilia and their management continues to challenge health care professionals. FEIBA NF PASS provides an opportunity to collect data on hemophilic patients with inhibitors during routine care, and serves as an invaluable tool for documenting the safety and effectiveness of FEIBA NF in a variety of clinical settings including prophylaxis, surgery and bleed management during ITI.

PB 1.50-5

Thrombin generation profile of dehydrated solvent/detergent treated plasma and FFP

Gorkun O[1], Bode A[2] and DaCorta JA[2]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC;* [2]*Entegrion Inc, Research Triangle Park, NC, USA*

Background: The risk of infection during transfusion of plasma was significantly reduced with introduction of solvent/detergent (S/D) treatment. Also the S/D plasma delivers reduced antibody titers, reduced lipids and microparticles, reduced non-hemolytic transfusion reactions and more consistent content of clotting factors as compared to standard single donor FFP. S/D plasma, like banked FFP, remains dependent on frozen shipment and storage. Dehydrated plasma on the other hand, has been shown to possess stability at higher temperatures, and quicker availability due to elimination of the thawing step. Dehydrated plasma has been shown to function *in vitro* and *in vivo* in a similar manner to banked frozen FFP. Dehydration methods currently in development are lyophilization, and spray drying. However, there have been no reports in the literature of comparisons of these.

Methods: Effect on thrombin generation and inhibitions.

Aims: To compare the effect of dehydration methods on thrombin generation coagulation factor recovery and hemostatic function of S/D plasma as compared to banked FFP.

Methods: For the current comparison, spray dry and lyophilized plasmas were prepared in-house using S/D plasma from Kedrion (Lucca, Italy) or blood bank FFP (UNC Hospital, NC). All dry plasmas were reconstituted with 5 mM Citric/Phosphate pH 3.5 buffer, producing fully rehydrated plasma of the same pH and protein concentration as the original plasma before drying. We used calibrated automated thrombography (CAT) to evaluate hemostatic function of plasma. Using Thrombinoscope (Stago), we measured thrombin generation in S/D plasma or FFP and in their reconstituted spray-dried and lyophilized forms. In addition, we measured concentration of major clotting factors using STA-Compact Analyzer (Stago) and assessed plasma coagulation function with rotational thrombelastography (ROTEM, TEM Systems, NC).

Results: We found that the lyophilization of S/D plasma generated small but significant changes in thrombin generation profile but that spray-drying had a negligible effect: at 1pM TF, the ETP = 1354 nM*min for SDSDP vs. 1301 for S/D plasma and 1430 for lyophilized S/D, at 5pM TF the ETP = 1258 for SDSDP vs. 1286 for S/D plasma and 1372 for lyophilized S/D. The results with FFP products were more variable with ETPs 10–30% less than their S/D counterparts. Despite faster thrombin generation in S/D plasma and its derivatives, thrombin inhibition was equally fast, suggesting of intact thrombin inhibition pathways. ROTEM did not detect these same differences. There were variations in clotting factor levels between spray-dried and lyophilized preparations but not consistently across the S/D plasma vs. FFP groups, except for a reduced level of vWF activity in spray-dried plasmas.
Summary: In general, the thrombin generation profile of SDSDP was remarkably similar to the S/D plasma from which it was prepared. Both S/D plasma and SDSDP have shorter thrombin generation times and more rapid thrombin inhibition than FFP or its dried forms. Additional investigation is needed to understand the significance of the differences between lyophilized and spray-dried techniques on hemostatic function.

PB 1.50-6

Comparision of recombinant coagulation factor VII (ARYOSEVEN®) with NOVOSEVEN® in patients with FVIII & IX deficiency with an inhibitor

Faranoush M[1], Hassan A[2], Karimi M[3], Toogeh G[4], Eshghi P[1], Managchi MR[4], Hamid H[5], Kamyar K[6], Heshmat R[4] and Baghaiepour MR[7]

[1]Iranian Blood Transfusion Organization; [2]Shahid Beheshti University of Medical Sciences, Tehran; [3]Shiraz University of Medical Sciences, Shiraz; [4]Tehran University of Medical Sciences; [5]Isfahan University of Medical Sciences, Isfahan; [6]AryoGen Biopharma Company, Karaj; [7]Iranian Hemophilia Care Centers, Tehran

Introduction: Coagulation factor replacement therapy in severe hemophilia prevents disabling arthropathy and improves life expectancy and quality of life. This treatment is ineffective in patients with neutralizing antibodies to the deficient coagulation factor (inhibitors), in which case treatment with FVIIa is an option. The aim of this study was to compare the efficacy of a new biosimilar recombinant factor VIIa (Aryoseven®) with Novoseven® in controlling bleeding episodes in patients with hemophilia A or B with inhibitors.
Methods: A double blind clinical trial was conducted in comprehensive hemophilia care centers in Iran. Inclusion criteria were: 1-congenital hemophilia A and B and an inhibitor titer > 5 Bethesda units (BU); 2-age > 2 years; 3- intravenous access. Exclusion criteria were: 1- any other coagulation disease; 2- immune tolerance induction treatment during the last month with Novoseven®; 3- platelet count < 50,000/mL; 4-presence of anti-FVII antibodies; 5. history of advanced arthrosclerosis due thormbogenic of rFVIIa. We randomized 61 consenting male patients into two groups, with four consecutive block randomization, for treatment of one hemorrhage. Group A (28 patients, 45.9%) received Aryoseven® and group B (33 patients, 54.1%) received Novoseven®. Factor VII dosage was 90 μg/kg intravenously. Primary outcome was self-reported joint pain and joint movement with the Kavakli scoring system 9 h after infusion of FVIIa
Results: Mean age was 21 year (range: 2–53) and similar in both groups. Mean plasma level of Factor VII: C at inclusion was 104.3 (range 78–106) IU/dL in group A and 98.5 (range 76.2–119) IU/dL in group B. Mean inhibitor level was 36.9 BU (SD 45.7) in group A and 28.9 (SD 35.7) BU in group B. Time from self-reported start of bleeding symptoms to FVIIa infusion was similar in both groups (group A:1377 ± 1082, group B:2333 ± 1795 min). There were 28 bleeds treated with Aryoseven® and 33 bleeds with Novoseven®. Median Kavakli score for post-infusion pain and joint movement was similar in the two groups, at 7.00 (range 6.00–8.00). Response to treatment was positive in 27 (96.4%) in group A, and 29 (87.9%) in group B by self-reporting joint pain severity.
Discussion: We tested a biosimilar FVIIa concentrate in comparison with the standard concentrate in patients with neutralizing antibodies to FVIII or FIX, in the treatment of acute joint bleeding. The response to concentrate infusion was the same for both concentrates.

PB 1.51-1

Control of vitamin-K antagonist treatment by measuring thrombin generation in whole blood – effect of thrombomodulin

Bloemen S[1], De Laat M[1], Ten Cate-Hoek AJ[2], Ten Cate H[2], De Laat B[1], Hemker CH[1] and Al Dieri R[1]

[1]CARIM, Maastricht University; [2]Maastricht University Medical Centre, Maastricht, The Netherlands

Background: Whole blood thrombin generation (TG) testing has been recently introduced. If it can be used for evaluating the effect of antithrombotic treatment this would be a starting point for the development of point of care and home control of vitamin K antagonist (VKA) treatment. The antithrombotic action of VKA treatment results from the fact that its effect on factors II, VII, IX and X overrules the concomitant decreases of the natural anticoagulants protein C and S. In clotting tests the effect on anticoagulant factors goes unobserved, but not in TG experiments. We therefore also investigated the effect of addition of soluble thrombomodulin (TM).
Aims: To compare, in samples from patients taking VKA, TG in whole blood to TG in plasma and to investigate the effect of activation of the APC system with TM in both types of test and to relate the results to the degree of anticoagulation as assessed by the International Normalized Ratio (INR).
Methods: In blood samples from 105 consenting patients on VKA treatment (mainly because of atrial fibrillation) TG was measured with calibrated automated thrombinography (CAT) in the absence and presence of exogenous TM. This was performed in whole blood, platelet rich and platelet poor plasma (PRP, PPP). The INR was determined in PPP of the same patients.
Results: Endogenous thrombin potential (ETP), peak height, lag time and time to peak (ttpeak) measured in whole blood were all significantly correlated with the ones determined in plasma (P-value < 0.01). The concentration dependent parameters of TG (ETP and peak) from whole blood, PRP and PPP of the patients correlated significantly to the inverse of the INR (P-value < 0.01). The time dependent TG parameters (lag and ttpeak) correlated linearly with the INR (P-value < 0.01).
In the majority of the patients, addition of TM (20 nM) to a level that reduced the ETP to around 50% in normal plasma, caused less inhibition in plasma from the patients: 29.8 ± 12.8% in whole blood, 28.5 ± 19.8% in PRP) and 39.6 ± 12.0% in PPP. This effect was virtually independent of the INR (1.1–5.9).
Conclusion: This study demonstrates that whole blood thrombin generation can be considered as a reliable tool for determining the anticoagulant activity of vitamin K antagonists. VKA therapy induces TM - resistance when assessed by TG in whole blood as well as in plasma. This effect appears to be independent of the level of anticoagulation.

PB 1.51-2

False-positive results for a lupus anticoagulants occur in patients on low molecular weight heparin but not fondaparinux, by dilute activated partial thromboplastin time

Platton SJ, Nahar B, Dale C and MacCallum P
Barts Health NHS Trust, London, UK

Background: Recent International Society for Thrombosis and Haemostasis guidelines on the detection of lupus anticoagulants (LA) state that screening for LA in the presence of low molecular weight heparin (LMWH) is possible, and that the thrombin time (TT) should be used to identify the presence of heparin. We describe how reliance on the TT may lead to the mis-diagnosis of LA by dilute activated partial thromboplastin time (APTT) in patients on LMWH (prophylactic/therapuetic), and how the diagnosis of LA is not affected by fondaparinux.
Aims: To show that the dilute APTT cannot be used to detect LA in patients on LMWH; that TT cannot be used to rule out the presence of LMWH; and that fondaparinux does not affect LA results.
Methods: Plasma samples sent for routine LA testing from non-anticoagulated patients previously found to be negative by dilute Russell's viper venom time and dilute APTT were spiked with either enoxaparin, tinzaparin or fondaparinux. All samples were tested for LA by dilute APTT and TT.
Results: Twenty-five samples were spiked with enoxaparin. At 0.20 IU/mL, 9 (36%) of these gave results above the locally-derived cut-off for the dilute APTT assay, and of these 2 (8%) showed correction sufficient to make a false diagnosis of LA. At 0.80 IU/mL, all results were above the assay cut-off, with 5 (20%) giving a false positive diagnosis of LA.
Sixteen samples were spiked with tinzaparin. At 0.20 IU/mL, 11 (69%) of these gave results above the locally-derived cut-off for the assay, and of these 9 (56%) showed correction sufficient to make a false diagnosis of LA. At 0.80 IU/mL, all results were above the assay cut-off, with 3 (19%) giving a false positive diagnosis of LA.
Twenty samples were spiked with fondaparinux. At 0.20 μg/mL, 3 (15%) of these gave results above the locally-derived cut-off for the assay, but none of these showed correction sufficient to make a false diagnosis of LA. At 0.80 μg/mL, 5 (25%) gave results above the assay cut-off, but none of these showed correction sufficient to make a false diagnosis of LA.
When measuring TT on samples spiked with enoxaparin or tinzaparin, TT was raised only when anti-Xa activity exceeded 0.25 IU/mL. This is above the level of LMWH observed to affect LA assays by dilute APTT. TT measurements were not affected by fondaparinux.
Conclusions: The results of this study suggest that LA cannot be measured accurately in the presence of LMWH, and that prophylactic levels of LMWH will not affect the thrombin time. Fondaparinux did not interefere with the detection of LA by dilute APTT in our study.

PB 1.51-3

Monitoring of parenteral anticoagulant drugs with the prothrombinase induced clotting time (PICT)

Hoppensteadt D, Walenga JM, Cunanan J, Iqbal O and Fareed J
Loyola University Medical Center, Maywood, IL, USA

Introduction: Several parenteral direct thrombin inhibitors have been approved for the anticoagulation in heparin compromised patients. These agents include hirudin (Refludan, BayerHealthcare, Germany), argatroban (Acova, Mitsubishi, Japan) and angiomax (Bivalirudin, Medicines, Co, Parsippany, NJ). The parenteral thrombin inhibitors do not require antithrombin as a cofactor and have a short half life. They are used in the anticoagulation of patients undergoing percutaneous coronary angioplasty (PTCA). These agents do not require monitoring however, in some patients such as those with liver or kidney disease, monitoring may be necessary.
Materials: Citrated blood was drawn from five donors and spun at 3000 rpm to obtain platelet poor plasma (PPP). The PPP was supplemented with hirudin, argatroban or angiomax in a concentration range of 0–10 μg/mL. The plasma samples were analyzed using three PT/INR reagents (Innovin, Dade-Behring, Germany; Recombiplastin, Instrumentation Laboratories, Bedford, MA; Neoplastin, Stago, Parsippany, NJ), two APTT reagents (Platelin, TCoag, Ireland; Actin FSL, Instrumentation Laboratories, Bedford, MA), Heptest and the two stage PICT (Pentapharm, Basal, Switzerland). The PICT assay is a new clot-based assay that was developed for the monitoring of anticoagulant drugs. In the two step assay, FXa, phospholipid and RVV-V are incubated with the sample. The formed thrombin is inhibited by the presence of the thrombin inhibitor. Following recalcification the clotting time is measured. All assays were performed on the ACL 300 Plus (Instrumentation Laboratories, Bedford, MA). The PICT was also run on the ST4 (Stago, Parsippany, NJ).
Results: In the citrated plasma the hirudin, angiomax and argatroban demonstrated assay dependent differences in the clotting times. In the PT/INR, angiomax showed the strongest response with Innovin, however using Neoplastin or Recombiplastin both angiomax and argatroban gave similar results. Hirudin showed the weakest activity. In the APTT assay, angiomax was strongest, but similar results were observed for both hirudin and argatroban. In the Heptest, argatroban was the strongest. In the two stage PICT assays all three agents demonstrated a concentrated dependent response. Hirudin showed the strongest prolongation of the PICT at 5 μg/mL followed by angiomax and argatroban (Hirudin, 190.7 + 17.8 s; Angiomax, 131.6 + 15.3 s; Argatroban, 95.3 + 9.7 s),.
Conclusion: These results demonstrated the different reagents, within the same assay, show differential responses to the parenteral antithrombin agents. Therefore depending on the type of reagent used different response can be measured using the same test. The two stage PICT is a simple, fast assay that can be adapted to any coagulation instrument and is sensitive to all types of anticoagulants including the parenteral antithrombin agents. Therefore the PICT assay may be a universal clot-based method that can be used to monitor all types of anticoagulant drugs.

PB 1.51-4

Evaluation of in-house normal pool plasma for activated partial thromboplastin time mixing test as a part of diagnosting protocol for lupus anticoagulant detection

Margetic S, Butorac T, Vrkic N and Novosel R
Medical School University Hospital, Zagreb, Croatia

Background: Mixing test is commonly used as screening assay for laboratory investigation of inhibitors, thus respresenting an integral part of routine diagnostic protocol for lupus anticoagulant (LA) detection. The first criterion in identifying LA is prolongation of at least one laboratory test dependent of phospholipids, such as the activated partial thromboplastin time (APTT). This prolonged test must then be repeated on a mixture of patient¢s plasma and normal plasma (APTT mixing test, APTTmt) to distinguish between inhibitor such as LA and a single factor deficiency.
Aims: The aim of this study was to evaluate in-house pool normal plasma (NP) for APTTmt compared with commercial NP that is routinely used in our laboratory in the diagnosting protocol for LA detection.
Methods: A total of 158 subjects were evaluated for LA, of which 11 subjects were LA positive. In-house pooled NP was obtained from 40 subjects directed to routine screening for prothrombin time (PT) and APTT, without any known coagulation disorder and with PT and APTT results within reference interval. Immediately after collection

and centrifugation (3000 rpm 10 min), in-house pooled NP was divided into aliquots and frozen at −20 °C until analysis. Immediately before use, aliquoted in-house NP was thawed at 37 °C for 15 min. Commercial NP (Control plasma N, Siemens, Germany) was routinely used for APTTmt (Actin FSL, Siemens, Germany). Patient¢s samples were mixed in the equal volume (1 + 1) with commercial NP as well as with in-house pool NP and evaluated in parallel for APTTmt. For in-house prepared pool NP we determined within-run precision by 10 consecutive measurements of APTTmt and between-run precision by measuring of APTT in 10 consecutive days after freezing and thawing of aliquoted in-house NP. Comparison of APTTmt results with commercial NP and in-house NP was evaluated by Passing-Bablok regression and Bland and Altman difference plot.

Results: Within-run coefficient of variation (CV) was 1.5% for APTTmt determined with in-house pool NP. Between run CV was 2.4% for APTT determined in aliquoted pooled NP. The results of APTTmt (seconds) comparison expressed as median (range) were as follows: in-house NP 27.0 (22.0–32.0); commercial NP 27.0 (23.0–33.0). Passing and Bablok regression analysis showed that there were no significant constant or proportional differences between the two methods regression line equation y = 0.000 + 1.000x; 95% confidence interval (CI) for intercept 0.000–5.200 and 95%CI for slope 0.800–1.000, thus indicating good agreement, linear relationship and statistically unbiased results between in-house and commercial NP used for APTTmt. These results were also confirmed by Bland and Altman difference plot. Commercial NP and in-house NP gave the same number of positive screening LA results (11/11) and positives were detected in the same specimens.

Conclusions: Comparison between in-house pool NP and commercial NP for APTTmt indicated that a careful selection of donors allows use of in-house pooled NP that fits the quality demands for routine APTTmt. Our results confirmed that use of in-house prepared NP could be implemented in routine diagnostic protocol for LA detection.

PB 1.51-5

Prothrombin time with recombiplastin 2G correlates strongly with plasma rivaroxaban levels

Tait RC[1], McGurk M[2], Hickman GM[1], Conkie J[1], Lawrence C[1] and Bagot C[1]

[1]Royal Infirmary; [2]Western Infirmary, Glasgow, UK

Background: The new oral anticoagulants are now being increasingly used in clinical practice. Although routine monitoring of their anticoagulant activity or plasma level is not indicated there is a realisation that, in certain situations (e.g. acute haemorrhage or emergency surgery), the ability to estimate residual anticoagulant effect may be clinically useful. Therefore, it has been suggested that haemostasis laboratories develop suitable quantitative assays as well as determining the sensitivity of their routine coagulation assays, prothrombin time (PT) and activated partial thromboplastin time (APTT), to these agents.

Aims: To calibrate an anti-Xa chromogenic assay for rivaroxaban plasma concentration, and assess the sensitivity of our local PT and APTT assays to rivaroxaban levels.

Methods: The Liquid Anti-Xa chromogenic assay (IL, Instrumentation Laboratories) run on an IL TOP 700 was calibrated using lyophylised standard rivaroxaban plasmas (Hyphen Biomed, France) to create a rivaroxaban assay linear between 0 and 400 ng/mL. Lyophylised plasmas from Diagnostica Stago (France) were used for internal quality control. Citrated plasma samples were obtained at routine clinic visits from patients receiving therapeutic dose rivaroxaban for treatment, or secondary prevention of DVT. All patients had been receiving rivaroxaban, and had avoided other anticoagulant therapy (low molecular weight heparin or warfarin), for at least 7 days (median 3 weeks). PT (Recombiplastin 2G, laboratory reference range 9–13 s) and APTT (Synthasil, laboratory reference range 27–38 s) were determined on IL TOP 700.

Results: Samples from 20 patients receiving rivaroxaban (six during 15 mg bd dosing and 14 during 20 mg od dosing) were obtained either around peak (1–4 h, $n = 10$) or trough (12–30 h, $n = 10$) time points. Anti-Xa rivaroxaban levels around peak were generally higher than expected (median 378 ng/mL, range 204–707 ng/mL) while trough levels were as expected (median 45 ng/mL, range 11–215 ng/mL). One patient with a 2.5 h 'peak' level of only 35 ng/mL was suspected of medication non-compliance. Corresponding PT results (range 10–29 s) showed a strong linear correlation with anti-Xa rivaroxaban levels (correlation co-efficient 0.971) whereas APTT results (range 30–52 s) were less well correlated (correlation co-efficient 0.461). All eight patients with PT ≤ 13 s had an anti-Xa rivaroxaban level < 60 ng/mL.

Conclusions: We have demonstrated that the IL Liquid Anti-Xa chromogenic assay can be easily calibrated to measure plasma rivaroxaban levels. Routine PT (using Recombiplastin 2G on an IL TOP 700), more so than APTT, may provide an approximate estimate of rivaroxaban anticoagulant activity. A PT ≤ 13 s appears to imply a low rivaroxaban level of < 60 ng/mL, perhaps inferring suitability for surgery or other invasive procedure. However, these findings will require validation in a larger cohort (including rivaroxaban-treated patients scheduled for invasive procedures).

PB 1.51-6

A global hemostasis assays in laboratory monitoring of low molecular weight heparin treatment in patients after surgery

Poletaev AV[1], Balandina A[2], Rabotinskiy S[1], Orel E[1], Ataullakhanov F[1] and Shulutko E[1]

[1]National Research Center for Hematology; [2]Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Low molecular weight heparin (LMWH) treatment can be complicated by such adverse events like bleedings or thrombosis, so the laboratory control of the LMWH effect can be useful.

Aims: To investigate the efficacy of the global hemostasis assays to monitor the LMWH treatment in patients after surgery.

Methods: Twenty one patients after surgery were enrolled in the study. Thrombosis risk was scored by Caprini risk assessment model: two patients had low risk (but coagulation tests showed hypercoagulation state direct after surgery), six patients had medium risk and 13 patients had high risk. Five patients also had thrombocytopenia ($< 150 \times 10^9$ platelets/mL). The thromboelastography (TEG), Thrombodynamics, D-dimers and anti-Xa activity were determined before LMWH treatment (daily bemiparin injection 2500 or 3500 IU), then before and 3 h after each injection during 3 days. Thrombodynamics is a new global assay based on a spatial fibrin clot growth registration; the stationary clot growth rate (Vst) and spontaneous clotting (SC, indicator of prothrombotic risk) are registered.

Results: These global tests showed procoagulant deviation from normal state in patients with high thrombosis risk. Before LMWH injection, TEG parameters R, K, Angle and MA demonstrated the hypercoagulation state in 38% of measurements, but the average values were normal: 14.2 ± 5.5 min, 4.6 ± 2.8 min, 46.6 ± 14.5° and 64.2 ± 10.9 mm, respectively (the normal ranges were 9–27 min, 2–9 min, 22–58° and 44–64 mm, respectively). The Thrombodynamics parameter Vst was increased in 70% of measurements and the average value was 33 ± 6 μm/min (the normal range was 20–30 μm/min). SC was observed in eight patients. D-dimers were increased in 85% of measurements.

After LMWH injection, all parameters of global assays except MA returned back to normal or even mild hypocoagulation state. R and K increased in 1.6 ± 0.8 and 2.7 ± 1.8 times respectively, Angle and Vst decreased in 2.0 ± 1.1 and 2.0 ± 0.5 times respectively. No SC in Thrombodynamisc was observed. Anti-Xa activity was 0.88 ± 0.39;

yet it is known that this parameter indicates only LMWH activity in blood plasma but not overall hemostasis state of patients.
All parameters of laboratory tests performed before LMWH injection did not show any dynamics within the first 3 days after the surgery; the same picture was observed for the tests performed after LMWH injection. The one exception was observed: SC in Thrombodynamics registered in six patients on 1st day, three patients on 2nd day and two patients on 3rd day. There was no difference between patients with or without thrombocytopenia ($P > 0.05$).
Conclusion: Thrombodynamics and thromboelastography assays are sensitive to hypercoagulation in patients with high thrombosis risk and can be effective in monitoring LMWH treatment.

PB 1.52-1

Comparison of calibrated automated thrombogram and chronometric or chromogenic assays for the monitoring of DOACs in patients with non-valvular atrial fibrillation

Douxfils J[1], Classen J-F[2], Baudar J[2], Walbrecq S[2], Chatelain C[2], Chatelain B[2], Dogné J-M[1] and Mullier F[2]
[1]University of Namur, Namur; [2]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: Direct oral anticoagulants (DOACs) include anti-IIa agent (dabigatran etexilate: DE) and anti-Xa agents (rivaroxaban, apixaban and edoxaban). DOACs do not require monitoring nor frequent dose adjustment. However, searching for the optimal dose in the individual patient may be useful in some situations. Recent studies have shown that activated partial thromboplastin time (aPTT), Hemoclot Thrombin Inhibitor® (HTI) and ecarin clotting time could be used to monitor dabigatran whereas PT and anti-Xa chromogenic assays are preferable to monitor anti-Xa agents. HTI, aPTT and PT only measure the initiation phase of the coagulation cascade. Calibrated Automated Thrombogram (CAT) which measures the entire thrombin generation process could be used to better discriminate the inhibitory profile of DOACs in patients.
Aims: The aim of this study is to assess the impact of DE and rivaroxaban in patients suffering from non-valvular atrial fibrillation by thrombin generation assay. Results will be compared to other traditional chronometric and chromogenic assays.
Methods: Five patients under DE (150 mg *bid*) and five patients under rivaroxaban (20 mg *od*) for atrial fibrillation were included in this study. Blood samples were taken at 2 and 3 h after drug administration, and just before the next scheduled intake of the drug (C_{trough}: 12 h for DE and 24 h for rivaroxaban). The following tests were performed at each time-point.
Calibrated Automated Thrombogram: The most sensitive reagents were used based on results from previous in house *in vitro* studies. PPP-Reagent and PPP-Reagent High were used for rivaroxaban (Peak and mVRI). For DE, PPP-Reagent Low and PPP-reagent were used (Lag Time and T_{max}).
Chronometric and chromogenic assays: For rivaroxaban, PT was assessed using Triniclot PT Excel S® and Innovin®. Biophen Direct FXa Inhibitors was used to estimate the plasma drug concentrations,
For DE, aPTT was assessed using CK-Prest® and Synthasil®. The HTI was also performed to estimate the plasma drug concentrations.
Results and Discussions: The correlation between rivaroxaban plasma concentration and the Peak showed an exponential decay relation ($r^2 = 0.98$ and 0.94 for PPP-Reagent and PPP-Reagent high respectively). The same relation was observed for the mVRI ($r^2 = 0.98$ and 0.95). The correlation between PT and CAT parameters is less pronounced than those with the estimated plasma concentration ($r^2 < 0.90$).
The correlation between dabigatran plasma concentration and the Lag Time showed no specific relation (r^2 for linear correlation = 0.45 and 0.25 for PPP-Reagent and PPP-Reagent Low, respectively). The same dispersion in the results is observed with other parameters. There is no good correlation between CAT parameters and the aPTT ($r^2 < 0.35$).
Conclusion: In this pilot study, CAT results obtained in patients treated with DE are inconclusive. On the other hand, the good correlation results obtained between CAT parameters (Peak and mVRI with PPP-Reagent) and plasma drug concentrations in patients treated with rivaroxaban is encouraging. Such data should be confirmed in a larger cohort study with the aim of providing cut-offs CAT parameters reflecting a therapeutic level of anticoagulation.

PB 1.52-2

Minimizing the impact of preanalytical variables on intrinsic coagulation during blood collection improves sample quality for thromboelastography and the calibrated automated thrombogram

Sinquett FL and Moskowitz KA
BD Diagnostics, Preanalytical Systems, Franklin Lakes, NJ, USA

Background: Thrombelastography (TEG) is useful in testing coagulation efficiency of whole blood (WB) and has found important applications during surgery and anesthesiology. The calibrated automated thrombogram (CAT) assay performed in plasma is used to investigate patients with hypo- or hypercoagulopathies. These assays are highly sensitive relative to traditional coagulation tests and vulnerable to contact activation where accumulated FXIIa in citrated specimens can markedly augment down-stream thrombin generation (TG). Accordingly, we examined the effect of blood collection tubes comprised of different polymeric containment materials and the select use of targeted intrinsic pathway inhibitors on select outputs of the TEG and CAT assays.
Methods: Citrated human WB was transferred from a blood collection bag into coated (siliconized) glass or plastic blood collection tubes, or uncoated glass, polypropylene (PP), polystyrene (PS), or polyethylene terephthalate (PET) conical bottom tubes, either alone or in the presence of inhibitors targeting kallikrien or FXIa. After 15 min incubation, the TEG *R* value was obtained immediately after addition of 10 mM $CaCl_2$. Matched plasma specimens were analyzed by the CAT in the presence and absence of 1pM Tissue Factor (TF) and by APTT (Stago Compact). Data were analyzed by ANOVA with Tukey's post-test and by linear regression.
Results: Plastic blood collection tubes delivered significantly higher WB clotting 'R' times (CT) (15.0 ± 1.02 min) than either uncoated glass (6.3 ± 0.73) or coated glass tubes (9.9 ± 0.58) $P < 0.01$ while providing equivalent results to all other plastic containers which ranged from 15 ± 1.0 to 17.7 ± 1.9 min, $P > 0.05$ APTT assays were insensitive to differences between uncoated glass (29.5 ± 1.6 s) and PP (29.8 ± 0.6 s) tubes. Moreover, CAT peak thrombin levels were significantly lower in plastic collection tubes relative to coated glass both in the absence (22.2 ± 4.4 vs. 167.7 ± 2 nM, $P < 0.05$) and presence (16.7 ± 3.4 vs. 127.3 ± 9 nM ($P < 0.05$) of TF. TEG WB CT correlated well with TF-initiated CAT lag time ($R^2 = 0.8116$), time to peak TG ($R^2 = 0.8308$) and peak TG, the latter in the absence of intrinsic inhibitors ($R^2 = 0.8401$). Targeted inhibition of kallikrien also increased WB CT in uncoated glass samples from 4.9 ± 0.30 to 27.5 ± 8.30, which was significantly higher than both coated glass tubes (9.4 ± 0.40) or plastic tubes (14.3 ± 2.60) in the absence of inhibitor ($P < 0.001$). Similarly, targeted inhibition of FXIa increased WB TEG CT in coated glass and plastic tubes above 18 min and abrogated TG in the absence of TF.
Conclusions: Plastic blood collection tubes offered advantages over coated glass for the CAT and TEG while the APTT was insensitive to these polymeric differences. Inhibition of kallikrein, even in uncoated glass, elevated WB CT beyond that of plastic suggesting additional

benefits of contact pathway inhibition beyond those polymer-mediated. Inhibiting FXIa abolished TG in the absence of TF, suggesting quantitative intrinsic pathway blockade may require inhibition downstream of FXIIa.

PB 1.52-3

Spatial fibrin clot growth dynamics: interlaboratory evaluation of the assay reproducibility and standardization

Korotina N[1], Vuimo TA[1], Balandina A[2], Shcherbina I[3], Sokolova L[1], Potapova N[1], Khrapkova O[1], Panteleev MA[4] and Ataullakhanov F[5]

[1]LLC, HemaCore; [2]National Research Center for Hematology; [3]Centre of Pediatric Hematology, Oncology and Immunology; [4]Moscow State University; [5]Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow, Russian Federation

Background: A new global clinical test of blood coagulation, Thrombodynamics, based on the *in vitro* spatial clot growth imaging has recently become available. Thrombodynamics mimics the *in vivo* blood plasma coagulation processes occurring during the vessel damage.
Aims: To develop and test a stable and user-friendly assay protocol, consumables and controls.
Method: The standard operating procedure of the assay includes putting the recalcified platelet free plasma sample into a special plastic cuvette and contacting it with the activator insert containing surface-immobilized tissue factor. Plasma clotting process propagates from the activation surface into the bulk of plasma. Fibrin is detected by light scattering videomicroscopy and numerical parameters characterizing clot formation are calculated with a specially designed software[1].
Results: A new kit including lyophilized reagents with long term shelf life was developed. Aliquots of reagents allowed quick, comfortable and unified test performing. Besides, lyophilized form removed additional dilution of the sample and precisely dosed amount of reagents. Specially developed lyophilized plasma control allowed to verify all test measurements. To study the test reproducibility using the new kit, there were four analytical series of measurements performed, each one with a new lot of reagents (not less than $n_1 = 400$ tests each, $n_2 = 3226$ tests total). Each analytical series was performed by different operators (3÷5) at four different laboratories using four pools of fresh blood plasma (from at least five healthy donors each one), respectively. The coefficient of variation measured for the spatial velocity of fibrin clot growth did not exceed 6% in each analytical series and was equal 5% between analytical series, respectively. For the test verification research using plasma control ($n_3 = 572$ tests total), the coefficient of variation measured for the parameters of spatial fibrin clot growth did not exceed 10%.
Conclusion: The obtained data confirm sufficient reproducibility of Thrombodynamics both within and between the reagent lots, and both within and between laboratories. The developed reagent kit and control plasma meet the laboratory requirements of usability and standardization.

PB 1.52-4

Assessment of rotational thromboelastometry in cardiac surgery: correct prediction of clinically relevant thrombocytopenia and hypofibrinogenaemia after 5 min

Olde Engberink HG, Kuiper JAJM, Wetzels JH, Nelemans PJ, Lancé MD, Beckers AM and Henskens YMC

Maastricht University Medical Center, Valkenswaard, The Netherlands

Background: Rotational thromboelastometry (ROTEM) has proven to be an important diagnostic tool in cardiac surgery partiallydue to its short turn around time (TAT) compared to conventional laboratory tests. Multiple guidelines still recommend the conventional laboratory measurements in situations of major blood loss but appoint that thromboelastometry might be an important diagnostic tool to assist in characterizing the coagulopathy and in guiding haemostatic therapy and therefore need to be studied further.
Aims: In the present study we have prospectively investigated whether ROTEM could predict a clinically relevant thrombocytopenia and hypofibrinogenaemia in cardiac surgery using the clot amplitude after 5 min (A5) compared with the established A10 and maximal clot formation (MCF). A new parameter, PLTEM, in which the contribution of fibrinogen is eliminated by subtracting FIBTEM from EXTEM, was investigated. TAT for ROTEM tests and conventional laboratory tests were determined in the central laboratory.
Methods: In a prospective study including 97 cardiac surgical patients, the correlation between EXTEM/FIBTEM A5 and A10/MCF values, EXTEM A5/A10/MCF and platelet count, and FIBTEM A5/A10/MCF and fibrinogen was evaluated using the Pearson's correlation coefficient. Moreover, predictive values of ROTEM tests for clinically relevant thrombocytopenia and hypofibrinogenaemia were evaluated using receiver operating characteristic (ROC) curves and corresponding areas under the curve (AUCs). The study was approved by the medical ethical committee of the Maastricht University Medical Center (MUMC+).
Results: EXTEM A5 and FIBTEM A5 showed an excellent linear correlation with A10 (R:0.99, 0.99) and MCF values (R:0.97, 0.99). The correlation between EXTEM A5 and platelet count (R:0.75) was comparable with A10 (R:0.74) and MCF (R:0.70), and FIBTEM A5 predicted fibrinogen levels (R:0.88) as well as A10 (R:0.88) and MCF (R:0.88). PLTEM A5/A10 (R:0.86/0.85) correlated better with platelet count than EXTEM A5/A10 (R:0.75/0.74) and showed significantly better AUC values in ROC-curves than EXTEM for predicting clinically relevant thrombocytopenia (A5 $P = 0.025$; A10 $P = 0.019$). Turnaround time of emergency requests for platelet count and fibrinogen level were 13 and 26 min respectively and TAT for ROTEM tests was approximately 12 min.
Conclusion: ROTEM is able to detect hypofibrinogenaemia and thrombocytopenia during cardiac surgery using A5, instead of the frequently used A10. PLTEM predicts platelet count and thrombocytopenia more accurately than EXTEM. Implementation of these parameters in ROTEM guided-transfusion protocols might reduce the use of blood products. Further studies are needed to evaluate whether implementation of EXTEM A5, FIBTEM A5 and PLTEM A5 in ROTEM-guided transfusion protocols will result in improved transfusion management.

PB 1.52-5

Calibrated automated thrombography in identification of patients with high bleeding risk on vitamin K antagonists treatment

Shmeleva V, Namestnikov Y, Matvienko O, Saltikova N, Soldatenkov V and Papayan L

Russian Research Institute of Hematology and Transfusion, St-Petersburg, Russian Federation

It is suggested that an individual's potential to generate thrombin better correlate with patients phenotype compared to traditional coagulation tests and so it may allow individualized treatment with vitamin K antagonists (VKA), particularly in patients with thrombophilia. VKA treatment affects the protein C system as well as the procoagulant system and this aspect can be assessed if thrombin generation (TG) is evaluated in the presence of thrombomodulin (TM). Aim of our study was to evaluate relationship between TG parameters both in the presence and in the absence of thrombomodulin (TM) and international normalized ratio (INR) – standardized method of wide clinical utility. Methods. The study involved 28 controls and 48 patients with venous thromboembolism (VTE) in the extended-treatment phase (M/F 24/24, mean age 54.6 ± 15.8 years). Duration of VKA was of 1.5–4 years, and INR range of 0.9–3.3. Thrombin generation in platelet poor plasma was measured using the Calibrated Automated Thrombogram (CAT), developed by Hemker et al. The concentrations of tissue factor and phospholipids in the test system were 4 pm 5 μm respectively. The procedure was carried out with an automated fluorometer (Fluoroscan Ascent, Thermolab system, Finland). Thrombin generation curves were calculated using the Thrombinoscope software (Thrombinoscope BV, The Netherlands). Four parameters were derived from the thrombin generation curves: Lag time (min), endogenous thrombin potential ETP (nMmin), peak height for thrombin (nM), time to peak (min). STATISTICA 6.1 was used, data are given as mean ± SD. Results. Lag time, ETP, peak height for thrombin, time to peak obtained with and without TM demonstrated strong positive correlation (R between 0.93 and 0.98, $P < 0.05$). Both in the absence and in the presence of TM strong inverse correlation with INR was found for ETP ($R = -0.85$ and $R = -0.79$, respectively, $P < 0.05$) and peak height ($R = -0.84$ and $R = -0.79$, respectively, $P < 0.05$). Lag times and times to peak showed a positive correlation with INR both in the absence of TM ($R = 0.61$ and $R = 0.57$, respectively, $P < 0.05$) and in the presence of TM ($R = 0.60$ and $R = 0.59$, respectively, $P < 0.05$). ETP and peak height for thrombin measured in the absence of TM were higher than those measured in the presence of TM. In patients ($n = 15$) with INR 2-3, which is considered optimal, ETP was 358 ± 210 nMmin in the absence of TM and 293 ± 167 nMmin in the presence of TM. Importantly in one patient with INR 2.8 having no bleedings at the time of observation ETP and peak thrombin either in the absence or presence of TM were markedly decreased (73 and 71 nMmin; 4.6 and 4.9 nM respectively), lag-time and time to peak were markedly prolonged (31.0 and 24.3 min; 41.6 and 34.3 min respectively). Summary. A strong correlation between all TG parameters and INR was observed both in the absence and in the presence of TM. We suggest that in certain patients with INR within therapeutic range high risk of bleeding can be assessed by CAT and these patients could benefit from dose adaptation under CAT control.

PB 1.52-6

The value of epistaxis as a predictor of a bleeding disorder: a prospective study in an Egyptian cohort of children

Abdelwahab M[1], Ismail R[1], Fathy A[1] and Nancy A[2]

[1]Cairo University Pediatric Hospital; [2]Zarayeen Hospital, Cairo, Egypt

Background: Epistaxis is a common problem in children with 40–56% presenting by at least one episode by age of 5–10 years. Some studies showed that one third of children referred for recurrent epistaxis have a diagnosable coagulopathy.

Aim: To identify prevalence of previously undiagnosed bleeding disorder in Egyptian children with significant epistaxis and determine predictors of such an underlying disorder.

Patients and Methods: A prospective study recruiting all children 2–18 years old presenting to the Pediatric Ear Nose and Throat (ENT) and Hematology outpatient clinics, emergency department and inpatient wards over a 6 months period with the following inclusion criteria, not having a known bleeding disorder with recurrent epistaxis lasting longer than 10 min and/or requiring intervention. All were subjected to the questionnaire of a bleeding disorder including personal, family and bleeding history as well as physical examination including ENT. Severity of epistaxis was graded using epistaxis scoring system by Katsanis et al,1988. All patients underwent testing for haemostasis including complete blood count, full coagulation screen and specific tests accordingly.

Results: The study included 63 children (84.1% ≤ 10 years, 52.4% males) with 38.1% of consanguineous marriage and 47.6% having similar condition. Epistaxis was severe in 41.3% of patients leading to anemia in 38%, bilateral in 65.1% precipitated by hot weather in 43% and post-traumatic in 19% of children. Other bleeding symptoms were reported in 30 (47.6%) children though a diagnosis of a bleeding diathesis was only reached in 18 (28.6%). This included eight with thrombocytopenia, eight with inherited disorders; platelet dysfunction (4Glanzmann's thrombasthenia and 4Bernard Soulier syndrome), one mild hemophilia A and one von Willebrand Disease type 1. Interestingly, 39.7% had ENT causes and 31.7% were idiopathic. Clinical predictive factors for having a bleeding diathesis were explored and included young age, consanguinity, epistaxis severity, the presence of other bleeding symptoms and decreased hemoglobin level (P 0.004, < 0.001, < 0.001, < 0.001, < 0.001) respectively.

Conclusion: Children with recurrent significant epistaxis should be screened for an underlying bleeding tendency especially if having any predictor factors.

PB 1.53-2

The impact of reference ranges in platelet aggregation study

Matos MF, Dói AM, Taniguchi E, Finazzo C and Duarte A

Hospital do Coração, São Pauo, Brazil

Background: Platelets play an important role in primary hemostasis, however may have deleterious effects, participating in the atherothrombotic process and in the pathogenesis of Acute Coronary Syndromes. More than 30 years have been studying the use of antiplatelet drugs in the prevention of thromboembolic events. However, some patients, even under antiplatelet therapy may have thrombotic events that may be related to an ineffective inhibition of platelet function. Studies show that factors such as patient's clinical condition, risk factors and genetic polymorphisms may be related to different degrees of reactivity and responsiveness to antiplatelet therapy. There is no consensus in establishing laboratory criteria which may be used to describe a poor response to antiplatelet agents. However, some laboratory methods have been described and evaluated, such as the platelet aggregation test by Light Transmittance Aggregation (LTA) or Impedance Method.

Aims: This study aimed to compare the results of platelet aggregation in patients in use of antiplatelet drugs (aspirin and clopidogrel) obtained by impedance method and LTA applying local reference ranges.

Methods: For this comparative study, platelet aggregation was performed in 53 patients. The reference range (RR) for the impedance method was performed in 41 normal subjects.

The LTA was performed in platelet rich plasma (PACKS-4 – Helena Laboratories) and impedance method in whole blood (Multiplate Platelet Function Analyer- Dynabyte). The agonists used in comparative studies were: Adenosine diphosphate – ADP (final concentration – LTA: 2.5 μM; impedance method: 6.5 μM) and Arachidonic Acid – AA (final concentration – LTA: 50 μg/mL; impedance method: 0.5 mM). For LTA the response was considered normal when the final percent final aggregation was higher than 60% (for AA and ADP). The impedance RR recommended by the manufacturer is 38–85 AUC for ADP and for 16–71 AUC for AA. The RR obtained from 41 normal subjects were 45–89 AUC for ADP and 39–83 AUC for AA.

Results: Comparing the two methods, we realized that using the reference values recommended by the manufacturer we had a lower concordance between both methods (69.3% and 57.7%) than when we used the calculated RR (75% and 77%) for ADP and AA respectively.

When evaluating results of patients in use of aspirin, we found that 88% were poor responsive for AA in LTA. We noted lower rates in impedance method (29% with AA) when using RR method recommended by the manufacturer. By using the RR calculated rates rise 76.5% with AA.

Regarding patients in use of clopidogrel, 100% of patients were poor responsive with ADP in LTA method. We noted lower rates in impedance method (40% with ADP) when using reference range method recommended by the manufacturer. The rates increase to 80% with ADP when we use the RR calculated for impedance method.

Conclusions: Consistent data are observed when using the impedance methodology based on calculated reference values. We conclude that it is essential to define RR specific to each lab, obtained from a local normal population to interpret platelet aggregation by the impedance method.

PB 1.53-1

A new clotting biomarker for predicting sepsis severity

Davies GR[1], Mills GM[1], Stanford SN[1], Lawrence MJ[1], Davies N[1], Aubrey R[1], Williams R[2], Thomas D[3] and Evans PH[1]

[1]Morrisston HBRU; [2]Swansea University; [3]Morriston Hospital ABMU LHB, Swansea, UK

Background: It is well known that the regulation of the coagulation cascade is abnormal in sepsis. A procoagulant state is induced due to exposed tissue factor and inflammatory modulation of the coagulation cascade [1]. Fibrinolysis is also inhibitied due to an increased activity of PAI-1, impaired thrombomodulin activity and reduced active protein C [2]. A procoagulant state and inhibited fibrinolysis can lead to formation of microthrombi throughout the vasculature known as Disseminated Intravascular Coagulation (DIC). It is hypothesised that these microthrombi contribute to multi-organ failure in sepsis by impairment of circulation and perfusion into the major organs [3]. Formation of thrombi systemically can eventually lead to consumption coagulopathy, in which bleeding is prevalent. We hypothesise that the progression and severity of sepsis can be detected from observation of the clot formation process in these patients. This project aims to assess the potential of a novel new clotting biomarker of clot structure, D_f [4], in predicting the severity of sepsis by comparison with organ failure assessment scores.

Methods: This study was undertaken with full ethical approval from the local research ethics committee. Informed written consent was given by all patients that had capacity to do so. Informed written ascent was given in cases where consent was not possible. Patients with a diagnosis of sepsis were recruited on admission to the Intensive Therapy Unit in a large teaching hospital in Wales. Blood was taken for routine testing, ROTEM thromboelastometry, and rheological analysis (New biomarkers T_{GP} and D_f) on admission, at 2–6, 24 h and 3–7 days to assess progression. Disease Severity was assessed by APACHEII Score on admission and by SOFA score at each sampling point. Eighteen patients were recruited: nine with Severe Sepsis and nine Septic Shock. Eighteen Healthy volunteers were recruited as a matched control.

Results: Mean D_f in the control group was 1.74 ± 0.04. Mean D_f in the severe sepsis and septic shock groups was 1.67 ± 0.09 and 1.64 ± 0.07 respectively. A moderate but non-significant negative correlation was observed between D_f and APACHEII at baseline (Pearson correlation coefficient = −0.36, $P = 0.1$). A weak correlation between D_f and SOFA was observed at baseline (Pearson correlation coefficient = −0.26), however when compared at sequential data points, a moderate significant correlation between D_f and SOFA was observed (Pearson = −0.36, $P < 0.05$).

Summary: D_f correlates with severity in sepsis patients on admission to ITU and, furthermore, significantly correlates with organ failure in these patients when observed at sequential data points.

It is unclear if a weakened clot structure in the more severe patients is due to disease progression or more aggressive treatment that could be received by these patients i.e. fluid resuscitation.

Further analysis is required to assess the impact of treatment on D_f.

If sensitive to dilution, D_f could be a useful biomarker of adequate fluid resuscitation. This will have to be investigated further.

Robustness of the thrombin generation assay in factor VIII-supplemented hemophilic plasma

Woodle A, Gourley M, Lee TK and Ovanesov MV

U.S. Food & Drug Administration, Bethesda, MD, USA

Background: Fluorogenic thrombin generation assay (TGA) is a popular global hemostasis assay extensively used in preclinical and clinical evaluation of hemophilia A treatments. Some researchers believe that TGA has advantages over current methods of treatment monitoring, e.g., because TGA may better reflect clinical endpoints. However, published evidence on the clinical utility of the TGA in hemophilia is inconsistent and controversial despite several standardization exercises and a decade of studies that utilized a fairly harmonized protocol.

Aims: We hypothesized that inconsistent predictive value of the TGA may be related to poor robustness of the existing method implementation. Therefore, we evaluated the effects of analytical variables, instrumentation and software algorithms on the fundamental property needed for treatment monitoring: the ability to discriminate between Factor VIII (FVIII)-deficient plasma samples before and after FVIII supplementation.

Methods: We used several fluorescent microplate readers as well as manual and automated pipetting techniques. In house and commercial software were used for evaluation of thrombin generation curves using a variety of published algorithms. The potential effects of small variations of analytical variables on the TGA outcomes were evaluated using commercial congenital FVIII-deficient human plasma supplemented with FVIII.

Results: Thrombin peak height (TPH) was chosen as the most robust and sensitive measurement of procoagulant activity in hemophilic plasma. The following parameters were found to affect the absolute value of the TPH: tissue factor (TF) concentration and specific activity, lipid concentration and specific activity, fluorogenic substrate and calcium concentrations, ratio of human plasma volume to the TF and calcium concentrations. Mathematical algorithms, e.g., correction of substrate consumption, instrument noise and non-linearity (inner filter effect) were non-consequential under typical conditions. However, the relative difference between the FVIII-deficient and FVIII-supplemented plasmas and the low limit of FVIII detection depended almost

entirely on the plasma source and the presence of exogenously added or contact-activated intrinsic factors IXa and XIa.
Conclusions: Stability and lot-to-lot variability of reagents used for the TGA may negatively affect the robustness of the method. Use of external plasma calibrator, e.g., reference plasma sample, may potentially correct for these deficiencies. These studies may assist in establishing the consensus pre-analytical and analytical test conditions by which TGA can be standardized across laboratories.
Disclosure: This is an informal communication and it represents authors' own best judgment. These comments do not bind or obligate FDA.

Results of performance assessment of CoaguChek XS INR monitors by external quality control

Meijer P and Kluft C
ECAT Foundation, Leiden, The Netherlands

Introduction: External quality assessment (EQA) of test results is a manner to establish whether a laboratory is able to produce accurate results as well as to assess the between-laboratory variation for a particular test. EQA is nowadays a well-known and accepted procedure for the assessment of the quality of regular laboratory testing. However, EQA for point-of-care testing (POCT) has not yet been widely introduced. One of the problems is the availability of suitable control material. POC monitors are designed for the use of whole blood. Unfortunately it is difficult to distribute to participants stable whole blood samples suitable for measurement of the International Normalised Ratio (INR).
Aim: Fortunately with the CoaguChek XS monitor, the most widely used monitor inEurope, it is also possible to use citrated plasma. The ECAT Foundation therefore designed an EQA programme for CoaguChek XS INR monitors using lyophilised plasma pools of patients on anticoagulants. Because of the direct relationship between the measured INR value and the treatment of the patient it is important that a POCT monitor measure the correct INR value. Therefore in our EQA approach for the CoaguChek XS we focus on the trueness of measurement (accuracy).
Methods: The quality set consists of four different plasmas, covering the whole therapeutic range (INR 2–4.5). The results of all four measurements are evaluated in an integrated linear regression model. With this model it can be assessed whether it is possible to measure accurate results over the entire therapeutic range. The assigned values are established by the Dutch Reference Laboratory for Anticoagulation (RELAC) using different lot numbers of test strips as well as different monitors and are traceable to the international human thromboplastin reference preparation. The quality control (QC) samples are stable for up to 6 h after reconstitution. Acceptance criteria are based on the deviation from the target value (target value $\pm$ 15%), slope ($0.77 <$ slope < 1.79), intercept ($-1.78 <$ intercept < 0.72) and correlation coefficient (> 0.900). The acceptance criteria are established by modelling the regression analysis.
Results: Up to now 150 different CoaguChek monitors have been evaluated. The established acceptance criteria were met by 136 monitors. Thrombosis Service Centers may test monitors batch-wise with one set of QC samples. In the case of 10 batch-wise-tested monitors a systematic error in one of the QC samples could be observed, which may indicate a pre-analytical error. This means that only four out 150 monitors did not met the acceptance criteria for accurate testing. The between-monitor variation varied between 2.3% and 6.6%. No differences were observed between different lot numbers of test strips.
Conclusion: Current experience with this novel EQA programme for CoaguChek XS monitors shows that it is a valuable tool for quality control of POC INR testing. In the first experience with this EQA programme < 3% of the monitors fail to met the acceptance criteria which indicates a good performance of the CoaguChek XS monitors.

PB 1.53-5
Comparison of Biophen DiXaI®, prothrombin time with a reference HPLC-MS/MS method to monitor patients receiving rivaroxaban

Douxfils J[1], Tamigniau A[2], Classen J-F[3], Baudar J[3], Walbrecq S[3], Chatelain C[3], Chatelain B[3], Mullier F[3], Wallemacq P[2] and Dogné J-M[1]
[1]University of Namur, Namur; [2]UCL, Clinique Universitaire Saint-Luc, Woluwé; [3]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: Pharmacokinetic properties of rivaroxaban seemed to be relatively predictable. However, dependence of renal or hepatic function could result in considerable variation in drug plasma concentrations. Moreover, according to the recent update of the EU-SmPC of rivaroxaban, a reduction of the dose from 20 mg once daily to 15 mg once daily should be considered if the patient's assessed risk for bleeding outweighs the risk for recurrent DVT and PE in patients with moderate or severe renal impairment. This may suggest that monitoring could be used to assess the response of an individual patient. Furthermore, it may also be useful in patients with hepatic impairment, drug interaction, severe bleeding, recurrence of thrombosis, in case of anticoagulation bridging, before urgent or elective surgery, in infants or pregnant women or in patients with extreme body weights. PT or chromogenic anti-Xa assays such as Biophen Direct Factor Xa Inhibitor (DiXaI)® have been proposed to estimate plasma drug concentration but these findings are based on *in vitro* analysis.
Aims: To compare the measurement of calibrated PT and Biophen DiXaI® with the reference High Performance Liquid Chromatography coupled with tandem mass spectrometry (HPLC-MS/MS) in patient's plasma samples.
Methods: Fifty-two plasmas from patients treated with rivaroxaban were included in this study. Calibrated PT was performed using the most sensitive reagent (Triniclot PT Excel S®) and home-made calibrators to give results expressed in ng/mL. Biophen DiXaI® has been performed according to the instructions of the manufacturer on a STA-R Evolution® coagulometer. For the HPLC-MS/MS, after preparation of the sample, separation of the analytes was achieved on a Phenomenex Kinetex® column shield RP18 and the detection was performed using a MICROMASS QUATTRO Micro® mass spectrometer operating in positive electrospray ionization mode.
Results: The plasma-concentration range was from 0 to 485 ng/mL as measured by the HPLC-MS/MS method.
The Biophen DiXaI® and HPLC-MS/MS are highly correlated (Pearson correlation coefficient [r^2] of 0.95 [95% confidence interval: 0.91 to 0.97; *P*-value: < 0.0001]). The Bland-Altman analysis showed a mean difference of −16 ng/mL (standard deviation (SD): 25 ng/mL; 95% limits of agreement: −65 to 32 ng/mL). The limits of detection were 9 and 3 ng/mL for Biophen DiXaI® and HPLC-MS/MS, respectively.
The calibrated PT and HPLC-MS/MS were poorly correlated (Pearson correlation coefficient [r^2] of 0.53 [95% confidence interval: 0.33–0.70; *P*-value: < 0.0001]). The Bland-Altman analysis showed a mean difference of −24 ng/mL (SD: 79 ng/mL; 95% limits of agreement: −179 to 132 ng/mL).
Conclusions: There is an important inter-individual variability with Triniclot PT Excel S® and even calibrated, it poorly correlates with rivaroxaban plasma concentrations in patients measured by HPLC-MS/MS. Therefore, PT should not be used to estimate plasma drug concentrations. On the contrary, Biophen DiXaI® is highly correlated with HPLC-MS/MS and is poorly influenced by inter-individual variability. Biophen DiXaI® should therefore be recommended to estimate rivaroxaban plasma concentration.

PB 1.53-6

Relationship between thromboelastometry measurements, hemostasis factors and two global hemostasis tests: thrombin generation and thromboplastin-thrombomodulin-mediated time

Llobet D, Borrell M, Font M, Morera A, Vallvé C, Carrasco M, Mateo J, Souto JC and Fontcuberta J

Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Global hemostasis assays have been used for decades as the first step to study the hemorrhagic tendency of patients. In the last years the interest has focused on global assays that generate information regarding thrombophilia tendency. Here we describe the correlation between Thromboelastometry (TEM) and hemostasis factors such as fibrinogen and coagulation factors as well as Thrombin generation (TG) and Thromboplastin-Thrombomodulin- mediated time (Tp-TM.T).

Material and Methods: *Subjects:* Blood samples were examined from 137 individuals unrelated to each other (69 women and 68 men) with a mean age of 52 years (range 27–85).

Hemostasis assays: TEM Rotem®: device (Pentapharm GmbH, Munich, Germany) was used for thromboelastometric analysis determined in citrated blood with the reactive intem (with ellagic acid). We studied the Maximal Clot Firmness (MCF) and the maximal Velocity (maxVel)

Thrombin generation (TG) was studied with the Calibrated Automated Thrombograpy method and the Fluoroskan Ascent instrument. It was determined in platelet poor plasma with 5 pM tissue factor and 4 μM phospholipids. We studied the endogenous thrombin potential (ETP) and the maximal thrombin generation (Peak height)

Tp-TM.T: a modified prothrombin time (1) in the presence and absence of thrombomodulin. The results are expressed as R1: ratio of the patient's clotting time vs. control clotting time using the reactive with thrombomodulin and R2: the same ratio using the reactive without thrombomodulin.

Fibrinogen, platelet count, FVII, FVIII, FIX, FXI, FXII was determined by standard methods.

Statistical analysis: Relationship among TEM parameters and the other tests were studied with the Pearson correlation coefficient. A value of $P < 0.05$* or $P < 0.01$** was considered statistically significant.

Results: The *MCF* showed a significant correlation with the following parameters: Fg ($r = 0.59$**), platelet count ($r = 0.53$**), FVII ($r = 0.27$**), FIX ($r = 0.26$**), FXI ($r = 0.36$**).

Also it showed a significant correlation with Tp-TMT R1 ($r = -0.32$**), Tp-TMT R2 ($r = -0.43$**) and TG ETP ($r = 0.30$**), TG Peak ($r = 0.28$**). No correlation was found with levels of FVIII and FXII.

- The *MaxVel* showed a significant correlation with the same parameters with the following coefficients: Fg ($r = 0.43$**), platelet count ($r = 0.52$**), FVII ($r = 0.2$*), FIX ($r = 0.17$*), FXI ($r = 0.34$**), Tp-TM.T R1 ($r = -0.26$**), Tp-TM.T R2 ($r = -0.29$**), TG ETP ($r = 0.32$**), TG Peak ($r = 0.28$**). Again no correlation was found with FVIII and FXII.

Conclusions:

- TEM activated with ellagic acid (*MCF* and *MaxVel*) is sensitive to levels of the studied parameters except for FVIII and FXII. TEM also has a good correlation with Tp-TM.T (R1 and R2) and TG (ETP and Peak)
- MCF and MaxVel are good parameters to evaluate thromboelastometry as indicators of coagulation physiology.

Normalized ratio for silica clotting time and dilute Russell venom time is an excellent tool for diagnosis of lupus anticoagulant

Nardi MA

NYU School of Medicine, New York, NY, USA

Background: The laboratory criteria for the lupus anticoagulant (LA) diagnosis have been updated (JTH, 2009;10:1737–40). The report recommends a% correction (%CORR), as calculated by the equation [(screen result – confirm result)/screen result] × 100%, greater than the locally determined cut-off value be considered as positive. The package inserts for the Hemosil Silica Clotting Time (SCT) and the Hemosil LAC Screen (LAC-S)/LAC Confirm (LAC-C) tests (Instrumentation Laboratory), however, recommend the use of a Normalized Ratio (NR) to determine positivity for LA. The NR is calculated by dividing the Screen Ratio (patient screen result/mean of screen normal range) by the Confirm Ratio (patient confirm result/mean of confirm normal range). The normalization using the mean normal value for each individual test is intended to compensate for any day-to-day variation associated with the test as well as the differences in the normal ranges of the individual tests.

Aim: This laboratory sought to compare the final interpretation of laboratory results using the %CORR vs. the NR for consecutive samples submitted for LA testing.

Methods: Blood collection and processing of specimens submitted for LA testing were done according to the LA Scientific Standardisation Committee (LA-SCC) recommendations. Using a single aliquot, the SCT and the LAC-S/LAC-C tests were performed simultaneously on an ACL TOP CTS 500 (Instrumentation Laboratory) with the Hemosil reagents. The PT/INR and Thrombin Time (TT) were measured on all specimens to detect significant anticoagulant therapy. The results for LA testing on 1556 consecutive samples, with INR < 1.5 and TT < 80 s, were analyzed using both the calculated % CORR and the NR. The normal value cut-off for each test was set at the 99th percentile as obtained from 50 normal donors (SCT-%CORR < 35%, SCT-NR < 1.33, LAC-%CORR < 33% and LAC-NR < 1.33).

Results: Positivity for %CORR vs. NR for SCT [6.3% vs. 5.8%) and for LAC (15.2% vs. 14.5%) showed 96% and 91% concordance, respectively. The mean ± 1SD of positive results were 50.8 ± 13.7% (SCT-%CORR), 2.07 ± 0.82 (SCT-NR), 60.5 ± 3.7% (LAC-% CORR) and 1.61 ± 0.36 (LAC-NR). All discordant samples were in the lower range of the %CORR for both SCT (mean = 35.5, range 35.5–36.0) and LAC (mean = 33.7, range 33.5–33.8%). Regression analysis of %CORR vs. NR demonstrated excellent correlation for both SCT (semi-log relationship, $r^2 = 0.9416$, $P < 0.001$) and LAC (linear relationship, $r^2 = 0.9907$, $P < 0.001$).

Conclusions: The NR for the determination of the presence of LA shows excellent agreement by concordance and regression analysis with the %CORR, the method currently recommended by the LA-SCC. The small percentage of discordance seen here may be accounted for by the determination of the cut-off values and/or by the natural variation seen in the performance of these tests. In conclusion, the use of NR for the determination of the presence of LA is a viable alternative to the %CORR.

PB 1.54-2

Dynamic APTT characteristics in a case–control study of venous thrombosis

Ziyatdinov A[1], Morera A[2], Borrell M[2], Orantes V[2], Llobet D[2], Mateo J[2], Fontcuberta J[2] and Souto JC[2]

[1]IIB-Sant Pau; [2]Unitat d'Hemostàsia i Trombosi. Hospital de Sant Pau, Barcelona, Spain

Background and Aims: High levels of clotting factors (VIII, IX, XI) and short Activated Partial Thromboplastin Time (APTT) have been related with venous thrombosis risk. Recently, dynamic APTT parameters have been assessed in venous thrombosis patients (*B. Sørensen and J. Ingerslev, J Thromb Haemostas 2012;10:244–50*). We explored this relation among a sub-group of patients in the framework of an ongoing case-control study of venous thromboembolism (RETROVE project: Riesgo de Enfermedad TROmboembólica VEnosa). The aim of RETROVE project is to investigate algorithms for predicting the individual risk of venous thrombosis.

Methods: An initial group of 37 individuals of RETROVE project where included in this analysis. The data set contained 27 subjects (14 females and 13 males, aged 22–88 years old) and 10 controls (four females and six males, aged 20–87 years old).

The APTT was measured in a ACL-TOP analyzer using SynthAsil as a reagent, both from Instrumentation Laboratory, Spain. The clotting time digital signals were recorded by the equipment, which had an output profile consisting of the normalized signal and its first derivative. Both were cleared of high-frequency noise artifacts. The digital signals allowed us to extract two static and two dynamic parameters: (i) maximum clot firmness or APTT-MCF, (ii) time to maximum clot firmness or APTT-t-MCF; (iii) maximum velocity or APTT-MaxVel, and (iv) time to maximum velocity or APTT-t-MaxVel. We applied the Welch student's t-test with a significance level less than $P = 0.1$ to measure the statistical difference between the patients and the controls.

Results: Both the APTT-t-MaxVel and the APTT-t-MCF were shorter in the patients than in the controls (P-values 0.0881 and 0.0774 respectively). However, we have not found any statistically significant difference in the other two parameters (APTT-MCF and APTT-MaxVel).

Conclusions: We have confirmed the previous results concerning the relation of dynamic APTT characteristics and thrombosis. Our analyses are preliminary, due to the small sample size, although the results could be considered as promising. In the future we plan to test a larger set of dynamic APTT phenotypes and on a larger sample of individuals. Also, we will attempt to apply multi-variate and time-series methods for a better description of the dynamics of APTT signals.

PB 1.54-3

Comparison between different point of care systems for PT INR testing

Bassi L, Paoletti O, Cancellieri E, Damiolini E, Cogrossi A, Dellanoce C, Zimmermann A and Testa S

Haemostasis and Thrombosis Center-A.O. Istituti Ospitalieri, Cremona, Italy

Background: Portable coagulation systems are used to perform PT-INR test on capillary blood, to monitor antivitamin K antagonists (AVK). Differences in PT INR determination depend on reagents, coagulometers and calibrations. Agreement between portable monitors and reference systems should be evaluated.

Aims: Evaluate microINR and Coagucheck XS, two commercial portable monitors, in comparison with PT-INR provided by central laboratory reference system, using two different thromboplastins

Methods: PT INR was performed on two portable monitors: Coagucheck XS (Roche Diagnostics, Basel, Switzerland) using freeze-dried rabbit thromboplastin with ISI of 1.84 and microINR (IL Instrumentation Laboratory – Werfer Group) using human thromboplastin with ISI of 1.00. As reference system for PT-INR determination from venous blood specimens a magneto-mechanical coagulation analyzer was used (STA-R, Stago France). All venous samples were tested with two different thromboplastins: a rabbit thromboplastin with an ISI=1.28 (Neoplastin Plus Stago Paris, France) and a recombinant thromboplastin (Hemosil IL International Laboratory) with an ISI = 0.99.

One hundred and fifty-three AVK patients, with PT INR ranging from 2 to 4 (INR range 2–4), were evaluated. In the same daily session venous blood samples *were collected, centrifuged and frozen at* −80 °C and capillary PT-INR test was performed on the two portable monitors. Statistical analysis was performed by linear regression and Bland Altman method.

Results: The correlation among different systems was good showing: Coaguchek XS vs. neoplastin plus = 0.953 and vs. Hemosil = 0.965; microINR vs. Neoplastin Plus = 0.883 and vs. Hemosil 0.910. Differences in PT INR $> \pm 0.5$ were observed in about 5% of the total patient population, except for the comparison between Coaguchek XS and Hemosil, that showed a higher disagreement (PT INR $> \pm 0.5 = 14.4\%$). Bias calculated by Bland Altman are the following: Coaguchek XS vs. Neoplastin Plus = 7.8; Coaguchek XS vs. Hemosil = 13.3; microINR vs. Neoplastin Plus =1.9; microINR vs. Hemosil = 3.1.

Conclusion: Results showed good correlation between the different methods. MicroINR ratio system is simple to use and sufficiently accurate. The disagreement showed by Bland Altman method probably depends on thromboplastin calibrations and their different sensitivity. The correlation among portable monitors and reference methods is good and improves comparing systems with homogeneous reagents. Before use a portable monitor we suggest to evaluate the agreement with reference system. Companies should communicate ISI value of thromboplastin used in portable monitors and calibration model

PB 1.54-4

Local verification and assignment of ISI values: recent mayo clinic experience and outcome

Tange I, Grill D, Koch C, Ybabez R, Krekelberg BJ, Wiese C, Block DR, Karon B, Chen D and Pruthi R

Mayo Clinic, Rochester, MN, USA

Background: Warfarin dosing relies on an accurate international normalized ratio (INR) which is calculated from the prothrombin time (PT), International Sensitivity Index (ISI) of the PT reagent (thromboplastin), and geometric mean (GM) of PT. FDA approved certified plasma's and ISI assignments are not available for all instruments. ISI varies with reagent/instrument combinations and change with each lot of thromboplastin. Failure to harmonize INR results may result in the same patient to receive varying warfarin dosing instructions when tested at different anticoagulation clinics utilizing different instruments and/or thromboplastins. CLSI guidelines encourage laboratories to verify/establish local ISI and GM, however, the process is challenging.

Aims: To develop a standardized process that will verify/establish ISI and GM assignments of a single thromboplastin across multiple instruments.

Methods: Over a 2 year period, two lots of thromboplastin (RecombiPlasTin 2G, R2G, Instrumentation Laboratories, Medford, MA) were compared at 4 (lot# 1) and 6 (lot# 2) sites on four different instruments: ACL TOP (Instrumentation Laboratory, Bedford, MA) and the STA-R Evolution, Compact, and Satellite (Diagnostica Stago, Parsippany, NJ). For lot# 1, the ISI for the thromboplastin on the ACL TOP (established by Instrumentation Laboratory) was verified on site by orthogonal regression analysis using 31 stable warfarin patients and 20 random normal donors; establishing the TOP as the reference method. Using the same 51 samples, PT results from the reference method were plotted against PT results from the other three sites and analyzed by orthogonal regression to assign individual ISI's. Forty random healthy donor samples were recruited to verify GM at each testing site. For lot# 2, 13 sets of pooled plasma samples (INR range: 1.3–4.0) were created from 142 stable warfarin patients. The manufac-

turer's assigned ISI was first verified on the reference method, then at the additional five sites using orthogonal regression analysis. GM at each site was verified or established by both small scale normal range verification procedure (using 25 random healthy donor samples) and the intercept of INR linear regression analyses as described by Favaloro et al (2012). Finally, both local ISI and GM were further verified by three sets of WHO certified plasma samples.

Results: Lot# 1: the manufacturer assigned ISI (1.05) and laboratory established GM (11.0) were verified on the TOP. Locally assigned ISI and GM values were derived as follows, respectively: Evolution, 1.14, 12.3; Compact, 1.12, 10.9; and Satellite, 1.11, 10.6. Linear correlations of the INR results from all four laboratories demonstrated an r^2 of > 0.99. Post implementation internal proficiency tests among all four laboratories demonstrated excellent agreement. Lot#2: (manufacturer assigned ISI of 0.95), locally derived ISI and GM values as follows, respectively: TOP, 0.95, 11.0; Evolution, 1.04, 11.6; Compact, 1.02, 11.5; and Satellite, 0.99, 10.9. Linear correlations of the INR results from all six laboratories demonstrated an $r^2 > 0.98$.

Summary/Conclusion: This method for ISI and GM verification/assignment across instruments provides a simple, robust and reproducible approach. The data confirm the change in ISI on different instruments with different lots of thromboplastin reaffirming the need for this exercise.

PB 1.54-5

Thrombin generation and post-operative bleeding in patients undergoing surgery requiring cardiopulmonary bypass

Percy CL[1], Jones M[1], Mehta D[2], Balachandran S[2], Hall JE[1], O'Donnell VB[1] and Collins PW[1]

[1]Cardiff School of Medicine; [2]University Hospital of Wales, Cardiff, UK

Background: Bleeding following surgery requiring cardiopulmonary bypass is a major cause of morbidity. Evidence has suggested thrombin generation (TG) assays may identify patients at risk of excessive post-operative bleeding. However, TG lacks standardisation and optimal conditions remain to be finalised. Altering the conditions may improve the ability of TG to identify an increased risk of bleeding.

Aim: To measure TG in the presence and absence of corn trypsin inhibitor (CTI), at different concentrations of tissue factor (TF) and correlate the results with post-operative bleeding.

Methods: After ethical approval and informed consent, 102 patients were recruited who were undergoing elective valve surgery, surgery on the thoracic aorta or undergoing coronary bypass grafting plus another procedure. Blood samples were collected into 3.2% citrate with or without 20 μg/mL CTI before heparin, and 30 min after heparin reversal. TG was performed using the method of Hemker. Trigger solutions contained 0.5, 1, 5 and 10 pM of TF and 4 μM phospholipids (20% PE, 20% PS, 60% PC). Commercially available trigger solutions (PPP low and PPP, a gift from Stago) were also used. Before TG assays, the 96-well plate was warmed to 37 °C for 30 min.

Abnormal post-operative bleeding was defined as drain loss of more than 1 L at 24 h, more than 200 mL/h for two consecutive hours, more than 2 mL/kg/h for two consecutive hours in the first 6 h, the need for haemostatic treatment or the need to return to theatre for bleeding.

Results: For samples collected into CTI, the median Endogenous Thrombin Potential (ETP) with 0.5 pM TF pre-surgery was 59.33 vs. 5.25 post ($P < 0.0001$); 1 pM TF 133 nM/min pre, 77.67 nM/min post ($P = 0.337$); 5 pM TF 605 nM/min pre, 530.33 nM/min post ($P = 0.013$); 10 pM TF pre 756.67 nM/min, 614.33 nM/min post ($P < 0.0001$); PPP low 339 nM/min pre, 191.67 nM/min post ($P < 0.0001$); PPP 987.67 nM/min pre, 777.50 nM/min post ($P < 0.0001$).

When collected into citrate alone the median ETP with 0.5pM TF was 710 nM/min pre vs. 197.67 nM/min post ($P < 0.0001$); 1 pM TF 640 nM/min pre, 228 nM/min post ($P < 0.0001$); 5 pM TF 754.67 nM/min pre, 543.33 nM/min post ($P < 0.0001$); 10 pM TF 806.33 nM/min pre, 639.50 nM/min post ($P < 0.0001$); PPP low 841.67 nM/min pre, 345.67 nM/min post ($P < 0.0001$); PPP 1087 nM/min pre, 806.33 nM/min post ($P < 0.0001$). The ETP was lower for samples collected into CTI, regardless of the trigger used ($P < 0.0001$ except for 5 pM TF post where $P = 0.003$, and PPP where $P = 0.460$). There was a significant increase in the ETP with increasing concentrations of TF ($P < 0.0001$).

The only statistical difference in the ETP between those who did and did not bleed excessively was seen in pre-operative samples using 0.5 and 1 pM TF and blood loss > 200 mL/h as an end-point ($P = 0.029$ and 0.023 respectively).

Conclusion: TG assays performed in the manner and time points selected in this study do not identify those at increased risk of post-operative bleeding. CTI and different TF concentrations produce different results but do not change sensitivity to predict bleeding.

PB 1.54-6

The overall haemostasis potential; A novel global coagulation assay for use in canine plasma

Dengate A and Morel-Kopp MC

Kolling Institute for Medical Research, St Leonard's, Australia

Background: The overall haemostasis potential (OHP) is a turbidimetric global coagulation assay, dynamically measuring fibrin generation (overall coagulation potentialcurve, OCP) and lysis (OHP curve). By subtracting the OHP from the OCP, we can calculate the overall fibrinolytic potential (OFP). Thromboembolism and hypercoagulability is increasingly being recognised in canine patients, though cost and limited availability of global assays impede our ability to pre-empt and recognise these conditions. The OHP is cost effective and can be run with common absorbance spectrophotometry equipment.

Aims: The purpose of this study was to optimise the OHP assay for use with canine platelet poor plasma, determine normal ranges, and compare OHP results with those for a thrombin generation assay (CAT) and thromboelastography (TEG).

Methods: Citrated plasma was collected from 40 clinically healthy dogs. The OHP assay and standard coagulation assays (prothrombin time [PT], activated partial thromboplastin time [APTT], and fibrinogen [Fg]) were performed for each sample. TEG and OHP was performed in nine dogs, and CAT and OHP in 23 dogs.

Results: Modifications to the published methodology for the OHP assay were required, with less coagulation activator (thrombin) and more fibrinolytic agent (tPA). The canine fibrin-time curve was generated faster and had a lower maximal optical density (MaxOD) than the human curve. Males had a higher OHP than females ($P = 0.04$). Stress during sampling was associated with increase in speed of clot generation ($P = 0.02$). High fibrinogen levels were associated with increased Max OD and OCP ($P \leq 0.05$), and a reduced PT was associated with increases in Max OD, OCP, OHP & Maximum slope ($P \leq 0.05$). The OHP parameter correlated with TEG parameters K (speed of clot generation), angle, maximum amplitude and G (clot strength) ($P < 0.05$). The OHP parameter correlated with the peak thrombin generation in the CAT assay ($P = 0.02$).

Summary: These results support the use of the OHP assay as an accessible, cost-effective global coagulation assay for use in canine plasma as an alternative to TEG andCAT.

Amino acid sequence epitope mapping of four factor VIII monoclonal antibodies

Batty P[1], Skelton S[2], Shepherd AJ[3] and Hart DP[2]
[1]Royal London Hospital; [2]Barts and the London School of Medicine and Dentistry, QMUL; [3]Birkbeck, University of London, London, UK

Background: Inhibitory antibodies (inhibitors) form the greatest challenge in the care of haemophilia A. The majority of inhibitors in congenital haemophilia A are polyclonal (IgG) directed primarily against the A2 and C2 domains of Factor VIII (FVIII). There is as yet no high throughput technology to define amino acid specificity of inhibitors. We describe the first application in haemophilia of a novel, ELISA based re-usable microarray (Pepscan®) to describe the amino acid sequence epitope of a series of domain characterised anti-FVIII monoclonal antibodies. This platform uses overlapping 20-mer linear peptide or 15-mer overlapping looped peptide libraries. Usage of looped peptides aims to mimic secondary structure, creating a conformational epitope that may enhance antibody binding. This technology has previously been used to describe the binding epitope of two anti-CD20 monoclonal antibodies (rituximab and GA101).
Aims: To assess the amino acid binding sequence epitopes of six anti-FVIII monoclonal antibodies and correlate these with their known domain specificities.
Methods: Six anti-FVIII monoclonal antibodies (mAb): 58.12 (anti-A1), C5 (anti-A1), R8B12 (anti-A2), 2D2 (anti-A3), GMA-8011 (anti-A3) and B02C11 (anti-C2) were tested on both linear and looped arrays. A negative control (buffer media) was tested prior to and in between each monoclonal antibody tested. R8B12 was tested in two separate experiments using the linear and looped FVIII arrays to demonstrate reproducibility of its identified epitope. This antibody was also tested using a FIX looped and linear array to demonstrate FVIII specificity.
Results: Of the six monoclonal antibodies, binding peaks were seen for four antibodies (58.12, C5, R8B12 and 2D2) on both linear and looped arrays (shared epitopes). All epitopes demonstrated solvent accessibility as modelled on PyMOL. All four of these antibodies showed binding within their previously described domains. Of the two non-binding antibodies (GMA-8011 and B02C11), B02C11 has been documented as having a complex discontinuous epitope. The amino acid sequence epitopes were as follows: mAb 58.12 YLGAVELSWD (A1 domain positions 6–15); mAb C5: TDSEMDVVRF (a1 domain positions 351–360); mAb R8B12: ISAYLLSKNN (a2 domain positions 726–735) and mAb 2D2: EPRKN (A3 domain positions 1801–1805). The binding epitope of R8B12 was reproducible on repeat testing and no binding was seen on the negative control array (FIX linear or looped arrays). The R8B12 epitope we describe is discrete from the previously published discontinuous epitope. No demonstrable carry-over of binding was seen between testing of monoclonal antibodies on this re-usable platform.
Conclusions: This approach offers a simple novel technique for amino acid epitope mapping of FVIII monoclonal antibodies. Data from our experiments has demonstrated solvent accessible binding within the domains previously described. We describe candidate amino acid binding sequences for three monoclonal antibodies not previously characterised to this level. We continue to optimise this technology for wider applications.

PB 1.55-2

Excretion and pharmacokinetics of glycopegylated rFVIII (N8-GP) after single intravenous dose administration to rats

Bjoernsdottir I[1], Kappers WA[1], Sternebring O[1], Kornoe HT[1], Kristensen JB[1], Thygesen P[1], Stow R[2], Fernyhough P[2] and Bagger M[1]
[1]Novo Nordisk A/S, Maaloev, Denmark; [2]Covance Laboratory Limited, Harrogate, UK

Background: N8-GP is a FVIII (turoctocog alfa) which is O-glycoPE-Gylated in the B-domain and currently in clinical development for prophylaxis and on-demand treatment of bleeding in haemophilia A. The B-domain contains a single 40 kDa branched PEG.
Aims: Excretion data for N8-GP with focus on the fate of the [^{3}H]-labelled PEG moiety will be presented together with PK parameters of total plasma radioactivity. The results will be compared with data obtained from rats dosed with the [^{3}H]-labelled 40 kDa PEG moiety only.
Methods: Han Wistar rats (n = 3) were dosed with a single intravenous dose of either [^{3}H]-labelled N8-GP (0.23 mg/kg, ~1900 U/kg, and a PEG load of 0.05 mg/kg) or 40 kDa [^{3}H]PEG (1, 12, 100 or 200 mg/kg). Animals were kept in metabolism cages continuously for the first 3 days of the study period and thereafter for 24 h intervals on a weekly basis up to 12 weeks. Recoveries of radioactivity were extrapolated to obtain accumulated recovery data. Plasma samples were collected for up to 12 weeks at all dose levels and analysed by liquid scintillation counting (LSC) and HPLC coupled to a radiochemical detector. Selected urine samples were also analysed by HPLC. All pharmacokinetic parameters were calculated using a standard two-compartment model.
Results: For [^{3}H]N8-GP, an estimated mean recovery of total radioactivity of 103% was found over the 12 week period, with 60% excreted renally and 33% recovered in faeces. Low levels of radioactivity were still detected in excreta and plasma 12 weeks post-dose. Terminal plasma half-life ($t_{½}$) of radioactivity was 12.5 days. The total volume of distribution (V_{ss}) was estimated to be 325 mL/kg – the volume of the central compartment (V_c) being 50 mL/kg and the peripheral (V_p) 280 mL/kg. The total plasma clearance (CL) was 1.9 mL/h/kg. For [^{3}H]PEG, an estimated mean recovery was found in the range of 88–93% for the different dose levels with 58–68% excreted renally and 12–13% in faeces. Dose linearity was confirmed between the four dose levels, but the $t_{½}$, V_p and therefore also V_{ss} were found to vary with dose. The $t_{½}$ increased with dose (range: 25–54 days), which appeared to be driven by an increase in V_p (range: 310–680 mL/kg), while V_c (80–90 mL/kg) and CL (range: 0.8–1.1 mL/h/kg) were found to be constant.
Summary/Conclusions: [^{3}H]N8-GP and the 40 kDa [^{3}H]PEG moiety were shown to be excreted both via urine and faeces – urine being the major excretion route for radioactivity pertinent to both compounds. [^{3}H]N8-GP was excreted to a higher degree in faeces compared to 40 kDa [^{3}H]PEG which may be associated with N8-GP being cleared by the liver.
This observation is supported by a 2-fold higher plasma CL of [^{3}H] N8-GP compared with [^{3}H]PEG. Further, terminal half-life of [^{3}H]N8-GP was 12.5 days compared to 25 days for [^{3}H]-PEG at 1 mg/kg. In conclusion, 40 kDa [^{3}H]PEG has been shown to be excreted both via urine and faeces. The clearance of [^{3}H]N8-GP was twice as high as for [^{3}H]PEG, probably due to liver-specific clearance of N8-GP.

PB 1.55-3

Accessibility to thrombin cleavage does not limit the circulating half-life of longer-acting factor VIII molecules

Tang L, Kretschmer P, Manzana W, Xia W, Tran K, Sim D, Mallari C, Shiroma D, Ho E and Murphy JE

Bayer HealthCare Pharmaceuticals, San Francisco, CA, USA

Background: A number of strategies, including Fc-fusion and PEGylation, have been used to prolong the circulating half-life ($t_{½}$) of factor VIII (FVIII). Strikingly, all of these strategies attain the same upper limit of 1.5- to 2-fold prolongation of $t_{½}$ in preclinical and clinical testing. Thus, it is possible that there is a common limiting factor. Because thrombin cleavage is an essential step in the activation of FVIII, all longer-acting FVIII molecules have been designed to maintain the ability to be cleaved by thrombin. Once cleaved by thrombin, activated FVIII (FVIIIa) is subject to numerous clearance pathways. Cleavage releases von Willebrand factor, which has been shown to protect FVIII from receptor-mediated clearance by low-density lipoprotein receptor-related protein (LRP) and from binding to membranes where it is subject to further degradation by activated protein C. Furthermore, thrombin cleavage is hypothesized to change the conformation of the A2 domain, exposing an additional LRP binding site. Finally, FVIIIa is highly unstable because of rapid A2 dissociation. It is therefore possible that low-level basal activation of FVIII by thrombin may play an important role in the clearance of FVIII and variants of FVIII that are designed to be longer acting.
Aim: To explore the possibility that accessibility to thrombin cleavage is the common limiting factor in FVIII $t_{½}$ prolongation.
Methods: To test this hypothesis we expressed and purified variants of FVIII, including a PEGylated FVIII from which the thrombin cleavage sites were removed (R373Q and R1690Q). The pharmacokinetics of the thrombin-resistant FVIII and thrombin-sensitive FVIII were identical when tested in FVIII knockout hemophilia A (HemA) mice.
Results: Combination of thrombin-site mutants with site-specific PEGylation, which has been previously shown to increase $t_{½}$ by approximately 2-fold in HemA mice, did not lead to a significant improvement beyond this 2-fold threshold.
Conclusion: In this study we have demonstrated that susceptibility to cleavage by thrombin does not limit the circulating $t_{½}$ of longer-acting FVIII.

PB 1.55-4

Evaluation of recombinant canine FVIII production from three cell types transduced with either a B domain deleted or codon optimized and truncated B domain cFVIII transgene

Crawford BA, Ozelo MC, Harpell L, Hegadorn C, Powell S, Hough C and Lillicrap D

Queen's University, Kingston, ON, Canada

Background: Historically, canine cryoprecipitate has been used to maintain the severe hemophilia A dog colony at Queen's University. Recombinant canine FVIII (rcFVIII) provides a substitute consistent with animal care principles of replacement, refinement, and reduction. However, expression of FVIII is significantly lower than other recombinant proteins of similar size.
Aims: To develop an expression system for colony-scale rcFVIII production and characterize the effect of vector engineering and host cell type on productivity and efficacy in the canine hemophilia A model.
Methods: A codon-optimized (CO) transgene was developed from canine B-domain-deleted (BDD) FVIII with the addition of a Kozak consensus sequence, the re-introduction of a portion of the 5′ B-domain sequence containing six N-linked glycosylation sites flanked by SQ-linkers, and 24% base pair substitution to optimize translation efficiency with respect to canine codon bias. Both transgenes (BDD and CO) are regulated by the ubiquitous EF1α promoter with the addition of a strong endothelial enhancer element (EPCR). VSV-G pseudotyped lentiviral vectors containing either transgene were used to transduce canine blood outgrowth endothelial cells (cBOEC), Madin-Darby canine kidney (MDCK), and human endothelial kidney (HEK) 293T cells at MOIs between 5 and 250. FVIII activity was measured using a 1-stage assay against a canine pooled-plasma standard. Integrated transgene copy numbers were determined with qPCR using human or canine β-actin as an endogenous reference. rcFVIII was purified with anion and cation exchange chromatography. Candidates for larger-scale production were expanded in triple-flasks or on collagen-coated microcarrier beads to produce test lots for pharmacokinetic (PK) evaluation in three hemophilia A dogs. Treatment-scale lots were tested for endotoxin and dogs were administered 20–29 U/kg. FVIII levels were determined at 0.5, 1, 2, 4, 8, 12, 24, and 48 h post-infusion.
Results: Regardless of cell type, the CO transgene showed significantly greater ($P < 0.001$) FVIII productivity per transgene copy than the BDD version, representing a 3.4-, 6.4-, and 6.5-fold increase for HEK 293T, MDCK, and cBOECs respectively. Additionally, CO cBOECs showed the highest specific productivity at 2.0 U/10^6 cells/24 h. However, this protein was also the least stable, as rcFVIII activity was reduced to 79% following a 2 h incubation in hemophilic plasma at physiological temperature. Inefficient expression following culture polarization in MDCK cells procluded the use of these cells for larger scale production. Pharmacokinetic evaluation in three hemophilia A dogs showed that the CO cBOEC protein achieved less than half the dose-normalized peak recovery of the BDD cBOEC protein, and also demonstrated significantly reduced ($P = 0.037$) bioavailability measured by area-under-the-curve (AUC).
Summary/Conclusions: Six cell lines were developed to express either CO or BDD cFVIII transgenes. Although the CO transgene showed markedly improved productivity, the resulting rcFVIII had reduced performance in procoagulant stability and efficacy. HEK 293T products were more cost-effective per activity unit due to high cell densities and simple media requirements. Production efficiencies will be further developed from a process engineering perspective.

PB 1.55-5

Instability of the His118Arg mutation in both factor VIII and activated factor VIII causing discrepancy in FVIII assays

Ding Q, Guoling Y, Min W and Xuefeng W

Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

Background: A wide range of factor VIII activity (FVIII:C) levels is presented in different haemophilia A (HA) patients with an identical missense mutation in the F8 gene, which usually causes a mild or moderate HA. Studies to date, however, have not elucidated the reasons clearly for discrepant FVIII:C levels based on genetic factors and molecular mechanisms.
Objective: To assess the effect of the FVIII His118Arg mutation on FVIII:C assays.
Patients and Methods: Two patients from the same family with severe laboratory phenotype but mild bleeding expression were investigated. To evaluate the stability of FVIII in the patients, FVIII:C was determined with one-stage assay kept at 25 and 4 °C for designed times during 2 h after samples collecting, as well as after storing at −20 or −80 °C for indicated days. The amount of FVIII heterodimer was assayed with ELISA using an anti-FVIII light chain monoclonal antibody as a capture antibody and a radish peroxidase-conjugated heavy chain monoclonal antibody as a detection antibody. To evaluate the stability of the patients' FVIIIa, FVIII:C was detected by chromogenic assay after indicated incubation times. Genetic analysis of the F8 gene was carried out by directly sequencing.
Results: Plasma FVIII:C levels were dramatically reduced over the indicated times from 18.9 to 1.6 IU/dL (at 25 °C) and to 0.8 IU/dL

(4 °C) for 2 h in patient 1, from 14.7 to 0.9 IU/dL and to 0.9 IU/dL in Patient 2. After storage at −20 and −80 °C for 2, 14 and 28 days, plasma levels of FVIII:C in both patients were dramatically reduced to the range of 2.6–4.6 IU/dL at 2 days and to ≤ 1 IU/dL at 14 days with a similar reduction pattern between −20 and −80 °C. The intramolecular stability of FVIII was calculated as the residual amounts of FVIII heterodimer relative to initial values (%). The data showed that the amount of FVIII heterodimer decreased rapidly to < 2% in plasma of the two patients. Plasma FVIII:C levels decreased significantly during incubation from 3 to 5 min, and continued to decrease up to 10 min in both patients using chromogenic assay, indicating that the stability of FVIIIa was reduced. His118Arg mutation in the F8 gene was identified in the patients. These data revealed that the instability exhibited by the His118Arg mutant FVIII in both the FVIII and FVIIIa forms caused discrepancies observed in FVIII assays.
Conclusion: Our results indicate that FVIII genotypes causing destabilization of both FVIII and FVIIIa may be associated with discrepant FVIII:C values and misdiagnosis of the severity of HA.

PB 1.55-6
Functional characterization of rVIII-SingleChain and comparison with commercially available recombinant FVIII products

Horn C, Watzka B, Metzner HJ, Dickneite G and Schulte S
CSL Behring GmbH, Marburg, Germany

CSL Behring is developing a novel recombinant human coagulation factor VIII product for the prophylaxis and treatment of acute bleeding episodes in haemophilia A patients. It is expressed in Chinese hamster ovary cells as a single-chain factor VIII molecule (rVIII-SingleChain) with a molecular weight of approximately 170 kDa. The harvests containing rVIII-SingleChain are subjected to a sequence of chromatographic and virus inactivation/removal process steps, formulated and lyophilized. The aim of the present study was the functional characterization of rVIII-SingleChain, also in comparison to commercially available, recombinant factor VIII products.
The activation of rVIII-SingleChain using thrombin was analyzed by SDS-PAGE and Coomassie Blue staining. rVIII-SingleChain fully activated by thrombin resulted in a band pattern consisting of light chain, A1-domain, and A2-domain. The pattern was comparable to activated commercially available rFVIII products.
The thrombin generation potential of rVIII-SingleChain in FVIII depleted plasma initiated by either intrinsic or extrinsic activators was investigated by a thrombin generation assay. With increasing activity rVIII-SingleChain showed a decline of the time-to-peak values and an increase of the peak height, respectively. The results were in good agreement with other commercially available rFVIII products.
The activated FVIII (FVIIIa) dependent activation of factor X by activated factor IX was analyzed by a chromogenic, FXa-specific substrate. rVIII-SingleChain revealed a time dependent increase in absorbance comparable to that of the rFVIII comparators that was leveling off at the maximum incubation period.
The inactivation of activated FVIIIa in absence or presence of activated protein C (APC)/protein S was analyzed by a one-stage FVIII clotting assay. In absence of APC/protein S the activated rVIII-SingleChain and rFVIII comparator products showed a comparable decline of the activity down to 10–20% of the initial value within a period of about 20 min. As expected, in presence of APC and protein S, an accelerated activity decrease down to 1–3% within 20 min was observed for all products investigated.
In summary, this study demonstrated the characteristics of rVIII-SingleChain concerning the activation by thrombin, the thrombin generation assay, the co-factor function of FVIIIa, and the inactivation of FVIIIa in absence or presence of APC and protein S. The comparison of rVIII-SingleChain with commercially available rFVIII products demonstrated a comparable behavior on the basis of the methods used.

PB1.56 – Tissue Factor – I

PB 1.56-1
Platelets do not express the oxidized or reduced forms of tissue factor

Bouchard BA, Gissel MT, Whelihan M, Mann KG and Butenas S
University of Vermont, Burlington, VT, USA

Background: Tissue factor (TF) expression and activity on the platelet surface is controversial and dependent upon the laboratory and reagents used. Due to the recent characterization of two forms of TF, it can be hypothesized that these discrepant results may be due to the expression of oxidized (active) vs. reduced (inactive) TF on the platelet surface. Previous observations by our laboratory, based on flow cytometric analyses using a well-characterized monoclonal antibody (anti-TF-5) that recognizes the oxidized form of TF and functional assays, demonstrate a lack of active TF expression by unactivated or activated platelets.
Aims: The goal of this study was to extend our observations by assessing platelet TF expression using a specific polyclonal antibody and biotinylated active site-blocked factor VIIa, both of which recognize the oxidized and reduced forms of TF.
Methods: Expression of TF by platelets activated under different conditions was determined by flow cytometry. In additional experiments, active TF expression was measured using functional and immunoassays that can detect picomolar concentrations of factor Xa and factor IXa.
Results: Western blotting analyses of full-length, recombinant and natural placental TF under reducing and non-reducing conditions demonstrated that, in contrast to anti-TF-5, a sheep polyclonal antibody directed against human TF (sheep anti-hTF) recognizes both reduced and oxidized forms of TF. As we previously have shown using anti-TF-5, there is no expression of oxidized or active TF on the platelet surface. Sheep anti-hTF was used to confirm these observations and determine whether platelets express the reduced or inactive form of TF on their membrane surface. Unactivated platelets or platelets activated for 15 or 120 min with thrombin receptor agonist peptide (SFLLRN-NH_2) (100 μM) were used. Platelet activation was confirmed by flow cytometry using a specific fluorescently-labeled monoclonal antibody directed against the activation-dependent marker, P-selectin. Additional flow cytometric analyses demonstrated that fluorescently-labeled sheep anti-hTF did not react with the surface of unactivated platelets or platelets activated under either condition. This observation was confirmed using 10 nM biotinylated, active site-blocked factor VIIa: no binding was observed by flow cytometry following its detection with fluorescently-labeled streptavidin. Similarly, and consistent with these observations, no factor Xa or factor IXa generation was observed on the surface of these platelets in the presence of 10 nM active factor VIIa using highly sensitive functional assays. The specificity of these reagents and assays was confirmed in parallel experiments using lipopolysaccharide-treated monocytes as a positive control.
Summary/Conclusions: Platelets do not express either the active or inactive forms of TF.

PB 1.56-2
Inflammation and tissue factor expression by acute promyelocytic leukemia cells

Kruithof E and Dunoyer-Geindre S
HUG, Genève 4, Switzerland

Background: Acute promyelocytic leukemia (APL) is a subtype of acute myeloid leukemia, mostly characterized by a chromosomal translocations t(15;17) resulting in creation of PML- RARα fusion protein that inhibits cell differentiation. APL cells show a high expression of tissue factor (TF) and of annexin 2, a receptor for tissue-type plasminogen activator (t-PA), which strongly increases the activity of

t-PA. The combined action of these prothrombotic and pro-fibrinolytic activities contributes to the severe bleeding complications that are characteristic for APL. Of these activities TF is the triggering factor for the complications. APL used to be invariably fatal, but introduction of treatment with all-trans retinoic acid (ATRA) and chemotherapy has considerably reduced mortality. Still, severe hemorrhage is responsible for death in 5% of the patients. APL cells express besides the inflammatory cytokines, tumor necrosis factor (TNF) and interleukin 1b, which are capable of increasing TF expression in many cell types.

Aim: The study the role of inflammation in expression of TF by APL cells.

Methods: Two cell lines were used: NB4 cells, an APL cell line containing the t(15;17) translocation; treatment with high ATRA concentrations counteracts the effect of the PML- RARα fusion protein and leads to differentiation. U937/PR9 is a myeloid cell line stably transfected with DNA encoding PML- RARα under control of the methallothionin promoter. U937/PR9 cells express PML- RARα only when treated with Zn^{2+}. We used quantitative PCR to investigate the effect on TF and TNF expression of treatment with ATRA, with inhibitors of TNF (adalimumab) of IL-1b (ANAKINRA) or with drugs that inhibit the inflammatory signaling proteins NFkB (inhibitor BAY11-7085) or p38 (SB203580, SB202190 or Birb796)

Results: Treatment of U937/PR9 cells with Zn^{2+} for 24 h induced an increase in TF (3.3 ± 1.0 – fold, mean ± SD) and in TNF (4.8 ± 1.1 – fold). Treatment of NB4 cells with ATRA reduced TF and TNF mRNA (by 95 ± 2% and 86 ± 3%, respectively), but increased IL1b mRNA. Inhibition of TNF reduced TF expression by 50%, whereas inhibition of IL1b had only a modest effect (< 20% reduction). Inhibition of the inflammatory signaling protein NFkB reduced TF mRNA and TNF mRNA (by 65 ± 10% and 78 ± 14%, respectively), whereas inhibition of p38 reduced TF mRNA (at a maximum by 38 ± 11%) and rather increased TNF mRNA. The maximal inhibitory effect of NFkB inhibition was attained within 30 min.

Conclusions: The PML- RARα fusion protein is responsible for an increased expression of TNF and TF by APL cells. ATRA-mediated differentiation of APL cells strongly reduces expression of TNF and TF. At least part of the elevated TF in APL cells seems to be due to an autocrine inflammatory stimulation by TNF, but not by IL1b. Inhibition of the signaling intermediate NFkB rapidly reduces TF and TNF expression. Clinically, inhibition of inflammatory signal transduction should be investigated as an adjunctive therapy to further reduce hemorrhagic complication in APL in the early treatment phase.

PB 1.56-3

Disulfide reduction abolishes tissue factor cofactor function

Butenas S, Krudysz-Amblo J, Jennings ME, Knight T, Matthews DE and Mann KG

University of Vermont, Colchester, VT, USA

Background: Tissue factor (TF), an *in vivo* initiator of blood coagulation, is a transmembrane protein and has two disulfides in the extracellular domain. The integrity of one cysteine pair, Cys186-Cys209, has been hypothesized to be essential for an allosteric 'decryption' phenomenon, presumably regulating TF procoagulant function, which has been the subject of a lengthy debate. The conclusions of published studies on this subject are based on indirect evidences obtained by the use of reagents with potentially oxidizing/reducing properties.

Aim: To evaluate the influence of disulfides on the TF co-factor function.

Methods: The status of disulfides in recombinant TF_{1-263} and natural placental TF in their non-reduced native and reduced forms (with or without alkylation) was determined by mass-spectrometry. Activity-based assays were performed to assess TF cofactor function and immunoassays were used to evaluate TF binding to factor VIIa.

Results: In native proteins, all four cysteines of the extracellular domain of TF are oxidized. Upon reduction, TF retains factor VIIa binding capacity but completely loses the cofactor function in both a membrane-independent fluorogenic assay using a low molecular weight synthetic substrate and a membrane-dependent extrinsic factor Xase.

Conclusion: The reduction of TF disulfides (with or without alkylation) eliminates TF regulation of factor VIIa catalytic function.

PB 1.56-4

Perioperative plasma tissue factor levels in patients with advanced coronary heart disease and heart failure subjected to off-pump coronary bypass grafting

Sovershaev M[1], Sovershaev T[2], Egorina E[1], Sovershaeva S[3], Gubkina V[3], Hansen JB[1] and Sovershaev M[1]

[1]University of Tromsø; [2]University Hospital of North Norway, Tromsø, Norway; [3]Northern State Medical University, Arkhangelsk, Russian Federation

Background: Disturbances in the coagulation system after coronary bypass grafting (CBG) surgery is a major cause of perioperative mortality. In circulation, tissue factor (TF), a major initiator of blood coagulation, is found on the surface of activated monocytes and as a soluble protein in plasma. To date, levels of soluble TF in patients with advanced coronary heart disease (CHD) subjected to off-pump CBG has never been assessed.

Aims: We wanted to investigate plasma TF before and after CBG surgery.

Methods: The study has been approved by the institutional committee on the research ethics. Twenty eight patients with established three-vessel CHD were initially enrolled in the prospective study after the informed consent has been obtained. Twelve patients withdrew there participation, two patients were lost to follow up. Patients did not receive anticoagulants or platelet inhibitors for a minimum of 3 days prior to surgery. Blood samples were collected 2 days prior to, 1 and 17 weeks after surgery. Plasma TF levels were measured using ELISA kit (Hyphen BioMed, France), as well as plasma pro-BNP, NYHA heart failure functional class, left ventricle ejection fraction (LVEF), end diastolic volume (LVEDV), end systolic volume (LVESV) were assessed at the same times. Multiple regression analyses were performed between variables, group means were compared using t-test, two-sided $P < 0.05$ were considered significant. Data are presented as percentages, or mean ± SEM.

Results: The study included 11 males and three females aged 56.0 ± 7.9 years, with following distribution of NYHA classes (I-IV): 21.4%, 64.3%, 7.1%, 7.1%, respectively, prior to surgery (2.0 ± 0.2 on average), and 71.4%, 21.4%, 7.1%, and 0%, respectively, at 17 weeks postop (1.4 ± 0.2 on average). Average preop levels of plasma TF were 102.1 ± 8.5 pg/mL and were 133.3 ± 27.5 pg/mL in NYHA I patients, 96.9 ± 7.1 pg/mL in NYHA II, and 78.5 ± 20.7 pg/mL in NYHA III/IV, with a strong negative correlation between preop NYHA class and plasma TF levels ($R = -0.568$, $P = 0.034$). Preop LVEF, LVESV, LVEDV and pro-BMP levels correlated well with NYHA class. After surgery, TF plasma levels temporarily decreased to 87.0 + 5.2 pg/mL ($P > 0.05$) after 1 week and came back to the preop levels after 17 weeks postop. Noteworthy, we found strong positive correlation between plasma TF levels prior to surgery with plasma TF levels 1 week postop ($R = 0.671$, $P = 0.009$) and 17 weeks postop ($R = 0.737$, $P = 0.003$).

Conclusions: Preoperative values of plasma TF correlates well with short-term and long-term postoperative TF values as well as clinical parameters of heart failure in patients with advanced CHD subjected to CBG surgery.

PB 1.56-5

Eicosapentaenoic acid and docosahexaenoic acid suppress the release of tissue factor as cell-derived microparticles, from cancer cell lines

Xiao Y, Collier MEW, Harley MA, Ettelaie C, Hardege JD and Maraveyas A

The University of Hull, Hull, UK

Background: Recent studies suggest that treatment of cancer patients with the polyunsaturated omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) may have beneficial influence. EPA and DHA have been reported to downregulate pro-inflammatory and pro-angiogeneic factors and have been shown to inhibit the growth of cancer cells *in vitro*. Cell derived microparticles have been implicated in the pathogenesis of a number of chronic diseases and in particular, tissue factor (TF)-bearing microparticles have been implicated in the promotion of cancer-related venous thromboembolism. However, the beneficial potential of EPA and DHA treatment on the release of TF as cell derived microparticles has not been investigated.

Aim: In this study, we have examined the influence of EPA and DHA supplementation on the release of TF-microparticles and the associated procoagulant activity in cancer cell lines from five different tissues.

Methods: Five cells lines representing pancreatic (AsPC-1), breast (MDA-MB-231), colocarcinoma (Caco-2), ovarian (SKOV-3) and melanoma (A375) cancers were cultured in the recommended complete media and were supplemented with EPA (0–90 mg/mL) or DHA (0–60 mg/mL). The conditioned media were harvested at intervals for up to 7 days. Microparticles were isolated from the conditioned media by ultracentrifugation and the density of microparticles determined using the Zymuphen microparticle assay. Microparticles were resuspended in PBS and the microparticle-associated TF antigen and activities were measured using an ELISA and a thrombin generation assay, respectively. Cell numbers were determined by crystal violet staining. Total cell surface TF antigen was analysed by flow cytometry and ELISA. Analysis of the incorporation of EPA and DHA into the cells and microparticle membranes was carried out by tandem gas chromatography-mass spectroscopy.

Results: Incubation of cells with a low dose of EPA (30 μg/mL) or DHA (10 μg/mL) resulted in increased release of microparticles from all the cells examined. In contrast, both the total concentration of the released TF and the adjusted values, calculated as the ratio against the respective microparticle densities, were reduced in the majority of the cell line examined. Treatment of cells with EPA or DHA also resulted in the suppression of cell proliferation in an EPA/DHA concentration-dependent manner, in all the cell lines tested. Furthermore, the reduction in cell numbers correlated with the amount of EPA and DHA incorporated into cell membrane but was cell-type dependent. However, increased levels of cell death, together with augmented TF release were observed at higher concentrations of omega-3 fatty acids.

Conclusions: Our studies suggest that omega-3 fatty acids may have anti-inflammatory properties which may in turn alter the procoagulant potential of cancer cell-derived microparticles. Our findings agree with previous data suggesting that these fatty acids may also be anti-proliferative, and at higher concentrations they may induce cell death. Throughout this study, we have used concentrations of fatty acids which encompassed those that may be detected as a consequence of an omega-3-rich diet. Therefore, omega-3 fatty acids may have an anti-inflammatory influence which may be helpful in the prevention of thromboembolism in susceptible individual including cancer patients.

Plasma tissue levels and risk factors for cardiovascular disease in the cancer (EPIC)-Italy cohort

Iacoviello L[1], Agnoli C[2], Guarrera S[3], Krogh V[2], Mattiello A[4], Matullo G[3], Panico S[4], Sacerdote C[5], Tumino R[6], Vineis P[7], Lorenzet R[1] and Donati MB[1]

[1]Catholic University, Campobasso; [2]National Cancer Institute, Milano; [3]Human Genetic Foundation HuGef, Torino; [4]Federico II University of Naples, Napoli; [5]Cancer Prevention Centre (CPO) Piemonte, Torino; [6]Cancer Registry ASP, Ragusa, Italy; [7]Imperial College, London, UK

Background: Tissue factor activity has been associated with risk factors for cardiovascular disease. However few studies have evaluated such an association for circulating levels of TF. We evaluated the association between plasma TF and risk factors for cardiovascular disease in a random subcohort of four out of five of the (EPIC)-Italy cohort.

Materials and Method: We measured TF in 834 men and women, in citrate plasma samples collected at baseline (1993–1997) and stored in liquid nitrogen.

TF levels was measured by ELISA (IMUBIND, TF ELISA, Instrumentation Laboratories, Milan, Italy). The association between TF levels and cardiovascular risk factors was evaluated by linear regression and expressed as β and 95% CI.

Results: The levels of TF in our cohort of apparently healthy subjects ranged from 0.070 to 2318.0 pg/mL (median: 310.7, interquartile range: 192.2–491.2 pg/mL). TF levels were significantly lower in women (β −131.62; 95%CI −174.36, −88.88) and they were inversely associated with HDL-cholesterol (β −3.19; 95%CI −4.91, −1.47)) and positively associated with triglycerides (β 0.76; 95%CI 0.43, 1.10), insulin (β 5.63; 95%CI 2.52, 8.73) and waist circumference (β 3.19; 95%CI 1.39, 5.00).

Conclusions: Our data further support the evidence for a link between TF levels and risk factors for cardiovascular disease in the population. High TF levels could represent a link between metabolic risk and cardiovascular disease.

PB 1.57-1

Dysfibrinogenemia associated with obstetric complications in four unrelated female patients

Zhou J[1], Jiang L[2], Ding Q[3], Xi X[2], Wang X[3] and Wang H[2]

[1]Shanghai Institute of Hematology, Ruijin Hospital; [2]Shanghai Institute of Hematology; [3]Ruijin Hospital, Shanghai, China

Background: Women with dysfibrinogenemia are at risk of vaginal bleeding, recurrent miscarriages, placental abruption, fetal death, postpartum haemorrhage and so on, although the incident rate is relatively lower than that in women with afibrinogenemia or hypofibrinogenemia.

Aims: Our study is to investigate the obstetric complications occurred in four unrelated female patients with dysfibrinogenemia.

Methods: The antigen level (Fg:Ag) and activity level (Fg:C) of fibrinogen in plasma of the patients were detected by immunoturbidimetric assay and clauss assays, respectively. Thromboelastogram (TEG) test was performed to evaluate the comprehensive coagulation status of patients. PCR amplification and direct sequencing technology were used to identify the mutations in these patients. Aα, Bβ and γ chains of fibrinogen were detected by Western blot. Fibrinogen polymerization and fibrinolysis measurement were applied to evaluate the function of fibrinogen in patients.

Results: Proband A experienced vaginal bleeding twice during her pregnancy, while proband B had indication of threatened premature labor. Proband C, gravida 2 para 1, suffered fetal death after her seven-month pregnancy and proband D, gravida 4 para 1, underwent

fetal death and abnormal embryo growth throughout her life. Fg:C in them were 0.57, 0.84, 0.22 and 0.46 g/L, respectively. The ratio of Fg:C and Fg:Ag was < 0.5 in all four probands, so they were diagnosed as dysfibrinogenemia. Since Fg:Ag in proband C was < 1.5 g/L, so she was diagnosed as hypodysfibrinogenemia. CI value in TEG test in proband A and B were both within the normal reference range, while that in proband C and D were lower than the low limit of normal reference range, with the value of −13.1 and −6.3, respectively, which was consistent with their severe clinical manifestations. Heterozygous AαArg16Cys, AαPro18Leu, γAla327Thr and γTrp208Leu were identified in four probands, respectively. Western blot showed normal molecular weight of three chains in probands except proband C, who had abnormal glycosylated γ chain caused by γAla327Thr mutation. In the fibrinogen polymerization measurement, the take-off time of proband A, B and D was prolonged compared to that of normal pooled plasma, suggesting impaired fibrinogen polymerization caused by these mutations. Fibrinolysis rate in these four probands was much slower than that in normal pooled plasma. At the end of fibrinolysis test, only the fibrin formed by proband D can be dissolved completely with the addition of plasminogen and uPA, with the dissolving rate of 100%, while it was 20.8% and 26.7% in proband A and B respectively, and 0% in proband C, indicating the fibrinolysis defects in them.

Conclusion: Dysfibrinogenemia patients caused by heterozygous AαArg16Cys, AαPro18Leu, and γTrp208Leu mutations may have obstetric complications due to impaired fibrinogen polymerization, while γAla327Thr mutation may lead to the generation of insoluble embolus, causing fetal death during pregnancy in affected women. TEG was applied in our study, first highlighting its sensitivity and accuracy in predicting the severity of obstetric complications and its vital role in guiding the replacement therapy in pregnant women with dysfibrinogenemia.

PB 1.57-2

Optimisation of fibrin clot microstructure: mechanical and microstructural properties of fibrin clots, from incipiency to the acquisition of haemostatic functionality

Hawkins KM[1], Chernysh I[2], Curtis DJ[1], Badiei N[1], Brown R[1], Evans A[1], Lawrence MJ[1], Weisel J[2] and Williams R[1]

[1]Swansea University, Swansea, UK; [2]University of Pennsylvania School of Medicine, Philadelphia, PA, USA

Background: Fractal analysis of the mechanical properties of whole-blood clots provides a method of quantifying clot microstructure of the incipient clot in terms of a fractal dimension, *df*, which can be used as a functional biomarker of haemostasis [1]. A recent haemorheological study of healthy volunteers (n = 52) showed a narrow range of d_f for healthy blood (= 1.74 ± 0.04) and significant correlations of d_f ($P < 0.005$) with fibrinogen concentration [2].

Aims: The aims of the present study were to investigate the possibility that the narrow range *df* encountered in healthy volunteers represents a highly efficient mechanism of clot assembly, in terms of the amount of polymerised mass required to establish a functional network capable of achieving haemostatic functionality.

Methods: Concurrent rheological measurements and Confocal Laser Scanning Microscopy (CLSM) were performed on fibrin gels formed by polymerisation of Fibrinogen (10 mg/mL) in the presence of a range of thrombin (0.02–0.2 NIH Units/mL). The latter technique provides the high speed imaging during fibrin network formation necessary for real time visualization of microstructure during the early stages of polymerization and provides assessments of the instant at which the fibrin networks acquire sufficient mechanical rigidity to withstand motion (i.e. become static).

Results: The incipient clot formed at 0.02 NIH/mL is characterized by the lowest value of *df* (1.82), indicating that its fibrin network is relatively open and tenuous whereby the incipient gel formed at 0.2 NIH/mL is characterized by a higher value of *df* (2.03), indicating the formation of a far tighter, more densely structured fibrin network. Assessment of the CLSM images showed that, in the case of high thrombin levels, approximately 95% of the mass required to perform haemostatic functionality is present at incipiency. This is in stark contrast to clots formed at low thrombin levels, where < 20% of the mass required to perform haemostatic functionality is present at incipiency. In the latter, it is evident that a significant part of the incipient clots rapid growth is attributable to its ability to scavenge additional polymerized mass by incorporating adjacent, pre-existing clusters.

Conclusions: The clots formed at relatively low levels of thrombin may represent the optimal mechanism for the efficient construction of a functional clot insofar as (i) the incipient clot can be established in the most parsimonious manner in terms of the polymerized mass required and (ii) the clot is capable of rapid enhancement to attain sufficient elasticity to withstand motion. Large levels of thrombin result in incipient clots which are relatively inefficient, in the sense that their production involves the incorporation of extravagant amounts of mass and results in extravagant levels of elasticity. The consequences of such clots forming must be assessed in terms of their resistance to lysis and fluid mechanical stresses.

PB 1.57-3

Investigation of exogenous fibrinogen substitution on fibrinogen synthesis in a chronic pig model of blunt liver injury

Zentai C[1], Van Der Meijden PEJ[2], Rossaint R[1], Ten Cate H[2], Spronk HMH[2] and Grottke O[1]

[1]RWTH Aachen University Hospital, Aachen, Germany; [2]Maastricht University Medical Center, Maastricht, The Netherlands

Background: The early application of fibrinogen concentrate has been shown to be effective to reduce blood loss in trauma-induced coagulopathy. As fibrinogen is an acute phase protein with proinflammatory properties, a potential influence of exogenous fibrinogen substitution on endogenous fibrinogen synthesis may have important consequences for immune response.

Aims: In a coagulopathic pig model with blunt liver injury we investigated the effects of fibrinogen substition on endogenous fibrinogen synthesis over 24 h.

Methods: After local ethical approval this study was performed in 20 anaesthetised male pigs. After cannulation, haemorrhagic shock and grade III blunt liver injury were induced. A 10 min shock phase was followed by re-transfusion of washed red blood cells to avoid early death from severe anaemia. Subsequently animals were randomized to receive either fibrinogen (100 mg/kg; F-group, n = 10) or normal saline (NF-group, n = 10). Plasma fibrinogen (both Clauss method and porcine specific ELISA), synthesis of fibrinogen mRNA (rtPCR from liver tissue), thromboelastometry (ROTEM), and thrombin generation were monitored for 24 h and blood loss was measured. Statistical analysis was performed using ANOVA with Tukey *post hoc*. A $P < 0.05$ value was considered as statistically significant.

Results: Haemorrhagic shock and trauma caused a significant alteration of coagulation parameters, as indicated by a prolongation of ROTEM clot formation (baseline: 45 ± 9 s; post-injury: 130 ± 21 s) and prothrombin time (baseline: 9 ± 1 s; post-injury: 18 ± 2 s). Correspondingly, clot strength (baseline: 72 ± 4 mm; post-injury: 48 ± 4 mm) and concentrations of fibrinogen (baseline: 150 ± 28 mg/dL; post-injury: 43 ± 5 mg/dL) were significantly reduced ($P < 0.05$ for all). The substitution with fibrinogen restored clot strength (63 ± 3 mm), shortend clot formation time (70 ± 11 s) and was associated with reduced blood bloss (1062 ± 216 mL) compared to

non-treated animals (1643 ± 244 mL, $P < 0.05$). Although fibrinogen supplementation initially increased plasma fibrinogen levels (Clauss-method) as expected, a significant decline in plasma fibrinogen was observed in the 360 min following fibrinogen administration, although major blood loss was already terminated 120 min post-injury. Correspondingly, the mean difference in fibrinogen levels between treated and non-treated animals decreased over time. In contrast, both ELISA and rtPCR analysis revealed an increase of fibrinogen (starting 6 h post-inury) and mRNA levels (starting 2 h post-injury), respectively. The levels of the proinflammatory cytokines, interleukin-6, and tumor necrosis factor-α showed a modest increase over time, but did not significantly differ between the groups. Aside, only small effects of fibrinogen on thrombin generation were detected.

Conclusions: The substitution of exogenous fibrinogen has no impact on endogenous synthesis of fibrinogen nor on the inflammatory response, and is not associated with adverse events. Despite termination of major bleeding the constant gradual reduction in plasma concentrations of fibrinogen over time suggests that exogenously provided fibrinogen might be metabolised. The clinical importance and the pathway of clearance need further investigations.

PB 1.57-4

Effects of homocysteine-thiolactone on fibrin networks

Genoud V[1], Lauricella AM[2], Kordich L[2] and Quintana I[3]
[1]Quintana, Irene, Facultad de Ciencias Exactas y Naturales, UBA; [2]Facultad de Ciencias Exactas y Naturales, UBA; [3]Facultad de Agronomía, Universidad de Buenos Aires, Buenos Aires, Argentina

Background: Hiperhomocysteinemia has been proposed as an independent risk factor for vascular disease. Non enzymatic chemical reactions between biological molecules and homocysteine or homocysteine-thiolactone (HTL) are named S or N-homocysteinylation. HTL reacts with proteins by acylation of free basic amino groups; in particular, the epsilon-amino group of lysine residues form adducts and induces structural and functional changes in plasma proteins.

Aim: To study the effects of HTL on plasma fibrin networks.

Methods: Normal human plasma was incubated with HTL solutions (final concentrations: 0 – 100 – 500 and 1000 μM); 18 h, 37 °C. Saline solution was used as control. Determinations of protrombin time (PT), activated partial tromboplastin time (APTT) and thrombin time (TT) were assayed according to established methods. In order to perform fibrinoformation studies, clots were generated by adding thrombin (0.05 IU/mL) and calcium chloride (20 mM) to the preincubated plasma. The kinetics was evaluated measuring optical density (OD) at 405 nm every 1 min up to constant values. Assays were carried out in polystyrene strips. The sigmoid curves obtained (OD vs. time) were characterized by three parameters: lag phase, maximum velocity achieved and final network OD. All assays were performed in quadruplicate. Suitable fibrin networks were evaluated by electronic microscopy. Each network was characterized measuring number of fibers per field, network percentage (ratio between total surface of the fibers and the total field area x 100), and width and length of the fibers.

Results: HTL significantly prolonged global coagulation tests in concentration dependent manner respect to control. For HTL (1 mM) the increases were 7.3%, 14.5% and 7.2% for PT, APTT and TT respectively. Fibrinformation kinetic parameters showed statiscally significant differences between HTL treated plasma respect to control in concentration dependent manner. In particular, with HTL 1 mM, lag phase: 19.30 ± 0.88 vs. 11.58 ± 0.22 min; V_{max}: 0.044 ± 0.005 vs. 0.087 ± 0.004/min and final network OD: 0.884 ± 0.009 vs. 0.939 ± 0.011; in all cases, $P < 0.01$. Electronic microscopy analysis showed that HTL related networks were more compact (network%: 81 ± 7 vs. 63 ± 8; number of fibers/field: 61 ± 7 vs. 39 ± 4) and shorter than control (length: 0.82 ± 0.20 μm vs. 2.87 ± 0.83 μm). No significant differences in fibers width were observed.

Conclusions: N-homocysteinylation process modifies the structure of fibrin networks and alters the kinetics of fibrin formation.

PB 1.57-5

The clinically asymptomatic dysfibrinogenemia (FGG H103N) is associated with abnormal polymerization but no thrombin generation impairment

Hanss M[1], Devignes J[2], De Mazancourt PH[3] and Ffrench P[1]
[1]Hospices Civils de Lyon, Bron; [2]CHU Nancy, Vandoeuvre-les-Nancy; [3]Université de Versailles St-Quentin, Versailles, France

Background: Dysfibrinogenemia is a rare disease characterized by an abnormal fibrinogen present in plasma with a normal amount but an abnormal function. It is due to occurrence of a mutation of one of the three coding genes, FGA, FGB and FGG. Moreover fibrinogen has been shown to potentiate thrombin generation when using a fluorogenic thrombin substrate (Hemker HC and coll., Pathophysiol Haemost Thromb 2003).

Aims: To look for potential implication of fibrin polymerization in the facilitating effect of fibrinogen on thrombin generation in a new case of dysfibrinogen.

Methods: Plasma fibrinogen was measured by Clauss functional and immunonephelometric assays. Fibrinogen was extracted from plasma by Kazal precipitation and further studied by SDS PAGE, fibrinopeptide liberation by thrombin, repolymerization of fibrin monomers, facilitating effect on thrombin generation. For this last technique, the thrombin generation was evaluated by calibrated automated thrombinography in presence of fibrinogen depleted normal plasma, 1 g/L patient fibrinogen, 4 μM phospholipids and 5 pM tissue factor.

Results: A case of familial dysfibrinogenemia was discovered in a 9-year old patient presenting on emergency ward with a Human Herpes Virus 6 infection. Symptoms (fever and lymphopenia, late cutaneous eruption) were spontaneously regressive. A clear discrepancy was found between decreased plasma coagulable fibrinogen concentration (0.60 g/L, normal values = 1.8–4.1 g/L) and antigenic concentration (2.9 g/L, 1.80–3.5 g/L). These values were confirmed several months after initial diagnosis and found also in the mother. APTT and PT were slightly prolonged; reptilase time was prolonged over 120 s. None of both affected family members presented any thrombotic or hemorrhagic features, even following several dental extractions for the child and a breast surgery for the mother. Sequence analysis revealed a heterozygous C2587>A mutation of the gene coding for the gamma chain (FGG) in both affected family members, leading to a p.H129N mutation in the native protein (His103Asn in the circulating protein). Gamma chain appeared as a duplicate on electrophoresis under reducing conditions, with similar amounts for each band. Fibrinopeptide liberation was found normal. However patient's fibrin monomers were not able at all to repolymerize as compared to controls. The effect of extracted fibrinogen on thrombin generation was similar to controls.

Summary/Conclusions: A case of gamma chain mutation has been found in an asymptomatic patient and his asymptomatic mother. It is associated to the expression of two gamma chains found in plasma with similar amounts. The heterozygous mutation is awaited to change a His by an Asn in the coiled coil portion and give rise to a NXS sequence, a potential new glycosylation site (asparagine-X-serine). Such a glycosylation could explain the clear electrophoretical mobility difference. The only noticed functional impairment is a deficient monomer repolymerization, as often found in case of gamma chain impairment. It could be due to abnormal steric interactions of monomers with each other. The normal capacity of dysfibrinogen to enhance thrombin generation is not in favour of a role of monomer polymerization in facilitating thrombin generation.

PB 1.57-6

A new automated D-Dimer assay optimized for minimizing interferences to heterophilic antibodies

Esteve F

Diagnostica Stago, Gennivilliers, France

D-Dimers are the terminal products of stabilized fibrin degradation. D-Dimer assays represent an important aid in the diagnosis of the exclusion of venous thromboembolic disease. Immunoassays, which are commonly used in diagnostic testing, may be prone to interferences with heterophilic antibodies when present in patient plasma.

The prevalence of these interferences with D-Dimer assays in the diagnosis of VTE is low but may cause an overestimation of the result.

The new STA® – Liatest® D-Di PLUS has been developed, based on the same formulation as the well-known STA® – Liatest® D-Di with an improvement aimed at minimizing these interferences.

The dosage buffer includes a blocking agent targeting heterophilic antibodies, therefore minimizing the interference toHAMAand eliminating the interferences to Rheumatoid Factor (RF) up to 1000 IU/mL.

The level of RF which does not interfere has been determined with plasma RF levels to be < 1000 IU/mL. This limit has been confirmed based on a regression study using serial dilutions of plasma with RF using a plasma pool with a D-Dimer concentration of 1.0 µg/mL FEU. Four patient plasmas of known RF concentration were also analyzed and correlated using an ELISA assay (which is insensitive to RF) and STA®-Liatest® D-Di Plus.

In addition, a correlation study on 200 plasmas with D-Dimer levels ranging from 0.28 to 18.21 µg/mL FEU has been carried out with STA®-Liatest® D-Di PLUS and STA®-Liatest® D-Di. Results obtained are as follow: $r = 0.998$, slope = 1.006 and intercept = −0.057.

In conclusion, the STA® – Liatest® D-Di PLUS performs as well as STA® – Liatest® D-Di with additional benefits as it is insensitive to rheumatoid factor levels up to 1000 IU/mL.

PB1.58 – Other Coagulation Factors – I

PB 1.58-1

A platelet-targeted factor VIIa. XTEN fusion protein with increased circulating half-life and improved clotting activity

Tan S[1], Salas J[1], Chen K[1], Kistanova E[1], Ashworth T[1], Acosta M[1], Johnson B[1], Pape B[1], Pierce GF[1], Light D[1], Mei B[1], Schellenberger V[2], Peters RT[1] and Jiang H[1]

[1]Biogen Idec Hemophilia, Waltham, MA; [2]Amunix Inc., Mountain View, CA, USA

Background: Recombinant activated factor VII (rFVIIa) is used for treatment of bleeding in hemophilia A and B patients with inhibitors. Because of its short circulating half-life of 2–3 h and low binding affinity to activated platelets, rFVIIa is primarily limited to on-demand treatment and often requires repeated dosing for efficacy. A long-lasting and more potent form of rFVIIa will significantly improve the clinical management of hemophilia patients with inhibitors and the prevention and treatment of bleeding episodes.

Aims: To develop a rFVIIa variant using a strategy that combines half-life extension and activity improvement. The approach is to extend the circulating half-life of rFVIIa by fusing with XTEN, a hydrophilic and unstructured polypeptide that increases the hydrodynamic radius of proteins, while enhancing the coagulation activity by targeting it to platelets with a single chain fragment variable region (scFv) that binds to receptor αIIbβ3 with high affinity.

Methods: rFVIIa variants were expressed in HEK293 cells by transient transfection and purified from conditioned media. The clotting activity of purified rFVIIa variants was measured by soluble tissue factor-dependent prothrombin time (sTF-PT) assay, thrombin generation assay (TGA), and rotational thromboelastometry (ROTEM). The pharmacokinetics in hemophilia A mice was determined using sTF-PT assay. Effect of rFVIIa variants on human platelet clearance was evaluated in human platelet transfused NOD/scid/gamma (NSG) mice.

Results: rFVIIa-$XTEN_{288}$, which was produced by recombinantly fusing the XTEN sequence of 288 amino acids into rFVIIa, was found to have a terminal half-life of about 9 h in hemophilia A mice, representing an 8-fold increase in half-life compared with rFVIIa. However, the activity of rFVIIa-$XTEN_{288}$, based on the whole blood ROTEM assay, was lower than that of rFVIIa. To improve its activity, we incorporated a platelet-targeting scFv into rFVIIa-$XTEN_{288}$. This scFv was derived from a monoclonal antibody that specifically recognizes the human platelet receptor αIIbβ3. When fused to rFVIIa, the scFv increased binding of the protein to platelets with no detectable effect on platelet activation and clearance *in vitro* and *in vivo*. Furthermore, we identified an optimal configuration that allows recombinantly fusing both the $XTEN_{288}$ and the platelet-targeting scFv into rFVIIa to obtain a platelet-targeted rFVIIa–XTEN fusion protein with enhanced binding to platelets, and more importantly, with a significant increase in clotting activity compared to rFVIIa, as measured by TGA and ROTEM assays.

Conclusions: Combining XTEN and platelet-targeting is a novel approach that results in marked improvements in both the circulating half-life and clotting activity of rFVIIa. Our results demonstrate the potential for developing a long-lasting, platelet-targeted rFVIIa suitable for both on–demand and prophylactic treatments of hemophilia A and B patients with inhibitors.

PB 1.58-2

Hepatocyte growth factor down-regulates protein C inhibitor expression in hepatocytes via MEK pathway

Akita N[1], Okamoto T[2], Nishioka J[3], Suzuki K[3] and Hayashi T[4]

[1]Suzuka University of Medical Science, Suzuka; [2]Mie University School of Medicine, Tsu; [3]Faculty of Pharmaceutical Sciences, Suzuka University of Medical Science, Suzuka; [4]Department of Biochemistry, Mie Prefectural College of Nursing, Tsu, Japan

Background: Protein C inhibitor (PCI), a member of the SERPIN family, inhibits an anticoagulant activated protein C (APC), which inactivates blood coagulation cofactors, factors Va and VIIIa in plasma. We have shown that PCI is expressed in various human tissues, including liver and kidneys, and suppresses the tumor infiltration by inhibiting urinary plasminogen activator (uPA), and tumor metastasis by inhibiting angiogenesis. Recently, we demonstrated that PCI also plays a role as an inhibitor for hepatocyte growth factor activator (HGFA), a factor XIIa-like serine protease, which is an activator of HGF precursor to HGF. HGF plays an important role in tissue repair and regeneration, and the precursor of HGFA (proHGFA) is activated by thrombin generated at the sites of tissue injury. Thus, PCI may control liver regeneration by regulating the activation of HGF precursor by means of the HGFA inhibition.

Aim: In this study, we investigated the effect of HGF on expression of proHGFA and PCI in hepatocytes.

Methods: Concentrations of proHGFA and PCI in culture medium of primary hepatocytes or HepG2 cells were measured using specific ELISA for each protein. PCI mRNA expression in HepG2 cells was evaluated by real-time PCR analysis. Binding of HGF to c-Met, a receptor of HGF on hepatocytes, was determined by Western blot analysis using antibody to phosphorylated c-Met. The signal transduction pathway related to the HGF-induced change of PCI expression in HepG2 cells was analyzed by measuring the PCI production using specific ELISA in the presence of HGF and inhibitors of signal transduction factors.

Results: HGF showed no effect on the proHGFA production in both primary hepatocytes and HepG2 cells, but it dose-dependently reduced

the PCI production in both cells by reducing the mRNA expression of PCI. Western blot analysis showed that HGF induces c-Met phosphorylation in HepG2 cells. The HGF-induced decreased expression of PCI in HepG2 cells was restored by MEK inhibitor, but not restored by NFκB inhibitor, nor by inhibitors of various signal transduction factors such as JUN kinase, and p38 MAP kinase.
Conclusion: The present study suggests that, in liver regeneration, HGF down-regulates the expression of PCI, an inhibitor of HGFA, by means of the phosphorylation of c-Met followed by the activation of MEK, to enhance the HGFA-mediated activation of HGF precursor, which may lead to further promotion of the hepatocyte regeneration.

PB 1.58-3

Quantitative whole body autoradiography (QWBA) study on the biodistribution of a recombinant factor rVIIa linked to human albumin

Herzog E[1], Harris S[2], McEwen A[2], Pragst I[1], Dickneite G[1], Schulte S[1] and Zollner S[1]
[1]CSL Behring GmbH, Marburg, Germany; [2]Quotient Bioresearch, Rushden, UK

Background: The recombinant fusion protein linking the human coagulation factor VIIa to recombnant human albumin, rVIIa-FP (CSL Behring GmbH), is currently undergoing clinical investigation in the clinical trial program PROLONG-7FP.
Aim: The present study was conducted to evaluate the effects of albumin fusion on the biodistribution of rVIIa-FP.
Methods: [^{3}H]-rVIIa-FP, [^{3}H]-rFVIIa or [^{3}H]-albumin, labeled using the N-Succinimidyl [2,3,-^{3}H] propionate (NSP) method, were administered intravenously to male rats at a single radioactive dose of approximately 400 μCi/kg. Using whole-body autoradiography (QWBA), tissue radioactivity was determined up to 24 ([^{3}H]-rFVIIa) or 240 ([^{3}H]-rVIIa-FP, [^{3}H]-albumin) hours (h). In addition to full body sections, the hind limbs were separately subjected to QWBA to obtain more detailed information on the products' distribution within the bone marrow and knee joint region. In parallel, plasma, urine and feces were collected at several time points throughout the observation period to calculate excretion balance and assess physiological elimination pathways. The radioactivity associated with the [^{3}H]-labelled proteins was determined by quantitative radiochemical analysis (QRA) and high performance liquid chromatography (HPLC). The radioactivity associated with plasma, urine and feces samples was also determined by QRA. Biological activity of rFVIIa and rVIIa-FP after [^{3}H]-labeling was confirmed measuring FVII activity by means of a chromogenic assay.
Results: For both proteins, [^{3}H]-rVIIa-FP and [^{3}H]-rFVIIa, the major route of elimination was urinary excretion accounting for approx. 80% of total. While 144 h were required for the urinary excretion of 72% of [^{3}H]-rVIIa-FP associated radioactivity, equal proportions of [^{3}H]-rFVIIa radioactivity could be recovered within 24 h, indicating accelerated clearance of [^{3}H]-rFVIIa compared to [^{3}H]-rVIIa-FP. However, the biodistribution profile of [^{3}H]-rVIIa-FP and [^{3}H]-rFVIIa were comparable, both distributing predominantly into well vascularized tissues and major metabolic organs with both proteins being rapidly present within the bone marrow. Analysis of the knee joint region also confirmed distribution of [^{3}H]-rVIIa-FP and [^{3}H]-rFVIIa to synovial and mineralized joint regions where they seemed to mostly localize to the zone of calcified cartilage within the growth plate regions of long bones. The longest retention time was observed in the bone marrow and endosteum of long bones. In contrast, the biodistribution of [^{3}H]-albumin appeared to be different with only very low initial penetration of bone marrow and liver but rapid, homogeneous distribution throughout the whole body including muscle, skin and connective tissue. While both [^{3}H]-rVIIa-FP and [^{3}H]-albumin were well detectable over 72 h after administration, comparable [^{3}H]-rFVIIa derived signals could only be observed up to 24 h further supporting the extended tissue half-life of [^{3}H]-rVIIa-FP due to albumin fusion.
Summary/Conclusion: Consequently, this study shows that rVIIa-FP exhibits biodistribution characteristics comparable to competitor products but clearly distinguishes itself by its extended plasma half-life and tissue retention potentially allowing a reduction in dosing frequency leading to increased convenience and compliance in haemophilia patients with inhibitors.

PB 1.58-4

Utilization of FXIII concentrates by FXIII deficiency patients in Canadian hemophilia treatments centers: 10 years national data from the canadian hemophilia assessment and resource management system

Traore AN[1], Chan AK[2], Warner M[2], Heddle N[1], Ritchie B[2], St-Louis J[2], Walker I[2] and Wu J[2]
[1]McMaster Transfusion Research Program, Hamilton, ON; [2]Association of Hemophilia Clinic Directors of Canada, Toronto, ON, Canada

Background: Factor XIII (FXIII) deficiency is a rare inherited bleeding disorder affecting both females and males. It is associated with a risk of life-threatening bleeds (intracranial hemorrhage); hence, infusions of FXIII concentrate for both prophylaxis and treatment of bleeds is recommended. The Canadian Hemophilia Assessment and Resource Management System (CHARMS) tracks the use of factor concentrates (FC) by patients in hospitals and at home.
Aim: To identify the number of patients with FXIII deficiency, FXIII concentrate usage and indications over a 10 years period.
Methods: All 26 Canadian Hemophilia Treatment Centres (HTCs) received infusion data from hospitals and patients' bleed diaries. HTCs export their local CHARMS data to the national CHARMS database (CentrePoint) which is validated and analyzed.
Results: From 2001 to 2010, data for 50 patients with FXIII deficiency (mild, moderate and severe) were sent to CHARMS CentrePoint. More than half (58%) were female and 21 patients (42%) had 10 years infusions data available. The number of patients increased from 26 in 2001 to 40 in 2010. Overall, 92% of patients (46/50) were registered in the Canadian Hemophilia Registry (CHR) at the time of the infusion; that number was at 98% by 2010. Over 10 years, these patients infused a total of 7,614,500 units of FXIII concentrates (*Fibrogammin P*®). The yearly total of units infused ranged from 992,750 in 2001 to 1,234,500 in 2005 (in large part due to immune tolerance induction in a single patient) then dropped to 435,750 in 2010. At 250 units per vial, the 2010 amount corresponds to 1743 vials for 40 patients. On average, pediatric patients used two vials per infusion for prophylaxis and one for bleeding whereas adults used respectively four and two. Infusions were mostly done for prophylaxis: 56–81% total units infused yearly; 80% in 2010. Only 1–4% of FXIII concentrates was infused for bleeding (maximum 7 patients a year). One patient had infusions for immune-tolerance in 2004, 2005 and 2006; the units infused corresponded respectively to 35%, 37% and 19% overall units infused by all patients.
Conclusion: This analysis showed that these FXIII deficiency patients were mostly infused with FXIII concentrates for prophylaxis as recommended. The single digit proportions of amount infused for bleeding seems to indicate that few patients have bleeding episodes each year. The longitudinal follow up of FC utilization by these rare bleeding disorder patients was possible because of the combination of the national registry (CHR) and FC tracking system (CHARMS).

PB 1.58-5

Ex vivo factor XIII supplementation dose-dependently improves clot stability in blood samples from cardiac and scoliosis surgery patients

Carling MS[1], Shams Hakimi C[2], Brisby H[1], Radulovic V[3] and Jeppsson A[2]

[1]*Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg;* [2]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg;* [3]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: Excessive blood loss remains a significant problem during and after major surgical procedures. Factor XIII (FXIII) contributes to clot stability and it has therefore been suggested that supplementation with FXIII concentrate may be used clinically to improve perioperative hemostasis. However, little is known about the functional effects of FXIII supplementation in surgical patients and the relationship between dose and response. Furthermore it is not known if potential effects are maintained when FXIII is combined with other prohemostatic blood products.

Aims: We assessed the effects of increasing doses of FXIII on clot formation, – alone or in combination with fibrinogen or platelets, in blood samples from two distinctly different surgical populations, cardiac and scoliosis surgery patients.

Methods: Whole blood samples were collected immediately after surgery in cardiac surgery patients (n = 6) and scoliosis surgery patients (n = 6). All blood samples were supplemented with three increasing, clinically relevant doses (+20, +40 and +60%) of plasma-derived FXIII concentrate (Fibrogammin^{O}, CSL Behring, Marburg, Germany) alone or in combination with a fixed dose of fibrinogen concentrate (+1.0 g/L) (Riastap^{O}, CSL Behring) or fresh apheresis platelets (+92 $\times$ 10^9/L) from the institutional blood bank. Clot formation was assessed with modified rotational thromboelastometry (ROTEM®) with FIBTEM maximum clot firmness (MCF) and EXTEM clotting time (CT).

Results: Cardiac surgery patients were markedly older and had higher BMI than scoliosis patients. Postoperative platelet count was lower in cardiac surgery patients (136 $\pm$ 32 vs. 233 $\pm$ 54 $\times$ 10^9/L, P = 0.004), while fibrinogen levels (2.8 $\pm$ 0.5 vs. 2.0 $\pm$ 0.4 g/L, P = 0.019) and FXIII activity was higher (82 $\pm$ 13% vs. 62 $\pm$ 9%, P = 0.013).

Despite differences in preoperative and postoperative variables, supplementation with FXIII had comparable effects on clot formation in postoperative samples from cardiac and scoliosis patients. FXIII alone caused a dose-dependent increase in FIBTEM-MCF in both cardiac surgery patients (+17% (10–25) with the highest dose (median and interquartile range), P = 0.028) and in scoliosis patients (+24% (14–33), P = 0.028) (P = 0.71 between groups). EXTEM-CT tended to decrease in both cardiac and scoliosis surgery patients when FXIII was added (P = 0.07 both).

The effect on FIBTEM-MCF was markedly more pronounced when fibrinogen was added to FXIII (+133% (88–150) for cardiac patients and +150% (140–166) for scoliosis patients, P = 0.028 both, P = 0.69 between groups). The dose-response effect of FXIII on FIBTEM-MCF was sustained also when fibrinogen was added. As expected, addition of platelets to FXIII did not influence FIBTEM-MCF. EXTEM-CT was shorter when fibrinogen or platelets was added to FXIII compared to supplementation with only FXIII. No dose-response effect of FXIII on EXTEM-CT could be detected in the presence of fibrinogen or platelet concentrates.

Conclusions: Ex vivo supplementation with clinically relevant doses of FXIII dose-dependently improved clot stability in blood samples from different groups of surgical patients, both when given as monotherapy and in combination with fibrinogen. The effect of FXIII on clot stability and clot initiation was however markedly less pronounced than the effect of fibrinogen.

PB 1.58-6

Compositional differences in commercially available prothrombin complex concentrates

Fareed J[1], Sadeghi N[1], Kahn D[1], Cunanan J[1], Hoppensteadt D[1], Jeske W[1], Harenberg J[2] and DeChristopher Ph[1]

[1]*Loyola University Medical Center, Maywood, IL, USA;* [2]*University of Heidelberg, Mannhein, Germany*

Introduction: Prothrombin complex concentrates (PCCs) are used to manage bleeding complications with warfarin. Since PCC activation generates factor Xa and IIa, these agents may neutralize Xa and thrombin inhibitors. This study compared the composition of currently available PCC's.

Material and Method: Protein content of PCCs was measured using Lowry's method. SDS-PAGE and Western blot analysis was performed to determine the presence of prothrombin, prethrombin, and thrombin. Native and tissue factor activated prothrombin complexes were characterized using surface-enhanced laser desorption/ionization (SELDI) mass spectrometry. Tissue factor mediated thrombin generation by each PCC was studied using a fluorometric method (Technoclone, Vienna, Austria).

Results: The protein content of the PCCs ranged from 18 to 106 mg/100 U. SDS-PAGE showed multiple protein bands ranging from 15 to 250 kDa. Other PCCs contained bands ranging from 15 to 66 kDa representing albumin and other degradation products. SELDI analysis was consistent with the SDS-PAGE profile. The immunoblotting studies showed a major band 70–75 kDa (prothrombin) along with a 50 kDa band (prethrombin). Feiba® exhibited a distinct additional 37 kDa band (thrombin). SELDI analysis indicated varying amounts of prothrombin peaks. Thrombin was generated upon activation of all PCCs. Functional thrombin generation by each prothrombin complex was concentration dependant and ranged from 103 to 1044 nM/1.25 units/mL. Octaplex and Cofact produced the strongest responses whereas Beriplex and Prothromplex produced the weakest effects.

Conclusion: This study showed that at equivalent Factor IX unit potency, PCCs widely vary in their composition. Beriplex® and profilnine® were relatively purer preparations. Upon activation by tissue factor each PCC is capable of generating different amounts of thrombin. Thus, each of these products should be considered as a distinct drug and their efficacy individually determined in a given indication.

PB 1.59-1

Absence of variation in tissue factor and procoagulant phospholipid activity after plasmapheresis in lung transplantation patients

Vasse M[1], Bourrienne M-CH[1], François D[1], Parquin F[1], Van Dreden P[2], Fischler M[1], Woodhams B[3] and Vasse M[1]

[1]*Hôpital Foch, Suresnes;* [2]*Diagnostica Stago, Gennevilliers, France;* [3]*HaemaCom Ltd, Bromly, Kent, UK*

Background: Plasmapheresis (PPR) is commonly used to prevent humoral rejection in lung transplantation. The replacement of patient plasma by a human serum albumin solution is frequently used but causes transient deficiencies of coagulation factors, which could increase the hemorrhagic risk. Despite a marked decrease of coagulation factors in some cases [prothrombin time (PT) < 10% and fibrinogen < 0.1 g/L], none of the patients exhibited a hemorrhagic syndrome after PPR.

Aims: We postulated that procoagulant activity could counteract the decrease in coagulation factors. To test this hypothesis we measured tissue factor activity (TFa), the main trigger of coagulation, and procoagulant phospholipids (PPL) before and after PPR, along with

classical hemostasis tests – PT, activated partial prothrombin time (APTT), fibrinogen and D-dimers.
Methods: In 20 cases of PPR, PPL and TFa were measured. PPL activity was measured using a factor Xa-based coagulation assay in which shortened clotting times are associated with increased levels of PPL. TFa was measured in a one-stage kinetic chromogenic method. This assay measures the ability of TF-FVIIa to activate factor X to factor Xa. D-Dimers were quantified using an latex immunoassay.
Results: The median PPL level of 31 healthy volunteers was 68.4 s (range 51.2–84.2) and 0.25 pM/L for TFa (range 0.08–0.45). Before PPR, TFa and PPL activity was significantly higher ($P < 0.001$) than in healthy controls (0.76 pM/L and 44.4 s, respectively). PT, fibrinogen and D-dimer were significantly decreased after PPR and the APTT were prolonged, due to the plasma dilution. Median PT before PPR was 99%, post PPR 43%, $P < 0.001$. The median APTT ratio before PPR was 1.1, post PPR 1.78 ($P < 0.01$), median fibrinogen before PPR was 2.2 g/L, post PPR 0.74 g/L ($P < 0.001$) and median D-dimer before PPR was 0.7 μg/L, post PPR 0.4 ($P < 0.01$). The variations in TFa and PPL were not significant (TFa after PPR 0.4 pM/L, $P = 0.13$, PPL after PPR 45.1 s, $P = 0.84$).
Conclusion: The persistence of elevated levels of TFa and PPL post PPR could indicate injury of the vessel wall or stimulation of TF synthesis by the endothelium or the leukocytes. This could induce a procoagulant state which counteracts the absence of any hemorrhagic state despite the decrease in coagulation factors

PB 1.59-2
Activation of FXII-dependent coagulation pathway by hand heating

Skov J[1], Gram AS[1], Ploug T[2], Sidelmann J[1], Stallknecht BM[2] and Bladbjerg E-M[1]
[1]University of Southern Denmark, Esbjerg, Denmark; [2]University of Copenhagen, Copenhagen, Denmark

Background: In many studies of metabolic variables, 'arterialized' venous blood is used as a proxy for arterial blood. The arterialization is usually induced by heating of the hand, which opens arterio-venous shunts. The considerable overlap between metabolic disorders, inflammation and cardiovascular disease emphasizes the potential scientific and clinical interest to determine biomarkers of metabolism, inflammation and cardiovascular risk in the same setting. Nevertheless, the possible effect(s) of the arterialization process on cardiovascular biomarkers is still unknown.
Aims: We investigated whether arterialization of venous blood by hand heating affects selected biomarkers of inflammation, coagulation, fibrinolysis and endothelial function.
Methods: Venous blood samples were drawn from the cubital vein of 10 healthy, non-fasting volunteers after the subjects rested in the supine position for 20 min. Thereafter, the contralateral hand and wrist joint were covered for 10 min. with a heating pad, in order to generate arterialized venous blood, which was drawn from a dorsal hand vein. Concentrations of albumin, C-reactive protein (CRP), tissue-type plasminogen activator (t-PA), plasminogen activator inhibitor type 1 (PAI-1), and von Willebrand factor antigen (vWF) were measured in platelet poor plasma (2000 g at 4◦) by validated assays. Thrombin generation was determined by the calibrated automated thrombogram method.
Results: The average sO_2 in blood drawn from the heated hand into a preheparinized syringe was 91.8% (SD: 3.9%) and pO_2 64.5 mmHg (SD: 16.4 mmHg), demonstrating that an arterialization of venous blood took place. The concentrations of the liver-synthesized proteins albumin and CRP were slightly but significantly lower in arterialized than in venous blood (albumin: 43.8 and 44.8 g/L, $P = 0.02$), indicating that normal haemoconcentration was reduced by the arterialization process. Concentrations of t-PA and PAI-1 did not differ between venous and arterialized blood with or without adjustment for albumin concentration. The concentration of vWF was lower in arterialized than in venous blood, but the difference was no longer statistically different after adjustment for albumin concentration. The endogenous thrombin potential (ETP, area under the thrombin generation curve) was significantly higher in arterialized blood (1929 vs. 1872 nM*min, $P = 0.02$), and the difference became even more pronounced after adjusting for albumin concentration. When the FXIIa inhibitor Corn Trypsin Inhibitor (CTI) was added before the thrombin generation test, no differences in ETP were detected between arterialized and venous blood.
Conclusions: The present results suggest that arterialization of venous blood by hand heating induces less haemoconcentration compared to normal capillary perfusion. Thrombin generation was enhanced by the arterialization process, reflected as an increased ETP. Since this effect was eliminated in the presence of CTI, we suggest that hand heating activates the FXII-dependent coagulation pathway.

PB 1.59-3
Severe factor XII deficiency presenting as over-heparinisation prior to urgent cardiac surgery for a right atrial myxoma

Low J, Rebeiro P, Jarvis S and Joseph J
St Vincent's Hospital, Sydney, NSW, Australia

Background and Aims: FXII (Hageman Factor), the zymogen form of FXIIa, is a plasma serine protease considered to play no active role in physiological haemostasis. Recent literature suggests a potential role of FXII in pathological thrombosis. Here we present the case of a patient with an incidental finding of severe FXII deficiency and its implications in the setting of cardiopulmonary bypass surgery.
Methods and Results: A 51 year old female presented with dyspnoea, cough and impaired exercise tolerance. Echocardiogram demonstrated a right atrial myxoma. The patient was admitted to a local hospital prior to transfer for urgent cardiac surgery. She was commenced on a heparin infusion and her initial coagulation screen demonstrated a markedly prolonged APTT. This was initially thought to be due to over-heparinisation as a baseline APTT had not been conducted. However, repeated testing demonstrated a persistently prolonged APTT despite heparin cessation. She was then referred to our facility where further investigations were conducted. The APTT was > 150 s (reference interval 25–35 s). The thrombin time was normal which excluded heparin contamination. Mixing studies with pooled normal plasma demonstrated a correction of the APTT to 34s, suggesting the presence of a factor deficiency. Factor assays demonstrated a FXII level of < 5% (RI 60–150%) indicating a severe deficiency. A review of the literature suggested the use of the activated clotting time (ACT) to manage the heparinisation required for cardiopulmonary bypass (CPB). Baseline ACT was markedly prolonged at 906s. Two units of fresh frozen plasma (FFP) were administered, resulting in a correction of the ACT to 204s prior to a bolus of 70,000 units of heparin being administered for CPB. ACT was measured at 30 min intervals and was 999 s until the cessation of CPB. On the completion of CPB, 800 mg of protamine was administered resulting in an ACT of 204 s. In view of ongoing mild bleeding, a further 200 mg of protamine and 2 units of FFP were administered with a resulting ACT of 190s. The patient was warfarinised post operatively and discharged when stable. Six days following discharge she represented with a syncopal episode (INR 2.7) and was found to have a pericardial effusion with compression of the left ventricle. This was drained and a decision to cease warfarin at that time was made. Two months later she presented to her cardiologist and was found to have a pulmonary embolism.
Conclusion: This case demonstrates the complexity of managing intravenous heparin in patients with FXII deficiency and highlights the importance of performing baseline coagulation studies prior to anticoagulation, as well as the challenges in managing such a patient for CPB. The administration of FFP prior to surgery helped to normalise the ACT to a measurable level initially. This case further illustrates that there may be an increased risk of pulmonary embolism in patients with Factor XII deficiency.

PB 1.59-4

Spectrum of the factor XI mutations in Chinese population and TEG apply to patients with factor XI deficiency

Cao Y and Dong L

Shanghai Ruijin Hospital, Shanghai, China

Background: Factor XI deficiency is a mild tendency bleeding disorder with an autosomal heredity. There were found several mutations occur in particular ethnic groups.

Aims: Our research is to investigate the mutation spectrum of FXI in Chinese patients with FXI deficiency and analyze the TEG use in evulate the FXI deficiency patients' coagulation.

Methods: Thirty-seven unrelated patients from different places of China were enrolled in this study. We analyzed their clinical and coagulation features, and used direct sequencing of the whole FXI gene to figure out the mutations in these patients. Two patients were analyzed by TEG to evaluate their coagulation condition comprehensively. One, in particular, was monitored by TEG before and after a surgery under the infusion of FFP.

Results: Twenty-eight different sequence variants were found in 37 patients from non-consanguineous families with FXI deficiency, including 14 missense mutations、six nonsense mutations、six splice site mutations and two small deletions. These mutations concentrate on exons 7, 8 and 11,12,13. Four mutations, W228X (p.W246X)、G400V (p.G418V)、C.1136-4 delGTTG and Q263X (p.Q281X),make up more than half of all. Out of the four mutations, W263X (p.W281X) and C.1136-4delGTTG have not been reported in other population except Chinese. In the use of coagulation condition evaluate, TEG showed a sensitive result of the coagulation condition evaluation.

Conclusion: Factor XI gene mutations remain highly heterogeneous at molecular level. Chinese FXI deficiency gene mutations have its special characteristic which is different from other races. Furthermore, the TEG may work as a useful measurement in patient with FXI deficiency.

PB 1.59-5

Understanding platelet-virus interaction

Negrotto S[1], De Giusti CJaquenod[2], Alberdi L[2], Fondevila C[3], Schattner M[1] and Gomez RM[2]

[1]Institute of Experimental Medicine, Buenos Aires; [2]Institute of Biotechnology and Molecular Biology, La Plata; [3]Bazterrica Clinic, Buenos Aires, Argentina

Background: Although the direct interaction between viruses and platelets was described many years ago, it is not yet clear whether platelets, by taking up viruses, contribute to the dissemination of infection, to the host antiviral defense or both. The ssRNA Coxsackievirus B (CVB), classified as an Enterovirus of the *Picornaviridae* family, represent an excellent candidate to study the platelet-virus interaction as the coxsackie adenovirus receptor (CAR) is expressed on the platelet surface, the CVB replication cycle is short (< 12 h) and platelets have the required machinery to translate constitutive mRNAs into proteins and hence, to potentially allow CVB replication.

Aims: To understand the interaction between platelets and virus and the role of platelets in viral infections.

Methods: Human blood platelets depleted of leukocytes were infected with CVB1 and CVB3 strains at 0.1–10 MOI for 1 h at 37 °C and then exhaustive washed to ensure viral removal. Supernatants and pellets were collected at different hours post-infection (hpi) in order to measure infectivity and analyze viral replication at a molecular levels. Results are expressed as mean ± SEM, $n = 5–7$, $*P = 0.05$ by ANOVA.

Results: We found that platelets interact with CVB1 and three as both RNA and a CVB1 capsid protein were detected at 24 hpi by RT-PCR and immunoblotting/immunofluorescence, respectively. Surprisingly, while CVB binding to HeLa cells was inhibited by a CAR-blocking antibody, this inhibitory effect was not observed in platelets, suggesting that CVB-platelet interaction might be mediated by platelet surface glycoproteins. Although RT-PCR amplification of intermediate negative strand was negative, implicating that platelet were not susceptible to a replicative infectivity cycle, titration assays with HeLa cells showed that infectious viral particles were detected in supernatants and pellets from CVB-infected platelets at 6, 24, 48 and 72 hpi. Flow cytometry analysis indicated that CVB binding to platelets resulted in an increased basal P-selectin expression (crucial mediator of platelet-leukocyte interaction) and phosphatidylserine exposure (phagocytosis signal for monocytes) after 1 hpi ($2.2 \pm 0.2*$ and $2.1 \pm 0.6*$ fold change vs. control, respectively) but not after 4, 24 or 48 hpi, suggesting that the augmented platelet reactivity was associated with the initial contact of platelets with CVB.

Conclusions: Our data suggest that platelets play an ambivalent role in CVB infection: on one hand, platelets might contribute to viral dissemination as they can harbor infectious CVB by several days and on the other hand, CVB enhances the exposure of surface proteins that mediate interaction with leukocytes, probably increasing platelet phagocytosis and subsequent destruction of the virus.

PB 1.59-6

Regulation of blood coagulation by poly-phosphate

Arneth B, Chavakis T and Siegert G

Technische Universität Dresden, Dresden, Germany

Background: Poly-Phosphate (Poly-P) is a large inorganic polyphosphate molecule localized in the dense and alpha granules of platelets. Recent studies have described initiation of the blood coagulation cascade by poly-P via activation of factor XII and pre-kallikrein.

Aims and Methods: Here, we determined the influence of poly-P on activation of blood coagulation by studying endogenous thrombin potential (ETP). To this end, we used $n = 45$ poly-P, which approximates platelet poly-P *in vivo*. Interestingly, the area under the curve (AUC) of the ETP was significantly reduced when increasing concentrations of poly-P were added to the standard plasma (unical). To further analyze this finding, we investigated the effect of poly-P in factor II-, V-, VII- and X-dependent coagulation, by engaging one-stage factor clotting assays.

Results: Factor V-dependent coagulation was prolonged in the presence of poly-P in a dose-dependent manner, whereas factor II-, VII- or X-dependent coagulation was unaffected by poly-P.

Summary: In conclusion, poly-P inhibits coagulation factor V-mediated thrombin generation. Given the storage of both factor V and poly-P in platelet granula1) and their release upon platelet activation, our present findings suggests a new potential regulatory role of platelet-derived poly-P in factor V function.

PB 1.60-1

Role of Gas6 in cancer-induced venous thrombosis

Aghourian Namagerdy M, Lemarie CA and Blostein MD

Lady Davis Institue for medical research/McGill University, Montreal, QC, Canada

Background: Venous thrombosis is the most common morbid complication related to cancer and its treatments. The onset of cancer predisposes patients to an increased risk of developing venous thrombosis.

Growth arrest specific 6 (gas6) is a vitamin K dependent secreted protein that is expressed by different cell types and is involved in several cellular processes such as cell proliferation, adhesion and survival. Gas6 null mice are protected against life threatening thrombosis, and develop smaller thrombi in venous thrombosis models as compared to wild type mice.

Aims: The objective of the present study is to elucidate the role of gas6 in cancer-induced venous thrombosis.

Methods: To test this hypothesis, wild type (WT) and Gas6 null (−/−) mice received an intravenous injection of M27 murine lung cancer cells. After 2 weeks, WT and $Gas6^{-/-}$ mice developed end stage cancer. Venous thrombosis was induced using 10% ferric chloride. Thrombus size was measured by (i) ultrasonography measuring surface area and (ii) pathologically using clot weight. For mechanistic *in vitro* studies we co-cultured murine endothelial cells, prepared from lungs of both WT and $Gas6^{-/-}$mice, with M27 cells. RNA was extracted from endothelial cells and whole genome microarray analysis was used to identify differential gene expression induced by cancer in the presence or absence of gas6.Microarray results were confirmed using real-time qPCR, western blot analysis and ELISA.

Results: We found that thrombi induced in WT mice with cancer were larger than those induced in healthy mice by both ultrasound ($P < 0.05$) and pathologically ($P < 0.05$). Furthermore, $Gas6^{-/-}$ mice were protected against the larger thrombi induced by cancer cells. Microarray analysis revealed that 28 genes were differentially expressed in WT or $Gas6^{-/-}$ cells in the presence of cancer. Of interest, when exposed to cancer, we found that thrombospondin 2 was downregulated in WT endothelial cells and even further decreased in $Gas6^{-/-}$ cells. We confirmed these results using real-time qPCR and western blot analysis ($P < 0.05$). Preliminary results also confirm that plasma levels of thrombospondin 2 levels is lower in $Gas6^{-/-}$ mice with cancer as compared to WT mice with cancer.

Summary/Conclusions: These results suggest the possibility that gas6, through the downregulation of thrombospondin 2, has a pathophysiologic role in cancer-induced thrombosis.

PB 1.60-2

Acceleration of lung metastasis of melanoma cells in mice fed a high-fat diet: changes in circadian expressions of thrombotic factors and cell-adhesion molecules through day-night reversal feeding

Horie S[1], Nakamura S[1], Oishi K[2] and Hiraishi S[1]

[1]Kagawa Nutrition University, Saitama; [2]Natl. Inst. Adv. Ind. Sci. Tech., Tsukuba, Japan

Background: Circadian clocks, which primarily comprise transcriptional/translational feedback loops involving set of clock genes, and a number of studies in mammals have indicated a connection between circadian clocks and feeding behavior, and peripheral oscillators can be strongly affected by daily feeding cycles. It is also known that there is a definite relationship between diabetes and increased risk of colon and rectal cancer, and recent studies have shown that metabolic syndrome may play a role in several cancers. Further, epidemiologic studies on large numbers of night and rotating shift workers have suggested an increase in the incidence of breast and colon cancer in these populations.

Aims: In the present study, we measured the number of metastatic colonies and expression levels of various factors including invasion, coagulation/fibrinolysis in lung of mice fed a high-fat diet under the day-night reversal schedule after administration of B16BL6 melanoma cells, to understand whether or not fluctuations of these factors might affect on cancer metastasis under the bad dietary habit.

Methods: Six-week-old wild and *clock* mutant mice were divided into each four groups and were fed a normal (5.2% fat) or a high-fat (24% fat) diet under the condition of daytime or mid-night feeding for 8–10 weeks. At 2 weeks before end of the feeding, BL16B6 melanoma cells were injected via tail vein and mice were sacrificed under anesthesia 2 weeks later, and then the number of colonies was determined. In the same time, plasma, lung, liver were recovered and, in addition to lipid level, antigens of adipocytokines, PAI-1, thrombomodulin, and gene expressions of molecular clocks (per2, bmal-1), adhesion molecules and MMP-2, were measured.

Results: The values of glucose tolerance test, fasted insulin, cholesterol, leptin in plasma from high-fat diet fed wild mice were higher than those from normal diet fed mice. The number of metastatic colonies in the lung was increased in the group of high-fat fed mice by 40% compared with that of control, regardless of its eating time. The colonies were also increased with significance in wild mice fed normal diet during daytime compared with the nighttime feeding. No difference was observed in *clock* mutant mice under the same condition. Comparing values from mice fed normal diet, those fed high-fat diet increased MCP-1 and PAI-1 in plasma, and reduced thrombomodulin in lung, and these changes were associated with disturbed expressions of per2 and bmal-1. Expressions of per2 and bmal-1 in mice fed the diet in daytime were phase advanced and those of PAI-1 and thrombomodulin were also phase shifted. Expressions of p-selectin and vcam-1 in the lung of mice increased under the same condition, though that of mmp-2 did not change.

Conclusion: These observations demonstrate that not only excess eating of high-fat diets but also irregular eating habit is objectionable to prevent cancer cell invasion, since tumor cell metastasis was accelerated by disturbed fluctuations of circadian clocks accompanied by changes in diurnal variation of thrombotic activities.

Microvesicles bearing tissue-factor: a new potential biomarker for thrombosis in acute promyelocytic leukemia

Gheldof D[1], Mullier F[2], Devalet B[2], Bailly N[2], Chatelain B[2], Dogné J-M[3] and Chatelain C[2]

[1]Department of Pharmacy Namur Thrombosis and Hemostasis Center (NTHC) -Narilis, Namur; [2]NTHC-NARILIS, CHU UCL Mont-Godinne-Dinant, Mont-Godinne; [3]NTHC-NARILIS, University of Namur, Namur, Belgium

Introduction: Patients with hematological malignancy have a 28-fold increased risk of venous thromboembolism (VTE). Among patients with acute myelogenous leukemia (AML), the 2-year cumulative incidence of VTE is 5.2%. The induction mechanism of a hypercoagulable state is not fully understood. Multifactorial aspects such as patients' immobility, chemotherapy adverse effects or the overexpression of several procoagulant substances (i.e. tissue factor (TF)) by cancer cells are often evoked. Several studies strongly suggest that microvesicles (MVs) harboring TF may have a procoagulant role in promoting deep vein thrombosis and possibly disseminated intravascular coagulation (DIC) commonly seen in acute promyelocytic leukemia (APL)

Objectives: The aim of this study is to assess the capacity of untreated (APL) cells to shed procoagulant MVs.

Methods: APL cell lines (NB4 and HL-60) were cultured for 48 h in liquid medium at 600,000 cells/mL. Cells and MVs were separated by filtrations (Millipore 0.1-0.22-0.45-0.65 μm). The Pro-Coagulant Activity (PCA) was assessed by thrombin generation assay. Alternatively, MVs were incubated with anti-TF antibodies (10 μg/mL), with annexin V (0.5 μM) to assess the contribution of TF and phospholipids to the PCA. Alternatively, the cells were incubated with with $HgCl_2$ (an activator of TF).

Results and Discussion: NB4 cells have a high PCA mainly triggered by MVs of size under 0.45 μm. Thus, NB4 cells spontaneously release MVs of various size, which can augment TGA. By using an anti-TF antibody (HTF-1) and annexin V, we confirm that the PCA of MVs is related to the expression of active TF and PL. Interestingly, we show

that HL-60 cells have a weaker PCA since TF is mostly present in an inactive form. Moreover HL-60, do not produce MVs < 0.65 μm associated with PCA.
Conclusions: Microvesicles could have a predicting value for venous thromboembolism and DIC in patients with acute promyelocytic leukemia and could inform hematologists for the thrombosis prophylaxis.

PB 1.60-4
Pro-metastatic human breast cancer cell line, MDA-MB-231 (MDA) and platelet interacctions in an '*in vitro*' aggregation assay

Alberto MF, Bermejo IE, Calderazzo JC, Meschengieser S, Lazzari MA and Sánchez-Luceros A
Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Metastasis remains the major cause of cancer treatment failure. Platelets play a key role in hematogenous metastasis and contribute to this process by both thrombin-dependent and -independent mechanisms.
Aims: Our aim was to characterize interactions between pro-metastatic human breast cancer cell MDA and platelets, and compare the effectiveness of antiplatelet therapies to define strategies to study the platelet role in metastasis.
Methods: MDA were cultured at 37ºCand 5%CO_2 in DMEM containing glucose and supplemented with 1% glutamine, 1% penicilin/streptomycin and 10% heat-inactivated fetal bovine serum. Cells were scraped, washed and suspended in Ca^{2+} Mg^{2+} Tyrode's buffer 3 days after being passed.
Blood was collected from healthy volunteers who had not taken any drugs known to affect platelet function for at least 14 days prior to the study. Washed platelets (WP) in Ca^{2+} Mg^{2+} Tyrode's buffer were prepared at 2.5×10^8 platelets/mL.
The interactions between WP and MDA were measured by light aggregometry. WP were placed in a lumi-aggregometer (Chronolog), incubated for 15 min at 37 °C, stirring at 1000 rpm, with increasing MDA cells with or without citrated plasma (1/800 final dilution). The effects of heparin (1 UI/mL) and three antiplatelet drugs (100 mM aspirin, 1 nM PGE1 and NO donnor 10 μM sodium nitroprusside) were assayed. The time to produce 50% aggregation of WP was registered (T50%).
Results: MDA cells were tested for their ability to induce WP aggregation. MDA cells ($1.3\ 10^5$–$6.5\ 10^5$ cells/mL) did not produce WP aggregation when they were incubated in the aggregometer for 15 min at 37 °C in absence of citrated plasma. However when citrated plasma was added, in a very low dilution (1/800) to avoid fibrin formation, MDA cells induced WP aggregation in a concentration-dependent manner ($1.3\ 10^2$; $1.3\ 10^3$; $-1.3\ 10^4$ cells/mL). A linear relationship was obtained when T50% was plotted vs. MDA cell concentration in linear-log mode. Heparin at 1 UI/mL completely inhibited WP aggregation suggesting a mechanism mediated by thrombin generation.
When WP were treated with asprin or PGE1, T50% increased a 45% (n: 4, $P = 0.03$) and a 76% (n: 4, $P = 0.03$) respectively for $1.3\ 10^4$ MDA cells/mL, keeping the same linear-log relationship for lower MDA cell concentration. When NO donor sodium nitroprusside was assayed, WP aggregation was completely inhibited at $1.3\ 10^2$ and $1.3\ 10^3$ cells/mL and T50% was increased a 280% (n: 4, $P = 0.01$) at $1.3\ 10^4$ cells/mL.
Conclusion: In our '*in vitro*'study, MDA-MB-231 (distinguished by their invasive phenotype) were capable of producing WP aggregation in a thrombin-dependent manner at very low concentrations of clotting factors and tumour cells, revealing their thrombogenic power.
Only the antiplatelet therapy with NO donor sodium nitroprusside was effective, this finding may help to define strategies to study the platelet role in metastasis in '*in vivo*' models. Impairment of platelet function within the tumour microenvironment may provide a clinically useful approach to inhibit metastasis.

PB 1.60-5
Activation of coagulation by lenalidomide-based regimens for multiple myeloma

Arai R, Isozumi Y, Fujimoto K and Koyama T
Tokyo Medical and Dental University, Tokyo, Japan

Background: Lenalidomide (Len) is a structural analogue of thalidomide. Combining Len with steroids led to improved response rates in the treatment of multiple myeloma. However, deep vein thrombosis (DVT) has been noted as one of the most serious side effects with this regimen, and the mechanism by which Len-based regimens cause DVT is unclear.
Aims and Methods: We investigated the procoagulant effects of Len-based regimens, focusing on tissue factor (TF) and phosphatidylserine (PS). Because we have previously shown that thalidomide- or Len-based regimens did not induce procoagulant activity (PCA) on myeloma cells, we further examined the effects of a pharmacological concentration of Len with or without the steroid dexamethasone (Dex) and the proteasome inhibitor bortezomib (Bor), using the human vascular endothelial cell line EAhy926 and the monocytic cell lines THP-1 and U937.
Results: Cell surface PCA was induced by Dex-including regimens on EAhy926, THP-1 and U937 cells. Expression of TF antigen on the cell surface and of TF mRNA was markedly increased by Dex-including regimens in all cell lines compared to control and Len alone. Exposure of PS was modestly increased by the Len-based regimen in all cell lines. Exposure of PS was modestly increased in EAhy926 cells, and markedly increased in THP-1 and U937 cells by the Bor-including treatment. An anti-TF monoclonal antibody almost completely blocked the induced PCA.
Summary/Conclusions: When Len is given in combination with Dex, PCA may be induced on endothelial cells and monocytes through TF expression and PS exposure. In blood vessels, Len, with its antiangiogenic activity, may disturb the repair of injured endothelium by other anti-tumor agents, and make other drugs' effects stronger and prolong the induced PCA. Therefore, monitoring procoagulant markers, such as D-dimers, and including prophylactic anticoagulant strategies should be considered in Len-based combination regimens.

PB 1.60-6
Development of the overall haemostatic potential assay for murine plasma and identification of elevated fibrin and thrombin generation in tumour bearing mice

Reddel CJ, Allen J, Kritharides L, Curnow J and Robertson G
ANZAC Research Institute, Concord, NSW, Australia

Background: Patients with advanced malignancies have an increased risk of thromboembolism which may be linked to elevated inflammation. While mouse tumour models provide opportunities to study the underlying mechanisms, there is a need for functional assays to assess coagulation potential in mice.
Aims: We aimed to optimise the overall haemostatic potential (OHP) assay for use with mouse plasma, and to validate the assay by investigating a murine model that exhibits features of enhanced clotting associated with an inflammatory state and cachexia. We assessed changes in *ex vivo* coagulation function in Colon 26 tumour-bearing mice using fibrin and thrombin generation and related parameters.
Methods: The OHP assay was validated in mice as follows. Conditions were optimised using plasma from non-tumour bearing mice. Four groups of immuno-competent mice were then studied: i) Mice engrafted subcutaneously with murine Colon 26 (C26) carcinoma cells ($n = 16$), with 16% weight loss at 14 days post tumour implant; ii) Mice engrafted with a variant C26 tumour that does not elicit cachexia ($n = 9$); iii) Non-tumour bearing controls ($n = 14$); iv) Non-tumour bearing mice pair-fed with food intake matched to the cachectic C26 tumour mice ($n = 10$). Plasma was prepared from citrated blood

collected after 14 days. The OHP assay was used to measure overall coagulation potential (OCP), delay to fibrin clot formation and clot lysis time (CLT) in a subset of each group. A modified calibrated automated thrombogram (CAT) assay was also performed to measure mean endogenous thrombin potential (ETP) and lagtime. Plasma fibrinogen was measured by Western blot, while tissue factor pathway inhibitor (TFPI) and IL-6 levels were measured by ELISA.

Results: The OHP assay was successfully adapted for murine plasma, and tumour bearing mice were found to have elevated fibrin generation (OCP) compared with non-tumour bearing mice (0.1 arbitrary units (AU)), with a trend towards even higher OCP in cachectic (3.7 AU) than non-cachectic mice (2.8 AU). There was no significant difference in CLT between any group. Cachectic mice had an ETP of 494.3 AU which was significantly higher than non-cachectic C26 tumour bearing mice (188.7 AU). Surprisingly, delay to fibrin formation and lag-time to thrombin generation were both significantly increased in tumour bearing mice, which may be explained by significantly higher levels of TFPI. Plasma fibrinogen was higher in tumour-bearing mice, and more so in cachectic than non-cachectic mice. Circulating IL-6 was below detection in non-tumour bearing mice and just detectable in non-cachectic mice, while markedly elevated in cachectic mice at 216 pg/mL.

Summary/Conclusion: We demonstrate a novel development of the OHP assay in murine plasma and show increased fibrin generation in C26 tumour variants, while fibrinolysis was not significantly altered. The elevated coagulation potential persisted despite increased TFPI in tumour bearing mice. The cachectic C26 variant had dramatically higher levels of circulating IL-6 and demonstrated significantly elevated thrombin generation and a trend towards higher fibrin generation.

PB 1.61-1

Pathogenesis of hemostatic abnormalities due to L-asparaginase in children with acute leukemia

Yamashita A[1], Nagae C[2], Ashikaga T[2], Muto S[2], Akita M[2], Yamazaki S[3], Takayama S[4], Tatsunami S[5] and Taki M[1]

[1]St.Marianna University School of Medicine, Yokohama City Seibu Hospital, Yokohama; [2]St. Marianna University School of Medicine; [3]St Marianna University School of Medicine Hospital, Kawasaki; [4]Daito Bunka University, Tokyo; [5]St. Marianna University School of Medicine, Kawasaki, Japan

Background: L-asparaginase (L-asp) is a key drug for treating acute lymphoblastic leukemia in children. Injection of L-asp often causes hemostatic abnormalities, which are critical issues for continuing chemotherapy in these patients. L-asp-induced hemostatic abnormalities are often associated with thrombotic rather than hemorrhagic events. Therefore, prophylactic replacement of anti-thrombin (AT) is generally performed. However, this method is not supported by scientific evidence, because the mechanism underlying the hemostatic abnormalities caused by L-asp remains unclear.

Aims: In order to clarify the mechanism underlying the hemostatic abnormalities caused by L-asp, we investigated hemostatic changes in children with acute leukemia during chemotherapy including L-asp.

Methods: Eleven children with acute leukemia, who received a total of 15 courses of chemotherapy including L-asp, were evaluated for thrombin generation potential (TGP) before and after L-asp injection. To neutralize the effect of heparin contamination in blood samples obtained via central venous catheter, heparinase was added to the samples just before coagulation tests including the thrombin generation assay. The heparinase used was hep-TEM®Lyo from Finggal Link Co. Ltd. To evaluate thrombin generation, Thrombogram® and PPP reagent (phospholipid, 4 mM, tissue factor, 5pM), both from Thermo Electron Corp, were used. Endogenous thrombin potential (ETP) served as the main parameter of TGP.

Results: In general, ETP was significantly increased after L-asp injection (1410 ± 341 nM*min) as compared with before (1164 ± 180 nM*min) ($P = 0.018$), indicating that L-asp induces a thrombotic tendency. This hemostatic change was suggested to be strongly associated with decreases in both AT and protein C (PC). We examined the effects of L-asp on hemostatic abnormalities during each treatment phase. ETP was increased in three cases and decreased in 2, after L-asp injection in the induction phase ($n = 5$), indicating that contradictory hemostatic changes involving thrombosis or hemorrhage are likely to occur with L-asp in this phase. ETP was increased in nine cases after L-asp injection in the re-induction or consolidation phase ($n = 10$), indicating that thrombosis is likely to occur with L-asp in these phases. There was a negative correlation between ETP and AT ($r = -0.66$, $P < 0.001$), while ETP correlated positively with CRP ($r = 0.45$, $P = 0.02$), on multiple regression analysis. Thrombotic change was related to decreased AT and the presence of infection.

Summary/Conclusion: In children with acute leukemia, the hemostatic abnormalities caused by L-asp involved mainly a thrombotic tendency, reflecting decreased AT and PC. Infection during chemotherapy exacerbated this thrombotic tendency. Therefore, we must keep in mind a high risk of thrombosis during the re-induction or consolidation phase, especially when infection is present.

PB 1.61-2

Simple laboratory variables are prognostic factors in hospitalized cancer patients with acute pulmonary embolism

Riva N, Squizzato A, Turato S, Grazioli S, Dentali F and Ageno W

Department of Clinical and Experimental Medicine, Insubria University, Varese, Italy

Background: The Pulmonary Embolism (PE) Severity Index has a poor prognostic value in hospitalized oncological patients with PE, because cancer is already included as a predictor. Only limited evidences are available on the clinical impact of laboratory variables on mortality rate.

Aims: The aim of this analysis was to assess the prognostic value of the most common laboratory tests performed in oncological patients with PE.

Methods: Consecutive patients admitted to the tertiary hospital of Varese (Italy) with an objectively diagnosed PE between January 2005 and December 2009 were included. Information on clinical presentation, risk factors, blood tests, treatment and mortality rate at 1-month follow-up was collected. This sub-analysis examines the 150 oncological patients extracted from the entire population.

Results: Mean age was 69.6 (± SD 11.6) years and 84 (56%) patients were male. Most common primary sites of cancer were lung (25.2%), colon-rectal (13.3%) and bladder (8.4%). Active cancer was present in 121 patients, of whom 47 had a metastatic disease. Overall mortality rate was 20.7% (95% CI, 15.0–27.8%) at 1-month.

In the subgroup of patients with active cancer, clinical predictors and laboratory test results, significantly associated with mortality at the univariate analysis, were: age > 80 years old (29.2% vs. 11.3%, $P = 0.049$), systolic blood pressure below 100 mmHg (37.5% vs. 7.2%, $P = 0.001$), altered mental status (16.7% vs. 0%, $P = 0.001$), leukocytes > 11,000/mm^3 (60.9% vs. 31.9%, $P = 0.010$) and creatinine clearance < 30 mL/min according to MDRD formula (20.8% vs. 6.3%, $P = 0.044$); while concomitant deep vein thrombosis was a protective factor (25.0% vs. 58.8%, $P = 0.003$).

These factors were therefore tested in a multivariate Cox regression analysis. Apart from well-established clinical variables (low blood pressure and altered mental status), also leucocytosis (HR 3.01, 95% CI 1.19–7.63, $P = 0.020$) and severe renal insufficiency (HR 2.91, 95%

CI 1.04–8.19, $P = 0.043$) emerged as independent risk factors for mortality.

Conclusion: The results of this analysis suggest that laboratory parameters should be merged with clinical variables in the creation of a new prediction rule, in order to redefine the risk of death in cancer PE patients.

PB 1.61-3
Bleeding rates and thrombotic complications in patients with hematological malignancies admitted to hospital

Peterson EA[1], Merkeley H[1], Leena C[1], Hocevar S[2], Yeung J[2] and Lee AYY[1]

[1]University of British Columbia; [2]Vancouver General Hospital, Vancouver, BC, Canada

Background: Thromboprophylaxis is recommended for cancer patients admitted to hospital. But for patients receiving high dose chemotherapy or undergoing allogeneic stem cell transplantation (SCT) for hematological malignancies, the risk of bleeding might outweigh the risk of thrombotic events. The incidence, management and outcomes of these complications are poorly studied in this patient population.

Aims: The objectives of this study are to determine (i) the bleeding rates and severity in the hospitalized leukemia/bone marrow transplant (LBMT) population; (ii) the rates and clinical outcomes of patients with symptomatic venous thrombotic events (VTE), including catheter-related thrombosis (CRT); and (iii) the prevalence of anticoagulant thromboprophylaxis.

Methods: A retrospective review of all admissions to the Vancouver General Hospital LBMT unit from January 1, 2010 to June 30, 2010 was performed. Only the first admission for each patient during the study period was included. Admissions to other hospital units or those lasting < 48 h were excluded. Data were extracted from chart review using standardized forms. Only objectively confirmed VTE were included. All bleeding events were graded according to ISTH criteria. Each patient's records were evaluated independently by two study members.

Results: One hundred and sixty-six patients with one or more admission during the study period were included. Median age was 52 years (range 18–76 years), 61.4% were male, and the median length of hospital stay was 19 days (range 2–182 days). Underlying diagnosis was acute leukemia in 51.8%, lymphoma in 28.3%, multiple myeloma in 9.0%, chronic myeloid leukemia 2.4%, myelodysplastic syndrome 2.4% and other 6.0%. VTE risk factors included prior VTE in 16 patients (9.6%), and indwelling central venous catheter in 145 patients (87.4%). Reason for admission was administration of high-dose chemotherapy in 39.2%, allogeneic SCT in 16.3%, autologous SCT in 16.9%, immunosuppressive therapy in 1.2% and acute medical management in 26.5%. At least one dose of VTE prophylaxis was prescribed during 11 (6.6%) admissions (seven received unfractionated heparin, four received low molecular weight heparin) and veno-occlusive disease prophylaxis with intravenous unfractionated heparin was prescribed in 29.5% of admissions. Bleeding events occurred in 31 patients (19%); 12 had major bleeding episodes and 13 had clinically relevant non-major bleeding episodes. Bleeding was associated with organ dysfunction in five patients and was fatal in two patients. 9/72 patients (12.5%) who received any anticoagulant compared with 23/98 patients (23%) without anticoagulation experienced bleeding. Thrombotic complications occurred in six patients (4%), including DVT and/or PE in three patients, CRT and PE in one patient, splenic infarct in one patient and superficial thrombophlebitis in one patient; only one patient received thromboprophylaxis prior to VTE diagnosis. Four patients were started on therapeutic anticoagulation during admission for documented (4/6) thrombotic events. Therapeutic anticoagulation was associated with a major bleeding episode requiring anticoagulant discontinuation in two patients.

Conclusions: Patients undergoing aggressive chemotherapy or SCT for treatment of hematological malignancies have high rates of clinically significant bleeding, even in the absence of anticoagulants. Further studies evaluating the risks and benefits of thromboprophylaxis in this patient population are needed.

PB 1.61-4
Management and outcomes of venous thromboembolic events in patients with concomitant cancer-associated thrombocytopenia: a retrospective cohort study

Kopolovic I and Wu C

University of Alberta, Edmonton, AB, Canada

Background: Hospitalized patients with active malignancy have an increased incidence of both venous thromboembolic events (VTE) and thrombocytopenia. Thrombocytopenia increases the risk of hemorrhage but does not confer protection from VTE. The optimal management of VTE in patients with thrombocytopenia is not established, and outcomes in such patients are largely unknown.

Aims: Our Objectives were to (i) describe a cohort of hospitalized cancer patients diagnosed with VTE in the setting of concomitant thrombocytopenia, (ii) describe management strategies implemented in this cohort (iii) determine incidences of and factors associated with subsequent thrombotic and hemorrhagic outcomes.

Methods: Retrospective cohort study of all inpatients admitted to the University of Alberta Hospital's hematology service, or the Cross Cancer Institute (Edmonton, AB) between 2006 and 2011. All adult patients (> 17 years) with imaging-confirmed VTE (excluding superficial venous thrombosis) and concomitant thrombocytopenia (plt < 100) were included. Primary outcome of interest was the composite of hemorrhagic and thrombotic events within 3 months of the index VTE.

Results: Seventy-four patient charts were reviewed. Mean (SD) age was 59 (15) years, 35 (47.3%) were male, 56 (75.7%) had hematologic malignancy, and 48 (64.9%) were undergoing chemotherapy at the time of the event. Median [IQR] platelet count at the time of VTE was 49[28,78] with median[IQR] nadir platelet count of 15 [8,46]. Thrombocytopenia was attributed to cytotoxic chemotherapy in 26 (35.1%) patients, marrow involvement with cancer in 15 (20.3%), a combination of marrow involvement and chemotherapy in 19 (25.7%), immune-mediated mechanisms in 4 (5.4%) and an unknown or other etiology in 10 (13.5%). Prolonged thrombocytopenia (> 1 month duration) was observed in 50 (67.6%) patients. Fifty-two patients (70.3%) had proximal limb deep vein thromboses, of which 21 were lower extremity, 31 were upper extremity, and 28 were catheter-associated. Twenty-seven patients (36.5%) had pulmonary embolism, and 3 (4.1%) patients had VTE at other sites. Patients were divided into treatment categories: 17 (23.0%) patients did not receive any anti-thrombotic therapy, 30 (40.5%) completed a minimum 3-month course of full-dose antithrombotic therapy, and 27 (36.5%) received a modified course of antithrombotic therapy. Over the 3-month period following the index VTE, 29 (39.2%) patients experienced a total of 36 events; 23 (31.1%) patients experienced a second symptomatic thrombotic event, and 13 (17.6%) suffered a clinically significant bleeding event (WHO class ≥ 2). Compared to those not suffering a hemorrhagic or recurrent thrombotic event, those who experienced an event were less likely to have received a full course of antithrombotic therapy (13.8% vs. 57.8%, $P < 0.001$), and were more likely to have received a partial course of therapy (55.2% vs. 24.4%, $P = 0.002$). Other factors associated with reaching the primary endpoint were duration of thrombocytopenia > 1 m (82.8% vs. 57.8%, $P = 0.04$), and hematologic malignancy (96.6% vs. 62.2%, $P < 0.001$). There were a total of 23 deaths; none were attributed to hemorrhage, and two were due to pulmonary embolism precipitating respiratory failure.

Conclusions: There remains considerable variability in the management of VTE in the setting of thrombocytopenia. This population carries a high risk of both recurrent thrombosis and hemorrhage. Future studies should aim to determine the optimal management of this complex clinical situation.

PB 1.61-5

Patients with advanced stage germ cell tumors have a high risk of thromboembolic events

Gordy L, Brames MJ, Einhorn LH and Manchanda N
Indiana University School of Medicine, Indianapolis, IN, USA

Background: Venous and arterial thromboembolism (TE) accounts for significant morbidity and mortality in cancer patients[1][2]. Rates of TE have been reported ranging from 0.9% to 28.0%, depending on the population and malignancy[3]. In patients with germ cell tumors, studies have reported a 4.0–8.4% risk of TE immediately following administration of chemotherapy with cisplatin-containing regimens[4][5].
Aims: Our population of germ cell tumor patients comprises a higher-risk population with advanced disease, many of whom receive high-dose chemotherapy and peripheral blood stem cell rescue. To more completely understand the role played by advanced germ cell tumors in causing TE events in addition to the risk presented by administration of chemotherapy, we sought to evaluate these events in patients with long-term follow-up.
Methods: Data were collected through a retrospective chart review of germ cell tumor patients with regard to patient, disease and treatment variables, as well as clinical TE events, from diagnosis until the occurrence of a TE event (ranging from TE on presentation to almost 20 years after diagnosis). A logistic regression model was fitted to determine variables that predispose patients to TE.
Results: Forty-four consecutive patients visiting our germ cell tumor clinic between 11/05/2012 and 1/22/2013 were selected for the study. Seven patients (15.9%) were identified as having had venous thromboembolic events whereas none had arterial events. Five of seven patients (11.4%) had TE events within 16 weeks of chemotherapy, two had TE events 10 and 19 years after diagnosis, respectively. Two had bilateral pulmonary emboli (PE) (4.5%), three had upper or lower extremity DVTs, or both, and one patient had both bilateral PE and multiple DVTs. Five of seven patients with TEs had non-seminomatous germ cell tumors, two had non-testis primaries, four had relapsed disease, two with late relapse (> 7 years after initial diagnosis), six of seven had metastatic disease, three had retroperitoneal lymph node dissection, and all seven received platin-based chemotherapy. In logistic regression analysis, significant risk factors for TE included relapse ($P = 0.016$), bulky retroperitoneal lymphadenopathy ($P = 0.006$), alpha-fetoprotein > 10,000 ($P = 0.047$) beta-HCG > 1000 ($P = 0.020$), chemotherapy ($P = 0.031$), and platin-refractory disease ($P = 0.055$).
Conclusions: Germ cell tumor patients have a high risk of venous TE. Those with relapsed disease, bulky retroperitoneal lymphadenopathy, platin-based chemotherapy, and platin-refractory patients are at increased risk. Our risk estimates are higher than quoted in the literature and do not include any arterial events. To confirm these findings, we plan to extend this study to include 100 consecutive patients, most of whom have advanced disease states. If confirmed, these unique features of TE events may reflect advanced staging of disease in our patients and long-term follow-up.

PB 1.61-6

Venous thromboembolism-related mortality in cancer patients

Garcia-Garcia JA, Parra- Esquivel P and Lopez-Alonso RJ
University Hospital of Valme, Seville, Spain

Background: Thrombotic risk is increased in patients with cancer. Venous thromboembolism (VTE) is the second most common cause of death in this population. In this sense, it is important to provide information on predictors of mortality in cancer patients with VTE based in clinical data.
Aim: To determine the mortality and risk factors related to VTE among patients with cancer.
Methods: In a retrospective study, the survival of cancer patients admitted as a consequence of VTE between 2006 and 2010 was analyzed. The etiology of death was registered. Covariables included in the study were age, sex, functional status, comorbidities as Charlson index, and blood parameters such as hemoglobin, platelets, leukocytes and INR levels at the time of the event. Factors related cancer were the location, date of diagnosis and presence of metastasis. Cancer treatment and previous admissions were also included. All patients were followed until death or the date of the end of study on 31st December 2011.
Results: One hundred and eighty patients were included in the study. Of them, 130 (72%) died during the follow-up. The causes of death were: 36 (28%) due to VTE and 68 (52%) secondary to advanced cancer. Primary cancer included lung, gastrointestinal and breast in 23%, 18%, 12%, respectively. One hundred and four (58%) subjects were admitted as a consequence of pulmonary thromboembolism. Metastasis and cancer treatment was present in a 68% and 58%, respectively. Factors related associated with VTE-mortality were: previous admission, leukocytes > 13,000/μL, hemoglobin < 9 g/dL, advanced age, the presence of cancer metastasis and the ausence of anticoagulant therapy. No differences were found between low molecular weight heparine and oral anticoagulants.
Conclusions: Venous thromboembolism (VTE) is the cause of death in a high proportion of cancer patients. Cancer patients with older age, recent admission and metastasis are in high risk to fatal event after VTE. In these subjects, secondary prophylaxis should not be discontinuated.

Autoantibodies against component of complement 1 contribute to the complement activation and to the manifestations of refractory antiphospholipid syndrome (APS)

Oku K, Amengual O, Toshiyuki W, Yuusaku K, Yuuichiro F, Toshiyuki B, Tetsuya H, Shinsuke Y and Tatsuya A
Hokkaido University Graduate School of Medicine, Sapporo, Japan

Backgrounds: In the pathogenic mechanisms of antiphospholipid syndrome (APS), it is recognized that pathogenicity of antiphospholipid antibodies (aPL) has dominant effects. Complement is part of the innate immune system and is one of the main effector mechanisms of antibody-mediated immunity. We have previously reported that complement activation prevalently coexists in sera of APS patients and functions as source of procoagulant cells activation. Recently, autoantibodies against C1q, the component of complement 1, were reported to correlate with complement activation in patients with systemic lupus erythematosus (SLE). They are not neutralizing antibodies but target the neoepitopes of deformed C1q bound to various molecules such as anionic phospholipids. The binding of anti-C1q antibodies to C1q induces accelerated activation of complement pathway. There are

no previous studies discussing the involvement of anti-C1q antibodies in APS patients.
Aim: To investigate the existence and significance of anti-C1q antibodies in APS patients.
Methods: This study was comprised of 54 consecutive primary APS patients that visited Hokkaido University Hospital rheumatology clinic from 2002 to 2011. Informed consent was obtained from every patients and the study was approved by the ethics committee of the Hokkaido University Hospital. All the patients were retrospectively analyzed of their clinical manifestations and laboratory data. Refractory APS was defined as a clinical status of relapsing thrombosis or pregnancy morbidity during adequate secondary prophylaxis. Twenty patients with non-SLE connective tissue disease and 20 healthy control subjects were also included. An enzyme-linked immunosorbent assay (ELISA) was used to measure serum levels of anti-C1q antibody titers and anaphylatoxins (C3a,C4a). Association between anti-C1q antibody titers and the clinical or laboratory data were statistically analyzed.
Results: Anti-C1q antibodies were more frequently detected in primary APS patients (18/54) than in non-SLE connective tissue disease patients (2/20) or healthy control (0/20) ($P < 0.01$ for each). In APS patients, anti-C1q antibody titers were significantly correlated with serum C4a level ($P = 0.007$) and inversely correlated with serum C4 level ($P = 0.01$). Serum C3a and C3 levels showed positive and inverse association with anti-C1q antibody titer, respectively, but failed to arrive statistical significance ($P = 0.09$ and 0.11, respectively).
The prevalence or the titers of anti-C1q antibodies were not associated with any of the specific clinical manifestations of APS such as arterial/venous thrombosis, pregnancy morbidity or thrombocytopenia. Also, the prevalence of anti-C1q did not associate with specific aPL and the titer of anti-C1q antibody did not correlate with aPL score. However, all of the refractory APS patients had positive anti-C1q antibodies (7/7) while APS patients without flare had low prevalence (11/47). The titer of anti-C1q antibodies was significantly higher in the refractory APS patients compared with APS patients without flare. (refractory APS vs. APS without flare: 32.5 ± 4.72 vs. 9.91 ± 1.58 U/mL, $P = 0.0000016$). With cut off level of anti-C1q antibodies 20 units/mL, odds ratio of refractory APS was 61.5 (5.85–646 95% CI, $P = 0.00007$).
Summary/Conclusions: These findings indicate that anti-C1q antibodies are associated with complement activation in APS and may contribute to the manifestation especially in the refractory cases.

PB 1.62-2
Exploring the diagnostic opportunities of the measurement of circulating procoagulant phospholipids by a coagulation based assay in lupus anticoagulant positive samples

Coucke L and Devreese KMJ
Ghent University Hospital, Ghent, Belgium

Background/Aims: Cellular microparticles (MP) are associated with thromboembolic diseases, including the antiphospholipid syndrome (APS). In plasma the procoagulant phospholipids (PPL) mainly come from MP. We evaluated whether the presence of increased activity of PPL measured through STA-Procoag-PPL is applicable in patients with a lupus anticoagulant (LAC). LAC, one of the laboratory criteria of APS, has an *in vitro* anticoagulant effect resulting in prolongation of phospholipid-dependent coagulation assays and interference with the clotting time (CT) measured by STA-Procoag-PPL is expected.
Methods: Shortening of the CT (in seconds, s) of the STA-Procoag-PPL of the patient plasma (PP) means an increase in PPL. The CT is dependent of the patient's PPL only since in the test procedure, the PP is diluted 1:1 in PPL-depleted normal pooled plasma (MPfree NPP). The STA-Procoag-PPL was performed on citrated plasma in duplicate on STAR Evolution (both from Stago BNL B.V., Brussels, Belgium). Normal ($n = 25$), factor deficient ($n = 10$), LAC positive ($n = 60$) and LAC negative samples ($n = 22$) were analysed. To evaluate the sensitivity of the assay the CT was compared with the number of MP in a serial dilution of NPP spiked with MPs. Semi-quantitative MP analysis was performed by flow cytometry (CD41-Annexin V derived MP). Predilutions of LAC positive samples ($n = 7$) were made to dilute the LAC effect and to evaluate the effect on the CT in function of the number of MP. Equally, the change in CT was evaluated on prediluted (1/20 and 1/40) MPfree NPP spiked with MP.
Results: CT was comparable between LAC negative samples, normal and factor deficient samples. LAC positive samples showed a significantly prolonged CT compared to the normal samples.
NPP spiked with MP showed a clear correlation between the CT and the number of MP. A decrease in MP amount (e.g. $50*10^3/\mu L$, $20*10^3/\mu L$, $2.5*10^3/\mu L$ or $0.5*10^3/\mu L$) resulted in a prolongation of the CT (14s, 3s, 1.2s, 1.0s, respectively).
The effect of LAC on the CT in undiluted LAC positive samples was variable. The STA-Procoag-PPL in prediluted samples up to 1/80 with MPfree NPP indicated that a 1/20 or 1/40 predilution may neutralize the LAC effect, but inherently results in dilution of the amount of MP. Therefore, MPfree NPP was spiked with MP and diluted up to 1/80 with MPfree NPP. The dilution series showed a good correlation between the change in CT and the change in number of MP: a decrease of $10*10^3 MP/\mu L$ caused an increase of 12 s CT; a decrease of 200 MP/μL still showed an increase of 6 s CT.
Summary: The presence of increased activity of PPL in APS patients measured through STA-Procoag-PPL might be a good alternative for more labour intensive assays for MP analysis. The presence of LAC interfering with the STA-Procoag-PPL CT can be overcome by predilution of the samples. We demonstrated that in highly prediluted samples theSTA-Procoag-PPL CT still responds with the number of MP. This opens options to analyse LAC positive samples. Further study is needed to evaluate the clinical relevance of measuring the STA-Procoag-PPL in patients with APS.

PB 1.62-3
Beta2-glycoprotein I plasma levels are in relation to antiphospholipid antintibody profile in Antiphospholipid Syndrome

Banzato A, Traverso J, Buzzanca F, Bison E, Bracco A, Denas G, Padayattil S and Pengo V
University of Padova, Padova, Italy

Background: Antiphospholipid Syndrome (APS) is characterized by the presence of antiphospholipid (aPL) antibodies associated with thrombosis or pregnancy morbidity. The antibodies mainly involved in these disorders are directed against β2-Glycoprotein I (β2GPI).
Aim: The purpose of this study was to evaluate the plasma concentration of β2GPI in patients with different aPL antibody profiles.
Methods: It was set up a 'sandwich' enzyme-linked immunoadsorbent assay (ELISA) using a rabbit polyclonal anti-human β2GPI coated into plate, and a mouse monoclonal anti-human β2GPI to detect the plasma concentration of bound β2GPI. The system was developed by using a phosphatase-labeled goat anti mouse antibody. Increasing concentrations of human purified β2GPI were used to create a calibration reference curve. Plasma of 23 patients with APS and triple positivity (LAC+, IgG aCL+, IgG aβ2GPI+), eight with double positivity (IgG aCL+, IgG aβ2GPI+, LAC negative), five with single positivity (IgG aβ2GPI+, LAC and aCL negative) and 20 controls were evaluated. Median values between groups were compared by Mann-Whitney test.
Results: A linear dose-dependent optical density was obtained by using Increasing concentrations of purified β_2GPI (from 0.05 to 0.8 mg/mL). Mean β_2GPI concentration in control plasmas was 0.175 mg/mL. Plasma from patients with triple positivity (LAC+, IgG aCL+, IgG aβ2GPI+) showed a significantly higher mean β2GPI concentration than that obtained in control subjects (0.4 vs. 0.175 mg/mL,

$P = 0.009$). Plasma from double (IgG aCL+, IgG aβ2GPI+) and single (IgG aβ2GPI+) positive patients showed mean β_2GPI levels not different from those obtained in control subjects: 0.240 and 0.260 mg/mL, respectively.

Conclusions: Our results demonstrate for the first time that patients with antiphospholipid syndrome (APS) and high risk aPL profile (triple positivity) have significantly higher β_2GPI plasma concentration compared to controls. On the other hand no difference from controls in double and single positivity was found. These data may be of help in understanding the pathogenic mechanism underlying the clinical manifestations of APS.

PB 1.62-4

The influence of anti-tissue factor pathway inhibitor (TFPI) antibodies on thrombin generation (TG) in thrombotic patients with and without antiphospholipid syndrome

Efthymiou M[1], Mackie IJ[1], Lawrie AS[1], Machin SJ[1] and Cohen H[2]

[1]University College of London; [2]University College London Hospitals NHS Foundation Trust, London, UK

Background: Anti-tissue factor pathway inhibitor antibodies (αTFPI) have been reported in the antiphospholipid syndrome (APS). It has been suggested that these antibodies may impair TFPI activity, contributing to the observed hypercoagulability in these patients. TFPI acts as the principal inhibitor of the tissue factor (TF)-induced activation of the coagulation cascade, by forming a quaternary inhibitory complex with TF-FVIIa, and FXa.

Aim: To investigate the influence of αTFPI on thrombin generation (TG) in thrombotic patients with and without APS.

Methods: Ninety-one patients with arterial and/or venous thromboembolism, 46 with APS and 45 non-APS receiving warfarin anticoagulation, and 74 healthy normal subjects were studied. IgG αTFPI was measured using recombinant human TFPI (Chiron Corp, California, USA) by an optimised in-house ELISA. Results were expressed in arbitrary units (U/mL) with reference to a plasma sample from an index high titre αTFPI APS patient arbitrarily considered as 100 U/mL. A cut-off value of 60.8 U/mL was determined to be the 99th centile in the 74 normal subjects. TG was assessed using the automated calibrated thrombogram with PPP-reagent (5 pM TF, 4 μM phospholipid; Diagnostica Stago). Endogenous thrombin potential (ETP), peak, and lag time were assessed. Unless otherwise indicated, results are expressed as median and observed range.

Results: αTFPI levels were detected in 29.7% of the thrombotic patients, both APS and non-APS (45.7, 2.3–213 U/mL). Subgroup analysis revealed a higher prevalence of αTFPI in APS compared to non-APS patients, with αTFPI present in 37.0% (17/46) of the APS and 22% (10/45) of the non-APS group respectively ($P = 0.0413$). There was also a trend towards higher αTFPI values in the APS (52.2, 17.1–213.3 U/mL) compared with the non-APS (34.3, 2.3–167.0 U/mL) patients. Twelve of the 46 APS patients (26%) and only 4/45 (8.7%) of the non-APS patients had markedly raised αTFPI (> 100 U/mL) ($P < 0.001$). INR values were comparable in both APS (2.5, 1.0–4.4) and non-APS (2.2, 1.0–4.8) patients. However, evaluation of TG revealed longer lag times in both APS (9.8, 5.3–55.7 min) and non-APS patients (6.7, 3.7–15.6) when compared to normal subjects (4.3, 3.7–5.3). No association was observed between prolonged lag times and either αTFPI or LA positivity in either APS or non-APS patients. APS patients however, exhibited lower ETP and peak values compared to non-APS patients (median ETP 20.4 and 29.9 and median peak 26.5 and 38.5, respectively). No significant differences were observed between αTFPI positive and αTFPI negative APS patients in terms of lag time, ETP, and peak.

Conclusion: Our results suggest that the presence of αTFPI does not appear to have an effect on any of the parameters of TG in either APS or non-APS thrombotic patients. Possible influences on the protein C/S coagulation pathway that may modulate TG are under investigation. Despite comparable INR values and the observed prolongation of lag time in both thrombotic patient groups, APS patients tended to exhibit a greater prolongation of lag time, lower ETP and peak values compared to non-APS patients.

PB 1.62-5

Lack of association of serum mannose binding lectin or ficolins with complement activation in patients with antiphospholipid antibodies

Breen KA[1], Kilpatrick D[2], Swierzko AS[3], Cedzynski M[3] and Hunt BJ[1]

[1]Guys and St.Thomas' NHS Foundation Trust, London; [2]Scottish National Blood Service, Edinburgh; [3]Polish Academy of Sciences, Lodz, UK

Background: Complement activation is proposed to play a role in the pathogenesis of thrombotic and obstetric complications of APS with most evidence for this demonstrated in murine models of APS. Recently, we demonstrated increased levels of complement activation products, Factor Bb and C3aDesArg, in a large group of patients with primary APS (PAPS) or isolated antiphospholipid antibodies (aPL), confirming previous smaller studies but it is unclear how complement activation is occurring in these patients.

Complement activation occurs via the classical, alternative or lectin pathway. Mannose/mannan binding lectin (MBL), L-, H- and M-ficolins are components of the lectin pathway involved in recognition of pathogen-associated molecular patterns on microbial surfaces, leading to activation of complement by stimulation of MBL-associated serine proteases (MASPs). Most studies of the association of lectins with disease have been in patients with infection, although the lectin pathway has been implicated in development of autoimmune diseases such as systemic lupus erythematosus (SLE), but have not been studied in patients with aPL.

Aims: We hypothesised complement activation in patients with APS might be occurring through activation of the lectin pathway and sought to measure lectin pathway components in patients with PAPS or isolated aPL.

Method: Following approval from our local ethics committee, we obtained samples from patients at our institution who had PAPS according to International Consensus statement criteria, or had persistent aPL without associated complications. Patients with PAPS included 100 patients (median age 44, range 20–73 years) of whom 42 had previous thrombotic complications (venous and/or arterial), 27 had obstetric complications and 31 had isolated aPL. Thirteen healthy controls (median age 35, range 20–60 years) were also recruited. ELISA assays measuring MBL, L- and H-ficolins were performed. Statistical analysis of results was performed using Graphpad Prism statistical software. A P-value of < 0.05 was considered statistically significant.

Results: There were no significant differences in levels of MBL (mean 1.1 μg/mL, SD 1.0, $P = 0.6$), L- or H-ficolin levels (mean L-ficolin 1.9 μg/mL, SD 0.9, $P = 0.3$, H-ficolin 19.9 μg/mL, SD 8.1, $P = 0.09$) in patients with aPL/PAPS compared to healthy controls (mean MBL 1.1 μg/mL, SD 1.0, L-ficolin 1.7 μg/mL, SD 0.7, H-ficolin 21.6 μg/mL, SD 7.6), or when patients were analysed according to clinical phenotypes of aPL (thrombotic PAPS, obstetric PAPS or isolated aPL). MBL, L- and H-ficolin levels observed in this study were similar to previously reported human serum concentrations.

Conclusion: Low levels of C3 and C4 have been demonstrated previously in patients with aPL in addition to increased levels of complement activation products, C3a-desArg and Factor Bb so complement activation rather than deficiency has been proposed as a potential mechanism. Our findings of normal levels of potential initiating factors MBL, L- and H-ficolins provide no support for activation of the lectin pathway.

In conclusion, we have demonstrated normal levels of lectins, MBL, L- and H-ficolin in patients with aPL. Further studies of the mechanism of complement activation in patients with aPL are required.

PB 1.62-6

Resistance to anticoagulant activity of annexin A5 in patients with antiphospholipid syndrome with and without systemic lupus erythematosus receiving hydroxychloroquine

Breen KA[1], Wu X[2], Rand JH[2] and Hunt BJ[1]

[1]*Guys and St.Thomas' NHS Foundation Trust, London, UK;* [2]*Montefiore Medical Center, New York, NY, USA*

Background: Disruption of the annexin A5 (AnxA5) anticoagulant shield has been proposed to play a role in the pathogenesis of thrombosis and obstetric complications in patients with antiphospholipid antibodies (aPL)[1]. Hydroxychloroquine has been reported to decrease thrombotic events in patients with antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE)[2–4] and *in vitro* has been shown to reverse binding of aPL to syncytiotrophoblasts and restore AnxA5 expression[5]. To date there have been no human studies of the effects of hydroxychloroquine on the laboratory parameters of patients with aPL.

Aims: The aim of our study was to assess resistance to AnxA5 anticoagulant activity in patients with aPL before and after commencing hydroxychloroquine.

Methods: Following approval from our local ethics committee, we obtained samples from 18 patients with primary and secondary APS (16 females, two males, median age 55 (range 18–70) years). Eleven patients had primary APS and seven had APS in association with SLE. Of the patients with primary APS, 10 had previous thrombotic events and one patient had previous apl related obstetric complications. Of the patients with aPL associated with SLE, five had previous thrombosis, and two had previous apl related obstetric complications. Twelve patients were receiving Vitamin K antagonists and four were receiving aspirin. AnxA5 anticoagulant activity of patient plasma was assessed before, and 3 months after starting hydroxychloroquine 200 mg daily. The anticoagulant activity of AnxA5 was calculated as follows: AnxA5 anticoagulant ratio = (coagulation time in the presence of AnxA5/coagulation time in the absence of AnxA5) × 100%.

Results: No significant differences in AnxA5 anticoagulant activity ratio were observed in patients 3 months after commencing hydroxychloroquine (mean 193% SD 31.0). compared to before commencement (mean 187.3% SD 29.4)

Conclusions: In conclusion, no changes in resistance to AnxA5 anticoagulant activity were found in this small patient cohort with APS after commencing hydroxychloroquine.

PB 1.63-1

Effects of exercise stress testing on blood coagulation and fibrinolysis in asymptomatic aortic stenosis

Undas A[1], Trela R[2] and Fil K[2]

[1]*Jagiellonian University Medical College;* [2]*John Paul II Hospital, Krakow, Poland*

Background: A role of haemostasis in aortic valve stenosis (AVS) is still unclear. Enhanced thrombin formation combined with platelet activation in circulating blood and fibrin deposition on the aortic valve were observed in AVS patients. Recently, we have reported that hypofibrinolysis is more common in these patients than in controls. Acute physical exercise is known to increase blood coagulation and fibrinolysis in healthy subjects.

Aim: We sought to investigate changes in coagulation and fibrinolysis parameters in AVS caused by physical strain.

Methods: Exercise stress echocardiography was performed by 32 consecutive asymptomatic moderate to severe AVS patients. We measured peak thrombin generated [C_{max}] using the calibrated automated thrombogram, clot lysis time [CLT], thrombin activatable fibrinolysis inhibitor [TAFI], plasminogen activator inhibitor-1 [PAI-1], tissue plasminogen activator [tPA], and plasminogen four times: at rest, at peak exercise, 1 and 24 h after exercise. Thirty-two age-and sex-matched individuals served as controls.

Results: The duration of echocardiography stress test was shorter in AVS group ($P = 0.008$), and mean workload reached 81.3 Watt. C_{max} at peak exercise was 25% higher (median, 309.8 vs. 253.7 pg/mL, $P < 0.001$) in AVS group, and reached its highest level 24 h from exercise, while it gradually decreased with time post exercise in controls. CLT was 13% longer in AVS patients at baseline (median, 104.5 vs. 92.3 min, $P = 0.006$) and further increased at peak exercise in AVS group, while decreased in controls; the intergroup difference was 28% ($P < 0.001$). CLT decreased in AVS patients by 41% 1 h after exercise reaching a level similar to the control group. Twenty hours after physical strain CLT became longer with its 15% higher value than in controls ($P < 0.001$). TAFI activity was higher in AVS group than in controls in all time points (all $P < 0.001$). TAFI tended to increase at peak exercise, and after 1 h its activity decreased ($P < 0.001$), and after following 24 h reached a higher value than prior to the exercise ($P = 0.003$). No such changes in TAFI activity were observed in the control group. Plasminogen was higher in AVS group at peak exercise ($P = 0.023$), and then one ($P < 0.001$) and 24 h after its termination ($P = 0.019$). Under exertion no changes in PAI-1 and tPA antigens were observed in AVS patients. There were no associations of coagulation and fibrinolysis markers with disease severity and exercise induced changes in echocardiographic parameters.

Conclusion: This study is the first to show that asymptomatic moderate or severe AVS patients respond to physical activity with a more pronounced increase in thrombin activation and impaired fibrinolysis compared with age and sex-matched controls. The prothrombotic in AVS patients following exercise may promote fibrin deposition on aortic valve leaflets, thus enhancing the progression of this heart disease.

PB 1.63-2

Fibrin clot formation and fibrinolysis in patients with coronary stent thrombosis

Godschalk TC[1], Konings J[2], Govers J[2], Ten Berg JM[3], Hackeng CM[4] and Ten Cate H[2]

[1]St. Antonius Hospital, Nieuwegein; [2]CARIM, Maastricht University Medical Center, Maastricht; [3]Department of Cardiology, St. Antonius Hospital; [4]Department of Clinical Chemistry, St. Antonius Hospital, Nieuwegein, The Netherlands

Background: Coronary stent thrombosis (ST) is a feared complication of percutaneous coronary intervention (PCI) leading to high morbidity and mortality. The incidence of ST is approximately 1–5%, despite dual antiplatelet therapy with aspirin and clopidogrel. Multiple factors underlie the pathophysiological mechanisms of ST, such as stent underexpansion and high residual platelet reactivity. Fibrin clot formation and fibrinolysis may be different in ST patients compared to patients not suffering from ST and thus play a role in the occurrence of ST. A single study by Undas et al. (ATVB, 2010) showed that, compared to control patients, ST patients formed denser fibrin clots which were more resistant to lysis, suggesting that alterations in fibrin clot formation and lysis could indeed contribute to the pathophysiology of ST.

Aim: The present study aimed to assess the plasma fibrin clot formation and fibrinolysis of ST patients compared to control patients.

Methods: A single-center case-control study was performed. Cases had a history of an angiographically confirmed ST (Academic Research Consortium criteria). Controls had a stent implantation without ST during follow-up (minimal 12 months) after index PCI. Controls were matched based on indication and time of the index PCI of cases. Subjects using oral anticoagulants at the time of blood collection were excluded. Fibrin clot formation was measured with a turbidity assay for the parameters lag time and maximal absorbance. Platelet poor plasma (PPP) samples were diluted 1:1 with Hepes buffer (25 mM Hepes, 150 mM NaCl, pH = 7.5) and 0.75 nM human thrombin, 16 mM $CaCl_2$, and 10 μM phospholipids were added to initiate clot formation. All concentrations were final concentrations. Fibrinolysis was measured with a clot lysis assay for the parameter clot lysis time (defined as time from 50% clot formation to 50% clot lysis). PPP samples were diluted similar to the turbidity assay and 50 ng/mL tissue plasminogen activator (tPA) was added to start fibrinolysis. Fibrinogen levels were determined using the von Claus method. All subjects provided written informed consent. The study was approved by the local institutional review board and was conducted according to the principles of the Declaration of Helsinki.

Results: A total of 27 cases and 27 controls were included. From the cases, 12 patients had experienced an early ST (≤ 30 days after PCI) and 15 patients a late ST (> 30 days after PCI). Fibrin clot formation was not significantly different between cases and controls; lag time 173 ± 47 vs. 161 ± 27 s ($P = 0.26$), maximal absorbance 0.78 ± 0.16 vs. 0.83 ± 0.21 ($P = 0.36$). In addition, no difference in clot lysis time was observed for cases compared to controls; clot lysis time 69.2 ± 20.1 vs. 71.3 ± 25.3 min ($P = 0.75$). Fibrinogen levels were comparable in cases vs. controls (3.50 ± 0.73 vs. 3.60 ± 0.74, $P = 0.65$).

Summary/Conclusion: Plasma fibrin clot formation and fibrin clot lysis for ST patients are comparable to control patients. Based on the results of these ex vivo tests, a role for fibrin clot formation and lysis in the process of stent thrombosis is less likely. The reasons for this apparent discrepancy with previous data warrants further exploration.

PB 1.63-3

Risk of myocardial infarction and ischaemic stroke and the impact of hypercoagulability – the RATIO case control study

Siegerink B[1], Maino A[2], Rosendaal FR[1] and Algra A[3]

[1]LUMC, Leiden, The Netherlands; [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy; [3]UMCU, Utrecht, The Netherlands

Background: Myocardial infarction (MI) and ischaemic stroke (IS) are both acute forms of arterial thrombosis. Some risk factors are shared, but others are not, indicating possible different pathophysiological mechanisms.

Aims: This study aims to determine whether measures of hypercoagulability have a comparable impact on the risk of MI and IS.

Methods: The RATIO study is a case control study involving young women (< 50 years) with MI, non-cardioembolic IS and healthy controls. To compare the impact of prothrombotic factors we calculated relative odds ratios (OR_{IS}/OR_{MI}) and their corresponding confidence intervals based on published results. Additionally, we calculated population attributable fractions (prevalence in cases *(OR-1/OR)), which reflect the fraction of cases prevented if the exposure were to be eliminated from the general population. Informed consent was obtained from all participants and the study protocol was approved by the medical ethic committees from al participating hospitals.

Results: In total, 30 prothrombotic risk factors were identified as measures of hypercoagulability (see Figure 1). The population attributable fractions show that measures of hypercoagulability have a bigger impact on IS risk than for MI. Twenty-one of these risk factors have a relative odds ratios > 1, 14 > 2, and 6 > 2.75 being high levels of activated FXI and FXII, combination of oral contraceptive use and factor V Leiden trait, the presence of lupus anticoagulans, and a single nucleotide polymorphism in the gene coding for coagulation factor XIII.

Conclusion: Overall, prothrombotic factors have a bigger impact on the risk of IS that than of MI, suggesting a different role of hypercoagulability in the underlying mechanism of these two diseases. The results from the RATIO study are subject to potential sources of these biases, such as reverse causation and residual confounding. However, because we compare results within a single study, the impact of this bias is similar for the MI and IS analyses and therefore cannot explain the observed contrast.

PB 1.63-4

A pig model of primary angioplasty of acute myocardial infarction in human like conditions

Drouet L[1], Sideris G[1], Magkoutis N[1], Bonneau M[2], Kang C[3], Bal dit Sollier C[4] and Henry P[1]

[1]AP-HP, Paris; [2]INRA-CR2I, Jouy En Josas; [3]IVS- CR2I; [4]IVS, Paris, France

Background: The principal challenge in primary angioplasty is not to achieve culprit vessel reopening (which is regularly obtained) but to prevent the myocardial microvascular obstruction: the no-reflow phenomenon which determines initial and long term prognosis of patients. The main factors of the no-reflow are the micro-thrombotic distal embolizations from the main thrombus and the ischemia reperfusion which includes endothelial reactivity induced by numerous cellular reactions. Although pig is a suitable animal to test human materials and conditions, as it is close to human thrombotic and vascular reactivity, the experimentally used animal model is usually a very young animal (to fit the size) with optimal endothelial reactivity. Besides the animal, the model of coronary occlusion is usually achieved mechanically, thus the existing models are poorly predictive of the human pathological conditions.

Aim: Thereby, we set up a new model of thrombotic coronary occlusion for primary angioplasty in elderly downsized naturally hypercholesterolemic pigs characterized by a major endothelial dysfunction.
Materials and methods: Coronary artery thrombotic occlusion was achieved by placing a commercially available coil (for reproducibility) into the right coronary artery (RCA) (size adapted to animal coronary size) via a guiding catheter in 13 elderly downsized swines genetically selected to be spontaneously hypercholesterolemic (FBM pigs). The RCA was chosen in order to limit the risk of irreversible ventricular fibrillation. Repeated angiographic imaging confirmed the progressive (mean time 20 min, from 1 to 60 min) RCA total thrombotic occlusion. After 1 h of waiting (aiming to mimic human conditions) the animal was treated with the usual antiplatelet and anticoagulant pharmacological preparation so as to allow to proceed to recanalization with a guidewire pre-dilatation with a semi compliant balloon. Thrombus was visualized and quantified with Optical Coherence Tomography (OCT) imaging and, finally, deployment of a stent (of a proportional to the coil length and diameter) and repeated OCT. Total occlusion time 90 min, mean recanalization time 15 min and post reperfusion waiting time till sacrifice 180 min. Myocardial infarction was confirmed by ECG, biochemical, histological, macroscopic examination and TTC (triphenyltetrazolium chloride) staining in all animals.
Results: Thrombotic occlusion has been acutely achieved in all 13 pigs. Eight of them presented ventricular tachycardia (VT) or/and ventricular fibrillation (VF) episodes in the early phase of revascularization· transthoracic direct current (DC) electrical cardioversion was succeeded in all these situations. MI was confirmed in all animals. Besides, all animals survived until the previously selected time for sacrifice.
Conclusion: The generation of thrombotic occlusion in atherosclerotic pigs is feasible by percutaneous intracoronary placement of a coil. The above described model is suitable for the purpose of experiments in materials and treatments efficacy. The model of elderly genetically selected to be hypercholesterolemic pigs allows short term evaluation as well as long term evolution of these animals. The whole experimental model is highly representative of usual AMI patients.

PB 1.63-5

Increased arterial thrombo-embolic events and major bleeding in patients with atrial fibrillation and chronic kidney disease on vitamin K-antagonist treatment

Kooiman J, Spaans B, Van De Peppel R, Van Beers CAJ, Cannegieter SC, Van Der Meer FJM, Rabelink TJ and Huisman MV

Leiden University Medical Center, Leiden, The Netherlands

Aim: To analyze the risk of arterial thrombotic events (ATEs), major bleeding and its predictors in patients with chronic kidney disease (CKD) compared with non-CKD patients, treated with vitamin K-antagonists (VKAs) for atrial fibrillation (AF).
Methods: Medical records of 417 CKD and 300 non-CKD (GFR > 60 mL/min) patients starting VKA therapy between 1997 and 2005 were searched for ATEs and major bleeding. ATE was defined by myocardial infarction, stroke/transient ischemic attack, claudicatio intermittens, unstable angina, carotid or peripheral bypass graft/angioplasty. Major bleeding was defined by bleeding being fatal, causing a drop in Hb level $\geq$ 1.24 mM, requiring transfusion of $\geq$ 2 units of whole blood/red cells, or being symptomatic in a critical area.
Results: ATEs occurred in 108/737 (14.7%, 95%CI 12.3–17.4) patients. Patients with a GFR < 30 mL/min were at increased risk of ATE compared with non-CKD patients (hazard ratio (HR) 3.4 (95% CI 2.1–5.6). ATEs occurred as frequent in patients with GFR 30–60 mL/min as in non-CKD patients (HR 1.1, 95%CI 0.7–1.7). Major bleeding occurred in 115/737 patients (15.6%, 95%CI 13.2–18.4). The risk of major bleeding increased in patients with a GFR < 30 mL/min compared with non-CKD patients (HR 1.8, 95%CI 1.1–3.0). Major bleeding risk was not increased in patients with a GFR 30–60 mL/min compared with non-CKD patients (HR 0.9, 95%CI 0.6–1.4). Low GFR levels were associated with high variability within a patients INR values (correlation term −0.17, $P \leq 0.001$). INR variability > 0.5 (HR 1.5, 95% 1.0–2.4) increased the major bleeding risk.
Conclusion: Patients with a GFR < 30 mL/min are at increased risk of ATEs and major bleeding compared with non-CKD patients. The increased bleeding risk may be due to high INR variability, a marker of suboptimal VKA therapy.

PB 1.63-6

Thromboembolic complications or intracerebral haemorrhages in patients with atrial fibrillation in the emergency departments. Complications of atrial fibrillation in Bologna: the CAF-BO study

Cosmi B[1], Salomone L[1], Cavazza M[1], Guizzardi G[2], Binetti N[3], Procaccianti G[2], Puddu GM[1] and Palareti G[1]

[1]S.Orsola-Malpighi University Hospital; [2]Maggiore Hospital; [3]Bologna North Area Hospital, Bologna, Italy

Background/Aims: To establish the incidence of thromboembolic and cerebral haemorrhagic events in subjects with non valvular atrial fibrillation in the area of Bologna, Italy. Design and setting: prospective study in the Emergency Departments in the area of Bologna, Italy.
Patients and Methods: In the area of Bologna a web based network of anticoagulation clinics allows the surveillance of approximately 8000 (57%) patients on vitamin K antagonists out of estimated 14 000 patients with atrial fibrillation in our area. We evaluated consecutive patients with atrial fibrillation referred to the Emergency Departements with either thromboembolic complications or spontaneous intracerebral haemorrhages from January to June 2012. All patients underwent computed tomography and on the day of admission demographic data were collected along with the presence of atrial fibrillation, use of vitamin K antagonists or antiplatelet agents.
Results: We recorded 178 patients with cardioembolic events and 20 patients with spontaneous intracerebral haemorrages. The majority of patients with events were in the age range 70–90 and females (66%). Atrial fibrillation was persistent in 97 (49%) patients, paroxysmal in 65 (33%) and diagnosed during hospitalization in 12 (6%). Thromboembolic events were cerebral in 159 (89%) and peripheral in 19 cases (11%). Patients with cardioembolic events were receiving vitamin K antagonists in 17% of cases, antiplatelet agents in 58% of cases and no anti-thrombotic treatment in 22% of cases. In patients treated with vitamin K antagonists the INR was in the therapeutic range in 42% of cases and subtherapeutic in 52% of cases. Among patients with spontaneous intracerebral haemorrhages, 12 were on vitamin K antagonists and the INR was in theraputic range in 85% of cases. The inhospital mortality rate was 19% (34 cases) in subjects with thromboembolic events and 45% (9) cases in patients with intracerebral haemorrhages. We can extrapolate that in patients with non valvular atrial fibrillation older than 70 year the incidence of thromboembolic events is 0.56% patients years while on vitamin K antagonists and 4.54% patients years when on antiplatelet agents or no treatment (relative risk reduction: 88%). The estimated incidence of intracerebral haemorrhages is 0.27% patients years on vitamin K antagonists and 0.26% patient-years when on antiplatelet agents or no treatment.
Conclusions: A relevant number of subjects with atrial fibrillation do not receive vitamin K antagonists and the estimated incidence of intracerebral haemorrhages is similar in patients treated with vitamin K antagonists and in patients treated with antiplatelet agents or not receiving any treatment.

PB1.64 – Diagnosis of VTE – I

PB 1.64-1

Clinical validity of a quantitative point of care d-dimer assay in an acute ambulatory DVT service

Strong J, Patel N, Briggs H, Clarke-Drury R, Coultas K, Dent J, Eggleston J, Frimpong V and Thornton D
University Hospitals of Leicester, Leicester, UK

Background: University Hospitals of Leicester acute ambulatory DVT service assesses 3000 patients a year. All patients are initially assessed using the modified Wells 2 level score. D dimer testing is carried out in patients with DVT unlikely scores and those with positive d-dimers have whole leg compression ultrasound (CUS) scans. Calf DVTs are treated. Turnaround time for laboratory d-dimer results is several hours. In an attempt to reduce patient waiting times and decrease the time to scan a pilot of a quantitative point of care (POC) d-dimer assay (Cardiac d-dimer, Roche) using the cobas h232 POC instrument was carried out. The initial pilot included 49 patients with the POC d-dimer with parallel laboratory d-dimer testing. Patients with a positive d-dimer by either method underwent whole leg CUS. Two patients (4%) with negative POC test but positive laboratory d-dimers had calf DVTs on CUS and this prompted a larger clinical validation study.
Aims: To clinically validate the performance of the POC d-dimer test in our acute ambulatory DVT service.
Methods: Five hundred patients with DVT unlikely Wells scores underwent parallel d-dimer testing with the POC d-dimer test and in the laboratory using the rapid STA Liatest method on the STA-R analyser. Patients with a positive d-dimer by either method had whole leg CUS. Those with negative d-dimers or CUS were followed up at 90 days.
Results: Two hundred and five of the 500 patients (41%) were discharged without a CUS scan as the POC and laboratory d-dimers were negative. Of the 295 scans performed 248 were negative for DVT. Forty-seven of the 295 (16%) of CUS scans demonstrated DVTs; 27 proximal (9%) and 20 distal (7%). There were 63 discordant d-dimer results (13%). 62/63 had negative POC results and positive laboratory results. Using the POC test alone with a cut off of 0.5 μg/L would have lead to three small calf DVTs being missed. The sensitivity and negative predictive value for the POC d-dimer for proximal DVTs was 100% using a cut off of 0.5 μg/mL. At this d-dimer cut off the sensitivity of the POC d-dimer for calf vein thrombosis was 86.9% and a negative predictive value (NPV) of 98.9%. Using the laboratory d-dimer test alone 59 of 62 positive POC d-dimer results (20% of CUS scans) would have been CUS scan negative and could have been avoided if the POC test had been used alone. Using a POC d-dimer cut off of 0.4 μg/mL there were 29 discordant results all with positive laboratory results. The sensitivity and negative predictive value for proximal and distal DVT was 100% with the POC d-dimer and would still have reduced the scans required by 29 (10%).
Conclusion: POC d-dimer testing in the initial screening of patients with suspected DVTs would reduce the number of CUS scans for patients with DVT unlikely Wells scores by 20% compared with our very sensitive laboratory method using a cut off of 0.5 μg/mL. Lowering the POC d-dimer threshold to 0.4 μg/mL is not justified for the minimal improvement in NPV from 98.9% to 100%.

PB 1.64-2

A review of computed tomography pulmonary angiograms in three teaching hospitals: the rise of subsegmental pulmonary emboli and their management

Goy J, Lee J, Levine O, Chaudhry S and Crowther M
McMaster University, Hamilton, ON, Canada

Background: The availability of Computed Tomography Pulmonary Angiography (CTPA) has led to an increase in the number of investigations for Pulmonary Embolism (PE). With more widespread use of these high resolution scans, the frequency of identification of isolated Small Sub-segmental Emboli (SSPE), which are of undetermined clinical significance, is also expected to increase.
Aims: To review the frequency of Pulmonary Embolism and Sub-segmental Pulmonary Embolism identified through CTPA as well as their management
Methods: Retrospective review of 1525 patient charts who underwent CTPA in three Hamilton teaching hospitals from 2009 to 2011. In depth chart review of patients with SSPE was undertaken to determine the indications for, frequency and complications of anticoagulation.
Results: Our patient population (mean age 64) consisted of 758 medical inpatients (50%), 512 surgical inpatients (34%) and 256 (17%) emergency department patients.
The frequency of PE was 26% (n = 392). Of these, the largest pulmonary filling defects were SSPEs in 58 patients (4% of total scans and 15% of identified PEs). In 40 of these 58 SSPEs, an alternative diagnosis to PE was identified on CT to explain the patients' symptoms. Isolated SSPE were present in 18 patients.
Approximately 44% (n = 26) received anticoagulation for SSPE.
Of the 1133 CTPAs that did not identify PE, an alternative diagnosis to account for the patient's symptoms was identified on CT in 737 (65%) and no alternative cause was found in 361 (35%).
Summary/Conclusions: Our study demonstrated a much lower frequency of pulmonary embolism in comparison to the 50% rate of PE reported in CTPA studies in the literature. SSPEs account for 15% of all PEs found in our study population – and were present in 4% of all patients undergoing CTPA. A substantial proportion of patients were anti-coagulated SSPE, though the safety and efficacy of this practice is unknown.

PB 1.64-3

Diagnostic accuracy of lung ultrasound for pulmonary embolism: a systematic review and meta-analysis

Squizzato A[1], Rancan E[1], Dentali F[1], Bonzini M[1], Guasti L[1], Steidl L[1], Mathis G[2] and Ageno W[1]
[1]University of Insubria, Varese, Italy; [2]Landeskrankenhaus Hohenems, Hohenems, Austria

Background: Computed tomographic pulmonary angiography (CTPA) has simplified the diagnostic approach to patients with suspected pulmonary embolism (PE). However, PE diagnosis is still probabilistic and CTPA should be used with caution in some patient groups, such as patients with severe renal insufficiency and pregnant women. Among alternative imaging tests, lung ultrasound is the most promising technique.
Aims: We aimed to systematically assess the diagnostic accuracy of lung ultrasound for PE diagnosis.
Methods: Studies evaluating the diagnostic accuracy of lung ultrasound for the diagnosis of PE were systematically searched in the MEDLINE and EMBASE databases (up to June 2012). QUADAS – 2 tool was used for the quality assessment of the primary studies. A bivariate random-effects regression approach was used for summary estimates of both sensitivity and specificity.
Results: Ten studies, for a total 887 patients, were included. A composite reference test was used in six studies, with single-row detector CTPA as the principal imaging test in four studies. Overall, seven studies used a proper reference test. Lung ultrasound bivariate weighted mean sensitivity was 87.0% (95% confidence interval [CI] 79.5, 92.0%), whereas bivariate weighted mean specificity was 81.8% (95% CI 71.0, 89.3%).
Conclusion: Our findings suggest that lung ultrasound may be a useful diagnostic tool in the management of patients with suspected PE. However, several methodological drawbacks of the primary studies limit any definite conclusion. Further well-designed accuracy studies are necessary before planning diagnostic management studies, in particular in those with a contraindication for CTPA

PB 1.64-4

Diagnosis, management and outcome of non-catheter related proximal upper extremity deep vein thrombosis

Chan N[1], Chunilal S[1], Tran H[1] and Merriman E[2]

[1]*Monash Medical Centre, Clayton, Australia;* [2]*North Shore Hospital, Auckland, New Zealand*

Background: Upper extremity deep vein thrombosis (UEDVT) occurs less commonly than leg DVT but is increasing in incidence given the use of central catheters. Studies often do not differentiate between catheter and non-catheter related UEDVT. There is a paucity of data regarding the diagnosis, management and prognosis of non-catheter related proximal UEDVT.

Aim: To explore the diagnosis, risk factors, management and outcome of proximal UEDVT in patients without central venous catheter.

Method: A retrospective case series of patients with objectively diagnosed proximal (axillary/subclavian) UEDVT identified through the radiology database at Monash Medical Centre (AUS) and through a pre-existing database at North Shore hospital (NZ) in the period of 01/2007 to 03/2012. Central venous catheter (CVC), or pacemaker associated UEDVT were excluded.

Results: We identified 65 patients (M:F = 36:29, mean age 51.6 years) with non-CVC UEDVT, categorised at diagnosis as: 32 (49.2%) primary, 8 (12.3%) minimally provoked, and 25 (38.5%) secondary UEDVTs. Twenty four (36.9%) patients had a history of active cancer at the time of diagnosis, and a further three out of 41 patients were diagnosed with cancer following UEDVT at a median age of 61 years, giving an incidence rate of 4.5 cancer diagnoses per 100 person-years for those categorised as primary UEDVT. In particular, the incidence rate of newly diagnosed cancer was 11.4 per 100 person-years if the over 50 years old were considered. Four (6.2%) patients suffered from concurrent symptomatic PE at presentation. All patients started anticoagulation with LMWH (95.4%) or heparin (4.6%). None underwent thrombolysis. Subsequently, 28 (43.1%) and 47 (56.9%) patients continued anticoagulation with LMWH (median duration = 3 months) and warfarin (median duration = 7 months) respectively. One patient underwent rib resection because of marked PTS. The patients with cancer related proximal UEDVT were older than the non-cancer UEDVT (mean age 63.8 vs. 44.5 years, $P < 0.001$). Cancer related UEDVT patients had a short median survival of 11.1 months, and higher estimated cumulative incidence of VTE recurrence at 12 months compared to the non-cancer group: 9.2% (95% CI: 2.5–34.6%) vs. 2.6% (95%CI: 0.4–18.2%). All VTE recurrences in the cancer associated UEDVT were pulmonary embolism. Overall major bleeding rate was 2/65 (3.1%, 95%CI: 0.2–11.2%). Repeat ultrasound showed residual defects in 29 (61%) patients in the 47 patients who were rescanned. Dynamic venography were performed in 12 patients with primary UEDVT. Evidence of a significant thoracic outlet obstruction defined by occlusion to flow > 90% on abduction was observed in five patients (41.7%, 95% CI: 19.4–68.1%). Quality of life and PTS score surveys are currently pending.

Conclusion: Age identified patients at higher risk of cancer associated UEDVT which has poorer prognosis both in terms of VTE recurrence (occurring as primarily PE) and mortality. Younger patients typically presented with primary UEDVT, with a diagnosis of thoracic outlet syndrome commonly observed in those assessed for it. Anticoagulation therapy alone appeared sucessful in managing most patients in our cohort with few undergoing lytic therapy or first rib resection.

PB 1.64-5

Development and accreditation of a standardized training program in thrombosis and vascular medicine – a Canadian initiative

Gonsalves CL[1], Bates SM[2], Wells P[3], Kahn S[4], Carrier M[3], Douketis JD[2] and Rodger M[3]

[1]*The Ottawa Hospital, University of Ottawa, AIME, Ottawa, ON;* [2]*McMaster University, Hamilton, ON;* [3]*The Ottawa Hospital, University of Ottawa, Ottawa, ON;* [4]*Jewish General Hospital, Montreal, QC, Canada*

Background: Having a policy statement on the educational mandate of a training program – a formal curriculum – is imperative in pursuing the goals of developing appropriate learning and evaluation strategies for trainees and providing quality care for patients on the receiving end of the products of clinical and research training initiatives. While the field of Thrombosis Medicine has rapidly evolved over the last few decades with respect to clinical and scientific advancements that continue to change the way consultants practice, there has been a distinct lack of progress in the development of standardized and accredited training programs in Canada and abroad that are accountable to licensing and government bodies. Canada has been a leader in the training of thrombosis consultants producing globally recognized prolific research and clinical careers. However, all thrombosis programs currently in existence are based on informal, locally developed curricula. The benefits of a formal and nationally accredited curriculum, which not only holds up an explicit standard to which teaching and learning take place, but also provides stakeholders with a measuring stick against which educational activities can be considered in view of practice requirements, cannot be ignored in this era of competency based education reforms and calls for greater accountability by the stakeholders in health care.

Aims: To develop and implement a standardized and nationally accredited training program in Thrombosis and Vascular Medicine through the Royal College of Physicians and Surgeons of Canada (RCPSC – the main licensing body for specialist physicians).

Methods: A multi-phase needs assessment was completed, and subsequently a committee was recruited and a curriculum document created based on the CanMEDS (RCPSC) framework of essential competencies for physician specialists. An application for formal national recognition and accreditation of a program in Thrombosis and Vascular Medicine was submitted to the RCPSC in the new area of accreditation designation, an 'Area of Focused Competence'.

Results: The application detailing the benefits of standardization and accreditation of training in Thrombosis and Vascular Medicine along with the extensive and practice-based Competency Training Requirements document have received favourable recognition and have been accepted for further review with the RCPSC. The proposed curriculum contains competency-based training requirements in areas of both venous and arterial thrombosis.

Conclusion: Canadian thrombosis training programs, accessed by national and international physicians, are on the route to obtaining formal, national, accreditation status. Given the ongoing growth in clinical care and research in Thrombosis and Vascular Medicine, establishing a standardized, validated curriculum is necessary to promote the highest standards of training and thus patient care. Similar training programs in other countries may find guidance in the needs assessment and formal curriculum to adapt them to their own population of trainees and clinical practice requirements. Future efforts will focus on the development of specific practice modules and assessment for this curriculum.

PB 1.64-6

An improved screening system for protein S type II deficiency: expanded versatility of total protein S activity assay

Tomohide T[1], Xiuri J[1], Hiroko T[2] and Naotaka H[3]
[1]Shino-Test Corporation, Sagamihara; [2]Nakamura Gakuen University, Fukuoka; [3]Nagasaki International University, Sasebo, Japan

Background: We have developed a total protein S-assay system to screen protein S type II deficiency (Tsuda, T. *et al*., *Blood Coagul Fibrinolysis* 23: 56–63, 2012). This assay system measures both the activity and quantity of total protein S at a high precision by using a commonly-used general-purpose automated analyzer and is proved to be a useful tool to screen molecular abnormalities of protein S.
Aims: The activity assay part of the system, a three-reagent system, comprises three reagents (R1, R2 and R3) and a dilution buffer (DilB) and requires 22 min for one assay. Because of these facts, not all analyzers can accommodate the assay. In the present study, we modified it to increase its applicability to a greater variety of instrument types in laboratories.
Methods: We modified the chemical compositions and the assay protocol of the total protein S activity assay to fit into a two-reagent system (R1, R2 and DilB), a more popular and less time consuming configuration, as opposed to the original three-reagent system (R1, R2, R3 and DilB). In the new assay, R1 contains activated factor V, R2 activated factor X, prothrombin, and a thrombin substrate S-2238 and DilB activated protein C. These chemical compositions were adjusted to obtain similar time course profiles to that of the original three-reagent assay. All data were collected using a Hitachi 7170S automated analyzer.
Results: The new two-reagent assay has fewer components which reduced reaction steps and assay time (10 min) compared with the original 22 min assay. The data of plasma samples (n = 33) obtained with the new two-reagent assay were well correlated with those with the three-reagent system ($y = 0.94x + 2.0$, $r = 0.93$), while intra- and inter-assay reproducibilities are better in the new one. The intra-assay C.V. improved to 0.9–2.0% from 1.4% to 4.5% of that of the three-reagent assay. Likewise, the inter-assay C.V. improved to 1.1–3.2% from 2.8% to 5.6%.
Conclusions: The modification presented here not only expanded the versatility of the total protein S activity assay but also shorten the assay time and made the reproducibility better. This enables us to screen molecular abnormality of protein S more efficiently and easily, and the screening system of protein S type II deficiency is now more practical.

PB 1.65-1

Health-related quality of life after pulmonary embolism – a case–control study

Tavoly M[1], Wik HS[2], Nori F[3] and Ghanima W[3]
[1]Sahlgrenska University Hospital, Göteborg, Sweden; [2]Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Østfold Hospital Trust, Fredrikstad, Norway

Background: Pulmonary embolism (PE) is a common acute medical emergency. Research and clinical practice mainly focuses upon the medical treatment and clinical outcomes of PE. Surprisingly the psychological aspects and the impact of acute PE on quality of life (QoL) have not been studied properly.
Aims: The study aimed to determine Health-Related Quality of Life (HRQoL) in patients surviving acute pulmonary embolism compared to age- and sex-matched population having no previous history of venous thromboembolism (VTE).
Methods: This case-control study evaluated HRQoL using the generic QoL questionnaire EQ-5D among patients who had objectively verified PE between 2002 and 2011 in Oestfold Hospital Fredrikstad – Norway. Each patient was asked to hand over the same questionnaire to two age- and sex-matched (± 5 years) relatives or friends having no previous history of VTE, so called Buddy Controls. The questionnaire consists of the following five dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. It also includes a vertical self-rated grading scale for total health-condition from 0 to 100, called EQ-VAS scale. Lower scores represent worse QoL. The EQ-5D dimensions can be converted to a single summary index value obtained from the general population. The study was approved by the Regional Ethics Committee; written and informed consent was obtained from all patients.
Results: A total of 208 patients (mean age 61 years; range 23–86 years) and 114 controls completed the questionnaire. When the five dimensions of health profile (mobility, self-care, activity, pain and anxiety) were dichotomized into no problems and problems, a statistically significant difference was found between cases and controls throughout all dimensions. The mean index value of EQ-5D was 0.81 (SD 0.22) among patients and 0.92 (SD 0.16) among controls. The difference between cases and controls in mean index value was 0.11. This difference was statistically significant ($P < 0.001$, Mann-Whitney) and also likely to represent a clinically meaningful difference (≥ 0.08). On the EQ-VAS patients reported a significantly lower mean score than controls, 67.2 (SD 21.3) and 81.3 (SD 16.9), respectively ($P < 0.001$, t-test).
Summary/Conclusions: This study indicates that the quality of life is reduced in patients who have sustained an acute pulmonary embolism as compared to age- and sex-matched population without previous history of VTE. These results confirms previous reports by Klok et al showing reduced QoL after PE in comparison to Dutch population norms, using the generic questionnaire SF-36. To our knowledge this is the first study in which health-related quality of life (HR-QoL) was compared to age- and sex-matched VTE – free controls. This is a novel research-field concerning PE, which should be further investigated specifically regarding the factors affecting HR-QoL and the socio-economic consequences after PE.

PB 1.65-2

Treatment patterns of venous thromboembolism in a real world population: the Q-VTE study cohort

Tagalakis V, Patenaude V, Kahn SR and Suissa S
Lady Davis Institute for Medical Research/Jewish General Hospital, Montreal, QC, Canada

Background: Describing treatment patterns of venous thromboembolism (VTE) in a real world population may identify remedial gaps in patient care.
Aim: We aimed to characterize anticoagulant use following incident VTE in a real world setting.
Methods: We used the linked administrative healthcare databases of the province of Québec, Canada, including the hospitalization, universal healthcare services, and out-patient prescription databases. We identified all beneficiaries with an incident DVT or PE between 2000 and 2009, which we classified as definite or probable VTE using *a priori* determined diagnostic algorithms based on ICD-9-CM or ICD-10-CA diagnosis codes. We formed two patient cohorts, one with definite and the other including definite or probable first-time VTE, that were followed until death or end of study (December 31, 2009). Anticoagulant out-patient prescription patterns were analyzed for both patient cohorts.
Results: From 245,452 Québec residents between 2000 and 2009 with at least one VTE diagnosis in RAMQ or MED-ÉCHO, we formed the definite VTE cohort including 40,776 definite cases and the any VTE cohort consisting of 54,803 definite or probable cases. In the definite cohort, 13,858 (34%) cases required hospitalization for VTE, 24,203

(59%) developed VTE during hospitalization, and 2715 (7%) were diagnosed and managed in the out-patient setting. In the any VTE cohort, 13,214 (24%) cases were hospitalized for VTE, 23,152 (42%) developed VTE in hospital, and 18,437 (34%) were diagnosed in the out-patient setting. In the definite cohort, 74% of cases filled an out-patient prescription for an anticoagulant, and most received a vitamin K antagonist (VKA) either alone or in combination with low molecular weight heparin (LMWH) (54% VKA alone, 33% VKA and LMWH, and 10% LMWH alone).

In the any VTE cohort, 71% were dispensed an anticoagulant. In the definite cohort, out-patient prescription dispensation varied according to the setting of diagnosis (91% for cases requiring hospitalization for VTE; 66% for cases diagnosed with VTE while hospitalized; and 55% for cases diagnosed and managed in the out-patient setting). Similar findings were found in the any VTE cohort, although a greater proportion of cases (63%) in the out-patient setting filled a prescription for an anticoagulant. Among definite cases who were dispensed a VKA and filled more than one VKA prescription (n = 26,684), 64% discontinued VKA within 3 months, 13% between 3 and 6 months, and 9% after 6 months of initiating therapy. In all, 50% of cases discontinued VKA after 64 days of use. The mean duration of VKA therapy was 109 days (Standard Deviation 164). Similar findings were found in the any VTE cohort.

Conclusions: Our study provides useful information on VTE management in a real world population. Our results suggest that there may be important treatment gaps since only 74% of patients with VTE were dispensed a prescription for an anticoagulant, those managed in the out-patient setting were less likely to fill a prescription for an anticoagulant than patients who had been hospitalized, and a significant proportion of patients discontinued VKA therapy early.

PB 1.65-3

Single whole-leg compression ultrasound for exclusion of deep vein thrombosis in symptomatic ambulatory patients: a prospective observational cohort study

Horner D[1], Hogg K[2], Body R[1], Nash MJ[1] and Mackway-Jones K[1]

[1]Central Manchester University Hospitals NHS Foundation Trust, Manchester, UK; [2]The Ottawa Hospital, Ottawa, ON, Canada

Background: United Kingdom guidance has recently recommended serial proximal compression ultrasound (CUS) as first line imaging for suspected deep vein thrombosis (DVT). Single whole-leg CUS is a routine alternative diagnostic strategy that can reduce repeat attendance and identify alternative pathology.

Aims: We sought to assess the performance characteristics of an established emergency department ambulatory protocol incorporating whole-leg CUS by non-physicians for exclusion of DVT.

Methods: A prospective observational cohort study. Consecutive, ambulatory, adult patients with suspected DVT and negative or inconclusive whole-leg CUS had anticoagulation initially withheld and were followed up after 3 months.

The primary outcome was a predefined clinically relevant adverse event rate: a subsequent diagnosis of symptomatic venous thromboembolism (VTE) or VTE related death during 3 month follow up. Secondary outcomes included alternative diagnoses, technical failure rate and patient characteristics associated with failure.

Results: Two hundred and twelve patients agreed to participate and were followed for 3 months. One patient was subsequently diagnosed with a calf DVT. The adverse event rate was thus 1/212, 0.47% (95% Confidence Interval [CI] 0.08–2.62%). For patients deemed at high clinical risk by Wells scoring prior to ultrasound (n = 47), the adverse event rate was 2.1% (95% CI 0.4–11.1). One patient died during the follow up period. This death was deemed unrelated to VTE by the central adjudication committee.

150/212 patients were provided with a clear documented alternative diagnosis. CUS directly contributed to or confirmed the alternate diagnosis in 55/150 patients, of which the top three diagnostic labels were musculoskeletal injury, Bakers cyst and venous incompetence. Technical imaging failure occurred in 11.3% of cases (95% CI 7.7–16.3). Several potential predictors of an inconclusive result were identified on multivariate analysis: obesity (odds ratio 4.15, 95% CI 1.5–11.2), recent immobilzation (odds ratio 4.9, 95% CI 1.5–16.2), active cancer (odds ratio 7.9, 95% CI 1.5–41.7) and acute infection (odds ratio 2.9, 95% CI 1.1–8.0).

Conclusion: Patients who have anticoagulation withheld following a negative or inconclusive whole leg CUS for suspected DVT have a low rate of adverse events at 3 months. In addition, whole leg CUS provided additional diagnostic information and confirmed an alternative diagnosis in over a quarter of patients within this study.

Technical failure remains an issue: several factors were significantly associated with an inconclusive result in our cohort and their presence may warrant an alternative diagnostic approach.

PB 1.65-4

Retrospective audit of incidental VTE events over 3 years in a large teaching hospital

Rowswell HR and Nokes TJC

Plymouth Hospitals NHs Trust, Plymouth, UK

Background: Studies previously reported the prevalence of incidental pulmonary embolism (PE) in patients having CT scans for reasons other than PE investigation. A subsequent meta-analysis of these studies found a mean prevalence of incidental PE of 2.6% (CI 1.9–3.4). Further retrospective review has elucidated the mean prevalence of abdominal vein Deep vein thrombosis as 1.74% (CI 1.29–2.34). We recently reported incidental VTE events from a 900 bed teaching hospital, with numerous tertiary services, as 1.64% (55 of 3358 scans) over 2011. The three most common VTE risk factors were Age, > 60 year (85%), active cancer (76%) and significant medical co morbidity (36%). Other associated information was the prevalence of Hospital Acquired Thrombosis (HAT) and the reason for CT scanning. The mortality associated with these diagnoses was 39 of 55 (71%), occurring a mean of 120 days after diagnosis, with 12 month mortality of 36 of 55 (65%).

Aims: Data has been collected for the last 3 years on incidental VTE events, to see if the prevalence, risk factors and association with HAT changed over that time. Also, to compare incidental findings pick-up rate with those scans that were targeted to investigation for VTE and to compare mortality.

Methods: The hospital radiology reporting system (CRIS) has been reviewed retrospectively, to determine incidental VTE diagnoses in CT scans of chest, abdomen and pelvis (or combination there of). This information was cross-checked with the hospital patient administration system (PIMS) to identify whether the patient event qualified as HAT.

Results: The incidental VTE prevalence rates for 2010, 2011 and 2012 were 76 of 6079 (1.25%), 55/3358 (1.64%) and 57/4914 (1.16%), for non-VTE targeted CT scans. HAT events were 28%, 20% and 33% respectively, yielding prevalence for HAT incidental findings of 0.34%, 0.33% and 0.39%. The pick-up rates for all VTE targeted investigations for the same periods were: 640/3819 (16.8%), 751/4660 (16.1%) and 738/4818 (15.3%). For HAT events, the targeted CT scan pick-up rates were: 31%, 31% and 27%.

The most prevalent risk factors for incidental findings in 2010, 2011 & 2012 are: age > 60 years: 78%, 85% and 91% respectively, Cancer: 68%, 76%, 67% and serious medical comorbidity: 32%, 36%, 30%.

The overall mortality for incidental VTE events is: 57/76 (75%) from 2010, 39/55 (71%) from 2011 and 29/57 (51%) for 2012, giving 12 month mortality rates of 63% for 2010 and 65% for 2011.

The three most common reasons for CT scanning, in order were: staging for cancer, further investigation for abnormal findings on previous scans and unexplained weight loss, for all 3 years.

Summary: As expected, this radiology outcome data identifies incidental VTE to be relatively low prevalence, when compared to targeted scans for VTE. Twelve month mortality associated with incidental VTE (63% and 65%) is significantly greater than published data related to all cause VTE events (15%). This is not surprising, acknowledging the high mortality associated with cancer the second most common risk factor.

PB 1.65-5

Provision of an external quality assessment programme for D-dimer point of care testing kits

Kitchen D, Munroe-Peart S, Kitchen S, Jennings I, Woods TAL and Walker ID

UK NEQAS BC, Sheffield, UK

Background: There is a drive towards Point of Care Testing (POCT) in areas of haemostasis other than INR monitoring and recent developments have led to the availability of POCT devices for D-dimer testing. These devices are portable desktop analysers that are well suited to non laboratory areas but still require quality control to ensure reliable test results. External Quality Assessment (EQA) is already available to laboratories with 681 centres registered in the UKNEQAS BC laboratory programme for D dimer testing.

Aims: To develop a specific programme for D-dimer testing to meet the needs of POC users.

Methods: In-house studies had previously been performed which validated the use of lyophilised plasma for EQA testing with the quantitative methods -Cobas h232 (Roche) and Triage (Alere) and with qualitative- Clearview Simplify kits (Alere). The precision of results on this material and the accuracy of results compared to the UK NEQAS BC laboratory programme medians for these samples were assessed. Interested POCT centres were then approached to take part in a series of pilot studies to evaluate the use of lyophilised material for POC D-dimer EQA testing. Samples were distributed over a period of 3 years with Cobas users receiving 14 samples and Clearview users receiving 7. Patient scenarios were introduced in pilot 4–7 (four samples for Clearview and eight for Cobas users). Users were asked to indicate whether deep vein thrombosis (DVT) could or could not be excluded using their result and the patient scenario provided. Seven pilot studies have taken place over a period of 3 years with up to 42 Clearview users and 35 Cobas users. Users of the Cobas device received two samples per pilot study with sample medians ranging from 0.17 to 1.2 μg/mL FEU. Users of the Clearview device received one sample per study and were asked to state if it was positive or negative.

Results: Precision for the Cobas device was similar to that observed in theUKNEQASBC laboratory programme for D dimer testing with coefficients of variance between 8% and 25% (outliers excluded – some results being clear outliers) from the median value. Of the seven samples circulated to the Clearview users only two samples had results on which all centres agreed. For those samples with patient scenarios provided the clinical interpretations (DVT excluded or not excluded) showed full agreement in 4/8 of the samples for Cobas users and 1/4 samples for the Clearview users. An exercise will take place for the Triage users in early 2013.

Conclusion: EQA is required for POC D-dimer tests and lyophilised UKNEQAS BC samples are suitable for this purpose. Our data shows that there is not only variance in both the results achieved and in their interpretation.

PB 1.65-6

Modified strain gauge plethysmography as an additional screening test for patients with suspected deep vein thrombosis

Hughes AS[1], Hall B[2], Piper B[2], Jennings K[2], Smith C[2], Charova F[3] and Dzora F[3]

[1]North East London Foundation Trust; [2]South West Essex Community Services, Brentwood; [3]Broomfield Hospital, Chelmsford, UK

Background: Only 15% of patients with suspected DVTs have Doppler scan confirmed thrombi. The use of clinical decision rules (e.g Wells score) and d-dimer testing can exclude DVT in 25–50% of patients presenting with suspected DVTs thus decreasing the need for confirmatory Doppler scanning. The introduction of point-of-care (POC) d-dimer testing has enabled DVT assessment to be carried out in the community. In 2009 at Brentwood Community Hospital we established a nurse led, haematologist supported primary care DVT screening service using the modified Wells score and a quantitative POC d-dimer test (cardiac d-dimer, Roche). Doppler scanning was carried out on site by vascular sonographers on patients who either had a Wells score of > 1 (DVT likely) or a Wells score of < 2 (DVT unlikely) but a raised d-dimer (cut off 0.5 μg/mL). Over the first 2 years 80% of referred patients required Doppler scans, but only 20% were positive.

Aims: To assess the potential usefulness of computerised Strain Gauge Plethysmography (SGP; Venometer V3, Amtec), utilising new software with a modified algorithm, as an additional screening test, to see if this might improve DVT screening effectiveness and decrease the number of Doppler scans necessary.

Methods: All patients continued to have modified Wells scores and POC d-dimer testing performed as above and the results continued to be the main determinant for Doppler scanning. In addition SGP scans were carried out by the trained nursing staff on patients with their verbal agreement but were not used to determine further management.

Results: One hundred and eighty-seven patients had all three screening tests carried out, Wells score, d-dimer and SGP, and also had Doppler scans performed. One hundred and eighteen patients had negative SGP scans and in only three were Doppler scans positive (2.5%; all being distal calf DVTs). Thus the sensitivity and negative predictive value (NPV) of a negative SGP scan for excluding proximal DVT was 100%. If all DVT positive Doppler scans were considered, the sensitivity and NPV of a negative SGP scan for excluding any DVT was 89% and 97% respectively. If all three screening tests were positive, 65% of patients had Doppler scan confirmed DVTs. If two out of three tests were positive, 11% had positive Doppler scans. If only one out of three tests were positive, only 5% of Doppler scans were positive. Selective use of SGP in our patients with discordant Wells scores and d-dimer results would have decreased the need for Doppler scans from 65% to 35%. Two distal calf DVTs would have been missed.

Conclusion: The addition of modified SGP to the Wells score and a d-dimer in the initial screening of patients with a suspected DVT improved the efficiency of DVT screening and could make more cost-effective use of Doppler scanning. This is a potential advantage when screening takes place in a primary care setting where Doppler scanning might not be locally or readily available. It is suggested that further prospective studies are undertaken to validate this approach.

PB1.66 – Hormones, Pregnancy, Women's Issues – I

PB 1.66-1

The pregnancy health-care program: a model for the prevention of venous thromboembolism in pregnancy

Testa S[1], Passamonti SM[2], Paoletti O[1], Zimmermann A[1], Bucciarelli P[2], Ronca E[3], Riccardi A[4] and Martinelli I[2]

[1]Haemostasis and Thrombosis Center-A.O. Istituti Ospitalieri, Cremona; [2]A. Bianchi Bonomi Hemophilia and Thrombosis Center, IRCCS-Policlinico, Milano; [3]Obstetrics Health Care Unit, ASL, Cremona; [4]Obstetrics and Gynaecology Division, AO Istituti Ospitalieri, Cremona, Italy

Background: Venous thromboembolism (VTE) is the leading cause of maternal mortality and morbidity in developed countries, with an annual incidence 7–10 times higher than outside pregnancy. There is a great variability of individual risk profiles, and recommendations on antithrombotic prophylaxis are based on case-control studies or experts' opinions that do not entirely satisfy the individual optimal management of pregnant women.

Aims: The aim of this study was to develop and use a 'Pregnancy Health-care Program' (PHP) that allows clinicians to tailor antithrombotic prophylaxis in pregnant women applying uniform criteria for evaluation of the individual risk of VTE.

Methods: The PHP was created inCremona, Italy, by a working group of haematologists who trained gynaecologists, obstetricians and medical practitioners. A number of risk factors, including personal and family history of VTE, several medical conditions, age, parity, BMI, and thrombophilia (when available), were expressed as odds ratios obtained from published studies and converted in a severity risk score ranging from 0.5 to 3. On the basis of different score ranges, women were stratified in three different categories and received clinical observation, compression stockings, LMWH or their combination during pregnancy. Visits were scheduled at the end of each trimester and if a woman changed risk category, antithrombotic prophylaxis changed accordingly. Physicians who did not join the PHP followed their pregnant women according to their clinical practice. Data on pregnancy outcome of the non-PHP women were obtained after delivery through hospital discharge records.

Results: From January 2008 to December 2010, 3715 deliveries occurred in Cremona hospital, of which 3697 were live births and 18 were intrauterine fetal deaths. The PHP reached 1787 pregnant women, whereas the remaining 1996 were managed without specific risk assessment. LMWH prophylaxis or therapy was prescribed to 85 women. In the PHP group only a pudenda vein thrombosis occurred. In the non-PHP group, eight events were recorded (0.4%), five VTE and three lower limb superficial vein thrombosis. The risk of VTE was higher in the non-PHP than in PHP group (c square test 4.49, $P < 0.03$). Thrombophilia abnormalities were searched in the nine symptomatic women and found in four of them (two homozygous and one heterozygous factor V Leiden, one heterozygous G20210A prothrombin mutation). Four women in the non-PHP group had positive family history of VTE in one 1st degree relative at an age < 50 years. No major bleeding was observed in LMWH users.

Conclusion: Management of pregnant women with our PHP based on stratification of individual risk of VTE resulted in a significant reduction of VTE events.

PB 1.66-2

Influence of maternal thrombophilia status on the outcome of assisted reproduction

Orlando C and Jochmans K

UZ Brussel, Brussels, Belgium

The chances of pregnancy after a first attempt of assisted reproduction technologies (ART) are about 30%. Pregnancy rate progressing to term and resulting in live birth of a child is somewhat lower, 25%. Repeated cycles of ART increase success rate. However, a substantial number of couples fail to achieve pregnancy after three cycles. Thrombophilia has been suggested to play a role in failure of ART by interfering with embryo implantation and placentation but available evidence remains controversial. Large prospective studies to confirm this hypothesis are lacking.

The objective of our study is to investigate the association of thrombophilia with outcome of ART in women with recurrent, unexplained failure of assisted reproduction.

We set up a prospective study including women with a history of at least three failures of fresh ART cycles with replacement of one or two good quality embryos.

Blood samples are taken before the start of a next treatment cycle to avoid influence of ovarian stimulation on coagulation parameters. All women are tested for inherited thrombophilia (antithrombin activity, protein C activity, free protein S antigen, factor V Leiden and prothrombin G20210A mutation) and evaluated for the presence of antiphospholipid antibodies (lupus anticoagulant, anticardiolipin and anti-b_2GPIb antibodies).

Study end point is reached after live birth or failure of ART after six treatment cycles. Follow-up information is obtained from the patients' medical records.

Implantation rate, clinical pregnancy rate and live birth rate are defined according to the ICMART glossary of ART terminology.

Stimulation cycles where aspirin, low molecular weight heparin and/or corticosteroids were used, were excluded as these drugs could influence outcome.

This study was approved by the medical ethics committee of the University Hospital of Brussels. All patients signed informed consent.

Between 2008 and 2012, 136 women were enrolled. Today, sixty-one women have reached study end point. Twenty-one women had a live-born baby while 40 did not. There were no significant differences in prevalence of thrombophilia between the two groups. Positivity for antiphospholipid antibodies was the most prevalent parameter among the two study groups, 5% (1/21) in the live birth group and 22% (9/40) in the non-live birth group ($P = 0.13$).

After inclusion, these 61 women underwent a total of 111 ART cycles. Cycles with interfering drug use were excluded, leaving 77 cycles for investigation. Implantation rate and clinical pregnancy rate were not statistically different in women with inherited and/or acquired thrombophilia compared to women without thrombophilia. There is, however, a trend towards lower live birth rate in the patient group with thrombophilia compared to the group without, 4.8% (1/21) and 18.5% (10/54) respectively ($P = 0.13$).

These results suggest that there is no significant association between maternal thrombophilia and failed embryo implantation. A slight trend towards lower live birth rate in women with thrombophilia was observed. The results presented here are the preliminary data of a large, prospective study that is still ongoing and thus need to be considered with caution. Failure to demonstrate statistical significance may be due to the limited sample size of this interim analysis.

PB 1.66-3

Pelvic vein thrombosis after cesarian-section delivery

Magalhães GHR[1], Ribeiro D[2], Rezende SM[2], Reis MGC[2] and Costa GAR[2]

[1]Minas Gerais Federal University; [2]University Hospital, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Venous thrombosis (VT) constitutes the leading cause of maternal mortality in the developed world. Pelvic vein thrombosis (PVT) is an important cause of VT during pregnancy and post-partum. Few studies have evaluated the occurrence and natural history of PVT after cesarian C-section delivery in the postpartum period.

Aims: Evaluate the incidence and natural history of PVT after cesarian C-section delivery.

Methods: Informed consent was obtained of all subjects. This study comply with the Declaration of Helsinki. We prospectively studied a cohort of 50 women after C-section delivery. Women underwent magnetic resonance venography (MRV) in the early postpartum period (1–7 days) and were followed for 3 months. Analysis considered two groups classified as low- and high-risk for venous thrombosis.

High-risk subjects had one or more of following characteristics: age above 35 years; obesity defined as body mass index above 35 kg/m^2 before pregnancy; immobility above 3 days; personal history of VT; hypertension grade 2 ($\geq$ 160 mmHg systolic blood pressure and/or $\geq$ 100 mmHg diastolic blood pressure) or higher; congestive heart failure class III or IV; preeclampsia or eclampsia; current infection; multiparity, i.e., above four previous deliveries; current gemelar pregnancy; current smoking and need for urgent modification of delivery mode (vaginal to C-section). Low-risk subjects had none of the characteristics cited above.

Results: We identified definite asymptomatic PVT in four women (8%), of whom one out of 25 (4%) in the low risk group and three out of 25 (12%) in the high risk group (RR 3.27; 95% CI [confidence interval], 0.34–31.46). Duplex scan of both legs was performed in all four women and proximal VT was detected in one. Anticoagulation was not instituted.

All four patients underwent a new MRV after 3 months, which showed complete disappearance of the intra-luminal filling defects. No symptomatic thrombosis developed in the remaining 46 women after 3 months' follow-up.

Conclusion: PVT occurs in the early postpartum period as an asymptomatic event in women undergoing C-section. The risk of developing PVT seems to be higher in women with high risk factors for VT. There was no complication of the PVT within 90 days' follow-up.

PB 1.66-4

The coagulation profile of preterm delivery

Keren Politansky A, Breizman T, Brenner B, Sarig G and Drugan A

Rambam Health Care Campus, Haifa, Israel

Background: The trigger initiating preterm birth is, in most cases, elusive and unidentified. Not all premature uterine contractions cause preterm birth, challenging to predict in which cases contractions will lead to preterm delivery. Coagulation anomalies were suggested to be etiologically involved in the development of preterm birth, however the coagulation state of preterm parturients is still incompletely revealed.

Aims: The aim of this study was to evaluate the haemostatic system of pregnant women with premature uterine contractions, and to observe the coagulation state of their infants.

Methods: This cohort study population consisted of healthy pregnant women admitted with regular uterine contractions before 37 weeks of gestation. Blood samples were collected from the recruited women, the clinical outcome and the week of gestation at delivery were recorded. The study group consisted of 38 women who experienced preterm birth, 14 of which were with preterm premature rupture of membranes (PPROM). The control group included 38 women who had premature contractions but eventually had normal term deliveries. Both groups were matched for maternal age, number of births and gestational age at admission. Blood samples were tested for parameters of the haemostatic system and coagulation activation markers. Furthermore, samples of umbilical cord blood were collected at delivery for coagulation studies from 43 patients with premature uterine contractions.

Results: We documented significantly shorter activated partial thromboplastin time (aPTT) in study than in the control group (25.7 $\pm$ 2 vs. 27.4 $\pm$ 2.7 s, $P = 0.003$). Prothrombin time (PT) was also shorter in the study group (9.96 $\pm$ 0.5 vs. 10.1 $\pm$ 0.4 s, $P = 0.05$). There was no significant difference between the two groups in the level of other haemostatic markers: Fibrinogen, D-Dimer, Protein C-Global, Free Protein S antigen (fPS), Factor VIII activity, von willebrand factor antigen, Plasminogen activator inhibitor-1, Prothrombin Fragment F1 + 2 (PT F1 + 2), and Tissue factor.

Within the study group, PT F1 + 2 levels were significantly lower in association with PPROM than with preterm deliveries without rupture of membranes (351 $\pm$ 99 vs. 561 $\pm$ 242 pM, $P = 0.003$).

All the haemostasis markers mentioned above were evaluated also in 43 umbilical cord blood samples collected at delivery. aPTT was found to be significantly longer in neonates that were delivered prematurely compared to neonates that were delivered at term (38.8 $\pm$ 7.5 vs. 34.4 $\pm$ 3.1 s, $P = 0.024$). fPS levels were remarkably lower in cord blood samples of prematurely delivered neonates than in normal term neonates samples (38.3 $\pm$ 11.6% vs. 48.7 $\pm$ 10.2%, $P = 0.004$).

Conclusions: Our findings suggest that shortened aPTT and PT time in women with premature contractions might be associated with preterm birth. Furthermore, low levels of PT F1 + 2 were found with PPROM preterm delivery. In addition, longer aPTT and decreased fPS levels at the neonate may be associated with premature delivery. These findings document increased thrombotic activity affecting both mothers and newborns in cases of 'real' preterm delivery, suggesting that a shortened aPTT and PT may be a sign that premature contractions will eventually lead to preterm labor.

PB 1.66-6

The effect of thrombotic markers on severity of bleeding symptoms in women with inherited bleeding disorders

Davies JS, Chi C, Shareif L, Tuddenham E and Abdul-Kadir R

Royal Free Hospital NHS Foundation Trust, London, UK

Background: Women with inherited bleeding disorders demonstrate heterogenicity in bleeding symptoms that does not always correlate to underlying clotting factor levels. This is problematic when predicting the bleeding risk, especially when haemostatic challenge is anticipated. The bleeding tendency is influenced by haemostatic factors and thrombotic variables that have the potential to counteract one another. The effect of thrombotic variables in reducing the overall bleeding tendency, have demonstrated a protective effect on bleeding disorders such as haemophilia. The correlation of clotting factor levels, presence of thrombotic variables, and bleeding score in women with inherited bleeding disorders have not been thoroughly investigated.

Aims: To assess the correlation between bleeding tendency, haemostatic and thrombotic variables in women with inherited bleeding disorders.

Method: Quantitative measurement of the bleeding tendency was assessed using the standardized ISTH Bleeding Assessment Tool. Fifty women with inherited bleeding disorders (42 with von Willebrand disease and eight carriers of haemophilia) and 20 women without any bleeding disorders were included. Blood samples were then obtained from the individuals for assessment of clotting factors (factor VIII and von Willebrand factor) and thrombophilia screen (lupus anticoagulant, antithrombin, protein C and protein S, factor V Leiden mutation and Prothrombin G20210A mutation).

Results: Bleeding score was inversely related to von Willebrand factor antigen (VWF:Ag), ristocetin cofactor (VWF:RCo) levels and factor VIII activity. So far no correlation has been demonstrated between bleeding score and protein C, protein S and antithrombin activity. Two women tested positive for prothrombotic mutation, one with lupus anticoagulant (bleeding score of 5) and another with factor V Leiden mutation (bleeding score of 7).
Conclusion: Although bleeding score is not influenced by levels of antithrombin, protein C and protein S activities this study is still in progress and further data is required for sufficient statistical analysis. It is useful to consider the history (bleeding score) as well as the possibility of underlying thrombotic markers, when performing a bleeding risk assessment.

PB1.67 – Inflammation: Basic – I

PB 1.67-1

PI3Kinase is a key regulator of CD40L surface expression and release from activated platelets

Grosdidier C[1], Chabert A[1], Bernot D[2], Morange PE[2], Alessi M-C[1] and Canault M[1]
[1]UMR Inserm1062, INRA 1260, Aix-Marseille University; [2]Laboratoire d'Hématologie, Hôpital de la Timone, AP-HM, Marseille, France

Background: Beside their crucial role in haemostasis, platelets are considered as important modulators of the immuno-inflammatory reaction. Among the inflammatory molecules expressed by platelets, CD40 Ligand (CD40L, CD154) is of interest since it is directly involved in the modulation of the immune response and inflammation. Activated platelets release large amounts of soluble CD40L (sCD40L). Platelets have been postulated to be the major source of circulating sCD40L.
Aims: Mechanisms regulating platelet CD40L availability are not fully understood. We aim to determine signaling pathways leading to CD40L expression and release by human activated platelets.
Methods: Flow Cytometry; CD40L ELISA; Gelatin Zymography; Western blot.
Results: Here, we show that PI3K pharmacological inhibition diminishes by 50% the release of sCD40L from human activated platelets with thrombin and PAR1 agonist, whereas the inhibition reaches 100% upon PAR4 stimulation. sCD40L release requires the $\alpha II_b\beta 3$ integrin activation that is controlled by PI3K. $MnCl_2$ that forces integrins to take an active conformation independently of intracellular signal, did not restore normal sCD40L release in presence of PI3K inhibitors. Thus, PI3K independently regulates sCD40L release and $\alpha II_b\beta 3$ activation. Then, we asked whether the PI3K involvement in sCD40L release could be a consequence of CD40L surface expression modulation. Inhibition of PI3K fully blocked CD40L surface expression when activated by PAR4 (500 μM AYPGKF), whereas it was not affected when induced via PAR1 (10 and 50 μM SFLLRN). The pharmacological inhibition of PI3K isoforms indicates the only contribution of PI3K-beta in CD40L surface expression during PAR4 activation. These results argue in favor of a differential implication of PI3K in the regulation of CD40L surface expression and release regarding the PAR engaged.
The observation that PI3K inhibitor decreases sCD40L release but has no effect on surface CD40L upon PAR1 stimulation prompted us to explore the involvement of PI3K in MMP2 release and activation. Indeed, MMP2 was shown to cleave CD40L from platelet surface. Zymography and western blot analysis of PAR1-activated platelet releasates did not show any implication of PI3K in MMP2 release and activity. Ongoing experiments of MMP2 activity measurement on platelet surface will help us to unravel the role of PI3K in sCD40L release through MMP2 activity.
Conclusion: PI3K regulates platelet CD40L bioavailability. However, its implication differs regarding the PAR engaged. Nevertheless, PI3K represents a key element of the platelet-mediated inflammatory process.

PB 1.67-2

T cells, inflammation and tissue factor in gastric malignancy

D'Elios M, Benagiano M, Amedei A, Della Bella C, Niccolai E, Grassi A, Silvestri E, Emmi G and Prisco D
University of Florence, Florence, Italy

Background: Thrombosis significantly contribute to the morbidity and mortality of patients with malignancy.
Aims: We investigated the role of T-cell subsets in the induction of tissue factor (TF) production by human monocytes in patients with gastric cancer. Helicobacter pylori is type I oncogenic factor for gastric adenocarcinoma and H. pylori-related inflammation contributes to gastric oncogenesis.
Materials and Methods: We derived T-cell clones from seven patients with gastric adenocarcinoma and we studied the ability to induce TF production of 10 T helper (Th) 1, 10 Th2 and 10 Th17 clones. T-cell blasts of antigen-specific clones (8×10^5/mL) were cocultured for 16 h with autologous monocytes (4×10^5/mL) in the presence of medium, mitogen or the specific antigen. TF was quantitated by a specific enzyme-linked immunosorbent assay kit (American Diagnostica Inc, Greenwich, CT).
Results: After activation, all T-cell clones with Th1 and Th17 cytokine profile, but not Th2 clones, induced TF production. T-cell blasts from Th1 and Th17 activated clones were fixed with paraformaldehyde and added to monocytes in the presence of medium alone or their supernatants. Addition of Th1/Th17 cells or supernatants induced low TF production (1.3 ng/mL + 0.13), whereas addition of cells/supernatants resulted in higher TF synthesis (2.9 ng/mL + 0.5). No TF synthesis was induced by Th2 cells, whereas addition of Th2 cells and Th1 or Th17 induced TF production. The addition of anti-IFN-gamma antibody, anti-IL-17 or Th2 supernatants to monocytes stimulated with Th1/Th17 cells plus supernatant resulted in inhibition of TF synthesis.
Summary: $CD8^+$ and $CD4^+$ T cells, Th1/Th17, but not Th2, T cells can help TF production. Both cell-to-cell contact with activated T cells, Th1-type and Th17 cytokines, in particular IFN-gamma and IL-17, are crucial for optimal TF synthesis, whereas Th2-derived cytokines (IL-4, IL-13, and IL-10) are inhibitory.
Conclusion: The results obtained so far are of potential interest for the development of novel future preventive or therapeutic strategies of thrombosis in patients with malignancy.

PB 1.67-3

Protease activated receptor 4 contributes to host defense in streptococcus pneumoniae induced pneumonia

De Stoppelaar SF, Van't Veer C, Van Den Boogaard E, Nieuwland R, Hoogendijk AJ, De Boer OJ, Roelofs JTH and Van Der Poll T
Academic Medical Center, Amsterdam, The Netherlands

Background: *Streptococcus (S.) pneumoniae* is a common causative pathogen of pneumonia and sepsis. Pneumonia and sepsis are associated with enhanced activation of coagulation, resulting in the production of several host derived proteases at the primary site of infection and in the circulation. Serine proteases cleave protease activated receptors (PARs), which form a molecular link between coagulation and inflammation. PAR4 is one of four subtypes of PARs and is widely expressed by multiple cell types in the respiratory tract implicated in pulmonary inflammation, by immune cells and by platelets. In mice, PAR4 is the only thrombin receptor expressed by platelets.
Aims: To determine the contribution of PAR4 to the host response during pneumococcal pneumonia.
Methods: Pneumonia was induced by intranasal inoculation with *S. pneumoniae* in PAR4-deficient (*par4*−/−) and wild-type mice. Mice

were sacrificed after 6, 24 or 48 h. Blood, lungs, liver and spleen were collected for analyses.
Results: After 48 h of infection, higher bacterial loads were found in the lungs of *par4*−/− mice ($P < 0.05$), accompanied by higher histopathology scores and increased cytokine levels ($P < 0.05$). At 24 h post infection *par4*−/− mice displayed lower plasma and lung thrombin-antithrombin complex (TATc) levels, whereas they showed higher TATc concentrations at 48 h. Of interest, *par4*−/− mice displayed a trend towards lower plasma platelet factor 4 levels at this latter time point, indicative of decreased platelet activation in spite of the apparently increased thrombin formation.
Conclusion: Our findings suggest that PAR4 contributes to antibacterial defence during murine pneumococcal pneumonia.

PB 1.67-4

Increased systemic interleukin-1β accelerates the onset of stroke in stroke-prone spontaneously hypertensive rats

Nakazawa T[1], Tsuyoshi C[2], Itoh T[3], Tabuchi M[3] and Satou T[3]
[1]*Otsuka Pharmaceutical Co., Ltd., Tokushima;* [2]*National Institute of Health and Nutrition, Tokyo;* [3]*Kinki University School of Medicine, Osaka, Japan*

***Background*:** Epidemiological data suggest that interleukin (IL)-1β is a potential cause of stroke. However, there is no direct evidence to suggest that IL-1β accelerates stroke onset.
***Aims*:** We therefore examined the effect of IL-1β on stroke onset in stroke-prone spontaneously hypertensive rats (SHRSP).
***Methods*:** We measured plasma IL-1β levels in male Wistar Kyoto rats (WKY), spontaneously hypertensive rats (SHR), and SHRSP. IL-1β signal-related gene expression was measured in cerebrovascular endothelial cells (CVECs) from each strain. To determine the direct effects of IL-1β on stroke onset, IL-1β or goat anti-rat IL-1β polyclonal antibody were administered continuously to SHR or SHRSP using an osmotic pump.
***Results*:** At 10 weeks of age, plasma IL-1β levels were significantly higher in SHRSP than in WKY ($P < 0.001$ vs. SHRSP) and SHR ($P < 0.001$ vs. SHRSP). Expression levels of IL-1β signal-related genes in CVECs, including IL-1β, IL-1 receptor (IL-1R)-1, IL-1R-2, caspase-1, monocyte chemoattractant protein-1 (MCP-1), and intercellular adhesion molecule-1 (ICAM-1), were significantly higher in SHRSP than in WKY or SHR. Furthermore, IL-1β (10 ng/mL) treatment significantly increased MCP-1 and ICAM-1 mRNA expression levels in CVECs. Continuous administration of IL-1β (2 μg/day) using an osmotic pump slightly increased the incidence of stroke in SHR ($P = 0.046$) and significantly accelerated the onset of stroke in SHRSP ($P = 0.006$) compared with vehicle controls. In addition, continuous administration of anti-rat IL-1β antibody (600 μg/day) to SHRSP slightly, but not significantly, delayed the onset of stroke compared with control. One rat in the control group, none in the IL-1β group, and three in the anti- IL-1β antibody group showed no signs of stroke at the end of the 4-week administration period.
***Conclusions*:** SHRSP had increased plasma IL-1β levels compared with WKY and SHR prior to the onset of stroke. Further, exogenous IL-1β accelerated stroke onset. These results suggest that a stimulated IL-1β signal might be a cause of stroke onset under conditions of concomitant severe hypertension, and suppression of the IL-1β signal might thus be a target for stroke prevention.

PB 1.67-5

Diverse roles of alphaMbeta2 integrin in lipopolysaccharide-mediated inflammation

Yu YB[1], Su KH[2], Gau J-P[1], Hsu HC[1], Tzeng CH[1] and Lee TS[2]
[1]*Taipei Veterans General Hospital;* [2]*National Yang-Ming University, Taipei, Taiwan*

Background: Several lines of evidence indicate that αMβ2 integrin mainly expresses on leukocytes and plays a crucial role in the differentiation of monocyte and macrophage.
Aim: Here we investigated the individual role of CD11b and CD18, the two major subunits of αMβ2 integrin, in the lipopolysaccharide (LPS)-induced inflammatory responses in macrophages.
Methods/Results: Our data showed that LPS treatment significantly increased the levels of tumor necrosis factor (TNF)-α, interleukin (IL)-1β, IL-10 and nitric oxide (NO) production. Preincubation with CD18 neutralizing antibody completely abrogated the LPS-induced IL-10 expression, but CD18 neutralizing antibody administration did not affect the expressions of TNF-α, IL-1β and nitric oxide (NO) production. In contrast, CD11b neutralizing antibody up-regulated the LPS-induced IL-10 expression with partial inhibition of TNF-α, IL-1β and NO production. In addition, inhibition of CD18 abrogated the LPS-induced activation of signal transducer and activator of transcription-3 (STAT-3), whereas blockade of CD11b had no such effect on STAT-3 activation. Moreover, inhibition of CD11b, but not CD18, attenuated the LPS-induced NF-κB activation. We also found that LPS increased the interaction of Toll-like receptor 4 and CD11b/CD18 complex in macrophages.
Summary: We proposed CD11b and CD18 may display differential regulatory roles during LPS-mediated inflammatory responses. These results will provide new insights into the diverse roles of CD11b/CD18 in LPS-mediated inflammation, which is important in the therapy of sepsis in the future.

PB 1.67-6

Plasmin induces *in vivo* monocyte recruitment through protease-activated receptor-1, MEK/ERK and CCR2 mediated signaling

Carmo AAF[1], Costa BRC[1], Vago JP[1], Oliviera LC[2], Tavares LP[1], Nogueira CRC[1], Brasil BSF[2], Dusse LM[1], Barcelos LS[3], Bonjardim CA[2], Teixeira MM[3] and Sousa LP[4]
[1]*Departamento de Análises Clínicas e Toxicológicas;* [2]*Departamento de Microbiologia, Instituto de Ciências Biológicas;* [3]*Imunofarmacologia- Departamento de Bioquímica e Imunologia, Minas Gerais;* [4]*Federal University of Minas Gerais, Belo Horizonte, Brazil*

Background: The Plasminogen/Plasmin (Plg/Pla) system is associated with a variety of biological activities beyond the classical dissolution of fibrin clots, including cell migration, tissue repair and inflammation. Although the capacity of Plg to induce cell migration is well defined, the mechanism *in vivo* underlying this process is elusive.
Aims: To investigate the effect of Pla on cell migration *in vitro* and *in vivo* and the role of mitogen-activated protein kinase (MAPK) ERK1/2, protease activated receptor-1 (PAR-1) and CCL2/CCR2 axis in this process.
Methods: We performed *in vitro* migration assay (wound healing assay) in culture of MEFs (Mouse Embryonic Fibroblasts) or mouse leukemia monocyte macrophage (RAW 264.7). The cells were treated with Pla (2 μg/mL) at different times, or pretreated with the MEK1/2 inhibitor U0126 (15 μM), a serine protease inhibitor Leupetin (25 μg/mL) or the lysine analog tranexamic acid (0.01 M) 60 min. prior to and throughout Pla treatment and processed for microscopic counting of migrating cells or western blot analysis for phosphorylated ERK1/2. BALB/C mice were challenged by i.pl. (intrapleural) injection of Pla (2 μg/cavity) and the cells present in the pleural cavity harvested at dif-

ferent times or 48 h after pre-treatment with specific inhibitors (U0126 60 μg/cavity, i.pl.; leupeptin 100 μg/mouse, i.p.; SCH79797, 5 mg/kg, i.p.) 1 hour before Pla. Cells were processed for total and differential leukocyte counts and western blot analysis for P-ERK1/2 and IkB-a. Pleural levels of cytokines IL-1β, IL-6 and TNF-α and the chemokine monocyte chemoattractant protein 1 (MCP-1/CCL2) were analyzed by ELISA. CCR2 knockout mice and wild-type littermates were injected with plasmin and the cells present in the pleural cavity were harvested at 48 h after and processed for total and mononuclear cell count. All procedures described here had prior approval from the Animal Ethics Committee of Universidade Federal de Minas Gerais (CETEA/UFMG, *Protocol number:* 19/2011).

Results: Pla induced *in vitro* migration of murine fibroblast and macrophages dependent on MEK/ERK pathway and by requiring its proteolytic activity and lysine binding sites on cell surfaces. Plasmin injection into the pleural cavity of mice induced a time-dependent influx of mononuclear cells that was associated with augmented ERK1/2 and IkB-α phosphorylation and increased levels of CCL2 and IL-6 in pleural exudates. *In vivo* inhibition of protease activity by using leupeptin or a PAR-1 antagonist (SCH79797) prior to Pla injection abolished Pla-induced mononuclear recruitment and ERK1/2 and IkB-α phosphorylation. Interestingly, inhibition of MEK/ERK pathway abolished Pla-induced CCL2 upregulation and mononuclear cell influx. In agreement with a requirement for CCL2 to Pla-induced cell trafficking, $CCR2^{-/-}$ mice were not responsive to Pla-induced mononuclear recruitment.

Conclusion: Pla-induced mononuclear cell recruitment *in vivo* was dependent on PAR-1 activation of the MEK/ERK/NF-kB pathway which led to the release of CCL2 and activation of CCR2.

PB1.68 – Inherited Risk Factors Venous Thrombosis: Basic – I

PB 1.68-1

Identification of rare variants in ADAMTS13 through next generation sequencing implicated in pediatric stroke

Stoll M[1], Barysenka A[1], Witten A[1], Arning A[1], Manner D[2] and Nowak-Göttl U[2]

[1]*Leibniz-Institute for Arteriosclerosis Research, Münster;* [2]*University Clinics Schleswig-Holstein, Kiel, Germany*

Background: Recently we reported a gene network of ADAMTS genes implicated in pediatric stroke through a genome-wide association study (GWAS)[1]. However, the causative variants underlying the association remain elusive.

Aim: To identify rare variants in ADAMTS13 contributing to stroke risk in children using next generation sequencing (NGS) in 48 affected children and 48 unaffected siblings.

Methods: Genomic regions implicated through our GWAS [1] were enriched using the Nimblegen EZ choice target enrichment kit yielding a target region for NGS of ~6.8 MB genomic sequence comprising total 48 genes from 15 chromosomes, among them ADAMTS13. The enriched paired-end libraries from 96 children were subsequently sequenced on 2 flow cells and 2 × 100 cycles using an Illumina HiScan-SQ instrument yielding a total of ~180 Gb sequence data at an average coverage of < 50X. Sequence mapping was performed using the BWA algorithm followed by bioinformatic analysis using the GATK software for variant detection, and Annovar and SNPEff for functional annotation. Statistical significance of found variants in 46 siblings was determined using the Sibship Disequilibrium Test (SDT). A collapsing test (CALPHA) was used to calculate the cumulative effect of rare variants in the ADAMTS13 gene on stroke risk. Promising genetic variants were subsequently verified using capillary sequencing and an ABI 3730 automated sequencer, followed by TaqMan genotyping of the full cohort comprising 248 nuclear families.

Results: A total of 194 SNPs were identified in the ADAMTS13 gene and its proximity (5Kb upstream and downstream), 23 of which are not present in dbSNP135. In addition, 16 indels were found, six of which are novel. One hundred and forty-six SNPs reside in intronic regions, 40 SNPS are located upstream and 10 downstream of the ADAMTS13 gene. Eight SNPs lead to synonymous, and seven SNPs leads to non-synonymous changes in the ADAMTS13 coding region. Four SNPs reside in the 5′untranslated region (UTR). One intronic SNP, rs4962153, was previously reported in a GWAS on liver enzyme levels, 10 SNPs affect transcription factor binding sites and two SNPs fall within a conserved genomic region. All exonic SNPs are involved in splicing regulation and alter splicing enhancer binding sites or transcription factor binding sites. Of the 194 SNPs, 65 have a minor allele frequency of < 0.02, 22 of which are novel. The CALPHA test for cumulative association of these SNPs shows a *P*-value of 6.3×10^{-5} and an association with pediatric stroke.

Summary and Conclusion: Our data support the presence of novel variants in the ADAMTS13 of functional relevance, which may shed light on the genetic architecture underlying the association between ADAMTS13 and pediatric stroke. Further studies are underway to characterize the functional consequences of these genetic variants on ADAMTS13 expression, splicing patterns as well as activity.

Identification of mutations in the protein C gene in a panel of 83 Spanish families with protein C deficiency

Martos L[1], Medina P[1], López-Fernández MF[2], Tássies D[3], Roldán V[4], González-Porras JR[5], González-López TJ[6], Herrero S[7], España F[1] and Navarro S[1]

[1]*Hospital Universitario y Politécnico La Fe Campanar, Valencia;* [2]*Complejo Hospitalario Universitario, A Coruña;* [3]*Hospital Clinic, Barcelona;* [4]*Hospital Universitario Morales Meseguer, Murcia;* [5]*Hospital Clínico, Salamanca;* [6]*Complejo Asistencial Universitario, Burgos;* [7]*Hospital Universitario, Guadalajara, Spain*

Background: There are no data on characteristics and molecular basis of the hereditary protein C (PC) deficiency in Spain.

Aims: To analyze a panel of probands with PC deficiency from symptomatic Spanish families.

Methods: We sequenced the nine exons (E) and their flanking intron (I) regions of the PROC in 83 unrelated probands with venous thromboembolism (VTE) and 174 relatives of 52 probands. Informed consent was obtained from all subjects of the study and it was approved by the ethics committee of our Institution.

Results: In 71 probands (86%) we found 35 different mutations in heterozygosis associated with the PC deficiency, 20 of them not yet reported. One mutation was localized in I1, four in E3, one in I3, three in E5, three in I5, three in E6, one in I6, six in E7, three in E8, one in I8 and nine in E9. Twenty-eight mutations resulted in the change of one nucleotide (nt), mainly missense mutations, but five caused a premature stop codon. Three mutations with one nt, four nt and 16 nt deletion caused a frameshit. One mutation resulted in a three nt deletion (p.Ile321del) and one in a six nt insertion (p.Lys241_Glu242 insLeuAsp). About 40% of the point mutations were localized in CpG dinucleotides. Three mutations were localized in two unrelated families, three in three families, four in four families and one in eight families. Three caused type II mutations, one in E3 (identified in four unrelated families) resulting in a p.Glu16Lys change in the PC Gla domain, one also in E3, resulting in the change p.Arg-1His, and one in exon 8 (p.Lys193Glu). The mean minus 2 SD PC level in 436 healthy individuals and 325 VTE patients without PC deficiency was 67% and 63%, respectively. In 10 probands with PC levels from 49% to 70%

and in two probands on coumarin therapy we did not find any mutation. Twenty-four relatives with PC levels ranging from 51% to 73% from 16 PC deficiency families did not carry the mutation found in the proband.

Conclusion: This is the first Spanish registry of PC deficiencies and confirms the considerable heterogeneity in the genetic abnormalities. The data suggest that the Glu16 is essential for the *in vivo* expression of the anticoagulant PC function, possibly by allowing a correct folding of the Gla domain. The study has provided genetic counseling to those patients and relatives whose PC levels were near lower normal limit. Thus, by adding a genetic test it is possible to assign a subject to either the normal or the deficiency group, and estimate precisely the correlation between the PC deficiency and thrombosis. The spectrum of recurrent mutations in the Spanish population is completely different from that found in the Netherland, where the most frequent mutations were Gln132 and Arg230, and is more similar to that of one French study where the most frequent were Arg178 and Pro168. In the present study, Val 297 (eight families) and Tyr124, Pro168, Arg178 and Lys16 (four families) were the most prevalent.

PB 1.68-3

What is the origin of factor V Leiden mutation in East Mediterranean Arabs and has it occurred there first?

Jadaon M, Dashti A and Lewis HL

Faculty of Allied Health Sciences, Kuwait University, Sulaibekhat, Kuwait

Background: Studies reported high prevalence of factor V Leiden mutation (FVL; G1691A) in Caucasian populations (1–15%) and patients with venous thrombosis (15–65%), but FVL was rare or absent in non-Caucasians like Africans and Asians. Molecular studies on Caucasians of European origin reported FVL to be associated with one haplotype consisting of nine single nucleotides polymorphisms (SNPs) in the Factor V gene. These data suggested that FVL should have occurred as a single event in the far past in a single European Caucasian ancestor whose offspring are the current carriers of FVL. However, more recent studies found a relatively higher prevalence of FVL in Arab populations living in Eastern Mediterranean countries (5–27%), who are not generally considered as Caucasians. This questioned the origin of FVL in Arabs: is it the same ancestor for Caucasians or a different one? Also, where did this mutation occur first?

Aims: This study was conducted focusing on Arab carriers of FVL to find what alleles they have at the nine SNPs positions associated with FVL, and whether Arabs have the same or a different haplotype than the one present in Caucasian carriers. Results should provide answers for the above mentioned questions.

Subjects/Methods: A total of 300 Arab subjects were studied: 100 cases known to have FVL from previous studies (18 homozygous and 82 heterozygous) and 200 cases without it. Real-time PCR was performed on DNA samples of all cases to confirm FVL (wild-type G or mutant A alleles) and determine nine SNPs in the Factor V gene: 327A/G, 495G/A, 1470C/T, 1806G/A, 2298T/C, 2325C/T, 2391G/A, 2833A/T and 5380A/G.

Results: The haplotype of nine SNPs reported to be associated with FVL in Caucasians [G, A, C, G, C, T, A, A, A] was found in our Arab cases. First and foremost it was present in all the 18 homozygous cases (100%) indicating complete association with FVL mutation. Also it was present in 17 of the heterozygous cases with FVL (20.7%), which was significantly more than its presence in non-carriers of the mutation (15 out of 200; 7.5%).

Conclusions: The results of this study argue that Arab and Caucasian carriers of FVL had most probably descended from the same ancestor, which is especially reflected in the homozygous cases. The study also combines the molecular results obtained here with the epidemiological and anthropological facts to strongly and systematically suggest that FVL should have occurred first in the East Mediterranean area and then moved to Europe.

PB 1.68-4

Molecular characterization of PCE29K missense mutation

Ye X

Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: We have detected compound heterozygous missense mutations of protein C (PC) E29K and PC R147W in a young male patient with hereditary PC deficiency and pulmonary embolism. The novel PC E29K missense mutation was also detected in his father with PC deficiency. The proband's father had experienced portal venous thrombosis in his forties.

Aims: To investigate the molecular pathogenesis of PC E29K gene missense mutation in patients with PC deficiency.

Methods: Expression vetor of PC E29K mutation was constructed by site-directed mutation method using wild-type PC plasmid as template. The plasmids were transfected into COS-7 cells by lipofectin transfection method and cultured. PC antigen levels of the supernatant and cell lysis medium of the COS-7 cells transfected with PC E29K plasmid were measured by ELISA method. Laser confocal microscope was used to detect the cellular immunofluorecent localization of the cultured cells.

Results: PC antigen level of the supernatant of COS-7 transfected with PC E29K plasmid was 23.7% of that of wild-type ones. The PC antigen level in the cell lysis medium of COS-7 cells transfected with mutant plasmid was 81.1% of that of the wild-type. PC E29K mutated protein was mostly trapped in the endoplasmic reticulum and its concentration was decreased in Golgi bodies.

Conclusion: Only part of PC E29K mutated protein was secreted from the cells and part of it was degraded inside the cells. Impaired secretion and partial degradation is the cause of PC deficiency resulting from PC E29K missense mutation.

PB 1.68-5

Venous thrombosis in adolescent girls on oral contraceptives – association with estrogen gene polymorphisms

Zia A, Callaghan M, Lusher J, Chitlur M and Rajpurkar M

Wayne State University, Troy, NY, USA

Background: Adolescent girls on oral contraceptive pills (OCPs) are at a high risk for venous thromboembolism (VTE). OCP induced changes on coagulation and fibrinolytic pathways are complex with high inter-individual variability. An increased risk of thrombosis related to the estrogen receptor a polymorphism (ESR-ap, c.454-397T>C) has been reported in post-menopausal women. Data in the adolescent age group are lacking.

Aims: Our study aims were to: (i) Determine the prevalence of ESR–ap in patients with OCP induced VTE (Cases) (ii) Correlate the prevalence of ESR–ap with markers of hypercoagulability as determined by global coagulation assays in healthy adolescent girls who started OCPs (Prospective cohort)

Methods: *Cases:* On 14 girls with OCP induced VTE, data were collected for age, ethnicity, sites of thrombosis, presence of other thrombophilic markers and the time interval between OCP initiation and occurrence of VTE. Archived DNA was available on 10 of the 14 cases and was tested for ESR-αp.

Prospective Cohort: In this ongoing study, 45 healthy non-pregnant adolescent girls starting OCPs were enrolled after IRB approval. Samples were obtained prior to and after 3 months of initiating OCPs and were analyzed for clotting and anticoagulant factor assays, tissue factor initiated thromboelastography (TF-TEG), with t-PA (tissue plasminogen activator) modification for detecting fibrinolysis (t-PA-TEG), thrombin generation +/− thrombomodulin (TM)(TG+/− TM) and

estrone levels. All participants were genotyped for FV Leiden, F2 G20210, plasminogen activator inhibitor-1 (PAI-1) promoter polymorphism and ESR-αp. SNP genotypes were compared to TG and TEG parameters and differences pre and on OCPs were examined.

Results: *Cases:* The median age of cases was 15 years with eight Caucasian, five African American and one Hispanic girls. The median time interval between the initiation of OCPs and occurrence of the thrombotic event was 3 months (range: 1–6 months). The sites of thrombosis were: lower extremity DVT (n = 7), PE (n = 2), both PE and DVT (n = 2), cortical sinus thrombosis (n = 2) and mesenteric thrombosis (n = 1). The ESR-ap was present in the heterozygous state in 55% and homozygous state in 33% of cases.

Prospective Cohort: Median age of participants was 17 years (range 13–20). All were African American except one Caucasian participant. The ESR-αp was present in the heterozygous state in 51% and homozygous state in 15% of the participants respectively. Although, CT and CC genotype was associated with shorter lag time at baseline with TG-TM (2.7 ± 0.25 vs. 1.7 ± 0.14 min, P = 0.026) and not with TF-TEG, no correlation was found with TG-TM or TF-TEG *after* initiation of OCPs. The ESR-ap polymorphisms did not correlate with estrone levels or other coagulation parameters in participants.

Conclusions: ESR-αp were highly prevalent in adolescent girls with OCP induced thrombosis but did not correlate with markers of hypercoagulability as tested by global coagulation assays in healthy girls who started OCPs. OCP induced VTE may be caused by mechanisms other than ESR-αp and larger studies are needed to further elucidate this mechanism.

PB 1.68-6

A common PROS1 variant and its association with reduced free Protein S levels in patients of African ancestry; a risk factor for thrombosis?

Wheeler RB[1], Cutler J[2] and Mitchell M[1]

[1]St Thomas' Hospital; [2]GSTS Pathology, London, UK

Protein S is a vitamin K dependent plasma glycoprotein which is an important anticoagulant. It functions in both an activated Protein C-dependent manner, acting as a non-enzymatic co-factor of activated Protein C in the degradation of FVa and FVIIIa, and in an APC- independent anticoagulant pathway. Protein S circulates in the plasma as 2 fractions, a bound fraction complexed to the complement C4b binding protein and an unbound free fraction. Only free Protein S, which comprises approximately 40%, has anticoagulant activity.

Protein S deficiency is an autosomal dominant disorder associated with an increased risk of venous thrombosis. Patients with hereditary Protein S deficiency usually present with free Protein S levels in the 35–60% range. The laboratory diagnosis of Protein S deficiency is fraught with difficulty as free Protein S levels are influenced by a number of factors, including age, gender, use of oral contraceptives, use of anticoagulants etc. Recently it has been observed that free Protein S levels also vary between different ethnic groups, with Black Africans having significantly lower free Protein S levels than age matched Whites. There is an increased risk of thrombosis in Africans and Afro-Caribbean's and reduced free Protein S levels may be a contributing factor.

Over the last few years there has been a significant increase in the number of African patients sent for *PROS1* analysis in our laboratory following a phenotypic diagnosis of Protein S deficiency. Causative mutations have been identified in only a subset of these patients. In 1994 a variant in exon two was described (p.Arg40Leu; c.119G>T/Arg-2Leu; rs7614835) which was found only to occur in individuals of African descent with a minor allele frequency of 0.007/15. This variant is located close to the propeptide cleavage site and has been shown to be associated with abnormal carboxylation of the Gla domains of the mature peptide. The status of this variant as either a polymorphism or mutation has not yet been fully elucidated. The initial identification of the variant suggested that it was associated with Type IIb Protein S deficiency so it was classified as a mutation, however a 2010 study suggested that it be classified as a polymorphism based on its high frequency in African populations; the heterozygous genotype is seen in approximately 6% of Yoruba and Luhya individuals.

We have observed this polymorphism at a higher than expected frequency in African patients who presented with consistently low free Protein S levels and in whom no other *PROS1* mutation was been identified. The polymorphism was not observed in a cohort of African patients with thrombosis but normal free Protein S levels. We suggest that the p.Arg40Leu variant is pathogenic and may be sufficient to explain the phenotype of reduced free Protein S in these patients.

PB1.69 – Non-Inherited Risk Factors VT – I

PB 1.69-1

Obesity measures and future risk of venous thromboembolism and myocardial infarction

Braekkan SK, Enga KF, Nyegaard C, Njolstad I and Hansen JB

University of Tromso, Tromso, Norway

Background: The prevalence of obesity has increased dramatically in populations of developed countries during the last decades. Obesity is recognized as a major risk factor for both venous thromboembolism (VTE) and myocardial infarction (MI). Previous studies have suggested that obesity, assessed by body mass index (BMI), is more strongly associated with future risk of VTE than MI. Moreover, different obesity measures have displayed different impact on risk estimates for VTE and MI in independent studies. It is not known whether the relationship between obesity and future outcome is mediated by the same mechanism for VTE and MI. Investigation of obesity measures for VTE and MI within the same population ensures that the degree of known and unknown confounding is similar, and allows for comparison between the two outcomes.

Aims: To compare risk estimates for VTE and MI by various obesity measures in a prospective cohort recruited from a general population, and to explore whether adjustment for traditional atherosclerotic risk factors affected the risk estimates.

Methods: BMI, waist circumference (WC) and waist-to-hip ratio (WHR) were registered in 6708 persons without prior cardiovascular diseases, aged 25–84 years, who were enrolled in the Tromsø study in 1994–95. Obesity was classified according to predefined cut-off values for BMI, WC and WHR normally used for Caucasian populations. Incident events of VTE and MI during follow-up were registered through 2010 (study end). Cox-regression models were used to estimate age- and multivariable-adjusted hazard ratios (HR) with 95% confidence intervals (CI95). Analyses were stratified for sex. Multivariable analyses included age, smoking, systolic blood-pressure, total cholesterol, HDL cholesterol, diabetes mellitus and estrogen supplementation (women only) as covariates. The study was approved by the regional committee for research ethics, and participants gave informed written consent to participate.

Results: There were 288 validated incident VTE-events and 925 MIs during a median of 13.3 years of follow-up. BMI and WC exhibited higher risk estimates for VTE than for MI in both women and men, whereas WHR displayed similar risk estimates for VTE and MI. In women, BMI ≥ 30 kg/m^2 yielded a HR of 2.05 (CI95: 1.34–3.11) for VTE and 1.27 (0.97–1.66) for MI compared to BMI < 25 kg/m^2. For WC > 88 cm the HR was 2.44 (1.59–3.76) for VTE and 1.17 (0.91–1.51) for MI compared to WC < 80 cm. In men, BMI ≥ 30 kg/m^2 yielded a HR of 1.60 (0.91–2.82) for VTE and 1.61 (1.23–2.09) for MI. WC > 102 cm vs. < 94 cm yielded a HR of 1.96 (1.28–2.98) for VTE and 1.54 (1.25–1.90) for MI. Multivariable adjustments for traditional atherosclerotic risk factors substantially weakened all risk estimates for MI, whereas the risk estimates for VTE remained essentially unchanged.

Conclusions: Our study indicates that obesity, assessed by BMI and WC, displays higher risk estimates for VTE than for MI. The substantial weakening of risk estimates for MI, but not for VTE, by traditional atherosclerotic risk factors implies that these factors are key intermediates for the relationship between obesity and MI, and that other mechanisms are likely to mediate the risk of VTE by obesity.

[1]Slotervaart Hospital; [2]Academic Medical Center, Amsterdam; [3]Máxima Medical Centre, Eindhoven/Veldhove; [4]Rode Kruis Hospital, Beverwijk; [5]Sint Lucas Andreas Hospital; [6]Rijnstate Hospital, Arnhem; [7]Slotervaart Hospital/Academic Medical Centre (AMC), Amsterdam, The Netherlands

Background: Deep vein thrombosis and pulmonary embolism are important causes of morbidity and mortality after bariatric surgery. The overall incidence of venous thromboembolism (VTE) after bariatric surgery and using thrombosis prophylaxis has been reported to range from 0.2% to 3.4%. Knowledge of factors associated with a higher risk of VTE after bariatric surgery may be essential to select patients who may benefit from either prolonged or intensified thrombosis prophylaxis.
Aims: The objective of this study is to determine the risk factors for VTE after bariatric surgery.
Methods: A retrospective multicenter case-control study was performed in patients who had bariatric surgery (gastric banding, gastric bypass, sleeve gastrectomy, duodenal switch, revisional procedures) between January 2008 and September 2011. All medical records were manually reviewed for the presence of all forms of VTE until 6 months after surgery, and all patients were called to ascertain the results. For every case of VTE after surgery, six control patients were selected who were matched for gender, age, participating center and type of surgery. Risk factors for VTE before and after surgery and duration of thromboprophylaxis were registered. Also postoperative complications (infection, major bleeding, leakage of the anastomosis, myocardial infarction), length of stay and intensive care admission were evaluated.
Results: A total of 2050 patients were included. In 12 patients a VTE occurred within 6 months after bariatric surgery (incidence 0.59%, 95% CI = 0.25–0.93). The majority of VTEs occurred within 1 month (67%). There was a very strong impact of complications after surgery (cases 83.3%, controls 9.7%, OR 46.4; 95%CI = 8.4–255.9) or intensive care admission (cases 58.3%, controls 6.9%, OR = 18.8; 95% CI = 4.3–81.1). The majority of postoperative complications were leakage or infection (90%), and these patients did not have a contraindication for therapeutic dose low molecular weight heparin. There was no clear association between classical thrombosis risk factors and postoperative VTE, only immobility was more present among the cases (16.7%) compared to the controls (2.8%, OR 7.0; 95% CI = 0.9–55.4).
Conclusions: The incidence of VTE is low after bariatric surgery using thrombosis prophylaxis. However, there is a very strong association between postoperative complications and VTE. Patients with a complication after surgery may benefit from more intensive thrombosis prophylaxis.

PB 1.69-3

In-hospital prevention of venous thromboembolism: how should we do it? Comparison of a surveillance project with the use of a validated risk score for thrombotic risk assessment

Faioni EM[1], Andreano A[1], Lussana F[2], Iannuzzi P[1], Bertinato E[2], Ferraroni M[1], Decarli A[1] and Cattaneo M[1]
[1]University of Milano; [2]Ospedale San Paolo, Milano, Italy

Background: Venous thromboembolism (VTE) is a leading cause of mortality and morbidity in hospitalized patients. Despite evidence on the efficacy of prophylaxis in preventing VTE in the hospital, it is largely underused worldwide. The absence of widely accepted procedures to identify patients at risk contributes to this shortcoming. Aims. To analyze the validity of a program for in-hospital antithrombotic prophylaxis and to compare it with the use of the Padua Prediction Score (PPS).
Methods: A risk chart within the hospital prophylaxis project (STOP) was developed and used by physicians throughout the hospital to evaluate the thrombotic risk of all patients at admission (n = 5195 patients), from May 2010 to August 2011. It contained risk factors chosen among those reported in the literature that were the most frequent and/or had the highest associated risk. After filling in the risk chart, doctors administered prophylaxis based on their own judgment. Prophylaxis hospital guidelines were prepared together with the ward doctors. In a random sample of patients (n = 433), PPS results and the attending physician judgment, made through the STOP risk chart, were compared to the risk assessment of two experts who retrospectively evaluated risk factors and indication to prophylaxis from clinical records. The concordance between the two specialists was assessed using Cohen K statistic. Sensitivity and specificity in evidencing patients at risk for VTE were estimated for both the PPS and the attending physician, in the whole sample as well as stratifying for medical vs. surgical departments.
Results: Percentage of risk charts within the STOP project filled in by the attending physician over the study period and taken as a measure of adherence to VTE risk evaluation, decreased over time. In 2010, five wards were above 70%, considered the goal threshold, and 10 above the 50% threshold, while in 2011 there were three wards above 70% and five above 50%. No significant differences in adherence were observed between surgical and medical wards. Prophylaxis was provided in 46% of patients overall (32% medical, 52% surgical, 84% critical care). Concordance between the two hematologists in the whole sample was high (k = 0.78). Overall, the PPS had a high specificity (99%, 96%) and a lower sensitivity (66%, 76%) compared to the evaluation of each expert, while the opposite was true for the attending physician (specificity = 68%, 62%, sensitivity = 72%, 73%). The highest number of discrepancies between the evaluation of the PPS, the attending physician and the experts was observed for the risk factor 'acute infection'.
Summary/Conclusion: In-hospital VTE surveillance is time and resource consuming and most surveillance models fail over time. One of the problems that leads to failure is personnel turnover, which requires large investments in permanent education. We showed that the thrombotic risk assessment performed by the attending physician, even when educated within a hospital-wide surveillance project, performs worse than a validated risk score, that automatically provides an indication for prophylaxis. The PPS showed high specificity compared to expert evaluation, and can be used to select patients at thrombotic risk both in medical and surgical departments.

PB 1.69-4

Impact of chronic obstructive pulmonary disease on future risk of venous thromboembolism in a general population – the Tromsø study

Borvik T, Enga KF, Brækkan SK, Melbye H and Hansen JB
University of Tromsoe, Tromsoe, Norway

Background: Hospitalization for exacerbations of chronic obstructive pulmonary disease (COPD) is associated with a substantial risk of venous thromboembolism (VTE). VTE in patients hospitalized for COPD exacerbations is associated with prolonged hospital stay and increased 1-yr mortality rate. It is not known, however, whether the risk of VTE in patients hospitalized for exacerbations of COPD is caused by the respiratory failure or by other associated factors such as immobilization and bronchial superinfections.
Aims: We wanted to investigate the association between COPD and future risk of VTE in a prospective cohort recruited from the general population.
Methods: Spirometry were measured in 8645 unique men and women, aged 25–84 years, who participated in one or two surveys of the Tromsø study (Tromsø 5; 2001–2, and Tromsø 6;2007–8). COPD was defined according to the Global Initiative for Chronic Obstructive Lung Disease (GOLD) criteria. Incident VTE-events were registered from the date of inclusion through the end of follow-up, December 31, 2010. Cox-regression models were used to calculate crude and multivariable-adjusted hazard ratios (HR) with 95% confidence interval (CI). The analyses were adjusted for age, sex, body mass index, smoking, and cardiovascular diseases. Moreover, to minimize regression dilution effects, Cox-regression was performed in subjects with two recordings of spirometry during follow-up, allowing for time-dependency of the exposure variable and important co-variates. The study was approved by the regional committee for research ethics, and all participants gave their informed written consent to participate
Results: There were 1727 (20%) subjects with COPD (FEV1% < 70) at baseline, and in total 187 subjects in the population developed VTE (3.56 per 1000 person-years) of which 53 subjects with COPD (28.3% of VTE events) during a median follow-up of 6.72 years. Subjects with COPD did not have higher risk of total VTE (Multivariable HR 1.19, 95% CI 0.85–1.66) and provoked VTE (Multivariable HR 1.48, 95% CI 0.98–2.22) compared to subjects without COPD. Moreover, the risk of VTE did not increase across advancing stages of COPD (*P* for trend 0.5). Only minor changes in risk estimates were observed in time-dependent analyses.
Conclusions: There was no association between the presence of COPD and risk of total VTE in the general population, but subjects with COPD had higher risk estimates for provoked VTE. Our findings may suggest that the risk of VTE in patients hospitalized with exacerbations of COPD is precipitated by additional predisposing factors such as immobilization and respiratory infections.

PB 1.69-5

The number of venous valves in the legs does not explain the association between body height and risk of venous thrombosis

Van Langevelde K[1], Segers AE[2], Büller HR[3] and Cannegieter SC[1]
[1]LUMC, Leiden; [2]ICTOM; [3]Academic Medical Center, Amsterdam, The Netherlands

Background: Several studies have shown that increasing body height is associated with risk of venous thrombosis, yet the mechanism remains unclear. It has been suggested that leg length could explain the association between body height and thrombotic risk. Thrombus formation often starts around venous valves, in local widenings of the veins called sinuses, where blood flow velocity is low and hypoxia adds to the thrombotic potential. When tall people would have more venous valves, the likelihood of thrombus formation increases, which could explain the risk. Alternatively, when relatively fewer valves are present, higher hydrostatic pressure and venous stasis may lead to more thrombus formation.
Aims: In this study we aimed to relate the number of valves in the upper leg deep veins to leg length, to increase our understanding of the mechanism underlying the association between tall stature and venous thrombosis risk.
Methods: This study was performed as a separate analysis in the Thrombo Genics study, a double blind, randomized clinical trial on a novel factor VIII inhibitor (TB-402). We assessed the number of valves in 54 patients who underwent contrast enhanced venography 3 weeks after elective hip surgery. Consent and ethical approval was obtained. We counted the number of venous valves in the deep veins from the popliteal fossa up to the level of the inguinal ligament. As in the calf superficial and deep veins are numerous, and their diameters are small, assessment of the number of venous valves is not possible here. Besides, we assessed whether there were double popliteal or superficial femoral vein segments. Body height and weight were documented, and leg length was measured. We analyzed the data using Poisson regression and assessed the effect of body height in tertiles.
Results: Patients came from six different countries and from 11 different medical centers. Mean age of the patients was 61 years (range 33–82). Twenty three (43%) patients were male. Body height was on average 1.68 m (range 1.52–1.85), whereas leg length was on average 88 cm (range 75–101). None of the patients had a history of PE or DVT. A positive history of varicose veins was present in nine of 54 (17%) patients. Patients had a median of three valves in the upper leg veins, with a range of 0–7 valves. Eighteen of 54 patients (33%) had a double venous segment, mostly the superficial femoral vein. We found no association between body height and the number of valves (RR 0.98; 95% CI 0.97–1.00). Stratified data for sex showed no association either.
Summary/Conclusions: We conclude that increased body height does not increase the probability of having more valves. The relatively lower number of valves present over an increased venous distance in people of tall stature suggests that higher hydrostatic pressure and venous stasis explain the increased thrombotic risk.

PB 1.69-6

Incidence of symptomatic venous thromboembolism among hospitalized patients with lung cancer in China

Jing ZC[1], Qi HW[1], Wang L[1], Xu X[1], He J[1], Wu DC[1], Wu WH[1], Konstantinides S[2] and Fan L-H[1]
[1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; [2]FESC Center for Thrombosis and Hemostasis (CTH), Johannes Gutenberg University, Mainz, Germany

Background: Cancer patients are at high risk of venous thromboembolism (VTE); however, the incidence, risk factors and prognosis of symptomatic hospitalized VTE in patients with lung cancer in China have not been well determined.
Aims: To determine the incidence of hospitalized symptomatic VTE of lung cancer in China and identify risk factors and prognostic impact of VTE.
Methods: A retrospective analysis was conducted to assess the incidence of VTE and clinical characteristics and laboratory test results associated with VTE in patients with new diagnosis of lung cancer in 2009. Univariate and multivariate logistic regression analysis was used to identify risk factors predictive of VTE. Kaplan-Meier analyses were performed to estimate and to compare death risk among patients with or without VTE. Cox proportional hazard models were used to identify the prognostic effect of VTE on survival.
Results: A total of 3741 patients with lung cancer were included in analyses. In all, 84 patients developed symptomatic VTE within two-

year follow-up, including 28 had pulmonary embolism (PE), 40 had deep venous thrombosis (DVT), and 16 had concurrent PE and DVT. The incidence of VTE was 2.2%. Multivariate analysis identified tumor stage IV, adenocarcinoma histology, and a baseline D-dimer level $\geq$ 500 μg/L as independent risk factors for VTE and VTE was a statistically significant factor affecting survival ($P < 0.001$).

Conclusions: The incidence of symptomatic VTE was about 2.2% in Chinese hospitalized patients with lung cancer. Advanced cancer stage, adenocarcinoma and high level of D-dimer were associated with increased risk of VTE and it is a poor prognostic factor for survival.

PB 1.70-1

Thyroid function, assessed by thyroid stimulating hormone, and future risk of venous thromboembolism -the Tromsø study

Lerstad G[1], Enga KF[1], Jorde R[2], Brodin E[1], Brækkan SK[1], Njølstad I[3], Svartberg J[2] and Hansen JB[1]

[1]Hematological Research Group, University of Tromsø; [2]Endocrine Research Group, University of Tromsø; [3]Department of Community Medicine, University of Tromsø, Tromsø, Norway

Background: Thyroid hormones are known to affect the coagulation system by influencing plasma levels of factor VIII and von Willebrand factor, and low levels of these factors in hypothyroidism are normalized by hormone substitution. Thyroid stimulating hormone (TSH) is generally considered the most sensitive measure of thyroid function. However, a recent population-based nested case-cohort study reported that high levels of free thyroxine (FT4) were associated with increased risk of venous thromboembolism (VTE), whereas TSH levels were inversely and less pronouncedly associated with VTE. No prospective cohort study has so far investigated the association between TSH levels and future risk of VTE.

Aims: The purpose of the present study was to examine the association between TSH and future risk of VTE in a prospective cohort recruited from a general population.

Methods: TSH was measured in 11,965 subjects, aged 25–89 years, who participated in one or more surveys of the Tromsø study, starting in 1994–95 (Tromsø 4; 1994–95, Tromsø 5; 2001–2, and Tromsø 6; 2007–8). Incident events of VTE were recorded to the end of follow-up, December 31, 2010. Cox's proportional hazard regression models were used to estimate crude and multivariable-adjusted hazard ratios with 95% confidence intervals. The analyses were adjusted for age, sex, body mass index and smoking. TSH was analyzed in predefined categories (< 0.2 mU/L; low (11% of the population), 0.2–4.0 mU/L; normal, and > 4.0 mU/L; high (38% of the population) and as a continuous variable. Moreover, to minimize regression dilution effects, Cox-regression was performed in subjects with at least two recordings of TSH during follow-up, allowing for time-dependency of the exposure variable and important covariates. The study was approved by the regional committee for research ethics, and all participants gave their informed written consent to participate.

Results: There were 289 validated first VTE events (2.94 per 1000 person years), of which 114 were unprovoked, during a mean of 8.20 years of follow-up. TSH was not significantly associated with future risk of VTE in analyses treating TSH either as a continuous variable or in predefined categories. The risk of VTE decreased by 1% per 1 SD (2.04 mU/L) increase in TSH (Multivariable-adjusted HR 0.99; 95% CI 0.89–1.10). In subjects with low and high TSH levels according to predefined criteria, the risk estimates for VTE were somewhat increased (HR 1.13; 95% CI 0.47–2.76 and HR 1.15; 95% CI 0.71–1.86, respectively). The risk estimates for deep vein thrombosis (DVT) for low and high TSH levels vs. normal levels were even higher (HRs 1.73; 95%CI 0.64–4.72 and 1.59; 95% CI 0.90–2.82, respectively). All risk estimates were essentially similar in time-dependent analyses.

Conclusion: We found no significant associations between TSH levels and future risk of VTE in a prospective population-based cohort. However, low (< 0.2 mU/L) and high (> 4.0 mU/L) TSH levels were associated with higher risk estimates for sole DVT. The latter observation may imply that factors other than thyroid hormones alone contribute to increased risk of VTE in thyroid dysfunction.

PB 1.70-2

Cardiovascular profile of individuals with deep vein thrombosis: results of the Gutenberg Health Study (GHS)

Ariza L[1], Keller K[2], Schulz A[2], Zeller T[2], Lankeit M[2], Konstantinides S[2], Espinola-Klein C[2], Munzel T[2] and Wild P[2]

[1]University Medical Center of the Johannes Gutenberg-University Mainz, Mainz; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Recent studies have shown that venous thromboembolism and arterial diseases may be related.

Aim: Our objective was to assess the cardiovascular (CV) profile of individuals with deep vein thrombosis (DVT) in a large-scale population sample.

Methods: GHS is an observational population-based cohort study (N = 15,010) comprising individuals aged 35–74 years selected representatively from local registry offices. Sociodemography, classical cardiovascular risk factors (CVRF), CV and other diseases were documented by computer-assisted personal interview, clinical assessment and laboratory examinations. DVT was defined as self-reported history of DVT, diagnosed by a physician in life time. Data underwent detailed quality control.

Results: The population-weighted prevalence for DVT was 3.6% (N = 534). The majority of individuals with DVT were women (62.1%; n = 362) and older than individuals without DVT (non-DVT; 60.2 ± 10.2 vs. 54.8 ± 11.1 years). CVRF like hypertension, diabetes, dyslipidemia, obesity and family history of myocardial infarction (MI), as well as cardiovascular comorbidities (coronary artery disease, MI, stroke, PAD, atrial fibrillation, heart failure) and cancer were more frequent in individuals with DVT. As expected, PE events were less frequently reported by non-DVT individuals (0.0% vs. 3.3%, $P < 0.0001$). In multivariable logistic regression analysis adjusting for all CVRFs, only sex (OR 1.86[1.55–2.22], $P < 0.0001$), age (OR 1.86 [1.55–2.22]; $P < 0.0001$) and obesity (OR 1.86[1.55–2.22]; $P < 0.0001$) were independently associated with DVT. Frequency of peripheral arterial disease (PAD) was remarkably higher in DVT compared to non-DVT individuals (19.1% vs. 2.7%, $P < 0.0001$). After adjusting for CVRF, PAD (OR 6.67[5.16–8.61]; $P < 0.0001$) was the strongest independently associated CVD with DVT (adjusted for all CVRFs), followed by heart failure (OR 2.54[1.51–4.26]; $P = 0.0004$) and atrial fibrillation (OR 1.86[1.29–2.64]; $P = 0.0095$). Stroke and cancer showed a weak association only. Overall, individuals with DVT presented a higher 10-year risk for incident cardiovascular disease (calculated by Framingham CVD Risk Score at time of data assessment) compared to non-DVT (9.0% vs. 7.2%; $P < 0.0001$).

Summary/Conclusion: DVT is related with a higher prevalence of CVRF and cardiovascular diseases. These findings may have implications for risk assessment and secondary prevention.

PB 1.70-3

Incidence of venous thromboembolism in patients undergoing laparoscopic surgery for colorectal cancer

Giustozzi M[1], Becattini C[1], Rondelli F[2], Boncompagni M[3], Camporese G[4], Balzarotti R[5], Flamini O[6], Donini A[7], Vedovati MC[1] and Agnelli G[1]

[1]Internal and Cardiovascular Medicine and Stroke Unit, University of Perugia; [2]Oncologic Surgery, University of Perugia; [3]General Surgery, S. Maria della Misericordia Hospital, Perugia; [4]Unit of Angiology, University Hospital of Padua, Padova; [5]General Surgery, Niguarda Hospital, Milan, Milano; [6]Angiology, S. Giovanni Battista Hospital, Foligno, Italy, Foligno; [7]General and Emergency Surgery, University of Perugia, Perugia, Italy

Background: The incidence of venous thromboembolism (VTE) after laparoscopic surgery for colo-rectal cancer is unknown.
Aims: We performed a prospective multicenter study aimed at assessing the incidence of and risk factors for VTE in patients undergoing elective laparoscopic surgery for colorectal cancer.
Methods: Complete compression ultrasonography of the lower limbs was performed at day 8 ± 2 after surgery. The primary outcome of the study was the incidence of any VTE at day 8 ± 2 after surgery. No restriction was given regarding antithrombotic prophylaxis.
Results: Overall, 298 consecutive patients were evaluated for inclusion in the study. Twenty-three patients were excluded (six conversion to laparotomic surgery; seven consent refusal; 10 indication for anticoagulant therapy). Thus, 275 patients were included in the study, 55% males, mean age 66 ± 11 years. Obesity (BMI ≥ 30) was found in 7%, bed rest in 1% and previous VTE in 2%. Mean surgery duration was 175 ± 74 min and mean post-surgery immobilization 33 ± 21 h. All patients received prophylaxis with low molecular weight heparin starting from 12 h after surgery to ultrasound assessment. After 6.2 ± 2.5 days, 46 VTEs were observed (16.7%), all deep vein thrombosis of the lower limbs. Thrombosis was symptomatic in two patients (0.7%) and proximal in two other patients (0.7%) for an overall incidence of major VTE of 1.4%. Bilateral DVT was found in 17 patients (6.2%). After surgery, one patients had a major bleeding and one patient had a clinically relevant non-major bleeding. Obesity (HR 3.4, 95% CI 1.5–7.6) and age ≥ 70 years (HR 3.7, 95% CI 1.9–7.1) were independent predictors for postoperative VTE. No correlation was observed between VTE and gender, comorbidities, surgical site, surgery duration or stage of malignancy.
Conclusion: The risk of developing VTE after laparoscopic surgery for colorectal cancer is substantial despite antithrombotic prophylaxis. Obesity and advanced age were risk factors for VTE.

PB 1.70-4

Outpatient treatment for PE and risk factors for mortality, recurrent VTE and pulmonary hypertension in a 6-month follow-up – results of a retrospective registry

Werth S[1], Kamvissi V[1], Stange T[2], Kuhlisch E[2], Weiss N[1] and Beyer-Westendorf J[1]

[1]University Hospital, C.G.Carus Dresden; [2]Technical University Dresden, Medical Faculty, Dresden, Germany

Background: Over the last 15 years, outpatient treatment for deep vein thrombosis (DVT) has become standard but most patients with pulmonary embolism (PE) are still hospitalized due to more severe comorbidities and a higher mortality. Recently, PE risk scores identified low-risk PE patients, for which outpatient treatment could be feasible. However, little is known about the distribution of PE risk categories, the management and outcome of unselected PE patients in daily care.
Aims: To evaluate distribution of PE risk categories, outcome and risk factors for mortality, recurrent VTE and pulmonary hypertension (PAH) in patients 6 month after PE.
Patients and Methods: Retrospective analysis of all outpatient PE patients presenting at our academic hospital between January 2000 and December 2010. Patients were identified in the PE-database of our Vascular Center and different hospital databases using ICD 10-code 'I26.x'. Patients with non-acute or asymptomatic PE were excluded. Data for 6 month FU were extracted from the PE-database of our Vascular Center, where all VTE patients are routinely seen after 6 month (echocardiography performed only in patients with suspected pulmonary hypertension).
Results: Between 2000 and 2010, a total of 439 patients presented as outpatients with symptomatic PE (mean age of 64.4 ± 16.7 years; 55.4% male; 82.7% with concomitant DVT). Of these, 49 patients (11.2%) were treated as outpatients (OP; in hospital < 24 h), 63 patients (14.4%) were discharged within 72 h (ED) and 327 patients (74.5%) were hospitalized for longer than 72 h (HO).
At 6 month, 17 patients (3.9%) had recurrent VTE, 48 (10.9%) had bleeding complications, 23 (5.2%) were found to have pulmonary hypertension and 47 (10.7%) were dead (0% HO; 3.2% ED and 13.8% HO, respectively).
In multivariate analysis, risk of recurrent VTE was significantly increased by low ESC-category (OR 2.4), initial RVESP > 40 mmHg (OR 3.2), symptomatic DVT (OR 2.4) and proximal DVT (OR 2.6). Increasing age was found to reduce the risk for recurrent VTE (OR 0.97; $P = 0.005$).
In all patients undergoing echocardiography at 6 month for suspected PAH, risk of PAH was significantly increased in patients with documented initial RVESP > 40 mmHg (OR 3.0), right heart strain in ECG at baseline (OR 6.6) and known thrombophilia (OR 8.4).
Mortality risk was significantly increased by age (OR 1.1/year; $P < 0.001$), concomitant diabetes mellitus (OR 4.2), underlying malignant disease (OR 4.4), right heart strain (OR 4.3), high ESC risk category (OR 8.7), but most strongly by INR values > 2 at diagnosis of PE (OR 59.0). In contrast, mortality was not increased by outpatient or early discharge treatment.
None of the tested parameters at initial VTE presentation were found to be predictive for bleeding complications.
Conclusion: We conclude that in cohorts of unselected PE patients, low risk PE can exactly be identified. Consequently, in daily care settings about 25% of patients can safely be treated as outpatients or early discharged. Our analysis identified several significant risk factors for unfavourable outcomes, some which are not described in the literature and might further improve decision making in PE treatment.

PB 1.70-5

Increased incidence of VTE prior to surgery in patients with renal cell carcinoma and tumor thrombus

Yokom DW[1], Ihaddadene R[1], Le Gal G[2], Moretto P[3] and Carrier M[2]

[1]University of Ottawa; [2]Ottawa Hospital Research Institute and University of Ottawa; [3]The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: Patients with kidney cancers are at increased risk of venous thromboembolism (VTE) with rates varying between 1% and 3% within 6 months of cancer diagnosis. Tumor thrombosis occurs frequently among patients with renal cell carcinoma (RCC) and has been reported to occur in 5–10% of all RCC patients. Venous tumor thrombosis disrupts vascular integrity and disturbs venous blood flow which could potentially increase the risk of VTE. The clinical impact of tumor thrombus and its potential association with increased risk of VTE in patients with RCC is unknown.

Aims: To determine if the presence of tumor thrombus in patients with RCC increases the incidence of VTE prior to radical nephrectomy and thrombectomy.
Methods: A retrospective cohort study of all late-stage (stage 3–4) RCC patients that underwent a radical nephrectomy at our institution between January 1, 2005 and July 1, 2012 was conducted. Radiological imaging data was reviewed for all patients to identify patients with tumor thombus seen on imaging. Tumor thrombus was defined as the presence of an intra-luminal filling defect in the renal, hepatic, portal or IVC directly extending from a renal mass detected on computed tomography or magnetic resonance imaging. Patients with VTE prior to or at cancer diagnosis were excluded. The primary outcome was the incidence of VTE between cancer detection and surgery. Venous thromboembolism was defined as proximal lower limb (popliteal vein or more proximal) deep vein thrombosis or pulmonary embolism. A two-sided Fisher exact test was used to compare the incidence of VTE between patients with and without tumor thrombus.
Results: A total of 179 RCC patients were included in the study. Fifty-six (31.3%) RCC patients had tumor thrombus diagnosed on imaging. The total population had a mean age of 62.5 years, men represented 68.2%. The number of patients at stage 3 was 51.4%. None of these patients received anticoagulation prior to surgery.
Three patients with tumor thrombus (5.4%; 95% CI: 1.1–14.6%) developed a VTE while awaiting surgery whereas none (0%; 95% CI: 0–2.9%) of the patients without tumor thrombus had an event ($P = 0.030$). Median time to VTE from tumor thrombus diagnosis was 15 days (range 5–21 days) and median time to surgery was 24 days (range 1 to 213 days) in the tumor thrombus group.
Conclusions: Tumor thrombus on imaging is a frequent finding among late-stage RCC patients awaiting radical nephrectomy. The presence of tumor thrombus in these patients increases the incidence of pre-operative VTE. Larger prospective studies are required to confirm these findings and assess the role of thromboprophylaxis in RCC patients with tumor thrombus.

PB 1.70-6
Incidence of Congestive Heart Failure-associated Venous Thromboembolism in Korean Population: from Health Insurance Review and Assessment Service database

Oh D[1], Jang MJ[1], Seo SE[1], Kwon HM[2] and Jeong MO[3]
[1]Department of Internal Medicine, School of Medicine, CHA University, Seongnam; [2]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul; [3]The Heart Research Center of Chonnam National University Hospital, Gwangju, South-Korea

Background: Congestive heart failure (CHF) has been known to be a major risk factor for venous thromboembolism (VTE) in Western countries. The reported incidence of VTE in CHF has ranged 1.65-59% in Caucasian population. However, its contribution to VTE risk has not been established in an Asian population so far. To address this issue, a population-based study was carried out to know the incidence and risk factors of VTE in Korean patients with CHF.
Methods: This population-based study used the Korean Health Insurance Review and Assessment Service database. VTE patients with CHF from 2004 to 2008 were retrospectively identified by both diagnostic codes and medication codes for drugs used in initial treatment of VTE.
Results: During the 5 years of the study, 20,737 VTE cases were identified among 2,424,206 CHF patients and the incidence of VTE with CHF was 0.855% (95% confidence interval [CI], 0.844–0.867). The incidence increased steadily with advancing age, from 0.422% (95% CI, 0.405–0.439) at 40–59 years of age, 0.991% (95% CI, 0.974–1.008) at 60–79 years of age, up to 1.061% (95% CI, 1.029–1.094) in patients over 80 years of age. The annual VTE incidence in patients with CHF was 0.573% (95% CI, 0.552–0.594) in 2007, 0.713% (95% CI, 0.690–0.737) in 2008, 0.862 (95% CI, 0.836–0.889) in 2009, 0.971% (95% CI, 0.944–0.998) in 2010, and 1.188% (95% CI, 1.156–1.221) in 2011 which suggested a yearly increasing incidence of VTE in patients with CHF in the Korean population.
Conclusions: The incidence of VTE in patients with CHF was lower in the Korean population than in Caucasians, However, it also demonstrates a yearly increasing incidence of VTE in patients with CHF in the Korean population.

PB1.71 – Paediatric Thrombosis – I

PB 1.71-1
Vitamin K antagonists (VKAs) for venous thromboembolism (VTE) in a pediatric cohort with persistent antiphospholipid antibodies (aPL)

Bonduel M, Hepner MD, Sciuccati GB, Annetta ES, Feliu Torres AS, Pieroni G, Cervio C, Pepe C and Frontroth JP
Hospital de Pediatria Dr. JP Garrahan, Ciudad Autonoma De Buenos Aires, Argentina

Persistent aPL is associated with an increased risk of VTE in children, and high rates of recurrent thrombosis were described. The intensity of anticoagulation in childhood has been extrapolated from adults. However, the optimal duration of this therapy is currently uncertain, and should be evaluated for the risk-benefit of extended therapy.
Objective: To determine the rate of recurrent thrombosis and major bleeding in a prospective pediatric cohort with VTE and persistent APLs, receiving acenocoumarol until the clinical risk factor is resolved and until aPL disappears.
From May 1992 to July 2012, 371 children, < 18 years old with objectively confirmed VTE were evaluated. Newborns were excluded. All the patients (pts) were given acenocoumarol at a target INR range of 2.0–3.0. Age-adjusted initial doses were given according to published guidelines. Lupus anticoagulant (LA), anticardiolipin antibodies (aCL) IgG/IgM and anti-β2-glyprotein I (anti-β2GPI) IgG/IgM were tested, according to recommendations, every 3–6 months until LA became undetectable and low titers of aCL and anti-β2GPI were achieved. Inherited thrombophilia was also assessed. Age-related local cut-off values were used.
During a 20-year period, 24pts (6.5%) with VTE, 15females, median age 5.1 years (range 0.2–16.9) were identified with persistent aPL and were evaluated for a total of 64.1 patient-years. The patients are described according to their clinical conditions (unprovoked VTE, SLE, *Streptococcus* or *Staphylococcus* infections, uremic hemolytic syndrome (UHS) and catheters along with other risk factors) and aPL profiles. One pt with an unprovoked VTE and 3/7 pts with SLE had triple positivity (LA, IgGaCL, IgGanti-β2GPI). Another 3/7 pts with SLE had positive LA and IgGaCL, and the remaining pt. with SLE had LA alone. All these 8 pts. still showed persistent aPL at their last control or discharge to an adult center, median time positivity aPL of 22.3 months (range 7.8–91.2). Five pts. with infections showed extensive VTE and LA for a median time of 20.6 months (range 8.7–29.7); in one of them, an inherited combined prothrombotic disorder was also found. One pt. with UHS had IgGanti-β2GPI for 9.6 months. Ten pts with catheters showed aPL positivity for a median time of 9.7 months, (range 3.0–13.9), eight of them showed single aPL positivity. The INR values at the ranges of 2.0–3.0 or 1.5–1.9 were observed for 47.6% and 43.7% of the follow-up time respectively. One to three monthly controls were required to maintain INR in the target range. Two adolescents with SLE who discontinued acenocoumarol presented recurrent thrombosis and died afterwards of arterial ischemic stroke and sudden death, respectively. No pt. had major bleeding.
Conclusion: This is the first prospective pediatric cohort with VTE and persistent aPL who received VKAs until the clinical risk was resolved and LA became undetectable or low titers of aCL and anti-β2GPI were achieved. Neither recurrent thrombosis nor major bleeding was

observed in patients with different clinical settings, maintaining INRs values within moderate and low-intensities acenocoumarol most of the long follow-up time. Further prospective multicenter studies are needed to investigate the optimal intensity and duration of the antithrombotic therapy taking into account the clinical entities and aPL profiles.

PB 1.71-2

Evaluating the impact low molecular weight heparin on quality of life for children and their families

Bruce AK, Bauman M and Massicotte P
University of Alberta, Canada

Background: Low molecular weight heparin (LMWH) is a common treatment available for long term anticoagulation in infants and children. LMWH appears to be safe and effective in preventing thrombosis, requires two injections per day which are painful and cause bruising. How LMWH impacts families has not been evaluated and requires assessment considering the launch of new anticoagulants believed to provide similar efficacy. Given the expense of these new agents it is essential to demonstrate superiority through patient preference and patient quality of life The GRADE system for evaluating quality of evidence calls for appraisal of patient outcomes such as health-related quality of life (HRQOL). HRQOL describes the patients' perception of their physical, social, and mental wellbeing. HRQOL is influenced by type of treatment. The objective measurement of HRQOL in children receiving LMWH will provide important information to guide clinicans, funding agencies and the family in treatment choices. The KIDCLOT PAC QL© (Pediatric AntiCoagulation Quality of Life inventory) for pediatric patients on vitamin K antagonists has undegone both validity and realibility testing and is currently being employed internationally to assess the impact of oral anticoagulation on the HRQOL of children and their families. This study is the first to develop and validate an inventory that objectively measures HRQOL in children receiving LMWH. This information will provide guidance to improve anticoagulant treatment options for children.

Aims: To modify an existing pediatric HRQOL inventory that assesses the impact of oral anticoagulation (KIDCLOT PAC QL©) for LMWH use. The modified inventory will describe the variables which represent the impact of LMWH on the lives and well-being (HRQOL) of children and their families.

Methods: Modification of the inventory requires the removal of irrelevant questions and addition of therapy specific questions. The new questions will be validated using cogntive debriefing interviews with both children and parents. The cognitive debriefing interviews will ensure clarity of wording, sentence structure, and inclusion of all relevant information. If two or more participants have difficulty understanding a question the question will be rewritten and additional interviews will be conducted to confirm clarity. Any suggested areas of missing data will be added to the inventory and tested to ensure clarity. Informed consent and ethics approval was obtained.

Results: A final inventory was developed and validated to assess the impact of LMWH on HRQOL of children and their families. Parent cognitive debriefing interviews were held and child/teen interviews were conducted. The LMWH PAC QL inventory is complete and the inventory will be available to be used internationally to measure HRQOL in children receiving LMWH.

Summary: The HRQOL measure for children receiving LMWH provides a novel, important strategy for assessing treatment choices especially with the introduction of novel anticoagulant therapies. It is validated and available for use. Modifications for international use such as cultural adapation must be considered prior to implementation.

PB 1.71-3

Chylothorax in neonates and children: diagnosis and antithrombotic therapy of a complication associated with upper venous system thrombosis (UVST)

Cervio C[1], Sciuccati GB[2], Hepner MD[1], Sierre S[1], Feliu Torres AS[2], Frontroth JP[1], Pieroni G[1], Annetta ES[1] and Bonduel M[1]
[1]Htal de Pediatria J.P. Garrahan; [2]Htal de Pediatria Garrahan, Buenos Aires, Argentina

Introduction: Chylothorax is a relatively rare complication with high morbidity and mortality, most frequently described in neonates and children after cardiothoracic surgery. Diet modification, octreotide and pleural drainage remain the standard initial therapy. Severe antithrombin loss in the chylous pleural effusion was reported. Only few cases of chylothorax related to UVST and its specific treatment have been published.

Objectives: To describe the demographic data, underlying diseases, clinical signs, imaging findings, treatment and outcomes of a series of neonates and children with chylothorax related to UVST evaluated in a single center.

From July 2006 to June 2012, 14 consecutive patients (pts.), seven females (50%), median age 51 days (range 10 days–8.8 years) with chylothorax and UVST were evaluated. The underlying diseases were: cardiac surgery, 7pts; infection, 2pts; preterm neonates with hyaline membrane disease, 2pts; hematopoietic stem cell transplant, 1pt., liver transplant, 1pt., congenital diaphragmatic hernia surgery, 1pt. All the patients had central venous access devices in the upper venous system. Twelve pts (85.7%) weighed < 10 kg. Clinical signs of UVST when the pleural effusion appeared were: swelling of the ipsilateral related limb, 2pts. and superior vena cava syndrome, 2pts. The median time between chylothorax onset and thrombosis diagnosis was 5 days (range 1–66), and it was longer than 7 days in 42.8% of the cases. The thrombosis was confirmed by ultrasonography, 11pts.; venography, 2pts. and angiotomography, 1pt. The involved veins were: subclavian, 13pts.; jugular, 6pts.; innominate, 1pt.; and extracardiac conduit following Fontan surgery, 1pt. The chylothorax was: right-sided, 3pts.; left-sided, 4pts. and bilateral, 7pts. All the pts. received standard initial management. Two children died due to their cardiovascular diseases before antithrombotic therapy could be started. Treatment in the remaining 12pts. was: Tissue plasminogen activator (tPA), median dose 0.2 mg/kg/h (range 0.1–0.5) for 3–6 h, 8pts.; heparin 12pts.; and vitamin K antagonists, 1pt. AT plasma levels were tested in 13pts. and its median minimum value was 0.33 U/mL (range 0.07–1.08). Levels below 0.45 U/mL were found in 11pts. AT concentrate or fresh frozen plasma were indicated in 11pts. to maintain AT levels above 50%. Chylothorax resolution was observed in the 12pts. in whom antithrombotic therapy was administered. The maximum drainage volume was, median 54 mL/kg/day (range 10–400). The median (range) duration of chylothorax in patients treated with tPA was 8 days (5–37) while in pts. without thrombolytic therapy, it was 17 days (11–24). Two pts. with Fontan surgery required pleurodesis.

Conclusion: Chylothorax related to UVST is underdiagnosed, especially in neonates and infants. Since extensive UVST was observed in most of the patients (71.4%) without clinical signs of thrombosis other than chylothorax, high clinical suspicion is necessary for an early diagnosis. UVST should be investigated even in patients with a recent cardiothoracic surgery. Acquired AT deficiency was found in most of the patients (84.6%), possibly increasing their thrombotic risk and heparin resistance. The use of antithrombotic therapy including thrombolytic agents and AT supplementation could reduce morbidity and mortality.

PB 1.71-4

Evaluating the impact of thrombophilia testing on health-related quality of life in children: development of an inventory

Bruce AK, Reynolds C, Bauman M and Massicotte P
University of Alberta, Canada

Background: Thrombophilia testing is one of the most common types of genetic testing performed in children. The impact of this testing on health related quality of life (HRQOL) has not been evaluated. The concept of HRQOL focuses on dimensions of QOL related to health and therapeutic management strategies. HRQOL must be measured to develop effectual therapeutic choices, create research strategies, and change policies for improvement of health care adherence and outcomes. HRQOL is now considered the 'gold-standard' measurement for patient relevant outcomes. A HRQOL inventory for children with thrombophilia would assess general constructs that are salient for this population. Identification and evaluation of these constructs is critical to recognizing influences on patients HRQOL. This then facilitates improvements in care and helps to determine potential benefits and harms in testing for thrombophilia in families.
Aims: To develop a pediatric HRQOL inventory that describes variables which represent the impact of thrombophilia on the lives and well-being (QOL) of children and their families.
Methods: Focus groups identified items and themes significant to children and parents with thrombophilia. After items and themes were identified participants rated variables as to the level of frequency and severity using a Likert scale. Items were grouped into themes and a conceptual framework generated. The inventory was pre-tested to ensure that patients understood the questions and there is a full range of responses. Data was analysed using SPSS 20© for item level variability (frequency distributions, means, standard deviations and bar graph), and reliability (precision) for item reduction. Finally, cognitive debriefing interviews were held to ensure that patients understood the questions and there is a full range of responses for validity. Collected demographics include type of thrombophilia, age of patient, and gender. Informed consent and ethics approval was obtained.
Results: Focus groups with parents revealed concrete (medical, insurance, and activity related concerns), emotional (worry, stress, guilt), reproductive (concern regarding oral contraceptive use, future pregnancies and labour), and generational concerns (fear and guilt regarding passing the thrombophilia to child). While focus groups with adolescents had clearly positive (increased activity level and knowledge) and negative (restriction of activities, changes in lifestyle and emotional distress) themes in response to living with thrombophilia. Two inventories have been created a child/teen and a parent inventory. A total of 25 parents and 15 teens have completed the inventories. The final inventories had 35 and 43 questions on the child/teen inventory and the parent proxy respectively. Cronbach's alpha for the parent inventory is 0.899 and the child/teen is 0.934.
Summary/Conclusions: The newly generated HRQOL inventory for children with suspected or confirmed thrombophilia is validated and useful to determine confounders to diagnosis and facilitate partnership in care. Once confounders are identified the 'best' management (improved QOL associated with the safety and efficacy) for this patient population can be established.

PB 1.71-5

Warfarin knowledge retention in families participating in a home INR monitoring program

Monagle KE[1], Monagle P[1], Jones S[2] and Newall F[2]
[1]The University of Melbourne; [2]The Royal Children's Hospital, Melbourne, Vic., Australia

Background: Treating children with warfarin is highly complex. The Royal Children's Hospital's home International Normalised Ratio (INR) program enables families to perform INR's at home, as required. This assists maintenance of the INRs within a strict target therapeutic range, with minimal impact on family life. Every family participates in an education program focusing on the mechanism of action, interactions and adverse effects of warfarin. Prior to commencing home INR monitoring, families must demonstrate a requisite level of knowledge and skill relating to warfarin management. Previous evaluations demonstrate this training program facilitates a high level of knowledge retention 6 months post training, however longer-term knowledge retention has not previously been measured.
Aim: To determine the long term warfarin knowledge retention of parents and patients participating in the Home INR Program.
Method: All parents and patients who successfully completed Home INR training between 2003 and 2011 were invited to complete a questionnaire evaluating the same knowledge content assessed at the time of completing their training. The results were compared to their original results using descriptive statistics, to assess knowledge retention.
Results: One hundred and one questionnaires were sent out to 88 families as in some families, both parents and older children had previously completed the education and questionnaire. Fifty-seven questionnaires (40 parents, 17 children) were returned (56%). The average length of participation in the Home INR program was 26.7 months (Range: 6.0–97.9). The mean questionnaire result at the time of original training was 29.1 (Range: 14–37) out of 40. The mean result from the repeat questionnaires mailed-out was 22.0 (Range: 14–30.5) out of 40, representing a statistically significant ($P < 0.001$) difference, with a mean decrease in knowledge of 7.1 marks. Of the 57 returned surveys, 24.6% ($n = 14$) said that they did not see a doctor in the clinical haematology outpatients department every 12 months. Furthermore, 38.6% ($n = 22$) of respondents said that they did not receive timely ongoing education about their child's warfarin therapy. The group who had an annual clinic review had an average questionnaire score decrease of −6.8. In comparison those who did not have an annual clinic review had an average decrease of −8.0. Whilst there was less of a knowledge reduction in those who had an annual clinic review compared to those that did not, this reduction was not statistically significant, most likely due to the small study numbers.
Conclusion: There was significant loss of warfarin knowledge between the two time points. Strategies need to be implemented to support families' ongoing knowledge retention and acquisition of new knowledge regarding warfarin management in children. This education could be delivered during annual clinic reviews, and we suggest these families attend a Haematology outpatient appointment at least every 12 months.

PB 1.71-6

A successful implementation of a pediatric thrombosis program to promote assistance to children, adolescent and young adults with cancer

Terzian CN[1], Gamba J[1], Senerchia A[1], Brandão LR[2] and Petrilli AS[1]
[1]Instituto de Oncologia Pediatrica, São Paulo, Brazil; [2]The Hospital for Sick Children (SickKids), Toronto, ON, Canada

Background: Venous Thromboembolism (VTE) is a serious complication in patients with cancer and this problem is increasingly being recognized in pediatric practice. Recently, literature has demonstrated a dramatic increase in the prevalence of VTE at children's hospitals worldwide. It is also suggested by the American College of Chest Physicians Evidence-Based Clinical Practice Guidelines that pediatric hematologists with experience in VTE manage such patients. In order to fulfill this recommendation, the Instituto de Oncologia Pediátrica/Grupo de Apoio ao Adolescente e à Criança com Câncer (IOP/GRAACC), São Paulo, Brazil, organized a dedicated thrombosis team to promote the care of children with VTE within our institution.
Aims: To evaluate the VTE epidemiology and demographics findings by the thrombosis team since the program started at our institution.

Methods: Children, adolescences and young adults with cancer who developed VTE between February 2011 and December 2012 were studied retrospectively. Demographics and clinical characteristics related to thrombosis and cancer were evaluated. Chi-square test was performed to evaluate the relationship between low molecular weight heparin (LMWH) interval and recurrent thrombosis.
Results: The incidence of VTE was 5%. Of 34 patients diagnosed with symptomatic VTE, the median age at diagnosis was 12.3 years (IQR = 9), and 62% were female. The most common types of conditions associated with thrombosis were extra cranial solid tumor (56%), leukemia (26%), brain tumor (15%), and lymphoma (3%). Cancer and VTE were diagnosed at their initial presentation in 7 (21%) patients [extra cranial solid tumor (5)]. VTE were located in thorax (n = 17), lower venous system (n = 8), upper venous system (n = 7), neck vessels (n = 7), intra-abdominal vessels (n = 7), and CNS vessels (n = 3). Of note, pulmonary embolism (PE) and intra-cardiac thrombosis was documented in 44% (n = 15) of patients. An identified thrombosis risk factor was present in 88% of patients (central venous lines 26/34 [74%]). Anticoagulation therapy comprised LMWH [q24 h (n = 22), q12 h (n = 8)], oral anticoagulant therapy (n = 2) and others (n = 2). The duration of anticoagulation treatment was < 3 months in three patients, between 3 and 6 months in eight and more than 6 months in 23. VTE recurrence occurred in seven of 28 patients who survived. Six died due tumor progression. Heparin interval administration (q24 or q12) was not significantly associated with recurrent thrombosis (P = 0.71).
Summary/Conclusion: The creation of a new pediatric thrombosis program within a tertiary pediatric oncology academic center allowed a better characterization of VTE within our population. While some of our findings were consistent with the previously described findings in the literature, a much higher frequency of PE and intra-cardiac thrombus in children with extra-cranial tumors was noted. In terms of LMWH interval and VTE recurrence, an interesting information will merit further exploration.

PB1.72 – Thrombophilia – I

PB 1.72-1

The F2G1787T prothrombin gene mutation is not present in a representative cohort of Spanish patients with venous thromboembolism or controls

Mateo J, Tirado I, Coll I, Souto JC, Santamaria A, Borrell M and Fontcuberta J

Hospital St Pau, Barcelona, Spain

Background: Known genetic abnormalities explain < 40% of patients with deep vein thrombosis. That is why there is an increasing interest in finding new mutations and new pathophysiologic explanations for this common disease. Recently, a new prothrombin gene mutation (p.Arg596Leu *F2* variant) has been identified in a Japanese family with hereditary thrombophilia. This mutant prothrombin was shown to have reduced activity in clotting assays and the produced thrombin was markedly resistant to inhibition by antithrombin (Miyawaki, NEJM 2012; 366: 2390).
Aims: We have investigated the presence of this mutation in a cohort of consecutive Spanish patients with venous thromboembolism previously reported (Tirado, Thromb Haemost 2005; 93:468).
Methods: We analyzed the F2G1787T prothrombin gene mutation by PCR. The fragment of 467 pb of exon 14 of F2 gene was amplified using these primers: forward F214-A-5′- AGGGCCTGGTGAA CACATCTTC-3′ and reverse F214-B-5′- CCAGGTGGTGGATTCT-TAAGTCTTC-3′. The 467-bp PCR product was digested with the restriction endonuclease *Msp*I (Biolabs) and electrophoresed in a Qiaxcel machine (Qiagen). The G allele leads to a cutting site for Msp I that digests the 369-pb fragments into 280 and 187 pb fragments. The pattern was confirmed by direct sequencing. Other classical thrombophilic parameters such as factor V Leiden mutation, PTG20210A mutation, antithrombin, protein C, protein S deficiencies, and ABO blood genotype were analyzed and reported previously (Tirado, Thromb Haemost 2005; 93:468).
Subjects: A Spanish cohort of Caucasian unselected patients with venous thromboembolism (n = 249; 111 males and 138 females; 47.1 ± 14.0 year) and unrelated matched controls (n = 248; 109 males and 139 females; 49.0 ± 14.9 year) was analyzed.
Results: The frequency of the classical parameters of thrombophilia in patients and controls was found to be consistent with a representative population of Spanish patients and controls. None of the patients or controls had the F2G1787T prothrombin mutation.
Conclusion: The F2C1787T prothrombin mutation seems to be very uncommon in the Spanish population and screening is not recommended in patients with venous thromboembolism.

PB 1.72-2

Thrombophilia in young patients with isquemic stroke. A prospective national study

Ceresetto JM[1], Duboscq C[1], Genoud V[2], Shanley C[1], Stemmelin G[1], Rabinovich O[1], Palmer S[1], Bullorsky EO[1] and AISYF[3]

[1]Hospital Británico de Buenos Aires; [2]Quintana, Irene, Facultad de Ciencias Exactas y Naturales, UBA; [3]AISYF, Buenos Aires, Argentina

Background: A Thrombophilia (TF) panel is usually performed as part of the work up in young patients with stroke, especially when there is no apparent cause for the event. Even though a clear relationship between TF and stroke has not yet been established and prospective and adequate data is scarce, almost 25% of the TF studies are done in the arterial setting. The Argentinean Initiative of Stroke in the Young and Fabry disease (AISYF) is a unique opportunity for centralized and adequate testing of TF in this population.
Objective: To evaluate a TF panel in a prospective young population with confirmed ischemic stroke.
Methods: This is a Multicenter National Study for the detection of Fabry disease in young patients (18–55 years old) with Stroke. Twenty selected Centers from all over the country enrolled patients within 180 days of the event. All cryptogenic strokes were included in this analysis. Thrombophilia studies were centrally performed (Antithrombin, Protein C and free Protein S, Anti Cardiolipin Antibodies Ig G and M, Lupus Anticoagulant, Factor V Leiden (FVL), the Prothrombin G20210 A gene mutation (P20210) and the PAI 4G/5G mutation).
Results: One hundred and eighteen patients with stroke were evaluated in the last 2 years for Fabry disease in the AISYF study. Thirty patients were excluded from this analysis (six with a cardioembolic stroke, six with cerebral vein thrombosis, eight with a hemorrhagic stroke and 10 with arterial dissection). A thrombophilia panel was performed in the remaining 88 patients with a Cryptogenic ischemic stroke. Mean age was 41 years old, 39 women. Three patients (3.4%) had an Antiphospholipid Syndrome and warfarin was indicated, four (4.5%) had FVL (one Homozygous and also anticoagulated), two (2.2%) were heterozygous for the P20210 mutation, one patient who was not taking warfarin had a PC level of 24% and another patient Antithrombin of 35%. The PAI mutation was present in 50% of the idiopathic strokes (17% Homozygous 4G/4G and 33% heterozygous) just like in the normal Argentinean population.
Conclusions: (i) A positive TF test was found in 12.5% of the Cryptogenic strokes but only four patients (4.5%) were anticoagulated because of this. (ii) The frequency of the PAI mutation was similar to the frequency found in our normal population and should not be routinarly performed. (iii) We don‘t know yet the importance of testing TF as part of the screening work up in ischemic stroke, even in patients with an idiopathic event, since only a few patients required anticoagulation and without a clearly defined benefit in this setting.

PB 1.72-3

Prothrombin G20210A and oral contraceptives are risk factors for cerebral venous thrombosis

Landau M[1], Campanate G[2], Juliana V[2], Irene B[2], Nelson S[2] and Telma G[2]

[1]Hospital Naval Marcílio Dias; [2]Universidade Federal do Rio de Janeiro, HUCFF/URFJ, Rio de Janeiro, Brazil

Background: Prothrombin variant G20210A (PT G20210A) and the use of oral contraceptives (OC) are major risk factors for cerebral venous thrombosis (CVT). A synergism between these factors has also been reported. However, the role of factor V Leiden (FV Leiden) and PT G20210A as independent risk factors for CVT according to gender and the intensity of the synergism with OC remain controversial

Aims: This study aimed to evaluate the association between FV Leiden and PT G20210A with CVT in each gender and also the interaction with oral contraceptives. The results were also compared with those observed in patients with venous thromboembolism of the lower limbs (VTE).

Methods: Ninety-one patients (73 women and 18 men) diagnosed with CVT were studied. A control group of 284 individuals with no history of thrombosis and a group of 343 patients (218 women and 125 men) with VTE were also studied. Cases and controls were tested for the presence of FV Leiden and PT G20210A.

Results: The presence of PT G20210A in women using OC were associated with a high risk of CVT (OR, 45, CI 95%, 5–346) and also with VTE (OR, 14, CI 95%, 2–115).

Conclusions: Our results confirm that PT G20210A is an independent risk factor for CVT, with a much higher risk than that observed in patients with VTE. The risk was similar in men and women. The association of PT G20210A with OC use had a strong synergistic effect. In contrast with the observed for VTE, FV Leiden was not a risk factor for CVT.

PB 1.72-4

Thrombophilia screening in malaysian patients with arterial & venous thrombosis – a cause for concern?

Ayadurai T[1], Afandi F[2] and Karim F[2]

[1]University Malaysia Sabah, Kota Kinabalu, Sabah; [2]National Blood Centre, Kuala Lumpur, Malaysia

Background: The pathogenesis of arterial and venous thrombosis is quite complex involving universally recognized risk factors that are multifactorial. However, thrombosis may even occur under trivial and unusual or paradoxical conditions. The different pathogenesis for arterial and venous thrombosis warrants different clinical managements; the use of antiplatelet drugs in the former and anticoagulants for the latter. The complexity shrouding this clinical condition compounded with the lack of competent health care professionals in this specialty has impeded the development of thrombophilia-care in the country.

Aims: To investigate the relevance of thrombophilia screening in Malaysian patients with arterial and venous thrombosis and justify its incorporation as an important tool in the diagnosis and management of a clinical disorder that is considered a leading cause of morbidity and mortality in the world today.

Methods: Three hundred and seventy patients (236 arterial, 134 venous) with confirmed thrombosis were investigated for thrombophilia using recognized standard procedures. FVL and PTG20210A were confirmed by real-time PCR; protein C (PC), protein S (PS), antithrombin (AT), lupus anticoagulant (LA) and anti-phospholipid antibodies (APA) were identified using clotting, chromogenic and ELISA tests.

***Results*:** Eighty-three patients (42 males and 41 females) had abnormal thrombophilia profile. Thrombophilia was identified in 12.3% (29 of 236) of the patients with arterial thrombosis, of which 86.2% (25 of 29) were *inherited* and 13.8% (four of 29) *acquired*. Of the 134 patients with venous thrombosis, 40.3% (54 of 134) had thrombophilia with 87.0% (47 of 54) *inherited* and 13.0% (seven of 54) *acquired*. PC, PS and AT deficiencies were identified in 29, 18 and four patients respectively. LA and APA were identified in six patients. There were no patients with *acquired* and *inherited* thrombophilia occurring simultaneously, however, there were four patients who had both PC and PS deficiencies. None of the patients had FVL or PTG20210A mutations.

Conclusions: Abnormal thrombophilia profile was identified in two-fifths (40.3%) of the patients with venous thrombosis and in more than one-tenth (12.3%) with arterial thrombosis. The prevalence of *inherited* thrombophilia far exceeded the *acquired* form by a factor of at least 6.6. The significant prevalence of thrombophilia in the local thrombosis-patients is indeed a 'wake-up' call for health care professionals in the country, to warrant the inclusion of 'Thrombophilia profile' as an integral part of laboratory investigations for thrombosis. The results of which would contribute towards competent clinical management in terms of identifying high-risk patients and providing diagnostic, prophylactic and therapeutic services. Another finding of interest is the complete absence of FVL and PTG20210A mutations in all the 370 patients. This is contradictory to the numerous papers published in the West citing FVL mutation as the most prevalent *inherited* thrombophilia marker in the Caucasians. Is FVL and PTG20210A mutations confined to the Caucasian population only? Are Asians 'immune' to these two thrombophilia markers and are therefore less susceptible to thrombotic events? These are some of the pertinent questions that need to be verified with in-depth studies involving the local patient-population.

PB 1.72-5

Thrombophilia and cerebral venous thrombosis: a systematic review

Lauw MN, Barco S, Coutinho JM and Middeldorp S

Academic Medical Center, Amsterdam, The Netherlands

Background: Cerebral venous thrombosis (CVT) is a rare manifestation of venous thrombosis with considerable morbidity and mortality. Several factors contribute to the pathogenesis of this disease, among which thrombophilia.

Aims: To estimate the strength of the association between thrombophilia and incidence of CVT. Also, the strength of the association between thrombophilia and recurrence of (cerebral) venous thrombosis, as well as between thrombophilia and an adverse prognosis of CVT were explored.

Methods: We systematically searched The Cochrane Central Register of Controlled Trials (CENTRAL, *The Cochrane Library*, Issue 1 2013), MEDLINE (January 1966 to January 2013 (week 2); accessed via Pubmed) and EMBASE (January 1980–2013 (week 2); accessed via OVID). We also checked references of included studies. Studies were eligible if they met all of the following criteria: (i) diagnosis of CVT was objectively confirmed; (ii) patients were compared with a control group of non-genetically related subjects, or (iii) patients were analyzed in a moderate to large-size retrospective or prospective cohort study of consecutive patients ($n \geq 40$); (iv) prevalence of at least one of the following thrombophilic factors was assessed: factor V Leiden mutation; prothrombin G20210A mutation; antithrombin, protein C or protein S deficiency; antiphospholipid syndrome (presence of anticardiolipin antibodies, anti-β2 glycoprotein antibodies, and/or lupus anticoagulant); JAK2 mutations; hyperhomocysteinemia or MTHFR mutations; high factor VIII levels; or PAI-I polymorphisms; and (v) inherited or acquired thrombophilic factors were measured in an objectively and commonly accepted manner. Both studies that assessed prevalence of CVT or thrombophilia, as well as therapeutic interventions for CVT, such as anticoagulation treatment, were eligible. Two authors independently assessed eligible articles for inclusion in this review and systematically extracted data from selected articles. Conference abstracts were only considered if sufficient data on study design, participants, events and outcome measures was available for data

extraction. Duplicate reports of the same study were excluded to avoid publication bias and the most recent full-text paper was used. If necessary, study authors were contacted for more information. Discrepancies were resolved through discussion or with the opinion of a third author. Risk of bias, quality of evidence, potential heterogeneity and reporting biases were explored, a sensitivity analysis applied if applicable.
Results: Of 1355 identified citations 207 articles were selected for full-text evaluation. Cross-referencing of articles yielded another 10 articles. Finally, 66 papers enrolling 5898 patients with CVT and 8270 controls fulfilled our inclusion criteria and were included in this review.
Conclusions: Final results of this review will be published at the meeting.

PB 1.72-6

Thrombin generation in Cushing's and metabolic syndrome

Spiezia L, Koutroumpi L, Bon M, Maggiolo S, Gavasso S, Woodhams B, Scaroni C and Simioni P
University of Padova, Padova, Italy

Background: The glucocorticoid excess found in patients with Cushing 's syndrome (CS) is thought to have both direct and indirect effects on the vasculature and the haemostatic system. CS is associated with an increased mortality, where hypercoagulability seems to play a crucial role in the development of both arterial and venous thrombosis.
In several recent studies in CS various abnormalities of coagulation have been described. These studies have concentrated on the use of single haemostatic and/or fibrinolytic marker. A better approach could be the use of a global test like the thrombin generation test (TGT).
Aims: To evaluate TGT in Cushing 's syndrome compared to patients with metabolic syndrome (MetS) and healthy individuals.
Methods: TGT (using the CAT method – Thrombinoscope, The Netherlands) as well as classical clotting markers (PT, aPTT, FVIII, antithrombin (AT), protein C and S) were evaluated in 33 CS patients and compared with both a group of 28 patients matched for the features of MetS and 31 healthy individuals. As well as the above haemostasis assays a full battery of endocrine and metabolic assays were measured using the routine hospital procedures – plasma, salivary and urinary cortisol, plasma ACTH, cholesterol, LDL, HDL and TG. All samples were only collected after obtaining informed consents from the patients.
Results: For the classical coagulation tests, PT was increased ($P < 0.0001$) in both CS and MetS patients, while PTT was shorter ($P < 0.0001$) in CS compared to both MetS and healthy group ($P < 0.0001$). FVIII, AT, protein C and S were increased only in CS patients ($P < 0.0001$). Both CS and MetS patients had a shorter TGT lag time ($P < 0.0001$), higher peak and ETP ($P < 0.0001$) than the healthy controls. The lag time was less reduced in CS ($P < 0.0001$) compared with the MetS group. BMI correlated negatively with lag time ($r = -0.40$; $P = 0.0001$) and positively to peak and ETP ($r = +0.34$; $P = 0.001$, $r = +0.28$; $P = 0.008$, respectively). Obese and diabetic patients had shorter lag time ($P = 0.0005$; $P = 0.0002$, respectively), higher ETP ($P = 0.0006$; $P = 0.007$, respectively) and peak ($P = 0.0003$; $P = 0.0005$, respectively) as well as a more prolonged PT ($P = 0.04$; $P = 0.009$, respectively). Hypertensive individuals had higher ETP ($P = 0.004$), Peak ($P = 0.0008$) and FVIII ($P = 0.001$).
Conclusions: Our findings confirm that a prothrombotic state could be seen in both CS and MetS patients using TGT. The lag time is shorter in the MetS than the CS patients indicating that the MetS patients may be at higher thrombotic risk then the CS patients. The high levels of endogenous physiological anticoagulants seen only in the CS patients could possibly represent a protective mechanism against the hypercoagulability in this patient group and account for the longer lag time in CS than MetS.

PB1.73 – Atherosclerosis: Miscellaneous – I

PB 1.73-1

Metabolic changes in rabbit atherosclerotic arteries: increased glucose uptake and metabolite levels of glycolysis, pentose phosphate pathway, tricarboxylic acid cycle and nucleotides

Yamashita A[1], Zhao Y[2], Matsuura Y[1], Yamasaki K[2], Sugita C[1], Kawai K[3], Tamaki N[2], Zhao S[2], Kuge Y[2] and Asada Y[1]
[1]University of Miyazaki, Miyazaki; [2]Hokkaido University, Sapporo; [3]Kanazawa University, Kanazawa, Japan

Background: Glucose utilization in atherosclerotic arteries is largely affected by inflammation and possibly hypoxia, which could alter many metabolic systems. However, metabolic changes in atherosclerotic plaques remain unknown.
Aims: The present study aims to demonstrate changes in metabolic systems in atherosclerotic arteries of rabbits relative to glucose uptake and hypoxic condition.
Methods: Macrophage-rich or smooth muscle cell (SMC)-rich neointima was created by balloon injury with or without a 0.5% cholesterol diet in rabbit femoral arteries. We evaluated comprehensive arterial metabolism in the non-injured femoral artery and in femoral arteries with SMC- or macrophage-rich neointima by performing metabolomics analyses of central carbon metabolites, nucleotides, amino acids, and others (56 metabolites) using capillary electrophoresis-time of flight mass spectrometry. We also evaluated glucose uptake and its relationship to vascular hypoxia using ^{18}F-fluorodeoxyglucose (^{18}F-FDG) and pimonidazole, a marker of hypoxia.
Results: The levels of many metabolites increased in the femoral arteries with macrophage-rich neointima, compared with femoral arteries that were not injured and those with SMC-rich neointima (glycolysis, four of nine; pentose phosphate pathway, four of six; tricarboxylic acid cycle, four of six; glyconeogenesis/glycogenolysis, one of one; nucleotides, 10 of 20; amino acids five of six and nicotinamide, two of two). Only gluconic acid among metabolites differed between femoral arteries with or without SMC-rich neointima. Pimonidazole immunoreaction and nuclear translocation of hypoxia inducible factor-1a were closely localized with hexokinase II expression in macrophage-rich neointima, and were undetectable in femoral arteries that were not injured or had SMC-rich neointima. The uptake of ^{18}F-FDG in arterial walls measured by autoradiography increased in femoral arteries with macrophage- but not SMC-rich neointima (6.1 ± 3.6 [$n = 69$], vs. 1.8 ± 0.8%ID $\times$ kg/m^2 [$n = 72$]; $P < 0.001$), and positively correlated with macrophage- and pimonidazole-immunopositive areas ($r = 0.76$, and $r = 0.59$ respectively; $n = 69$ for both; $P < 0.0001$). Although more ^{18}F-FDG was uptaken in areas with, than without macrophages (3.9 ± 1.4 [$n = 24$] vs. 2.2 ± 0.8%ID $\times$ kg/m^2 [$n = 12$]; $P < 0.001$), ^{18}F-FDG uptake in macrophage areas did not change irrespective of hypoxia (non-hypoxic vs. hypoxic areas: 3.7 ± 1.3 vs. 4.1 ± 1.6% ID $\times$ kg/m^2; both $n = 12$).
Conclusions: Infiltrative macrophages and hypoxia in atherosclerotic arteries affect metabolic systems and glucose uptake in arteries.

PB 1.73-2

The transmembrane chemokine CXCL16 mediates platelet adhesion to von Willebrand factor, HUVECs and human arteries under physiologic flow conditions

Meyer dos Santos S
University Hospital Frankfurt, Frankfurt, Germany

Background: CXCL16 is a member of the transmembrane chemokines and expressed at sites predisposed to atherosclerotic lesion formation and mediates monocyte adhesion to the endothelium.

Aim: In the present study platelet adhesion to CXCL16 is investigated.
Methods: Flow chamber experiments with CXCL16 immobilized in μ-slides and perfused with platelets in reconstituted were performed. Calcium Imaging was used to measure intra-platelet CXCL16 induced calcium flux. CXCR6 expression was demonstrated by western blotting and immunofluorescence techniques.
Results: Platelets in flowing blood adhered to CXCL16 transiently up to shear rates of 1800/s: platelets rolled on CXCL16 for 37 ± 3 μm before detachment (control was 13 ± 1 μm, $P < 0.001$) and rolling velocity was 0.43 ± 0.03 μm/s (control was 0.73 ± 0.12 μm/s, $P = 0.001$). However, for stable adhesion at these elevated shear rates the presence of additional adhesion ligands, such as von Willebrand factor (vWf) was mandatory (138.4 ± 6.2% of control, $P < 0.001$). CXCR6 is highly expressed in platelets and the cognate receptor for CXCL16 induced activation and intra-platelet calcium flux. CXCL16 is expressed on activated HUVECs and induced platelet adhesion in a CXCR6-dependent manner. Furthermore, CXCL16 is elevated expressed in TNF- and IFN-stimulated human internal mammaria arteries.
Conclusion: Therefore, CXCL16 is responsible for CXCR6 dependent platelet activation and more important, for platelet adhesion to HUVECs and vWf at shear rates up to 1800/s. Further flow experiments will be performed with human artery segments to evaluate CXCL16-CXCR6 dependent platelet adhesion to the endothelium of human vessels. These results demonstrate new mechanisms by which platelets might induce and accelerate atherosclerosis.

PB 1.73-3

Integrative bioinformatics analysis of genomic and proteomic approaches to understand the transcriptional regulatory program in coronary artery disease pathways

Vangala RK, Ravindran V, Madan G, Shankar J, Arvind P and Kakkar VV

Thrombosis Research Institute, Bangalore, India

Background: Patients with coronary artery disease (CAD) show a panel of differentially regulated serum biomarkers indicative of modulation of several pathways from disease onset to progression. Some of these biomarkers have been proposed for multimarker risk prediction methods. The underlying mechanism of the expression changes and modulation of the pathways in risk assessment needs to be addressed.
Aim: Our present work focuses on understanding the regulatory mechanisms at transcriptional level by identifying the core and specific transcription factors that regulate the CAD associated pathways.
Methods: Using the principles of systems biology we integrated the genomics (gene expression data of 10 CAD affected and 10 unaffected) and proteomics (400 affected and 400 unaffected) data with computational tools. The two sets of samples for gene expression and proteome analysis were selected from ongoing Indian Atherosclerosis Research Study (IARS) (Indian Heart J, 2010;6:286–95) which was designed according to the guidelines of World Medical Association Declaration of Helsinki and Indian Council of Medical Research and approved by Institutional Ethics Committee. Patients living in India for at least two generations were enrolled after signed informed consent was obtained (male ≤ 60 years and female ≤ 63 years at onset of disease, diagnosed as CAD) and all the blood samples were collected after overnight fasting of 12–14 h and stored at −80 °C. We selected biomarkers from seven different pathways based on their association with the disease and assayed 30 biomarkers by ELISA and built network modules using STRING database. The biomarkers selected were inflammation: Interleukin-6, Interleukin-8, Interleukin-10, Interleukin-12A, Interleukin-12B, Interleukin-18, Monocyte chemoattractant protein-1, High sensitive C reactive protein, Interferon gamma, Matrix metalloprotease-9 and secretary Phospholipase A2 and Gamma-glutamyltransferase-5, coagulation: Factor VII, Fibrinogen, Prothrombin, Plasminogen activator inhibitor-1, Plasminogen, Tissue factor, von Willebrand Factor, Platelet derived growth factor, cell adhesion: Clusterin and P-selectin, obesity: Adiponectin and Leptin, oxidative stress: Myeloperoxidase, stress: HSP27, HSP60, HSP70 and renal function: Cystatin C. The promoter sequence analysis for transcription factor binding sites was performed using Genomatrix software and microarray data was analyzed using R package v2.14.2.
Results: The Genomatrix software predicted 443 transcription factors binding profile in 30 different biomarkers, however, in global mRNA expression only 34 transcription factors were found to be differentially expressed in CAD affected and unaffected subjects. Out of these five transcription factors binding sites were highly represented in the promoter sequences of all 30 biomarkers thus forming the core regulatory transcription machinery which might influence the differential levels of biomarkers in serum of CAD affected subjects in comparison to unaffected. The five core transcription factors were PPARG, EGR1, ETV1, KLF7 and ESRRA and their combinatorial regulation may influence all the seven important pathways associated with CAD as outlined above.
Conclusions: Our analysis suggests that a profile of five core transcription factors binding to the promoters may play a major role in differential levels of biomarkers associated with CAD and thus use of this profile of transcription factors may be useful to identify new biomarkers which may play a role in risk assessment in CAD.

PB 1.73-4

CLL V-1, a synthetic phenanthrene compound, inhibits TNF-a-induced adhesion molecule expression through affecting reactive oxygen species production and NF-?B signaling in human endothelial cells

Wu WB[1], Lai TH[2], Hwang TL[3] and Wu PH[1]

[1]Fu-Jen Catholic University, New Taipei City; [2]Cathay General Hospital, Taipei; [3]Chang Gung University, Tao-Yuan, Taiwan

Background: Cardiovascular diseases (CVD) are a major leading cause of death in the world and the dominant risk factor responsible for CVDs is atherosclerosis. Inflammatory mediators such as TNF-α and interleukins, which can upregulate expression of leukocyte adhesion molecules on endothelium and enhance circulating monocyes adhesion to endothelium, leading to a chronic inflammatory environment during atherogenesis.
Aim: This study was to investigate the anti-inflammatory effects of several synthetic and natural compounds on human umbilical vein endothelial cells (HUVECs) and to elucidate their underlying action mechanism.
Methods: Western blotting and RT-PCR were used to determine adhesion molecule protein and mRNA expression, respectively. Fluorescence microscopy and measurement was used for determining monocyte-endothelial cell interaction and intracellular ROS production. Western blotting and Electrophoretic mobility shift assay (EMSA) was used to examine NF-κB signaling and NF-κB-DNA interaction, respectively.
Results: Of the screened compounds, CLL V-1, a synthetic phenanthrene compound, was found to be the most potent on TNF-α-induced adhesion molecule expression. CLL V-1 inhibited TNF-α-induced ICAM-1 and VCAM-1 expression in a concentration-dependent manner, 1 μM was sufficient to exert its inhibitory effect. CLL V-1 also functionally reduced monocyte adhesion to endothelial monolayer. These effects did not result from its cytotoxicity. A further analysis revealed that CLL V-1 affected ICAM-1 and VCAM-1 mRNA expression in HUVECs. CLL V-1 attenuated TNF-α-induced IκB phosphorylation and degradation and NF-κB p65 and p50 translocation from cytosol to nucleus. In addition, CLL V-1 compromised TNF-α-induced NF-κB-DNA interaction and attenuated H_2O_2-

induced intracellular reactive oxygen species level and IκB phosphorylation.
Conclusion: We have demonstrated that CLL V-1 affected TNF-α-induced endothelial adhesion molecule expression through inhibition of ROS production and NF-κB signaling pathway.

PB 1.73-5

Early postoperative thrombosis following bypass surgery and remote endarterectomy in patients with peripheral arterial disease: a comparative analysis

Arsenyev A, Gamzatov T and Svetlikov A
North-Western State Medical University named after I.I.Mechnikov, Saint-Petersburg, Russian Federation

Background: Over the last decades there has been a tremendous increase in the number of with peripheral arterial disease (PAD). Results of surgical treatment of this common pathology are shadowed by high rate of early and late postoperative complications. Thrombosis of the reconstructed arterial segment following successful surgery remains one of the cornerstones in the management of patients with PAD. Controversies exist regarding optimal surgical treatment in patients with PAD suffering from isolated superficial artery occlusion.
Aims: To compare the rate of early postoperative thrombosis in patients with PAD following remote endarterectomy (RE) and femoro-popliteal bypass grafting (FPBG) for isolated superficial femoral artery (SFA) occlusion.
Materials and Methods: Fifty-seven consecutive PAD patients (57 lower limbs to be treated) from two vascular surgery units underwent surgical intervention for isolated SFA occlusion. FPBG was performed on 23 lower extremities while the alternative technique (RE) was used to revascularize remaining 34 limbs. RE as well as FPBG was done through a uniform surgical approach involving two vertical skin incisions: one in the groin and another one in the lower third of the thigh along its medial aspect. RE involved two longitudinal arteriotomies followed by the remote endartectomy of SFA using metallic Vollmar ring dissectors and autologous vein angioplasty at the site of arteriotomy incisions. FPBG was done using 8–9 mm synthetic (Dacron) grafts.
Results: Age median for RE and FPBG groups were comparable: 63.3 ± 6.5 and 6.7 ± 6.8 respectively. Early postoperative thrombosis defined as thrombotic occlusion of SFA or bypass graft within the first 6 months after surgery was diagnosed in four patients following RE (11.8%) and one patient (4%) after FPBG. Additional clinical parameters was brought to the analysis including duration of reconvalescence period, number of local complications, rate of repeated surgical interventions and dynamics in the degree of chronic arterial insufficiency during 6 months following successful revascularization. Two patients (5.9%) with early thrombosis following RE required repeated thrombectomies of the operated arterial segment, but developed irreversible ischemia of the extremity and further demanded major amputation. Early postoperative thrombosis in the group of FPBG was found in one patient (4%) and required a repeated femoral-popliteal below-the-knee bypass with complete resolution of symptoms.
Conclusions: FPBG is superior to RE in the management of PAD patients with isolated SFA occlusion since it is associated with lower risk of early postoperative complications including thrombosis of the operated arterial segment and better resolution of symptoms of chronic lower limb ischemia.

PB1.74 – Acquired Coagulation Disorders – I

PB 1.74-1

Acquired haemophilia: clinical manifestations and management. A 15 years experience from a single centre

Kouramba A, Anastasopoulou I, Kotsi P, Chanos A, Kanellopoulou G, Gavalaki M and Katsarou O
Laiko General Hospital, Athens, Greece

Background: Acquired haemophilia (AH) is a rare, often life-threatening haemorrhagic disorder, in individuals with no prior history of clinical bleeding. It is caused by autoantibodies commonly against coagulation factor VIII, rarely to other coagulation factors. Management of this disorder consists in rapid accurate diagnosis, control of bleeding and eradication of the inhibitor by immunosuppression.
Aim: We report a retrospective cohort of 28 patients with acquired haemophilia A and 1pt with acquired FXIII deficiency in a Greek haemophilia center.
Methods: Data derived from patient files. Inhibitor presence was suspected by the prolongation of aPTT, in patients with acquired bleeding tendency and confirmed by detection of FVIII inhibitor measured by NIijmegen modification of the Bethesda assay (cut off < 0.5 BU). An inhibitor titer > 5 BU was considered as high inhibitor. FXIII inhibitor was measured with a mixing test. Complete response (CR) to therapy was defined as negative inhibitor titer at the end of immunosuppressive regimen.
Results: The twenty-nine patients, median age 61 (range, 25–85) years, were diagnosed between 1997 and 2012. The most common symptoms in admission were spontaneous haemorrhages into the skin (80%), muscle or soft tissue haematomas (85%), mucosal bleeding (17%) and post trauma and surgical bleeding (3%). Haemarthroses were uncommon (2 pts). In 12 (40%) patients no underlying disease could be identified. 17/29 pts in whom a cause associated with inhibitor appearance was diagnosed, four had malignancies, six autoimmune disorder, one MGUS, four were postpartum and two had diabetes mellitus. Factor VIII:C was < 5% in 20 (74%) patients; An inhibitor titer > 5 Bethesda units (high responder) was measured in 23 (60%) patients. At the time of diagnosis a drop of Hb levels requiring RBC transfusions was observed in 20 (75%) patients. Bleeding in these patients was controlled with recombinant factor VIIa (NovoSeven), or activated prothrombin complex concentrate (FEIBA). No difference in efficacy was observed between the two agents. Inhibitor eradication strategy included: Prednisolone (1 mg/kg/day), with a 4–6 weeks tapering based on clinical status and FVIII inhibitor titre, (eight pts) or in combination with oral cyclophosphamide (1.5–2.0 mg/kg/day) for a maximum of 6 weeks (21 pts). Bleeding diathesis stopped by the time of inhibitor disappearance, independently of FVIII:C increase. Rituximab has been used to treat two of our patients (1pt with post-partum and 1pt with MGUS) with very high inhibitor and non response to common strategy. The post-partum inhibitor had a CR, while MGUS patient failed to response. Overall median time to CR was 4 weeks (range 2–6). Relapse has been reported in 20% of our patients most of them diagnosed with cancer and was associated with uncontrolled underlying disease. Mortality was associated with underlying disease. No patient died from bleeding complications.
Conclusions: Prompt recognition and early initiation of immunosuppressive treatment together with control of severe bleeding using by passing agents, are essential for the outcome of AH. Inhibitor eradication strategy can be adapted to clinical severity and patient's comorbidities.

PB 1.74-2

An immunological mechanism underlies the development of acquired von Willebrand syndrome (AvWS): clinical usefulness of an ELISA system detecting anti-VWF antibodies

Kishimoto M[1], Suzuki N[2] and Matsushita T[2]

[1]Nagoya University, Nagoya; [2]Nagoya University Hospital, Nagoya, Aichi, Japan

Background: Acquired von Willebrand Syndrome (AvWS) causes bleeding due to acquired reduction of von Willebrand factor (vWF). AvWS develops and is associated with underlining lymphoproliferative or myeloproliferative disorders, other neoplasia, immunological and cardiovascular disorders. Cause of AvWS is widely variable but it might depend either on immunological or non-immunological mechanisms. Under immunological mechanisms, anti-VWF immunoglobulin binds VWF and higher molecular weight VWF multimers might be extensively cleared from circulation.

Aims: We experienced a case of AvWS and examined the spectrum of anti-VWF antibody by specific ELIZA method and found auto-VWF IgG antibody caused severe AvWS.

Description of a Case: A 36 years old woman who had extensive purpula and mucosal bleeding during past 6 months and was referred to our hospital. She had been prescribed valproic acid due to depression but there was no previous history of typical underlining disorders of AvWS. She had no family history of hemorrhagic diseases, nor suffered from any hemorrhagic manifestations. At initial presentation, her activated partial thromboplastin time (APTT) was 48.3 s (35.2 s in normal), factor VIII procoagulant activity (FVIII:C) was 20%, plasma ristocetin cofactor activity (VWF:RCo) was below 6%, and immunoreactive VWF antigens (VWF:Ag) was 23%, respectively. APTT cross-mixing test showed factor deficiency pattern. Microtiter plates were coated with purified human plasma VWF obtained from commercial plasma VWF concentrates. After blocking, serially diluted plasma samples were overlaid for 1 h at 22 °C. Washed plates were added by HRP-conjugated either rabbit anti-human IgG serum (Dako) or goat anti-human IgM serum (Sigma) and incubated for 1 h 22 °C, followed by quantification of color development at 490 nm absorbance. Similarly, each IgG subclass was determined using anti-human IgG 1, 2, 3, 4 mouse serum. As a result, IgG1 type of anti-VWF antibody was detected and autoantibody against VWF was a cause of her AvWS. Soon after diagnosis, she needed immediate hospitalization because of left ovary hemorrhagic rupture. The bleeding stopped by administration of 2000 units (40 IU/kg) of plasma VWF concentrates twice a day for 3 days. One hour after infusion, VWF:RCo, VWF:Ag, and FVIII:C elevated to 27%, 107% and 52% of normal, respectively, suggesting that higher molecular weight VWF multimers might be selectively inhibited. Recovery of VWF and factor VIII, however, returned to baseline 15 h after administration, indicating shortened VWF half life. Seven days after the first bleeding, right ovary bleeding happened and we tried DDAVP and her abdominal pain was relieved. Two hours after infusion of DDAVP, VWF:RCo, VWF:Ag, and FVIII:C elevated to 46%, 10% and 46%, respectively. VWF:RCo returned to baseline level 4 h after administration, whereas VWF:Ag and FVIII:C returned to baseline level 12 h after administration. Although several reports have indicated that children prescribed with valproic acid had lower VWF activities, this is the first report of severe von Willebrand disease with autologous anti-VWF antibody that appeared to be associated with valproic acid usage.

Conclusion: The AvWS diagnosis were rapidly capable of by using specific ELISA method and may be useful and sensitive for screening of suspected von Willebrand syndrome with bleeding diathesis.

PB 1.74-3

Managing acquired haemophilia A: relating the European acquired haemophilia registry (EACH2) data to experience in a South London centre, St George's Hospital

Luo PL, Mhonda D, Uprichard J and Austin S

St George's Hospital, London, UK

Background: Acquired haemophilia A (AHA) remains a rare and potentially fatal bleeding disorder characterised by the development of autoantibodies directed against coagulation factor VIII. Recently, the EACH2 Registry has provided the largest observational dataset from 117 European centres on the management of AHA. As a large tertiary referral unit in South London, AHA is a part of our regular practice.

Aims: To audit our AHA experience and to compare it to the data presented in the EACH2 registry.

Method: A single centre retrospective analysis of all AHA patients registered at our centre between 2006 and 2012. Data collected through paper and electronic records included demographics, aetiology, bleeding characteristics, immunosuppression and haemostatic agents used to control the first bleeding episode.

Results: We identified 11 female and five male patients with AHA. The median age at diagnosis was 78 years (40–99). At presentation, the median haemoglobin concentration, FVIII:C and inhibitor titre were 94 g/L (46–138) 2 IU/dL (0–20) and 14 BU/mL (< 1 to > 6000).

2/11 patients required surgical intervention for life-threatening bleeding. Severe bleeding, as defined by the EACH2 registry, was observed in 62% of patients. This group had higher peak inhibitor titres compared to those without severe bleeding (32 vs. 9 BU/mL). The overall survival was 75% with one acute fatality.

Only one patient did not receive any haemostatic agents. Of the remainder, 8/15 were treated with aPCC only, 3/15 received rFVIIa only and 5/15 required sequential therapy using both agents, primarily for invasive procedures. No patients were treated with desmopressin or factor VIII concentrate. To control the first bleeding episode, the median dose of aPCC was 47000iu. Of the few patients (3/15) who received rFVIIa, the median dose was 20 mg.

11/16 patients received dual immunosuppressive therapy with cyclophosphamide and prednisolone. Rituximab was reserved for poor response and administered to 3/16 patients.

Those treated with Rituximab took longer to achieve remission (negative inhibitor 183 days, normal FVIII 120 days).

An inhibitor titre < 16 BU/mL (8/16) was associated with quicker inhibitor eradication (10 days vs. 90 days) and quicker normalisation of FVIII:C (23 vs. 48 days)

Relapse was observed in five patients with the majority receiving subsequent rituximab. This group had a higher historical peak inhibitor titre than those who had sustained remission.

Summary: Our findings are not dissimilar to the data in the EACH2 registry. Despite the older age of our patients, all other baseline patient demographics and bleeding characteristics were similar. Bypassing agents were used to treat all patients with clinical bleeding, unlike only 70% in the EACH2 registry. Our patients received a higher total dose of haemostatic agent, which may reflect the frailty of our older patient population. Unlike the EACH2 registry, severe bleeding was more common in those with a higher peak inhibitor titre. However, our study did reinforce the finding of the EACH2 registry that an inhibitor titre < 16BU/mL was associated with reduced time to remission. Given the limitations of patient number, this single centre audit supports the importance of collecting registry data in rare diseases.

PB 1.74-4

Acquired hemophilia A: retrospective analysis of 49 cases from a single Chinese hemophilia center

Yang Y, Xuan M, Xue F, Fu R, Zhou F, Zhang L, Ji L and Yang R
Institute of Hematology and Hospital of Blood Diseases, Tianjin, China

Background: Acquired hemophilia A (AHA) is a rare bleeding disorder caused by the autoantibody directed against factor VIII in patients without previous history of a bleeding disorder. Its clinical features range from harmless bruises to life-threatening bleedings with a high mortality rate.
Aims and Methods: We retrospectively analyzed the characteristics and outcomes of 49 patients with AHA diagnosed in our center from February 1994 to December 2012. This study was approved by the medical ethic committee of Hospital of Blood Diseases, Peking Union Medical College. All patients signed an informed consent.
Results: The median age was 49 years (range 14–78 years). Associated diseases were observed in 9 (18%) patients. Nine patients had comorbidities. The most common symptoms were ecchymosis and hematoma. Twenty-four patients with acute bleeding episodes were treated with prothrombin complex concentrate (PCC) at a relative low dose of 30–50 U/kg/day and achieved good outcomes without adverse reaction. Corticosteroids alone or in combination with cyclophosphamide were used as first-line therapy to eradicate the inhibitors. In 39 evaluable patients, 35 (89.7%) achieved complete remission (CR). Four patients died of hemorrhage. The response time was not related to the titers of FVIII:C and inhibitor.
Conclusions: This study demonstrates that when bypassing agents such as recombinant activated factor VII and activated prothrombin complex concentrate are not affordable or available, low dose PCC is effective and safe to control acute bleeding in AHA patients. Corticosteroids alone or in combination with cyclophosphamide used as first-line therapy achieved good outcomes with CR rate of 89.7%. The comorbidities and side-effect of immunosuppressive agents in these patients probably have adverse impact on the prognosis.

PB 1.74-5

Telemedicine: physician supported rural hemophilia treatment center (HTC) making a difference for patients

Witkop ML[1], Hall M[1], Rushlow D[1], Wischman S[1], Andersen J[2] and Kulkarni R[3]
[1]Munson Medical Center, Traverse City, MI; [2]Barbara Ann Karmanos Cancer Institute, Detroit, MI; [3]Michigan State University Bleeding & Coagulation Center, East Lansing, MI, USA

Background: Telemedicine is defined as 'the use of medical information exchanged from one site to another via electronic communications to improve patients' health status.'[1] Persons with bleeding disorders (PWBD) live in wide geographic areas and often have to travel great distances to see specialists who understand and are able to treat their disorders.
The Northern Regional Bleeding Disorders Center (BDC) is located in Northern Michigan and provides services to approximately 200 patients covering a geographic area of > 11,000 sq miles/28,490 sq km. It is the only HTC in the USA that does not have a physician on site but collaborates with physicians from other HTCs to provide care for patients closer to their home. Traveling to distant HTCs would significantly add hours, if not days, to their schedules.
The HTC began telemedicine in 2010 with both pediatric and adult patients. Presented are metrics of the program including: demographics of patient population, description of miles/km traveled and miles/km saved by the patient, number of labs ordered, and patient/provider satisfaction scores.
Aim: Describe metrics from telemedicine visits at a BDC over a period of 2 years (2011–2012).
Methods: Pediatric and adult patients seen via telemedicine over a period of 2 years (2011–2012) were offered a patient satisfaction survey after their visit. Data was collected from their visit including: labs ordered, mileage, estimated time and travel costs saved by participating in telemedicine visit. Participating providers were queried on their satisfaction with telemedicine.
Results: Between 2011 and 2012, 48 patients (pediatric-11, adults-37) were seen via telemedicine. A total of 191 labs were ordered (pediatric-44, adults-147) for diagnostic, continued monitoring, and surgical planning. These 48 patients traveled 2419 actual miles/3893 actual km, saving a cumulative total of 17,980 miles/28,936 km by utilizing telemedicine. Eight 40 h work weeks were saved over 2 years by patients not traveling to a distant site to see the bleeding disorder specialist (17,980 m/55 mph = 326.9/40 h work week = 8.2 work weeks over 2 years). This equates to one working month per year saved by not traveling to a distant site. No adverse outcomes were experienced by any patients utilizing telemedicine.
Patients either agreed or strongly agreed in all areas of the patient satisfaction survey: they could clearly see and hear the distant provider, they knew what to expect and felt comfortable discussing their issues during the interview, they felt their questions were answered, their privacy was respected, the provider answered their questions thoroughly, by using telemedicine they were able to see the specialist sooner than if they had traveled to the distant site, they would recommend telemedicine to others, and the quality of their medical care met their expectations. Providers expressed satisfaction with telemedicine.
Conclusion: Telemedicine is an effective tool to utilize for evaluation and follow up in PWBD given the distance many patients live from an HTC. Patients, families and providers are very satisfied. Significant time and travel was saved. High quality care, including surgical and birth planning was provided with no adverse outcomes.

PB 1.74-6

Diagnosis and management of acquired haemophilia A (AHA) patients: experience of a single center

Mercanti C, Santoro C, Baldacci E, Abbruzzese R, Barone F, Bochicchio RA, Di Mauro R, Parlanti L and Mazzucconi MG
Hematology, Sapienza Univeristy, Rome, Italy

Background: AHA is a rare bleeding disorder with an incidence of 1.5/million/year. Mortality rate is high (9–22%), if diagnosis is delayed and treatment is not promptly established.
Aims: Retrospective evaluation of AHA affected patients diagnosed and followed at our Institution. Patients characteristics, bleeding symptoms and treatment, eradication therapy and response, occurrence of possibly related diseases have been considered.
Patients. Between 1984 and 2012, 34 patients (M, 14; F, 20), were diagnosed with AHA. Diagnosis median age: 70.2 years (25–89); median time from the first bleeding symptoms and diagnosis: 48.5 days (4–264); median follow-up (FU): 19.7 months (2.6–215.4).
Results: At diagnosis, bleeding symptoms were present in 33/34 patients (97%) (28 muscle haematomas, three haematuria, two postpartum haemorrhages, 1GI bleeding, one haemoperitoneum, one haemarthrosis, two post-surgery bleedings); median inhibitor title was 9.6 BU/mL (2.5–138), median FVIII:C level, 2% (0.01–21); in 16 patients FVIII:C level was < 1%. Clinical conditions triggering the inhibitor appearance were present in 17 cases (50%): previous delivery in 9, autoimmune diseases in 4, cancer in 4.
First-line eradication therapy was prescribed in all patients: prednisone (PDN) (median dose 1 mg/kg/day, range 0.5–2) for 4 weeks, in 23 (68%), dexamethasone (DXM) (median dose 24 mg/day, range 24–40) for 4-day courses, in 7 (20%), azathioprine (AZA) 100 mg/day for 3 months, in 2 (6%), cyclophosphamide (CTX) (0.5 and 1.5 mg/kg/day) plus PDN (standard doses) for 2 months, in 2 (6%). Thirty-one patients are evaluable for response, 27 treated with PDN/DXM, four

with other immune suppressive drugs. Inhibitor eradication (undetectable inhibitor, normal FVIII:C levels, absence of bleedings), was obtained in 24/31 patients (77%) (22/27 [81%] on PDN/DXM, 2/4 [50%] on other immune suppressants).
Second-line therapy was administered in 4/7 no responder patients: CTX + PDN in 2, DXM in 1, PDN in 1. Inhibitor eradication was obtained in 1. Third-line therapy was performed in 2/3 second-line no responder: 1 CTX + PDN, 1 AZA + PDN. No one responded. One of these two patients was treated with Rituximab, obtaining finally persistent inhibitor eradication. Three patients relapsed after first-line treatment (3/24, 12.5%).
At last control, 23 patients maintained persistent inhibitor eradication (median FU: 25.9 months [2.6–150.9]).
Bypassing agents (rFVIIa or FEIBA) were used in 21 patients with a high efficacy to control bleeding symptoms: FEIBA in 11, rFVIIa in 7, either FEIBA or rFVIIa in 3. A severe bleeder no responder, is on FEIBA prophylaxis three times a week with a good control of hemorrhagic events.
During FU, occurrence of diseases possibly related to the inhibitor presence (cancer) was recorded in 2/17 idiopathic cases (11.7%); 5/34 deaths, not bleeding related, were recorded.
No relapses were observed in two post-partum inhibitor affected patients who underwent three deliveries after a period of 2, 3.6, 7.3, years respectively after inhibitor eradication.
Conclusions: We confirm literature data as regard as idiopathic AHA cases percentage (50%). We observed a high response rate after steroid administration (81%). Bypassing agents were efficacious in all treated patients. Relapse rate was relatively low (12.5%). A good management of AHA reduce the mortality risk bleeding related.

PB2.21 – Antiplatelet Agents: ADP Receptors – III

PB 2.21-1

Absence of off-target prolongation of the bleeding time in prasugrel-treated rats and mice: additional evidence for selective P2Y12 inhibition by prasugrel

Sugidachi A[1], Ohno K[1], Jakubowski JA[2] and Tomizawa A[1]
[1]Daiichi Sankyo Co., Ltd., Tokyo, Japan; [2]Eli Lilly and Company, Indianapolis, IN, USA

Background: Prasugrel is the 3rd generation thienopyridine prodrug exhibiting more optimal pharmacokinetics and pharmacodynamics compared with clopidogrel. This profile results in both more effective platelet inhibition and greater clinical benefit in acute coronary syndrome (ACS) patients undergoing percutaneous coronary intervention. Ticagrelor is a cyclopentyl-triazolo-pyrimidine and non-competitive $P2Y_{12}$ antagonist recently approved for reducing the rate of thrombotic cardiovascular events in ACS patients.
Aims: Recent data suggest that thienopyridines result in off-target effects at the vessel wall that contribute to bleeding in mice (J. Pharmacol. Exp. Ther. 338, 22–30, 2011). However, our pilot non-clinical studies showed that high-dose prasugrel resulted in a similar prolongation of the bleeding time (BT) as a non-thienopyridine $P2Y_{12}$ antagonist, ticagrelor, suggesting no off-target effect of prasugrel. In the present study, we further examined the individual and combined effect of prasugrel and ticagrelor on BT in rats, wild-type mice and in $P2Y_{12}$ knock-out mice.
Methods: Four hours after the administration of single or combined agents to mice or rats, a needle (23 or 21G, respectively) was advanced 0.5 or 1 cm into each tail vein at a 4.5 or 3 cm point from the tail end and immediately withdrawn. Blood was blotted every 5 s with a filter paper and when blood no longer appeared the bleeding time was recorded with control (vehicle) values of 92 ± 5 s ($n = 10$) and 104 ± 6 s ($n = 10$) in mice and rats, respectively. In mice, additional experiments included measurement of platelet aggregation in platelet-rich plasma stimulated with 20 μM ADP 30 min after BT determination.
Results: A single dose of prasugrel alone (10 mg/kg, *p.o.*) or ticagrelor alone (30 mg/kg, *p.o.*) resulted in significant prolongation of the bleeding time in rats to 228 ± 23 s ($P < 0.001$ vs. vehicle, $n = 10$) and 231 ± 23 s ($P < 0.001$ vs. vehicle, $n = 10$), respectively. Combined administration of prasugrel (10 mg/kg) with ticagrelor (30 mg/kg) resulted in similar extent of prolongation of bleeding time (255 ± 21 s, $P < 0.001$ vs. vehicle, $n = 10$) compared to each individual dosing group. In wild-type mice, both prasugrel (3 and 10 mg/kg, *p.o.*) and ticagrelor (10 and 30 mg/kg, *p.o.*) prolonged BT in a dose-related manner with high-dose values for prasugrel and ticagrelor being 148 ± 7 s ($P < 0.001$, $n = 10$) and 149 ± 10 s ($P < 0.001$, $n = 10$), respectively. In $P2Y_{12}$ knock-out mice, similar prolongation of the bleeding time was observed in the vehicle group (146 ± 7 s, $n = 10$) and neither prasugrel nor ticagrelor had any significant prolongation of the bleeding time compared to the vehicle group. Platelet aggregation studies showed that both prasugrel and ticagrelor substantially inhibited platelet aggregation in wild-type mice, and these values were similar to those in all groups of $P2Y_{12}$ knock-out mice including the vehicle group.
Summary/Conclusion: These results support the contention that prasugrel is a selective $P2Y_{12}$ inhibitor with an apparent absence of off-target effects that influence the bleeding time or inhibition of platelet aggregation.

PB 2.21-2

Impact of cigarette smoking on clopidogrel antiplatelet effect in diabetic patients

Addad F, Oueslati C, Hammami N, Jebri F, Ibn El Hadj Z, Gargouri S, Ben Halima A, Kammoun I and Kachboura S
A. Mami University Hospital, Ariana, Tunisia

Background: High on-clopidogrel platelet reactivity (HPR) is associated with an increased risk of adverse events after coronary stenting and acute coronary syndromes. Pharmacodynamic studies have shown that residual HRPP is more common in patients with diabetes. Recent data suggest that cigarette smoking might enhance clopidogrel mediated platelet inhibition. Indeed, cigarette smoking is an inducer of cytochrome P450 1A2, a hepatic enzyme involved in clopidogrel metabolism.
Objective: The aim of our study was to investigate the influence of cigarette smoking on clopidogrel mediated platelet inhibition in diabetic patients presenting with an acute coronary syndrome.
Methods: This is a prospective study including 30 diabetic patients (mean age: 58.9 ± 9.7 years, 17 men) admitted with ACS without ST elevation who received 600 mg clopidogrel loading dose followed by a maintenance dose of 150 mg. 60.8% of patients were active smokers. Evaluation of platelet function was performed by the VerifyNow P2Y12 Test, 24 h after the loading dose and at the third day. Residual HPR under clopidogrel was defined as a PRU value > 230 at H24.
Results: The mean H24 PRU was significantly lower in diabetic smokers compared to non smokers (172.1 ± 61.7 vs. 255.6 ± 62.4, $P = 0.001$). HPR rate on clopidogrel in diabetic patients smoking was significantly lower on day 1 (17.6% vs. 69.2%, $P = 0.008$). Only 5.9% of diabetic smokers had HPR at the third day. In the multivariate analysis, current smoking has emerged as a protective factor of HPR on clopidogrel (OR = 0.08, CI 95% [0.007–0.9]; $P = 0.04$).
Conclusion: This pilot study confirms the enhancement of the antiplatelet effect of cigarette smoking even in coronary diabetic population admitted for ACS. This confirms that the main mechanism of HPR in this population is associated with a reduced production of active metabolite.

PB 2.21-3

The experience of the antiplatelet therapy by clopidogrel in the West-Siberian region of Russia: the effects of CYP2C19 and ABCB1 allelic variants

Knauer N, Voronina E and Lifshits G

Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

Background: Clopidogrel is known to be one of the principal drugs for modern antiplatelet therapy. However, the interindividual variability of the response to clopidogrel has been also shown. This variability depends both of the presence of certain genetic polymorphisms, in particular, allelic variants of CYP2C19 and ABCB1 genes, and of clinical factors. Clinical trials revealed the regional features of abundance of genetic polymorphisms influencing clopidogrel metabolism.

Aims: To examine frequencies of occurrence of allelic variants CYP2C19 *2, *17 and ABCB1 C3435T among the patients of the West-Siberian region of Russia receiving clopidogrel and to determine contribution of these markers to the clopidogrel laboratorial efficacy.

Methods: One hundred and fifty-eight patients with cardiologic pathology receiving clopidogrel were enrolled. The allelic variants of ABCB1 and CYP2C19 were determined by means of real-time PCR. The relative change of platelet aggregation with ADP before and 48 h after taking of loading dose of clopidogrel (600 mg) referred to as resistance index (RI) was assessed. RI was assumed to be a measure of the clopidogrel laboratorial efficacy. The relation of allelic variants of ABCB1 C3435T and CYP2C19 *2, *17 to RI was estimated. The study protocol was approved by the local ethic committee of the ICBFM SB RAS.

Results: Depending on RI the following subgroups of patients were assigned: sensitive (RI > 30%, 58.9%), semi-responders (RI = 10–30%, 20.9%), non-responders (RI = 0–10%, 7.6%), and 12.7% of patients demonstrated paradoxical laboratorial response: platelet aggregation increased after clopidogrel taking.

According to genetic analysis data, the CYP2C19 gene was presented by allelic variants *1/*2 (24.7%), *2/*2 (0.6%); *1/*17 (17.0%) and *17/*17 (1.0%), and the ABCB1 gene by 3435 CC (20.3%), CT (41.8%) and TT (37.9%) variants. The correlation analysis revealed the connection between CYP2C19*2 and RI. Both CYP2C19*17 and ABCB1 C3435T allelic variants have not been shown to make an effect in changes of platelet aggregation after clopidogrel taking. None statistically significant connection between considered genetic variants and paradoxical laboratorial response on clopidogrel was found.

Depending on the type of drug metabolism patients were divided into five subgroups: fast (*17/*17, *1/*17), extensive (*1/*1), intermediate (*1/*2, *1/*3), slow (*2/*2), 'uncertain' (*2/*17). Significant differences ($P < 0.05$) were found between average RI in groups of fast and extensive metabolizers and in groups of fast and «uncertain» metabolizers. As a result, the influence of allelic variant CYP2C19*2 is more significant than the influence of the variant CYP2C19*17 in the group of patients under study.

Summary/Conclusions: The frequencies of occurrence of CYP2C19 and ABCB1 allelic variants in a group of patients from West-Siberian region of Russia receiving clopidogrel therapy were calculated and the effect of these genetic variants on clopidogrel laboratorial efficacy was examined. 12.7% of patients in the group under study were found to demonstrate paradoxical laboratorial response on clopidogrel. Such unusual response has not been shown to be associated with genetic variants considered. CYP2C19*2 has been shown to make an effect on the laboratorial response on the clopidogrel. RI in the subgroup of fast metabolizers is higher than in subgroups of extensive and «uncertain» metabolism.

PB 2.21-4

The VerifyNow PRU is associated with optimal duration of clopidogrel interruption prior to CABG surgery: sub-Analysis of TARGET CABG study

Gurbel PA[1], Mahla E[2], Kevin BP[1], Tantry US[1], Jeong YH[1], Gesheff M[1] and Dahlen JR[3]

[1]Sinai Center for Thrombosis Research, Baltimore, MD, USA; [2]Medical University of Graz, Graz, Austria; [3]Accumetrics, Inc, San Diego, CA, USA

Background: The utility of thrombelastography (TEG) to determine the timing of CABG in pts treated with clopidogrel was evaluated in the first prospective study, TARGET CABG which showed that pts non-responsive by TEG had no greater chest tube output when operated within 24 h of last clopidogrel dose compared to clopidogrel naïve pts. The utility of VN to optimally time CABG is unknown.

Methods: In TARGET CABG, we also analyzed platelet function recovery (PFR) using VerifyNow P2Y12 assay in 81 patients on aspirin and clopidogrel therapy undergoing elective first time isolated on-pump CABG. CABG was done within 1 day (nonresponse), 3–5 days (moderate response), and > 5 days (high response) based on ADP induced platelet-fibrin clot strength (MA-ADP) as measured by thrombelastography. Proportion of patients achieving pre-surgical PRU > 208 was used indicate PFR.

Results: Baselines PRUs were in agreement with MA-ADP within each response group and there was significant difference in mean baseline PRUs between response groups ($P < 0.05$) (Figure 1). Ninety-seven percent of patients demonstrated PFR prior to surgery. The total amount of red blood cells transfused did not differ between response groups.

Conclusions: PFR by VN-P2Y12 assay agrees with TEG, suggesting that PFR specific to the P2Y12 receptor significantly influenced the primary results of TARGET-CABG. The use of platelet function testing may allow for improved pre-surgical management of $P2Y_{12}$ inhibitor therapy prior to major surgery, and further investigation is warranted.

PB 2.21-5

Comparison of the antiplatelet effect of crushed clopidogrel vs. whole tablet in diabetic patients presenting with an acute coronary syndrome

Addad F[1], Oueslati C[1], Ibn El Hadj Z[1], Hammami N[1], Jebri F[1], Ben Halima A[1], Kammoun I[1], Yaalaoui S[2] and Kachboura S[1]

[1]Department of Cardiology; [2]Department of Biology, A. Mami University Hospital, Ariana, Tunisia

Background: Pharmacodynamic studies have shown that persistently high residual platelet reactivity (HRPP) is common in patients with diabetes in spite of clopidogrel treatment. Even, a 600-mg clopidogrel loading dose is not sufficient to overcome this effect, especially in diabetic patients with ACS. This can be explained by altered resorption, altered liver metabolism, or altered platelet response. Recently, it was demonstrated that clopidogrel given crushed provided faster absorption and greater rate of clopidogrel inactive metabolite in healthy subjects.

Objective: The hypothesis of the study was that 600 mg clopidogrel loading dose (LD) administered crushed may provide more effective platelet inhibition than an equal clopidogrel dose taken orally as whole tablets in patients with type 2 diabetes mellitus presenting with ACS.

Methods: In a prospective, single-center, single-blind study, 30 (58.9 ± 8.4 years; 17 males) ACS diabetic patients were randomized to either 600 mg crushed clopidogrel ($n = 15$) or whole tablets ($n = 15$) follow by a maintenance dose of 150 mg, respectively. Pharmacodynamic assessment was performed by VerifyNow P2Y12 system accumetrics at 24 h and 3 days post LD. High Residual platelet reactivity (HRPR) was defined as platelet reactivity units (PRU) > 235.

Results: The baseline characteristics were no different in the two groups. We noted no difference between the antiplatelet effect produced by 600 mg crushed clopidogrel compared with whole tablets at both 24 h (PRU = 199.73 ± 79.3 vs. 216.9 ± 70.1; $P = 0.53$) and at 3 days (PRU = 164.3 ± 92.9 for crushed clopidogrel vs. 160.5 ± 73.5 for whole tablet; $P = 0.9$). HRPR rate also was similar in the two groups, 40% ($P = 1$) at 24 h and diminished significantly in both groups at 3 days to 20% of patients ($P < 0.001$).
Conclusions: Despite the small sample size, the present study demonstrates that clopidogrel given crushed in diabetic ACS patients is as effective as whole tablets.

PB 2.21-6

Rebound of ADP mediated platelet aggregation after abrupt cessation of long-term clopidogrel therapy positively correlate to thrombin and arachidonic-acid dependent platelet aggregation

Obradovic S[1], Djukanovic N[1], Todorovic Z[2], Njegomirovic S[1], Prostran M[2], Djenic N[1] and Ostojic M[3]
[1]Military Medical Academy; [2]Institute for Medical Statistics and Informatics; [3]Academy of Science, Belgrade, Serbia

Background: The interplay between various platelet agonist-receptor interactions during and after stopping antiplatelet therapy is insufficiently known and possible rebound phenomena may have important adverse consequences.
Aim: To investigate the influence of abrupt cessation of long-term clopidogrel therapy on platelet aggregation to adenosine diphosphate (ADP), arachidonic acid (AA) and thrombin receptor-acivating peptide (TRAP) in patients with coronary heart disease on aspirin.
Patients and methods. Two-hundred patients who underwent to elective PCI with stent who were on 1 year dual antiplatelet therapy (aspirin + clopidogrel) and had no adverse events during that time were enrolled in the study. Platelet function was measured by multiple electrode aggregometry using three agonists [ADP with PGE1 (ADPHS-test), AA (ASPI-test), and TRAP (TRAP-test)] at the last day of clopidogrel therapy and 90 days after stopping the drug.
Results: Platelet aggregation on ADP [320.5 AU × min (212.7–461.7) vs. 838.5 AU × min (728.0–968.7), $P < 0.001$], AA [155.0 AU × min (115.0–211.0) vs. 228.0 AU × min (154.0–375.7), $P < 0.001$] and TRAP (1134.7 ± 176.6 vs. 1158.1 ± 175.3 AU × min, $P = 0.041$) significantly increase after 90 days. Levels of TRAP and ASPI at 90 day significantly increase according to quartiles of ΔADP (difference between the ADP test at 90 day and baseline) $P < 0.001$ and $P = 0.021$, respectively.
Conclusion: Patients with higher increase of ADP dependent platelet aggregation after stopping clopidogrel had higher platelet aggregation on TRAP and AA.

PB2.22 – Platelet Function Tests: Clinical

PB 2.22-1

Platelet-reactivity tests identify patients at risk of secondary cardiovascular events: a review and meta-analysis

Wisman PP, Roest M, Asselbergs WF, De Groot PG, Moll FL, Van Der Graaf Y and De Borst GJ
UMC Utrecht, Utrecht, The Netherlands

Background: Antiplatelet therapy is standard treatment for the prevention of cardiovascular events (CVE). High-on-treatment platelet reactivity (HPR) is a risk factor for secondary CVE in patients prescribed aspirin and/or clopidogrel. Numerous platelet-function tests are available that assess HPR for aspirin (HAPR) or clopidogrel (HCPR).
Aims: The present review and meta-analysis aimed to assess the ability of individual platelet-function tests to reliably identify patients at risk of secondary CVE while being treated with aspirin and/or clopidogrel.
Methods: *Data Sources:* A systematic literature search using the terms 'aspirin resistance' and 'clopidogrel resistance' was conducted to identify studies on platelet-reactivity measurements and CVE. The years of publication ranged from January 1966 to September 2012; the publications were in English.
Study Selection: Main inclusion criteria were: (i) study design was prospective; (ii) study medication was aspirin and/or clopidogrel; (iii) a platelet-function test was performed at baseline; and (iv) data on baseline platelet-function-test outcome and CVE during follow-up available. The latter criterion was necessary to extract dichotomous frequency data. Of 2676 identified studies, 89 (3.3%; reporting on 29,018 patients) were included in the meta-analysis.
Data Extraction: Data abstraction and data-quality and -validity assessment were executed independently by two observers.
Results: With regard to HAPR, 21 different tests were discussed in 49 studies (12,687 patients). Pooled analysis showed that HAPR was diagnosed in 29.0% of patients, and associated with an increased risk of developing CVE (RR: 2.08; 95%CI: 1.74–2.48). The negative predictive value (NPV) was 89.8%, the positive predictive value (PPV) 19.0%. When the individual HAPR tests were compared, 11 showed an increased risk of CVE in patients with HAPR. As regards HCPR, 50 studies (21,037 patients) discussed 14 different tests and reported HCPR being present in 38.5% of patients and associated with an increased CVE risk (RR: 2.90; 95%CI: 2.44–3.44). The NPV of the HCPR tests was 95.2%, the PPV10.6%.
Conclusion: HPR is seen in a large number of patients on antiplatelet therapy. Patients with HPR are inadequately protected against future cardiovascular complications. Some HAPR and HCPR tests can identify patients at higher risk of secondary CVE.

PB 2.22-2

The real world relationship between VerifyNow PRU and device-reported percent inhibition: analysis from the GRAVITAS trial

Dahlen JR[1] and Price MJ[2]
[1]Accumetrics, San Diego, CA; [2]Division of Cardiovascular Diseases, Scripps Clinic, and the, La Jolla, CA, USA

Background: The VerifyNow P2Y12 Test is a rapid, point-of-care platelet function test that has been extensively validated as a tool for measuring the antiplatelet effect of P2Y12 receptor inhibitors. The VN P2Y12 Test reports results as P2Y12 Reaction Units (PRU) and device-reported percent inhibition of platelet reactivity (%I), based on using thrombin receptor-induced platelet aggregation as a substitute for a baseline, P2Y12 inhibitor naïve PRU result. The PRU result is highly specific for P2Y12 receptor blockade due to the effect of a P2Y12 inhibitor and is an absolute measure of the drug effect. The%I result is a relative measure of the drug effect because the absolute effect is normalized using baseline, thrombin-receptor induce platelet aggregation. PRU results have been clinically validated to identify patients at increased risk for thrombosis and bleeding due to the presence of a P2Y12 inhibitor antiplatelet effect.%I results have been clinically validated to correlate to a return to baseline platelet function following P2Y12 inhibitor cessation. The relationship between these two results has not been extensively described.
Aims: The objectives for this study were to (i) compare the actual relationship of PRU and%I results to a model based on true baseline platelet reactivity and (ii) determine the agreement of PRU and &I results at published clinical decision points.
Methods: Matched PRU and%I results were evaluated using measurements obtained from the GRAVITAS trial. A total of 10,375 Verify-

Now P2Y12 Test measurements from 5429 subjects were used for the analysis. The manufacturer-reported 95% confidence interval PRU reference range of baseline platelet reactivity (194–418) represents the range of PRU results when the 'true' %I is 0%. A PRU result of 0 is the expected result when 'true' %I is 100%. Taken together, a model for the relationship of PRU and%I was constructed using an inferred range of PRU results at each level of 'true' %I. Because the reference range is the 95% confidence interval of baseline PRU results, the model is therefore a prediction of the relationship between PRU and% I for at least 95% of the observations. The percent of actual measurements that were in agreement with the model was determined, and the agreement of results using PRU < 208 and % I > 20% cutoffs also was determined.

Results: 96.8% of the matched PRU and%I results were within the theoretical model, which was within the expected > 95% of results. The PRU > 208 cutoff reported to define high on-treatment platelet reactivity was 95% specific for the %I < 20% reported to define a baseline platelet function.

Summary/Conclusion: The results of this investigation confirm there the PRU and device-reported%I results from the VerifyNow P2Y12 Test are highly correlated and are consistent with a prediction model of their relationship. These observations suggest that device-reported %I is an acceptable surrogate for true percent inhibition calculated from a pre-drug and on-treatment PRU result. In addition, the results indicate that there is consistency between the clinically validated PRU and device-reported%I decision points.

PB 2.22-3

High platelet reactivity is associated with increased D-dimer levels in acute coronary sindrome patients

Marcucci R, Gori AM, Giusti B, Paniccia R, Fedi S, Romagnuolo I, Palombella AM, Priora R and Abbate R

University of Florence, Florence, Italy

Background: High platelet reactivity (HPR) on dual antiplatelet treatment is an independent predictor of adverse ischemic events in acute coronary syndrome (ACS) patients undergoing percutaneous coronary intervention (PCI). Few data are available on the possible association of this phenotype with coagulation and inflammation.

Aims: To investigate the relationship between HPR – by both arachidonic acid and ADP – and markers of clotting and fibrinolysis activation and inflammatory response.

Methods: We recruited 646 ACS patients undergoing PCI on dual antiplatelet therapy. Platelet reactivity was assessed by light transmission aggregometry by 10 μM ADP and by 1 arachidonic acid (AA). D-dimer levels were assessed by immunoturbidimetric method (IL Laboratory, Milan). HPR by ADP was diagnosed in the presence of LTA by ADP ≥ 55% according to our previous published data; HPR by AA in the presence of LTA ≥ 20%.

Results: D-dimer, fibrinogen and ESR levels were respectively: (median and interquartile range) 229.5 (119.7–413.2) ng/mL, 534.0 (451.5–612.2) mg/dL, 15.0 (11.0–21.0) mm/h.

HPR by ADP was detected in 357/646 (55.2%) and HPR by AA in 189/646 (29.2%).

LTA by AA values significantly correlated with D-dimer, fibrinogen and ESR values (D-dimer: $r = 0.15$, $P < 0.001$; fibrinogen: $r = 0.16$, $P = 0.02$, ESR: $r = 0.25$, $P < 0.001$).

D-dimer, fibrinogen and ESR levels were significantly higher in patients with HPR by AA than in patients without HPR by AA [D-dimer: 293 (156.5–537) ng/mL vs. 194 (107.8–376.3) ng/mL, $P < 0.001$; Fibrinogen: 549 (467–627.5) mg/dL vs. 525 (437.5–598.2) mg/dL, $P = 0.04$; ESR 25 (15–45) mm/h vs. 17.5 (8–27.7) mm/h, $P = 0.004$].

According to HPR by ADP we found significantly higher D-dimer and ESR levels in patients with HPR than in patients without HPR by ADP [D-dimer: 238 (124–456.5) ng/mL vs. 204 (112.7–363.2) ng/mL, $P = 0.03$; ESR 22 (12–36.5) mm/h vs. 16 (8–30) mm/h, $P = 0.03$].

Conclusions: HPR is associated with a prothrombotic and proinflammatory state suggesting a possible role of the antithrombotic therapy in modulating this phenotype associated with a higher incidence of ischemic events.

PB 2.22-4

Aspirin resistance and C-reactive protein predict long term mortality in STEMI patients

Marcucci R, Cau V, Valente S, Chiostri M, Lazzeri C, Saracini C, Galora S, Bucherelli S, Gensini G and Abbate R

University of Florence, Florence, Italy

Background: Data on long term prognostic value of high platelet reactivity (HPR) on aspirin in patients with acute coronary syndrome (ACS) undergoing PCI are limited. On the other hand, C reactive protein levels has been suggested to be associated with post-PCI atherothrombotic events.

Methods and Results: We evaluated 494 STEMI patients (366 M/128 F; age: 65.8 ± 12.4 years) undergoing PCI with stent implantation.

Platelet reactivity was assessed by light transmission aggregometry by 1 arachidonic acid (AA). HPR by AA was diagnosed in the presence of LTA ≥ 20%. At a median follow-up of 27.8 months (13.1–48.8), 58 patients died (11.7%).

Median values of LTA by AA were significantly higher in patients died with respect with the alive: 24.18 ± 21.1% vs. 16.2 ± 11.4%, $P > 0.001$. By the ROC curve analysis, 18% was found to be the value of LTA by AA associated with the higher specificity and sensitivity for death.

CRP values were significantly higher in patiebts died with respect with the others: 55.86 ± 62.46 mg/L vs. 24.68 ± 37.12 mg/L, $P < 0.001$. By the ROC curve analysis, 12 mg/L was found to be the value of CRP associated with the higher specificity and sensitivity for death.

Patients with HPR by AA were not at significantly higher risk of death [HR = 1.57 (0.5–4.9); $P = 0.440$]; patients with elevated levels of CRP were at higher risk of death [HR = 2.72 (1.1–6.76); $P = 0.031$]; the presence of both HPR by AA and elevated CRP levels was associated with the highest risk of death [HR = 4.19 (1.67–10.55); $P = 0.002$].

Conclusion: These results document that both HPR by AA and elevated CRP levels identify a subgroup of STEMI patients at significantly higher risk of death, for whom it might be crucial to optimize antithrombotic therapy.

PB 2.22-5

Pharmacogenomic study of clopidogrel poor response

Calderon Cruz B[1], Manzo Francisco LA[1], Roman Perez A[1], Rodriguez Galvan K[1], Herrera Gonzalez A[1], Vargas Alarcon G[2], Fragoso JM[2], Peña Duque MA[2], Reyes Gomez CA[2] and De La Peña Diaz A[1]

[1]UNAM; [2]National Institute of Cardiology, Mexico, Mexico

Background: The use of antiplatelet therapy with aspirin and clopidogrel, reduces significantly recurrent cardiovascular events in patients with acute coronary syndrome. Clopidogrel is a pro-drug, its absorption in the intestine is limitedby the P-Glycoprotein, encoded in the ABCB1 gene. It ismetabolized in the liver by theenzymes of the cytochrome P450 superfamily (CYP) to produce the activemetabolite that antagonizes the P2Y12 platelet receptor. There is a wide interindividual variability in response to clopidogrel. The poor response to clopidogrel has been associated with polymorphisms in ABCB1, CYP and P2RY12 genes. In Mexican population the frequency of these polymorphisms and their relation with clopidogrel poor response is unknown.

Aims: Determine the frequency of clopidogrel poor response and its relation with polymorphisms of the ABCB1, CYP2C19, CYP3A5 and

P2RY12 genes in patients underwent percutaneous coronary intervention.

Methods: A total of 276 patientswho underwent percutaneous coronary intervention and received a clopidogrel loading dose of 300 or 600 mg were included. Platelet aggregation was performed by a turbidimetric method on a Lumiaggregometermodel 810 AC AGGRO software/LINK Chrono-log, Havertown, PA, USA. Different concentrations of ADP (0.58–10 μM) were used as agonist to determinate clopidogrel's poor response. Single nucleotide polymorphisms (ABCB1, CYP2C19*2, CYP2C19*3, CYP3A5*3 and two polymorphic sites of the P2RY12 gene G52T and C34T) in genomic DNA were performed using 5′exonuclease TaqMan assays by a 7900HT Fast Real-Time PCR System (Applied Biosystem, Foster City, CA, USA). All patients signed informed consent, this protocol is according to the Helsinki declaration and it was approved for the ethics committee of the National Institute of Cardiology.

Results: Sixty one (22.1%) of the 276 patients included in the study, were clopidogrel poor responders. ABCB1 TT allelehas a frequency of 18.1% in our studied population OR2.4P = 0.015 (CI 1.23–4.66). A logistic regression model showed that omeprazole increase the risk to 7.82 ($P = 0.023$) of being clopidogrel poor responder.

The studied CYP and P2RY12 polymorphisms were not related with clopidogrel poor response, and had frequencies below 9% in our population.

Conclusions: Carriersof ABCB1 TT allele had a higher risk of being clopidogrel poor responders, compared with CC and CT carriers. Polymorphisms of the CYP and P2RY12 genes were not related to clopidogrel poor response and their frequencies were lower than reported for Caucasian populations.

PB 2.22-6

Prevalence of CYP2C19 variant alleles and pharmacodynamic variability of aspirin and clopidogrel in American Indians

Oestreich J[1], Best GL[2], Crowe BW[1] and Dobesh P[1]

[1]University of Nebraska Medical Center, Omaha, NE; [2]Turtle Mountain Community College, Belcourt, ND, USA

Background: Extensive variability to clopidogrel has been identified, and genetic variation in the metabolic enzyme cytochrome P450 (CYP) 2C19 is one important factor. The prevalence of important genetic polymorphisms of the CYP2C19 gene has been determined in most groups, but not in American Indians. Furthermore, the overall effectiveness of clopidogrel and aspirin has not been studied in the American Indian population, even though this group has some of the highest mortality rates in the U.S.A. for cardiovascular disease and diabetes.

Aims:

1 Identify the prevalence of CYP2C19 variant alleles in American Indians of the Oglala Sioux Tribe of South Dakota, U.S.A.
2 Assess the antiplatelet pharmacodynamic variability and the influence of candidate clinical and genetic predictors in American Indians.

Methods: Our protocol was approved by the appropriate medical ethics committees. We recruited and obtained consent from 50 American Indians of the Oglala Sioux Tribe with coronary artery disease (CAD) taking aspirin and clopidogrel. Whole blood was collected for analysis by the VerifyNow P2Y12 and aspirin tests. Saliva samples from the CAD patients and 50 additional healthy volunteers ($n = 100$ total) were genotyped for known CYP2C19 variants (*2, *3, and *17). Genotyping was conducted by real-time polymerase chain reaction (TaqMan assay) at a regional Tribal college. We analyzed single predictors of platelet reactivity with the Kruskal-Wallis and chi-square tests.

Results: The observed genotype distributions were in Hardy-Weinberg equilibrium. Genotype frequencies were: CYP2C19 *1/*1, $n = 62$; *1/*2, $n = 20$; *2/*17, $n = 2$; *1/*17, $n = 13$; *17/*17, $n = 1$. Twenty-two percent of American Indians were heterozygous for the *2 loss-of-function allele (allele frequency = 11%; 95% CI = 7–16%), and 16% of American Indians carried at least one CYP2C19*17 allele (allele frequency = 9%; 95% CI = 5–13%). The pharmacodynamic effectiveness of clopidogrel in American Indians (median = 194 P2Y12 reaction units (PRU), range = 29–400) was not statistically different from a historical control of primarily Caucasian patients (median = 186 PRU, range = 85–331; $P = 0.70$). There was no significant effect of genotype on platelet aggregation as measured by the VerifyNow P2Y12 test ($P = 0.72$; median and range for CYP2C19*1/*1 and *2/*17 = 218, 29–400 PRU; *1/*2 carriers = 194, 108–242 PRU; *17 carriers = 171, 74–354 PRU). The median aspirin reaction units (ARU) for American Indians was 437 (range = 350–659), and 73% had ARU values < 550. Higher PRU values were associated with never smoking ($P = 0.018$), a history of coronary artery bypass grafting ($P = 0.043$), no previous percutaneous coronary intervention ($P = 0.042$), and low aspirin dose (81 mg; $P = 0.013$). Never smokers ($P = 0.044$), low aspirin dose ($P = 0.037$) and age ≤ 65 years ($P = 0.005$) were significant predictors of high ARU values.

Conclusions: The variability to aspirin and clopidogrel in American Indians of the Oglala Sioux Tribe is consistent with reported values for other groups as measured by the VerifyNow assay. However, the tested CYP2C19 genotypes (*2, *3, and *17) did not explain the variability of clopidogrel response. Future work will further characterize genetic variation in a larger sample of this population with significant health disparities.

PB2.23 – Platelet Activation: Receptor Changes – I

PB 2.23-1

Modulation of α-thrombin function by platelet glycoprotein Iba

Ruggeri ZM, Zarpellon A, Zampolli A, Roberts JR and Mendolicchio GL

The Scripps Research Institute, La Jolla, CA, USA

Background: The protease α-thrombin (FIIa) interacts with several substrates to orchestrate biochemical reactions and cellular functions in response to vascular injury. Platelets – key participants in such events, including hemostasis and thrombosis – express glycoprotein (GP) Ibα on their membrane; this is the most abundant FIIa binding site, but its function relative to that of protease activated receptors (PARs) signaling after proteolytic cleavage remains unclear. We previously demonstrated that FIIa binding to GPIbα concurrently involves two independent sites – site 1 in the proximity of exosite I and site 2 involving exosite II. Thus, one FIIa interacts with two distinct GPIbα molecules and each GPIbα interacts with two distinct FIIa molecules.

Aims: The long term goal of our studies is to characterize in detail the functional consequences, *in vivo* and ex vivo, of FIIa binding to GPIbα.

Methods: To achieve our goal, we have generated mice expressing human (hu) GPIbα with wild type (WT) sequence or mutated at residues interacting selectively with FIIa site 2 (D277N) or both site 1 and 2 (Y276/278/279F).

Results: Mouse platelets expressed ≈9000 WT or mutant huGPIbα molecules; ≈10,000 FIIa molecules bound to huGPIbα-WT (with an apparent 1:1 stoichiometry and K_D of ≈3 nM), while binding to mutant huGPIbα was essentially abolished. Mice with defective FIIa binding to platelet GPIbα exhibited a pronounced prothrombotic phenotype, with a significantly ($P < 0.01$) shorter time to carotid artery occlusion following ferric chloride injury (median 550.5 s; $n = 18$) than mice with normal FIIa binding to platelets (median 1980 s; $n = 19$). Accordingly, the platelet-rich plasma (PRP) of mice with defective FIIa binding exhibited a significantly shorter clotting time in the presence of 4 nM FIIa and significantly enhanced intracytoplasmic Ca^{2+} transients and platelet aggregation following stimulation by 0.5 nM

FIIa. Mouse and human platelets differ significantly with respect to expressed PAR receptors, as the former express PAR3 and PAR4, while human platelets express PAR1 and PAR4. Human platelets bind FIIa like mouse platelets, with a 1:1 stoichiometry relative to expressed GPIbα and K_D of ≈3 nM. FIIa binding to human platelets is abolished by the previously characterized monoclonal antibody LJ-Ib10. In agreement with the results obtained with mutant mouse PRP lacking FIIa binding to platelets, addition of LJ-Ib10 significantly shortened the clotting time. However, in marked contrast, this antibody greatly reduced intracytoplasmic Ca^{2+} transients and platelet aggregation following stimulation by 1 nM FIIa.

Summary/Conclusions: Our findings identify GPIbα as a relevant FIIa activity modulator with respect to platelet activation and clotting. However, the consequences on platelet aggregation vary depending on the specific PAR type expressed. Human platelets depend on FIIa binding to GPIbα for efficient PAR1 cleavage and subsequent signaling. In contrast, binding to GPIbα competes for FIIa cleavage of PAR4 on mouse platelets and subsequent activation. Common in the two species is the competing effect of GPIbα binding of FIIa on fibrinogen clotting. Thus, through distinct mechanisms influenced by the expression of specific PAR subtypes, GPIbα can modulate FIIa function in hemostasis and thrombosis both with prothrombotic or antithrombotic consequences.

PB 2.23-2

Thrombin is a selective inducer of heparanase release from platelets via protease-activated receptor-1

Nadir Y[1], Shapira M[2], Axelman E[1], Keren-Politansky A[3], Bonstein L[4] and Nadir Y[1]

[1]Rambam Health Care Campus; [2]Hematology Laboratory, Hillel Yaffe Medical Center, Hadera; [3]Hematology Laboratory, Rambam Health Care Campus, Haifa; [4]Blood Bank, Rambam Health Care Campus, Haifa, Israel

Background: Heparanase, known to be involved in angiogenesis and metastasis, was shown to form a complex with tissue factor (TF) and to enhance the generation of factor Xa (Nadir *et al*, Haematologica, 2010). Platelets contain abundant amount of heparanase and were the primary source for the protein purification.

Aims: To identify the inducer and pathway of heparanase release from platelets.

Methods: Pooled platelet rich plasma from platelet units obtained from the blood bank or healthy donors was incubated with ADP, epinephrine, collagen, ristocetin, arachidonic acid and thrombin. Level of heparanase released from platelets was studied by ELISA and western blot analysis. The effect of selective protease-activated receptor-1 (PAR-1) inhibitor (FR171113) and thrombin receptor activator peptide (TRAP) were assessed using platelet aggregometry and heparanase procoagulant activity assays. In-house synthesized inhibitory peptides to TF/heparanase complex were used to evaluate platelet heparanase involvement in activation of the coagulation system.

Results: Heparanase was released from platelets only by the induction of thrombin while ADP, epinephrine, collagen, ristocetin and arachidonic acid exerted no effect on heparanase release. Level of heparanase in the plasma after thrombin induction was 250 folds higher compared to heparanase baseline plasma level. Activation of PAR-1 by TRAP dramatically increased heparanase procoagulant activity and was significantly decreased by the addition of PAR-1 inhibitor or TF/heparanase complex inhibitory peptides.

Conclusions: Heparanase is selectively released from platelets by thrombin *via* PAR-1 receptor. Platelet heparanase is involved in activation of the extrinsic coagulation pathway. The present study widens our understanding regarding potential anticoagulant effect, in addition to anti-platelet effect, of the new clinically studied PAR-1 inhibitors.

PB 2.23-3

Can platelet surface markers synchronize differential platelet secretion?

Miao X, Huang Z, Stålesen R and Li N

Karolinska Institute, Stockholm, Sweden

Background: Platelet a-granules contain a number of pro-angiogenic (e.g., vascular endothelial growth factor, VEGF, and stromal cell-derived factor-1a, SDF-1a) and anti-angiogenic regulators (thrombospondin and endostatin). Recent evidence indicates that different angiogenic regulators may be stored in different a-granules and differentially released upon different stimuli. Platelet surface expression of granule membrane embedded P-selectin is widely used as an indicator of platelet secretion/degranulation. Platelets also express specific receptors to some platelet angiogenic regulators (such as glycoprotein IV/CD36 for thrombospondin), which allows surface binding of those angiogenic regulators upon release. Our hypothesis is that distinct release of angiogenic regulators can lead to their distinct expression/binding on platelet surface.

Aims: To explore the possibility of using a multicolor flow cytometric assay of platelet surface markers to monitor differential release of platelet angiogenic regulators and the underlying signaling mechanisms.

Methods: Hirudinized or citrated whole blood samples from 15 healthy volunteers were stimulated at 37 °C for 10 min with a panel of platelet agonists: the thrombin receptor PAR1-activating peptide (PAR1-AP; 10 μM), PAR4-AP (100 μM), collagen-related peptide (CRP; 10 μg/mL), the thromboxane A2 analogue U46619 (1 μM), and ADP (100 μM). The samples were then labeled with various panels of different fluochrome-conjugated antibodies detecting P-selectin (a general marker of platelet secretion), fibrinogen (a platelet aggregability marker), SDF-1a (a proangiogenic regulator), and thrombospondin (an antiangiogenic regulator).

Results: Platelet activation by PAR1-AP led to marked elevations of platelet P-selectin expression (e.g., from 1.9 ± 1.0% of rest to 95.0 ± 3.1%), but milder elevation in fibrinogen binding (4.0 ± 2.7% to 77.5 ± 15.0%) and thrombospondin expression (1.9 ± 0.4%–50.7 ± 11.8%), and a minimal increase in SDF-1a expression (2.5 ± 1.0%–4.2 ± 2.4%). PAR4-AP stimulation elevated P-selectin, fibrinogen, and thrombospondin expression similarly (98.2 ± 0.4%, 99.0 ± 0.5%, and 89.6 ± 5.5%, respectively), but did not increase SDF-1a expression (2.5 ± 1.0% vs. 3.3 ± 1.6%). CRP stimulation induced similar responses as by PAR4-AP, while U46619 and ADP arose milder responses (e.g., 57.9 ± 33.8% and 68.8 ± 1.8% P-selectin expression, respectively). Moreover, multicolor analyses showed that there were not distinct platelet subpopulations expressing thrombospondin but not SDF-1a or vice versa. Follow-up work was hence focused on possible different impacts of intracellular signaling interventions on platelet P-selectin and thrombospondin expression using a panel of inhibitors: Src (PP2, 50 μM), PI3K (LY294002, 50 μM), Akt (Akt1/2 kinase inhibitor; 50 μM), and p38 (SB203580; 25 μM). None of these inhibitors influence PAR1-AP or PAR4-AP-induced P-selectin expression, whilst p38 inhibition mildly reduced PAR1-AP-induced thrombospondin expression. In CRP, U46619, and ADP-stimulated platelets, Src and PI3K inhibition reduced, while p38 inhibition most markedly decreased platelet P-selectin and thrombospondin expression in a similar manner. Hence, above signaling interventions did not elicit any distinct effects on the two platelet secretion markers.

Conclusion: Multicolor flow cytometry using whole blood samples seems to be less than an optimal approach to demonstrate differential releases of platelet angiogenic regulators, albeit it has the advantage displaying multiple surface markers on individual platelets.

PB 2.23-4

The effect of omega-3 supplementation on platelet GPVI levels

Gardiner E[1], Tan CW[2], McEwen BJ[2], Arthur JFJ[1], Morel-Kopp MC[2], Ward CM[2] and Andrews RK[1]
[1]Monash University, Melbourne, Vic.; [2]Kolling Institute, University of Sydney, Sydney, NSW, Australia

Background: The primary platelet receptor for collagen, glycoprotein (GP) VI plays a critical role in arterial thrombosis. GPVI is extremely stable on the surface of circulating platelets but is rapidly shed by a disintegrin and metalloproteinase (ADAM) sheddases, primarily ADAM10, upon GPVI ligand engagement or exposure of platelets to elevated shear. Statin therapeutics which work to reduce membrane cholesterol levels, have been shown to elevate ADAM10 activity in cell culture. Common therapeutic strategies to prevent cardiovascular disease such as cholesterol reduction and omega-3 supplementation may affect membrane GPVI and plasma soluble GPVI (sGPVI) levels.
Aims: To assess the effect of modulation of platelet cholesterol and membrane biochemistry on surface and soluble GPVI levels in platelet-rich plasma (PRP) under resting and shear-activated conditions.
Methods: In experiments conducted *in vitro*, PRP from healthy donors was treated with 5–15 mM methyl-β-cyclodextrin (MβCD) to remove cholesterol then resuspended in autologous plasma. Samples of citrated PRP were isolated from healthy donors before and after 1 month daily ingestion of 120 mg eicosapentaenoic acid (EPA) and 520 mg docosahexaenoic acid (DHA). All PRP samples were either untreated or exposed to 7500–10,000/s uniform shear stress using a cone-plate viscometer for up to 10 min. Shear-activated metalloproteolytic shedding of GPVI was monitored by flow cytometry and sandwich ELISA, and platelet-associated ADAM10 activity was measured using a quenched fluorescent peptide with unique sequence matching the ADAM10 cleavage site within GPVI (GPVI-FRET).
Results: Platelet suspensions that were treated with 5–15 mM MβCD had up to 8-fold increases in sGPVI in the absence of shear activation. Exposure to 10,000/s shear stress resulted in 16-fold increases in shedding of GPVI that was enhanced a further 20% by cholesterol depletion. Increased GPVI-FRET cleavage was observed in PRP samples that had been treated with 5- 15 mM MβCD compared to untreated PRP indicating that platelet ADAMs activity was enhanced by cholesterol depletion. Depletion of platelet membrane cholesterol may render GPVI more susceptible to proteolysis under both resting and high shear conditions. Levels of platelet GPVI on resting platelets were reduced by 11% in samples from eight healthy donors after 1 month ingestion of omega-3 fatty acids. The plasma lipid composition, as ascertained by mass spectrometry, was altered by omega-3 fatty acid ingestion.
Summary/Conclusion: Common therapeutic approaches to reduce cholesterol levels also modulate GPVI receptor density on resting platelets and accentuate shear-induced GPVI shedding, potentially reducing the risk of arterial thrombosis in patients with coronary artery disease. Future experiments will assess the consequences of accelerated loss of GPVI on platelet function, however our data imply an additional pleiotropic effect of omega-3 fatty acids *in vivo* that is cardioprotective.

PB 2.23-5

Lipid rafts in platelets: their role for TXA2-induced platelet activation

Moscardó A[1], Vallés J[2], Latorre A[2], Madrid I[3] and Santos MT[2]
[1]IIS La Fe; [2]Research Center, La Fe University Hospital; [3]Intensive Care Unit, University Hospital La Fe, Valencia, Spain

Background: Aspirin is the mainstay antiplatelet treatment in patients with cardiovascular disease; its best-characterized effect is the irreversible inhibition of cyclooxygenase 1 and the subsequent formation of thromboxane A_2 (TXA_2), a potent vasoconstrictor and platelet agonist acting on its specific receptor. Lipid rafts are cholesterol-rich microdomains present in the plasma membrane that are believed to serve as platforms for signal transduction processes by localizing or excluding receptors and signaling molecules. Lipid rafts play an important role in signal transmission in different cell types, including platelets. Currently is unknown if they regulate TXA_2-induced platelet responses.
Aim: To analyze the participation of lipid rafts in platelet responses to TXA_2.
Methods: Platelets from normal subjects were washed and aggregation was assessed by optical aggregometry. The release of adenine nucleotides was quantified by HPLC, the cytosolic concentration of calcium by fluorimetry in FURA 2AM-loaded platelets, and platelet activation (P-selectin and PAC-1) by flow cytometry. Lipid rafts isolation was performed by sucrose gradient ultracentrifugation of platelet lysates. The different fractions were analyzed for specific proteins by immunoblotting. The fractions corresponding to lipid rafts were identified by the presence of CD36, a protein commonly used as a marker of lipid rafts. The functional role of lipid rafts was studied by disrupting them with methyl-β-cyclodextrin (MβCD) prior to platelet activation.
Results: Disruption of lipid rafts with MβCD decreased platelet aggregation induced by the TXA_2 analogs U46619 or IBOP (> 85%), dense granule release (> 70%) and P-selectin exposure (> 80%). This demonstrates the importance of TXA_2 receptor association with lipid rafts for TXA_2-induced platelet function. However, platelet aggregation induced by U46619 could be at least in part mediated by the platelet-released ADP through the ADP receptor P2Y12, which has been previously demonstrated to be associated with the lipid rafts (1). Therefore, disruption of lipid rafts could also affect P2Y12 mediated effects. To elucidate this question, we explored two platelet responses known to be directly dependent on TXA_2 receptor: the cytosolic calcium increase and the activation of the integrin IIbIIIa (PAC-1+) (1). We found that disruption of lipid rafts also decreased platelet responses directly linked to the TXA_2 receptor, supporting the concept that lipid rafts are involved in signal transmission mediated by the TXA_2 receptor. In addition, the isolation of lipid rafts allowed the detection in the fraction corresponding to the rafts (CD36+) of a significant percentage (38%) of total TXA_2 receptor as determined by densitometry. MβCD-treatment strongly reduced the presence of both CD36 and the TXA_2 receptor in the lipid rafts. Using cholera toxin-Alexa488 as a marker of rafts simultaneously with the TXA_2 receptor antibody, we confirmed by confocal mycroscopy the co-localization of TXA_2 receptor associated with platelet lipid rafts.
Conclusion: These results demonstrate for the first time the importance of lipid rafts for the TXA_2-induced platelet responses, a process which could be related to the presence of the TXA_2 receptor associated with lipid rafts. Grants: PI07/0463; Retics06/0026. (1) Dorsam RT, JCI 2004;113:240

PB 2.23-6

Soluble CLEC-2 was released upon platelet activation and detected in human plasma

Inoue O[1], Nakamura J[2], Osada M[1], Oosawa M[2], Ozaki Y[1] and Suzuki-Inoue K[1]
[1]University of Yamanashi, Yamanashi; [2]Mitsubishi Chemical Medience Corporation, Chiba, Japan

Background: CLEC-2 is a recently-identified platelet activation receptor, which binds to snake venom rhodocytin or a membrane protein podoplanin. Soluble membrane proteins were released from activated platelets. However, whether soluble human CLEC-2 is released upon platelet activation has not been fully investigated.
Aims: The aim of this study is to investigate whether soluble CLEC-2 is released upon platelet activation and whether soluble CLEC-2 is detected in human plasma.
Methods: Human washed platelets were stimulated with various agonists for 2 h at 37 °C. Reactions were terminated by addition of EDTA.

The stimulated platelets were centrifuged at 13,000 G for 1 min. Resultant supernatants were further ultra-centrifuged at 100,000 G for 3 h. Supernatants after centrifugation (Sup), pellets after centrifugation (Pel), supernatants after ultra-centrifugation (ultra-Sup), and pellets after ultracentrifugation (ultra-Pel) were separated by SDS-PAGE and Western blotted with anti-CLEC-2 or anti-GPVI antibody. ELISA system to measure soluble CLEC-2 was established using mouse monoclonal anti-CLEC-2 antibodies. Blood samples from 40 healthy volunteers were taken into plastic tubes with EDTA, sodium citrate, or inhibitor cocktails for measurement of platelet factor-4 (PF4) and beta thromboglobulin (betaTG) to obtain plasma. Then, soluble CLEC-2, PF4, and betaTG in three kinds of plasma were measured by ELISA. Written informed consent was provided according to the Declaration of Helsinki.

Results: In the Sup fraction of rhodocytin-stimulated platelets, anti-CLEC-2 antibody detected 32/40 kD and 25 kD bands. However, only 32/40 kD bands were observed in the ultra-Sup fraction, and only 25 kD bands were observed in the ultra-Pel fraction, suggesting that soluble CLEC-2 is released both as a shed form and a membrane-associated form on the surface of microparticles. In the case of GPVI, however, membrane-associated form was only faintly observed. CLEC-2 shedding was almost equally observed upon platelet activation induced by various agonists including rhodocytin, thrombin, collagen-related peptide, whereas GPVI shedding was significantly increased in the presence of the GPVI agonist. CLEC-2 shedding, but not GPVI shedding, was significantly inhibited by recombinant tissue Inhibitors of metallo-proteinase 2, an intrinsic MMP-2 inhibitor. Concentrations of PF4 and betaTG were markedly increased in EDTA serum and sodium citrate serum compared with that in inhibitor cocktail plasma. On the other hand, concentration of soluble CLEC-2 is similar among three kinds of plasma. Concentration of soluble CLEC-2 in EDTA plasma of healthy volunteer was 63 $\pm$ 80 pg/mL.

Conclusions: Soluble CLEC-2 and soluble GPVI are released upon platelet activation by a different mechanism. Soluble CLEC-2 measurement is more convenient than measurement of PF4 and betaTG, because soluble CLEC-2 can be measured using frequently used EDTA or sodium citrate plasma. CLEC-2 can be used as a useful biomarker for platelet activation *in vivo*.

PB 2.24-1

Differences in platelet microRNA profiles after aspirin use are associated with differences in whole blood aggregation and might identify aspirin resistance

Kok MG[1], Mandolini C[2], Nieuwland R[3], Creemers E[4], Meijers JC[5] and Pinto S-J[6]

[1]Academic Medical Center; [2]Department of Experimental Vascular Medicine, Academic Medical Center; [3]Department of Clinical Chemistry, Academic Medical Center; [4]Heart Failure Research Center, Academic Medical Center; [5]Academic Medical Center Amsterdam; [6]Department of Vascular Medicine, Academic Medical Center, Amsterdam, The Netherlands

Background: MicroRNAs have been established as markers for cardiovascular disease in many studies. However, most of the patients included in these studies were treated with aspirin for secondary prevention reasons. It is known, that there are individual differences in the response of platelets to aspirin. Whether the response of platelets to aspirin shows differences in miRNA expression is not know. We therefore, studied the influence of aspirin on microRNA expression levels, in isolated platelets of healthy volunteers. Additionally we analyzed, whether the *in vitro* response of platelets to indometacine, a surrogate for aspirin, in ADP-mediated whole blood aggregation was related to differences in miRNA profiles.

Methods and Results: We measured relative expression levels of platelet microRNAs using microarrays before and after 2 weeks of aspirin use (100 mg, once daily) in 15 healthy individuals (age 45–65 years). Based on aspirin-induced changes in microRNA profile, two subgroups could be distinguished: a group of individuals (n = 9) with similar and a group with different (n = 6) miRNA profiles before and after aspirin use. Additionally, we performed *in vitro* whole blood aggregation studies to determine whether the observed difference in microRNA profile before and after aspirin use, could be linked to platelet function. Whole blood from the same individuals, in the absence of aspirin, was tested using Multiplate® aggregometry and was incubated with indometacine to mimic aspirin use. The subjects with a similar microRNA profile had significantly reduced ADP-mediated aggregation as compared to the group in which the microRNA profile was different before and after medication.

Conclusion: Differences in platelet microRNA profiles after aspirin use are related to differences in ADP-mediated indometacine-treated whole blood aggregation. This could imply that differences in miRNA profiles might identify individuals with aspirin resistance.

PB 2.24-2

Next generation sequencing analysis of human platelet polyA+ mRNAs

Osman A, Lindahl T, Kissopoulou A and Jonasson J

University Hospital, Linköping, Sweden

Background: Platelets are small anucleate cells circulating in the blood vessels where they play *a key role in hemostasis and thrombosis*. Platelet gene expression has been investigated in the past mainly by mRNA quantification using microarray and qPCR techniques, and the results published thus far contain considerable disagreements in both the magnitude and the nature of the platelet transcriptome. Here we used next generation sequencing (RNA-seq) to characterize the profile of the polyadenylated (polyA+) mRNA in purified human blood platelets.

Results: We utilized the Illumina HiSeq 2000 platform to sequence cDNA converted from platelet polyA+ RNA. We detected 58,155,680 high-quality reads which were mapped against the set of chromosomes of the Human Feb. 2009 (GRCh37/hg19) assembly. We found 35,322,009 (60.7%) reads of ~100 bp long that could be uniquely mapped to the human genome. Analysis of this data generated a list of highly abundant platelet transcripts (> 10,000 reads) encoding annotated as well as novel genes. We identified high transcript levels for genes related to the cytoskeleton function, chemokine signalling, cell adhesion, aggregation, as well as receptor interaction between cells. Consistent with previous findings our data also suggests that nearly two-thirds of the platelet transcriptome comprise mitochondrial-expressed genes.

Conclusion: We report on the global architecture of platelet transcriptome and identify genes that may hold significant functions in platelets in addition to several novel transcripts, at single-base resolution. We conclude that platelet-expressed transcripts are well-defined but limited in number, presumably reflecting the lack of ongoing transcription in the anucleate platelets combined with selective degradation of those transcripts that are unnecessary for platelet function.

PB 2.24-3

Mass spectrometry analysis showed comparable releasates and phosphorylation profiles after PAR-1 or PAR-4 stimulation of platelets

Van Holten TC[1], Bleijerveld OB[1], Wijten P[2], De Groot PG[1], Heck AJR[2], Scholten A[2] and Roest M[1]

[1]UMC Utrecht; [2]University of Utrecht, Utrecht, The Netherlands

Background: Platelets play a crucial role in haemostasis and the regulation of inflammation, angiogenesis and atherogenesis. It has

been proposed that differential release profiles of pro- and anti-angiogenic factors in response to stimulation of the protease activated receptors (PAR)-1 and -4 is important for the regulation of angiogenesis. Such analyses have been performed only for a small number of granule proteins. Such phenomena could be better studied in the context of the entire releasate. In addition, if differential release indeed occurs, clues as to how differential release is regulated should be obtained.

Aims: To comprehensively analyze differences in the releasates and intra-cellular phosphorylation profiles of unstimulated, and PAR-1 and PAR-4 stimulated platelets.

Methods: Isolated platelets from three different donors were maximally stimulated with PAR-1 agonist, PAR-4 agonist, or left unstimulated. These were lysed and subjected to differential stable isotope labelling. For determining platelet releasate, isotope-labeled samples were subjected to 2-dimensional chromatography and LC-MS/MS analysis. PF-4, β-TG, PDGF-AB, RANTES and thrombospondin levels were measured in the platelet releasate from four different donors with ELISA. Global analysis of serine/threonine phosphorylation was performed with Western blots. A more detailed analysis of the platelet phosphoproteome occurring upon PAR-1 and PAR-4 stimulation was performed using differential stable isotope labeling of the PAR-1, PAR-4, and control samples followed by strong cation exchange chromatography based enrichment, and LC-MS/MS analysis.

Results: We measured the quantitative release of 93 proteins from platelets stimulated with PAR-1 and PAR-4. A strong correlation between the proteins released after either stimulus was observed (Spearman's r: 0.93, r^2: 0.86, $P < 0.0001$). Quantification of the released proteins after stimulation with PAR-1 or PAR-4 with ELISAs showed a comparable release for PF-4 (PAR-1: 103.7 ± SEM 2.7 ng/mL, PAR-4: 119.2 ± SEM 5.1 ng/mL; not significant), β-TG (PAR-1: 141.5 ± SEM 15.7 ng/mL, PAR-4: 107.0 ± SEM 0.8 ng/mL; not significant), PDGF-AB (PAR-1: 4.0 ± SEM 0.1 ng/mL, PAR-4: 4.9 ± 0.3 ng/mL; not significant), and RANTES (PAR-1: 32.8 ± SEM 3.7 ng/mL, PAR-4: 45 ± SEM 6.7 ng/mL; not significant). Release of thrombospondin was slightly reduced for PAR-1 induced release (7.2 ± SEM 0.3 μg/mL), compared with PAR-4 (9.8 ± SEM 6.7 μg/mL; $P < 0.05$). Downstream signal transduction measurements after stimulation with PAR-1 and PAR-4 agonist revealed similar phosphorylation patterns on Western blot. With quantitative mass spectrometry 244 phosphorylation events on 183 proteins were quantified upon PAR-1 and/or PAR-4 stimulation. A significant correlation between PAR-1 and PAR-4 phosphorylation quantity was observed (Spearman's r: 0.49, r^2: 0.24; $P < 0.0001$).

Conclusions: After proteomics we did not observe different release patterns for any of the 93 proteins analyzed. PAR-4 stimulation showed stronger release of granules that PAR-1 stimulation. The difference in thrombospondin is probably due to overall stronger activation of platelets by PAR-4. Furthermore, we did not detect differences in signal transduction downstream of PAR-1 and PAR-4

PB 2.24-4

Proteins' synthesis in platelets: the key role of platelet's receptors

Sirotkina OV[1], Laskovets A[2], Andoskin AP[1], Taraskina A[1] and Vavilova TV[2]

[1]B.P.Konstantinov Petersburg Nuclear Physics Institute; [2]North-Western State Medical University named after I.I Mechnikov, St-Petersburg, Russian Federation

Background: Although platelets lack a nucleus or genomic DNA, they are able to translate mRNA into proteins *de novo*. Megakaryocytes and their progeny, circulating anucleate platelets, retain a subset of pre-mRNAs and it is spliced into mature mRNA in response to cellular activation.

The Aim of Our Study: To analyze the platelet's receptors GP IIb-IIIa, GP VI, GP Ia-IIa, GP Iba, P2Y1, P2Y12, P2X1 including numbers on platelet's membrane and pre-mRNA and mRNA of their genes in resting and activated platelets.

Methods: cDNA prepared from total RNA isolated from platelets of 50 healthy donors, the level of mRNA was analyzed by RT-PCR using the TaqMan assay, the presence of pre-mRNA and mature mRNA was detected by PCR with primers specified to exon-exon junction or intron. The GP IIb, GP IIIa, GP Iba, GP VI, GP Ia and P2Y12 genes' polymorphism were determined by PCR-RFLP. The numbers of GP IIb-IIIa, GP Iba, GP VI, GP Ia-IIa and P2 platelet's receptors and IL-1beta were analyzed by flow cytometry with FITC labeled antibodies as mean fluorescence intensity. The platelet's activation was analyzed both by photometric method (ADP-induced aggregation) and by flow cytometry (P-selectin expression per platelet).

Results: We found Spearman correlation between the levels of pre-mRNA GP IIIa, GP IIb, GP Iba (R from 0.67 to 0.87, P from 0.02 to 0.0004). And the level of mature mRNA was higher in donors with high level of platelet aggregation (R from 0.31 to 0.52, P from 0.08 to 0.003). Genetic variants Leu33Pro GP IIIa, Ile843Ser GP IIb, G36T P2Y12 and Thr145Met GPIba didn't influence gene expression and level of mRNA. At the same time, in resting platelets from carriers of mutant allele C18T P2Y12 the level of mature mRNA was higher compared with non-carriers, who had pre-mRNA mainly ($R = 0.59$, $P = 0.04$). The numbers of GPIIb-IIIa, GPIba and P2Y12 on platelet's membrane didn't depend on the level of respective mRNA. Only the number of GP IIb-IIIa receptors on platelet correlated weakly with level of mRNA of GP IIb gene – $R = 0.4$ ($P < 0.1$). However, we found strong positive correlation between the level of mRNA GP IIIa and numbers of ADP-receptors P2Y1 ($R = 0.71$; $P = 0.008$) and P2Y12 ($R = 0.71$; $P = 0.009$). On the other hands, the level of mRNA P2Y12 correlated with numbers of GP IIb-IIIa on platelet's membrane – $R = 0.34$; $P = 0.09$. The correlation between numbers of receptor GP IIb-IIIa and receptor P2Y12 on platelet's membrane was detected too ($R = 0.55$, $P = 0.00002$). According to above mentioned we may conclude that synthesis of GP IIb-IIIa and P2Y12 proteins is interdependent on levels of transcription and translation. The numbers of GP IIb-IIIa, GP Iba, P2Y1, P2Y12, P2X1 and IL-1beta were changed in activated platelets (by 10 mkM ADP). Moreover, in activated platelets we observed transformation of GP IIIa, GP IIb, GP Iba pre-mRNAs into mature mRNAs. This process was inhibited by selective blocker of GP IIb-IIIa receptors.

Conclusion: the GP IIb-IIIa receptor may play a key role in regulation of proteins' synthesis in platelets *de novo*.

PB 2.24-5

Quantitative PCR of platelet specific mRNA reveals significant upregulation of TLR-2 in patients with non-ST elevation myocardial infarction

Albrecht M[1], Duerschmied D[1], Colberg C[1], Zirlik A[1], Peter K[2], Bode C[1] and Ahrens I[1]

[1]Heart Center Freiburg University, Freiburg, Germany; [2]Baker IDI Heart and Diabetes Institute, Melbourne, Vic., Australia

Background and Aim: Recent evidence highlights the importance of platelets as part of the innate immune system in the pathogenesis of atherosclerosis and its clinical sequelae the acute coronary syndrome. Platelets do express several functionally active immune receptors of the toll-like receptor (TLR) family including TLR-2, which has been linked to the development of atherosclerosis. Platelets are capable of de novo protein synthesis via platelet specific mRNA. We hypothesized that platelet TLR-2 is involved in the pathogenesis of atherosclerosis and its clinical sequelae myocardial infarction.

Methods: Highly purified platelets from patients with NSTEMI and patients without coronary artery disease (CAD) sampled after coronary angiography were used for extraction of platelet specific mRNA.

Analysis of human TLR-2 mRNA expression was done by plasmid-based quantitative real-time PCR with beta-actin as house-keeping gene. Soluble TLR-2, which may act as a decoy receptor, was assessed by ELISA in serum of patients with NSTEMI and non-CAD controls.
Results: Mean age of patients was 59.4 ± 2.9 (SEM) years. Mean platelet count was 236.1 ± 21.25 K/μL for NSTEMI patients (n = 13) and 227.4 ± 12.06 K/μL for non-CAD patients (n = 11, P = ns for patients vs. controls). NSTEMI patients included patients with 3-vessel (31%), 2-vessel (46%) and single vessel (23%) disease. Mean CK and CK-MB levels for patients with NSTEMI were 321.8 ± 108.9 and 76.33 ± 28.02 U/L respectively. Platelet TLR-2 mRNA was significantly elevated in NSTEMI patients (12.10 e-005 ± 2.391e-005 copies in relation to platelet beta-actin) vs. non-CAD controls (4.738e-005 ± 7.128e-006 copies in relation to platelet beta-actin, P = 0.012). Plasma soluble TLR-2 was not significantly different in patients with NSTEMI (0.38 ± 0.17 ng/μL) compared to non-CAD (0.52 ± 0.21 ng/μL, P = 0.679) patients.
Conclusion: We identified significantly elevated platelet TLR-2 mRNA expression in Patients with NSTEMI compared to non-CAD patients, which was not accompanied by increased serum soluble TLR-2. Up-regulation of TLR-2 mRNA in platelets indicates a crucial role of platelet mediated innate immunity in the pathogenesis of ACS. Further exploration of platelet TLR-2 function in atherosclerosis is warranted as platelet targeted anti-inflammatory therapies may represent a novel therapeutic approach in the preventive treatment of ACS.

PB 2.24-6
Regulatory role of proteasome in determination of platelet life span

Nayak MK, Kulkarni P and Dash D
Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Limit of platelet life span (8–10 days) is determined by the activity of a putative 'internal clock' composed of Bcl-2 family proteins, while role of other molecular players in this process remains obscure. Here, we sought to establish a central role of proteasome in platelet life span regulation.
Administration of mice with inhibitors of proteasome peptidase activity induced significant thrombocytopenia. This was associated with enhanced clearance of biotin-labeled platelets from circulation and reduction in average platelet half life from 66 to 37 h. Cells pretreated *in vitro* with proteasome inhibitors exhibited augmented annexin V binding and drop in mitochondrial transmembrane potential indicative of apoptotic cell death and decreased platelet life span. These cells were preferentially phagocytosed by monocyte-derived macrophages, thus linking proteasome activity with platelet survival. Decisive role of proteasome in this process was underscored from enhanced expression of conformationally active Bax in platelets with attenuated proteasome activity, which was consistent with pro-apoptotic phenotype of these cells. The present study establishes a critical role of proteasome in delimiting platelet life span ostensibly through constitutive elimination of the conformationally active Bax. These findings bear potential implications in clinical settings where proteasome peptidase activities are therapeutically targeted.

PB2.25 – Platelet Disorders: Screening

PB 2.25-1
Evaluation of the diagnostic potential of a whole blood remote assay in assessment of platelet function in bleeding disorders

Dovlatova N[1], Lordkipanidzé M[2], Lowe GC[2], May J[1], Heptinstall S[1], Fox SC[1] and Watson SP[2]
[1]*University of Nottingham, Nottingham;* [2]*University of Birmingham, Birmingham, UK*

Background: Platelet function tests are widely used to diagnose inherited platelet function disorders. Light transmission aggregometry (LTA) is still regarded as the gold standard, however it is time consuming, requires a considerable volume of blood and samples must be processed within a finite time period after venepuncture. Among patients with excessive bleeding and suspected platelet dysfunction only around 60% are found to have an abnormality in platelet responses with lumi-aggregometry, implying that the remaining 40% may have defects in other parts of the haemostatic pathway (Dawood et al, Blood 2012; 120(25):5041–5049). We have developed an assay for platelet function where fresh whole blood samples are manipulated in a simple way that does not require specialized staff or equipment. The samples are then fixed, which stabilizes them for up to 9 days, and can be shipped for analysis to a central laboratory.
Aim: To assess the diagnostic potential of remote platelet function testing (RPFT) in the diagnosis of platelet function defects in patients with excessive bleeding.
Methods: Participants were recruited to the Genotyping and Phenotyping of Platelets study (GAPP, ISRCTN 77951167) from April 2012 to January 2013. This study was approved by the National Research Ethics Service Committee and all participants signed informed consent. Platelet function was assessed in 55 patients who had a history of excessive bleeding, and in 44 healthy volunteers using RPFT and lumi-aggregometry used as the reference method. For RPFT, blood was stimulated with the combinations of ADP (10 μM)/U46619 (1 μM) and arachidonic acid (0.5 mM)/epinephrine (100 μM), with TRAP (20 μM) alone and vehicle. Following stimulation blood samples were stabilized with a patented fixative solution (Platelet Solutions, Nottingham) and the expression of P-selectin and CD63 was measured by flow cytometry.
Results: Reference ranges for all measured parameters were set as mean ± 2SD obtained from healthy volunteers. Overall agreement between lumi-aggregometry and RPFT was good, with the diagnosis of a platelet function defect matching in 80% of cases (κ = 0.602, P < 0.0001). In 26 patients, platelet function appeared normal using lumi-aggregometry and RPFT. Twenty-eight patients were identified as having a platelet defect with lumi-aggregometry and 18 of these were also detected by RPFT. The majority of patients who had an abnormal pattern of response on lumi-aggregometry but not on RPFT had a mild platelet function defect based on dynamic kinetic information from lumi-aggregometry. In one further patient with a normal pattern of response in lumi-aggregometry, an isolated defect in alpha granule secretion (P-selectin) was detected using RPFT, whereas dense granule secretion was normal by both lumi-aggregometry and RPFT (CD63).
Conclusion: Our observations suggest that remote platelet function testing may be useful as an easy to use pre-test to select which patients with bleeding disorders would benefit from further extensive platelet phenotyping. This assay can be performed remotely and requires a small volume of blood, both of which offer significant advantages over lumi-aggregometry. Expression of glycoprotein receptors and immunologic platelet count can also be assessed in the fixed samples for RPFT and further evaluation of the test in patients with thrombocytopenia is warranted.

PB 2.25-2

Investigation of the utility of the ISTH bleeding assessment tool (BAT) in predicting platelet defects in participants with clinically diagnosed bleeding disorders

Lowe GC, Lordkipanidzé M and Watson SP
Birmingham Platelet Group, Birmingham, UK

Background: The ISTH/SSC Bleeding Assessment Tool (BAT) was developed as a tool to accurately record bleeding symptoms and to aid diagnosis in patients referred with a possible bleeding disorder. It is also a valuable research tool in studies that examine patients with excessive bleeding, allowing documentation of the severity of their bleeding. However, it has not been validated in patients with suspected inherited platelet function disorders.
Aims: To investigate the utility of the ISTH BAT in predicting platelet defects in participants with clinically diagnosed bleeding disorders.
Methods: Participants with clinically diagnosed excessive bleeding and healthy volunteers were recruited to the Genotyping and Phenotyping of Platelets study (GAPP, ISRCTN 77951167) from October 2011 to December 2012 from UK Comprehensive Care Haemophilia Centres. The study aimed to determine whether these patients had underlying platelet function defects and what the prevalence of these defects were in this patient group. The ISTH BAT was carried out in all participants by experienced personnel. Platelet function testing was carried out by light transmission aggregometry alongside measurement of ATP secretion. The bleeding assessment scores were compiled at entry to the study and therefore blinded to the platelet function testing results. This study was approved by the National Research Ethics Service Committee and all participants gave written informed consent.
Results: One hundred participants were included ($n = 79$ with suspected platelet function defects and $n = 21$ healthy volunteers). A platelet defect was found on platelet function testing in 56% of participants with bleeding symptoms (44% had no demonstrable platelet defect, 20% had a Gi-type defect, 18% had a dense granule secretion defect, 8% had a defect in the thromboxane pathway and 10% had a complex phenotype). The score obtained through the ISTH BAT in participants with suspected platelet function defects (12; IQR 8–16) was significantly higher than in healthy volunteers (0; IQR 0–0) ($P < 0.001$), thus confirming the clinical diagnosis of a bleeding disorder. There was no significant difference between participants in whom a platelet defect was detected by platelet function testing (11; IQR 8–16) and in whom platelet function was deemed normal (12; IQR 9–14) ($P > 0.05$). There was no association between the type of platelet defect detected and the ISTH BAT score. A ROC curve analysis was carried out to evaluate whether the ISTH BAT could discriminate between patients with and without a demonstrable platelet defect on platelet function testing. The area under the curve was 0.513 (95% CI 0.383–0.642, $P = 0.85$) thus demonstrating a lack of discriminative ability. Moreover, the ISTH BAT score was not associated with a demonstrable platelet defect on platelet function testing in a simple logistic regression model (OR 0.997 [95% CI 0.92–1.08], $P = 0.95$).
Summary/Conclusions: The ISTH Bleeding Assessment Tool is a useful tool in assessing and recording recurrent mild bleeding symptoms and appropriately documents the lifelong bleeding history. However, the score obtained is not predictive of the presence of a platelet defect on platelet function testing.

PB 2.25-3

Five year report of a multicenter project for characterization of inherited platelet disorders (IPD) in the Iberian Peninsula. Diagnosis of 23 severe IPD and identification of 14 new genetic variants

Sánchez Guiu I[1], Antón AI[1], Padilla J[1], González-Manchón C[2], Vicente V[1], Lozano ML[1] and Rivera J[1]
[1]*Centro Regional de Hemodonación, Hospital Universitario Morales Meseguer, Murcia;* [2]*Departamento de Medicina Celular y Molecula, Madrid, Spain*

Background: Inherited platelet disorders (IPDs) comprise a heterogeneous group of uncommon diseases characterized by abnormalities of platelet function/production giving rise to lifelong bleeding diathesis of variable intensity. Notwithstanding a century of research on IPDs, early identification and characterization of affected patients remain a challenge due to: heterogeneity of clinical and laboratory presentation; lack of specificity and complexity of platelet function assays; large number of causative genes; and absence of genotype-phenotype correlations. Multicentre projects on IPDs, consensus guides for diagnosis, and reference centers networks, could help to overcome this challenge.
Objective: To assist and to encourage the characterization of IPD patients in the Iberian Peninsula, we set up a project, under the scientific sponsorship of the Spanish Society of Thrombosis and Haemostasis.
Methods: In 5 years, around seventy unrelated patients with suspected IPD were referred from hospitals of twenty cities of Spain and Portugal. Clinical features were assessed by their hematological and bleeding manifestations graded by a unique simple scale. We received blood samples and performed a platelet phenotype characterization including: full blood count and film examination; PFA-100 tests; light transmission aggregation (LTA) with distinct agonists (mostly: arachidonic acid, ADP, epinephrine, TRAP, ristocetin, and collagen); flow cytometry (FC) assessment of surface receptors (Ib/IX/V, IIb/IIIa, Ia/IIa), activation status and granule secretion (PAC-1, CD62, CD63); and in some cases vWF binding, clot retraction assay, ^{14}C-serotonin uptake/release, and electron microscopy. A patient's parallel control and a healthy volunteer freshly extracted were always studied in parallel. DNA and RNA were extracted from peripheral blood. If laboratory results guided diagnosis of a particular IPD, candidate causative genes were chosen for PCR amplification and sequencing.
Results: Variable degree of platelet dysfunction, not attributable to acquired factors, was confirmed in most patients. In about one third of them, laboratory findings suggested defective platelet secretion or signalling of unknown aetiology. Platelet function testing (PFT) and molecular studies confirmed diagnosis of severe IPD as follows: Glanzmann Thrombastenia (GT) in 12 out of 18 suspected cases; Bernard-Soulier Syndrome (BSS) in eight out of 12; Hermansky-Pudlak syndrome (HPS) in one out of three; and Chediak-Higashi Syndrome (CHS) in the two suspected cases. Among these, we found eight novel molecular variants of GT: three in *ITGB3* [c.773–774delTG, c.647A/G (p.Tyr190Cys), c.431T/G (p.Met118Arg)]; and five in *ITGA2B* [c.1644G/T (p.Glu507STOP), c.2637delC, c.2964delG, g.9860–9862delAT, c.2473_2481del insTCACCTGGTC]. We identified three new mutations causing BSS: c.259T/C in *GP9* [p.Trp71Arg], 268 C/T [p.Pro90Ser] in *GPIBB*, and a rare heterozygous 358–366del9pb [p.Gln90_Leu92del] in *GPIBA*. Lastly, we recognised two new mutations in *LYST*, c.11362 G>A [p.Gly3725Arg] and c.961T>C, [p.Cys258Arg], in patients presenting with 'severe accelerated phase' and 'mild' forms of CHS, and a novel HPS type-1 caused by c.844G>T [p.Glu204Stop] change in *HPS1*. One suspicion of platelet-type-vWD and two of MYH9 were not confirmed.
Summary: This work illustrates the feasibility and usefulness of multicenter projects at international level to assist biological and molecular characterization of IPDs. Clinical suspicion of severe IPD was confirmed by both PFT and genetic studies in 23 (60%) out of 38 patients, among which 14 represent novel molecular variants.

PB 2.25-4

Storage pool disorder: a continuous whole blood flow cytometric method for the measurement of platelet calcium flux using an Accuri C6 cytometer

Pickering WM[1], Riddell A[2], Gomez K[2] and Chowdary P[2]

[1]*Novo Nordisk A/S, Måløv, Denmark;* [2]*Royal Free Hospital, London, UK*

Background: Storage Pool Disorder (SPD) results from abnormalities in the secretory mechanism or from deficiencies of platelet specific granules. Platelet dense granules are intracellular storage sites for calcium (Ca^{2+}), ADP, ATP, pyrophosphate and serotonin. The laboratory diagnosis of SPD is normally based upon abnormal platelet aggregation and demonstration of platelet nucleotide deficiencies. Other specialised investigations include the analysis of dense granule contents (serotonin, Ca^{2+}), flow-cytometry of mepacrine-treated platelets and electron microscopy of ultrastructure. A problem with measuring Ca^{2+} flux by flow-cytometry is that most analysers use a closed sampling system making analysis non-continuous.

Aim: The Accuri C6 Cytometer operates using an open fluid system. This allows the continuous recording of dynamic Ca^{2+} measurement after the addition of agonists. To validate the system and investigate its utility in the diagnosis of SPD, platelets in whole blood were exposed to different agonists and calcium modifying agents: ADP, Bovine Thrombin, Thrombin receptor-activating peptide (TRAP), U46619 (thromboxane receptor agonist), Calcium Ionophore (A23187) and EGTA a Ca^{2+} chelating agent.

Method: Citrated whole blood was diluted 1:10 using Ca^{2+}free Tyrode's buffer and loaded with an equal volume of 5 mM Fluo-4 (a Fluo calcium indicator) at 37 °C for 30 min. Cells (100 μL) were then stained with $CD41^{FITC}$ and $CD62^{PE}$ to identify the platelet population and to detect activated samples. Cells were resuspended in 4 mL Ca^{2+}free Tyrode's buffer. Ca^{2+} fluorescence was detected through the 585/40 band pass filter and collected in FL1-A. Fluorescence levels were recorded for 2 min at baseline and then a further 2 min following the addition of 5 or 10 μM ADP or other agonists. The difference between baseline and post agonist peak fluorescence was Ca^{2+} indicative of flux.

Results: Platelet Ca^{2+} flux was investigated in two groups: (i) Normal aggregation trace and normal nucleotide ADP (0.22–0.59 pmoles/10^9 platelets), $n = 12$ (ii) Abnormal aggregation trace and low nucleotide ADP and clinical features of a bleeding disorder, $n = 5$. The results are expressed as a ratio ± 2SD (Peak fluorescence induced by agonist/Baseline fluorescence) and compared using the t-test. Normal platelets responded in a dose-dependent manner to ADP (2 – 100 μM). The difference between the two groups was significant ($P < 0.05$ and $P < 0.005$) using 5 and 10 μM ADP, 1.86 ± 1.15 verses 1.10 ± 0.04 and 2.48 ± 1.41 verses 1.13 ± 0.05, respectively. Suggesting that 10 μM ADP is the concentration that discriminates SPD best. In both groups 10 mM EGTA totally inhibited Ca^{2+} release, 0.99 ± 0.08 and 1.00 ± 0.05, respectively. TRAP (500 μM) produced an impaired Ca^{2+} flux response in the SPD group, 1.23 ± 0.14 verses 2.66 ± 1.46, respectively ($P < 0.005$). In normal platelets Ca^{2+} flux could be induced by bovine thrombin (1 IU/mL), U46619 (10 μM) and A23187 (10 μM).

Conclusion: The Accuri C6 allows the continuous monitoring of Ca^{2+}flux in platelets and has utility in the diagnosis of dense granule SPD. Because of the heterogeneity of SPD further evaluation of this method is ongoing.

PB 2.25-5

Prevalence of disease and relationships between laboratory phenotype and bleeding severity in platelet primary secretion defects

[1]*Angelo Bianchi Bonomi Hemophilia and Thrombosis Center;* [2]*Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy*

Background: The prevalence of platelet primary secretion defects (PSD) among patients with bleeding diathesis is unknown. Moreover, there is paucity of data on the determinants of bleeding severity in PSD patients.

Aims: To determine the prevalence of PSD in patients with clinical bleeding and to study the relationships between the type of platelet defect and bleeding severity.

Methods: Data on patients referred for bleeding to the Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan (Italy) in the years between 2008 and 2012 were retrieved to study the prevalence of PSD. Demographic, clinical and laboratory information on 32 patients with a diagnosis of PSD was used to compare patients with or without associated medical conditions and to investigate whether or not the type and extension of platelet defects were associated with the bleeding severity score (BSS; crude and age-normalized) or with the age at first bleeding requiring medical attention.

Results: The estimated prevalence of PSD among 207 patients with bleeding diathesis and bleeding severity score above 4 was 18.8% (95% confidence interval [CI]: 14.1–24.7%). Patients without associated medical conditions had earlier age of first bleeding (18 vs. 45 years; difference: −27 years; 95% CI: −46 to −9 years) and different platelet functional defect patterns (Fisher's exact test of the distribution of patterns, $P = 0.007$) than patients with accompanying medical conditions. The number of agonists eliciting reduced secretion was not associated with BSS, age-normalized BSS or age at first bleeding requiring medical attention at linear regression analysis (BSS, beta: −0.4; 95%CI: −2.0 to 1.3; $P = 0.675$; age-normalized BSS, beta: −0.05; 95%CI: −0.19 to 0.09; $P = 0.442$; age at first bleeding requiring medical attention, beta: 5.8; 95%CI: −2.1 to 13.8; $P = 0.144$). The median values of the different proxies of bleeding severity were not different across patterns of platelet defect (pattern type vs. BSS, $P = 0.635$; pattern vs. age-normalized BSS, $P = 0.301$; pattern vs. age at first bleeding requiring medical attention, $P = 0.277$; all P-values calculated by Kruskal–Wallis test).

Summary/Conclusions: PSD is found in approximately one fifth of patients with clinical bleeding. PSD patients display mild to moderate bleeding tendency, the severity of which is largely unrelated to the type and extension of laboratory defect.

PB 2.25-6

Lumi-aggregation is useful for better defining platelet function defects in response to weak agonists

Peerschke E[1] and Dembitzer FR[2]

[1]*Memorial Sloan-Kettering Cancer Center;* [2]*Mount Sinai School of Medicine, New York, NY, USA*

Background: Platelet function studies are important for the diagnosis of patients with disorders of primary hemostasis. The diagnostic interpretation of platelet aggregation in response to weak agonists is often problematic, and it is uncertain if an evaluation of platelet dense granule secretion is useful in this regard.

Aims: To evaluate whether measurement of platelet dense granule ATP secretion by lumi-aggregation (Chrono-Log Corp., Havertown, PA) would clarify platelet aggregation defects in response to weak agonists (4 μM ADP, 100 μM epinephrine, 1.6 mM arachidonic acid), especially when the response to only one of these agonists is abnormal.

Methods: Platelet function studies (n = 146) in non thrombocytopenic patients with bleeding histories, who were referred for hemostasis consultation, were reviewed retrospectively. All patients were thought to have mild bleeding disorders by their consulting hematologist. Results from platelet aggregation and secretion studies in response to weak agonists were compared in 119 adults (29 male, 90 female, ages 21–85 years) and 27 children (13 male, 14 female, ages 7 months–18 years). Repeat testing was performed on 19 patients within 8 days to 11 months of the initial platelet function study, including seven studies ordered for confirmation of an isolated platelet function defect in response to a single agonist.
Results: Concordant aggregation and secretion findings were confirmed in 125/146 cases, including 25 (17%) that were classified as normal. Isolated abnormal aggregation in response to a single agonist was identified in 35/146 (24%) cases: 27 (77%) abnormal responses to ADP alone, 7 (20%) abnormal responses only to epinephrine, and 1 (3%) abnormal response to arachidonic acid alone. Both abnormal platelet aggregation and secretion in response to the same single agonist were demonstrated in 14/35 (40%) cases. In the remaining 21/35 (60%) cases, which comprised all of the platelet function studies with discordant platelet aggregation and secretion findings, abnormal platelet aggregation with normal dense granule secretion was observed in 5/21 (24%) cases, and secretion defects in response to multiple agonists were documented in 16/21 (76%) cases. Repeat analysis confirmed the original platelet function abnormality in six of 7 (86%) of the original 14/35 cases with isolated abnormal platelet aggregation in response to a single agonist, when concomitant abnormal secretion was present. Clinicians did not repeat platelet function testing on patients with isolated abnormal platelet aggregation in response to a single agonist when secretion studies were normal. Similar findings were obtained in a subanalysis of results from pediatric patients.
Conclusion: Platelet dense granule secretion measured by lumi-aggregation is useful for better defining platelet function defects in response weak agonists, ADP, epinephrine, and arachidonic acid, especially when an isolated aggregation defect in response to a single agonist is noted. In our case series, nearly one quarter of aggregation studies performed resulted in inconclusive findings (abnormal aggregation in response to a single weak agonist). In 60% of these cases, lumi-aggregation allowed discrimination between normal and abnormal platelet function.

PB2.26 – Platelet Procoagulant Activity

PB 2.26-1

Targeting platelet GPIbβ decreases GPIb-dependent signaling, platelet procoagulant activity and arterial thrombosis

Maurer E, Schaff M, Bourdon C, Receveur N, Ravanat C, Hechler B, Gachet C, Lanza F and Mangin PH
UMR_S949, Inserm, Université de Strasbourg, EFS-Alsace, Strasbourg, France

Background: The GPIb-V-IX complex regulates the adhesion, activation and procoagulant activity of platelets. We previously reported that RAM.1, a rat monoclonal antibody directed against the extracellular domain of mouse GPIbβ, diminished adhesion of platelets and CHO cells transfected with the human GPIb-IX complex to von Willebrand factor under flow conditions.
Aims: The aim of the study was to evaluate the functional importance of GPIbβ by studying the impact of RAM.1 on GPIb-mediated platelet responses and *in vitro* and *in vivo* thrombus formation.
Methods: GPIb-dependent signaling was monitored on the ability to extend filopodia and by measuring intraplatelet Ca^{2+} variations after adhesion of platelets or GPIb-IX transfected CHO cells to immobilized von Willebrand factor under static conditions. Procoagulant activity was measured with the Calibrated Automated Thrombin Generation method. PS exposure was determined by Annexin-V binding using flow cytometry. *In vitro* thrombus formation was assessed following perfusion of hirudinated blood over a collagen matrix. Thrombus formation was also evaluated in two *in vivo* models, after a laser-injury of mesenteric arteries and a forceps-injury of the aorta. Hemostasis was evaluated using a tail bleeding assay.
Results: RAM.1 dramatically reduced GPIb-mediated filopodia extension of murine platelets and CHO GPIb-IX cells and inhibited GPIb-mediated Ca^{2+} signaling of murine platelets after adhesion to von Willebrand factor. RAM.1 inhibited thrombin generation triggered by tissue factor or collagen in platelet-rich plasma, but interestingly did not impair phosphatidylserine exposure in response to strong agonists such as thrombin, CRP and A23187. In addition, RAM.1 reduced thrombus formation after perfusion of mouse whole blood over collagen in a shear-dependent manner. This effect was also observed *in vivo*, since injection of RAM.1 F(ab)'2 diminished thrombus formation induced by laser beam injury of mesenteric arterioles and forceps injury of the abdominal aorta. In contrast, RAM.1 F(ab)'2 did not increase the tail bleeding time and the volume of blood lost.
Conclusions: These findings provide new evidence that targeting a subunit other than GPIbα can lead to an antithrombotic effect via the GPIb-V-IX complex. This could represent an alternative way to reduce thrombus formation without impairing hemostasis.

PB 2.26-2

Aggregation of PS exposing platelets and activated (non-PS exposing) platelets

Choo H and Jobe S
Emory University and Children's Healthcare of Atlanta, Atlanta, GA, USA

Background: A common feature of platelets with high levels of PS exposure, whether initiated by agonist or ABT-737 mediated pathways, is a loss of mitochondrial membrane potential. Recently a novel form of PS exposing platelets with intact mitochondrial membrane potential and active integrin $\alpha_{IIb}\beta_3$ was described by Topalov et al (ATVB, 2012). Formation of this novel procoagulant platelet ($PS^{\Delta\psi m+}$) was promoted by an increased platelet concentration or shaking and mediated by integrin $\alpha_{IIb}\beta_3$.
Aims: To investigate the molecular mechanisms responsible for formation of the novel PS exposing platelet subpopulation in human and murine models.
Methods: Platelet activation and mitochondrial membrane potential were evaluated by flow cytometry. To assess platelet aggregation, separated platelets (1×10^8 cells/mL) were labeled with either Cell tracker green or violet. The labeled platelets were washed twice, and then incubated with TMRM for evaluating loss of $\Delta\psi_m$. The separate populations were mixed, stimulated for 15 min with thrombin, labeled with APC-annexin V and/or PE-JON/A, and evaluated either by standard flow cytometry or ImagestreamX[TRADEMARK]. ImagestreamX [TRADEMARK] images were analyzed with IDEAS[TRADEMARK] software.
Results: As reported by Topalov et al stimulation of either human or murine platelets with 100 nM thrombin resulted in a concentration-dependent increase of a PS exposing platelet subpopulation with intact mitochondrial membrane potential, low levels of intracellular calcium, and integrin $a_{IIb}b_3$ activation ($PS^{\Delta\psi m+}$). Absence of Bax/Bak did not affect $PS^{\Delta\psi m+}$ platelet formation. Somewhat surprisingly, absence of cyclophilin D (CypD) markedly decreased $PS^{\Delta\psi m+}$ platelet formation, despite CypD's known role in mediating mitochondrial permeability transition pore formation and $\Delta\psi_m$ loss.
A feature of the $PS^{\Delta\psi m+}$ platelet subpopulation was its characteristic high side scatter and forward scatter within the activated platelet subpopulation. This phenomenon suggested the possibility that $PS^{\Delta\psi m+}$ platelets might represent an aggregate. Cell tracker green or violet (CTG or CTV)-labeled platelets were examined after thrombin stimu-

lation. Evaluation of the PS $^{\Delta\psi m+}$ platelet subpopulation revealed its close correspondence with a CTG^+/CTV^+ platelet subpopulation. ImageStreamX[TRADEMARK] was used to directly visualize the $PS^{\Delta\psi m+}$ platelet subpopulation. This visual evaluation by high resolution microscopy revealed that almost the entirety of the $PS^{\Delta\psi m+}$ platelet subpopulation consisted of a platelet aggregate of an annexin V^+, JON/A^-, $\Delta\psi m^-$ platelet and an annexin V^-, JON/A^+, $\Delta\psi m^+$ platelet, thus lending the $PS^{\Delta\psi m+}$ subpopulation its fluorescence characteristics.

Conclusions: Formation of the $PS^{\Delta\psi m+}$ platelet subpopulation is dependent on the mitochondrial protein CypD. However, ImageStreamX[TRADEMARK] and population labeling experiments suggest that the $PS^{\Delta\psi m+}$ platelet subpopulation may represent a misleading result of heterogenously aggregated platelets, thus explaining this platelet subpopulation's fluorescence characteristics, concentration and integrin $\alpha_{IIb}\beta_3$ dependence, and regulation by CypD.

PB 2.26-3
Signalling via CLEC-2 generates a procoagulant response in human platelets

Alsahli MA[1], Appleby J[1], Pollitt AY[2], Turnbull E[1], Hughes CE[2], Hamali HA[3], Watson SP[2] and Goodall AH[1]

[1]University of Leicester, Leicester; [2]University of Birmingham, Birmingham, UK; [3]King Khalid University, Abha, Saudi Arabia

Background: The C-type lectin receptor CLEC-2 is a recently described platelet receptor that plays important roles in platelet cross talk and in development. It has also been shown to play a crucial role in thrombus stability. A natural ligand for CLEC-2 is podoplanin which is expressed on lymphatic endothelial cells, where it plays a role in vascular development, and on inflammatory macrophages, where it can activate platelets via CLEC-2. CLEC-2 can also be activated by the snake venom, rhodocytin. CLEC-2 signalling results in Src and Syk-dependent tyrosine kinase signalling and activation of PLCγ2 via a single YxxL hemITAM sequence. The downstream signalling pathway through CLEC-2 resembles signalling through another tyrosine kinase, ITAM-signalling receptor, the collagen GPVI/FcγR receptor complex, which is the major receptor that, on its own, is capable of generating a procoagulant response in platelets.

Aim: We sought to determine whether signalling through CLEC-2 is also capable of generating a procoagulant response in human platelets.

Methods: Platelets from healthy consenting donors were stimulated with either rhodocytin or podoplanin, and analyzed by flow cytometry for markers of a procoagulant response (Annexin V binding) and degranulation (P-selectin). Procoagulant phospholipid (PPL) activity was measured by the Calibrated Automated Thrombogram (CAT) assay using 1 pM TF reagent to trigger thrombin generation, and using peak thrombin (PT) as a measure for PPL activity.

Results: Rhodocytin induced Annexin V binding in a subset of 24 $\pm$ 4.9% of platelets (n = 5) accompanied by the release of Annexin V^{+ve} microparticles, with a maximum effect at 30 nM. At the same dose P-selectin was expressed on the majority (81 $\pm$ 4.9%) of the platelets (n = 5). These levels were similar to those induced by the GPVI-specific collagen-mimetic peptide CRP-XL. Addition of ADP, thrombin, U-46619 and CRP-XL showed synergism with rhodocytin resulting in a 1.47, 3.10, 1.81 and 2.52, fold increase in the percentage of Annexin V positive platelets respectively (P = 0.0003). The platelet procoagulant response to rhodocytin was inhibited by 37% with aspirin (P = 0.0337; n = 5) and was enhanced 1.61 $\pm$ 0.07 fold by platelet-platelet aggregation by (P = 0.0019; n = 7). Mouse podoplanin (20 μg/mL) also generated platelet Annexin V binding in 26 $\pm$ 3.1% of platelets (n = 6). In addition, 41 $\pm$ 12.4% of platelets became Annexin V positive (n = 3) when incubated with human podoplanin-expressing CHO cells. Both mouse podoplanin and human podoplanin-expressing CHO cells induced platelet microparticle generation. Rhodocytin-activated platelets showed significant PPL activity in the CAT assay with PT of 356 $\pm$ 2 compared to control samples 172 $\pm$ 6 (P = 0.0019; n = 3). Additionally, platelet-derived microparticles generated either by rhodocytin or human podoplanin-expressing CHO cells showed significant increase in PT with 88 $\pm$ 1 and 121 $\pm$ 4 compared to 17 $\pm$ 1 and 33 $\pm$ 5 respectively in control samples (P = 0.0003 and 0.0024 respectively; n = 3). Immunofluorescence studies showed that platelets bound to podoplanin-expressing CHO cells and expressed a procoagulant surface and P-selectin.

Conclusion: Signalling in platelets via CLEC-2 induces a procoagulant response in platelets and the generation of procoagulant microparticles. The response of platelets to CLEC-2 resembles signalling through GPVI. These data suggest novel findings of a procoagulant role for CLEC-2 in human platelets.

PB 2.26-4
Evidence for necrotic platelets in collagen dependent thrombus formation *in vivo*

Hua M, Hogg PJ and Chen VM

Lowy Cancer Research Centre, University of New South Wales, Sydney, NSW, Australia

Background and Aims: Platelets display heterogeneity in response to agonist stimulation with regards morphology and surface characteristics. Activation by strong agonists ex-vivo results in a phosphatidylserine expressing, highly procoagulant platelet subpopulation that has recently been proposed to be necrotic. It has been difficult to track the contribution of the 'necrotic' population to thrombus formation due to an overlap between markers of activation and necrosis, thus the functional relevance of these platelets is uncertain. Fluorescent tagged small trivalent arsenical (4-(N-(S-glutathionylacetyl) amino) phenylarsonous acid) named 'tagged-GSAO' is known to label late apoptotic and necrotic nucleated cells via covalent bonding with closely spaced di-thiol proteins in the cytoplasm. Here we aim to investigate tagged-GSAO as a potential marker of activated, 'necrotic' platelets after agonist stimulation and to determine if we could use this marker to explore the contribution of necrotic platelets to thrombus formation *in vivo*.

Methods and Results: Flow cytometry analysis of washed human platelets stimulated with dual agonists, collagen 5 μg/mL and thrombin 1 U/mL generated a subpopulation of P-selectin positive platelets that co-labelled with tagged-GSAO compared to its control, tagged-GSCA. This subpopulation is characterised by high annexin-V staining and a spectrum of calcein retention suggesting it encompasses platelets in the process of losing viability. Pre-incubation with control vs. pancaspase inhibitor did not affect this GSAO+ve population (74.1% vs. 74.5%) suggesting a caspase independent pathway. The GSAO+ve population was collagen dependent. Thrombin alone at doses up to 10 U/mL generated a minor GSAO+ve population compared with control (2.5 $\pm$ 1.2% vs. 0.2 $\pm$ 0.3%, P = 0.03), however collagen 5 μg/mL resulted in a significant increase in GSAO+ve platelets (0.2 $\pm$ 0.3% vs. 33 $\pm$ 5.7%, P = 0.0015). Dual stimulation increased this subpopulation of platelets further (33 $\pm$ 5.7% vs. 49.03 $\pm$ 16%, P = 0.0002). Generation of GSAO+ve platelets was dependent on exogenous calcium (20.42 $\pm$ 0.25% vs. 49.52 $\pm$ 0.34%, P = 0.0002). Treatment with calcium ionophore resulted in > 90% GSAO+ve platelets with high annexin- V binding. This data supports the concept that these platelets are necrotic.

To determine if tagged-GSAO compound could be used to track this platelet sub-population during thrombus formation *in-vivo*, we demonstrated that tagged-GSAO did not affect *in-vitro* platelet aggregation or coagulation studies. To assess the contribution of necrotic platelets *in-vivo*, we used confocal intra-vital microscopy to compare two mouse models of thrombosis: laser injury (thrombin dependent) and ferric chloride (collagen and thrombin dependent). We used platelet marker anti-CD42b-dylight 649 and tagged GSAO. Rhodamine-2 was used to monitor platelet calcium response. The laser injury model of thrombosis showed no co-localisation of tagged-GSAO and platelets in the first

3 min of thrombus formation, consistent with our thrombin alone *in-vitro* data. This is in contrast to the ferric chloride model, where platelet aggregates co-labelled with tagged-GSAO indicating a potentially necrotic platelet clot. GSAO+ve platelet aggregates were also Rhodamine-2 positive indicating prolonged high calcium state. The non-aggregatory platelets did not label with GSAO and were Rhodamine-2 negative.

Conclusion: Tagged-GSAO labels a platelet subpopulation likely undergoing necrosis. These platelets are seen to play a role in collagen dependent thrombosis, but not in early thrombin mediated aggregation *in-vivo*.

PB 2.26-5

Quantification of the platelet channelome in ultra-purified human platelet samples highlights the high expression level of TMEM16F

Wright JR[1], Amisten S[2], Goodall AH[1] and Mahaut-Smith MP[1]

[1]University of Leicester, Leicester; [2]King's College, London, London, UK

Ion channels play crucial roles in many aspects of cellular function. Approximately twenty ion channels have already been reported in platelets and/or megakaryocytes, although for many their relative expression and importance remains unclear. The human genome encodes more than 400 proteins that form or regulate functional ion channels, therefore platelets are likely to express additional ion channel proteins with as yet unidentified roles. We recently demonstrated that quantitative-PCR was a key tool in identifying Kv1.3 (KCNA3) as the sole K^+ channel responsible for one of the largest ionic conductances of platelets and megakaryocytes. Nevertheless, quantification of the platelet channelome using quantitative-PCR raises two main challenges; ion channels need only be present at small levels to regulate function, and platelets contain lower levels of mRNA than other blood cells.

We aimed to further develop our methodology to isolate ultrapure platelet mRNA, for use in assessing the platelet channelome using quantitative-PCR.

Platelet rich plasma (PRP) from healthy consenting donors was prepared from Acid-Citrate-Dextrose-anti-coagulated whole blood. Platelet activation was further inhibited with 2 mM EDTA, 0.1 μM PGE_1 and 0.3 μM acetylsalicylic acid and only the upper portion of PRP isolated. A series of immunomagnetic depletion steps removed leukocytes and platelet-leukocyte complexes using CD45, and erythrocytes using CD235a. Platelets were positively selected using CD42b-tagged magnetic beads, then washed and lysed for isolation of mRNA. Following reverse transcription, platelet cDNA was analysed by quantitative-PCR using 400 in-house-validated QuantiTect primer assays (Qiagen) for ion channel or channel regulatory genes (the 'channelome'). Expression levels were normalised to GAPDH.

All platelet cDNA samples were screened for expression of platelet, erythrocyte and leukocyte markers. No sample was positive for CD235a, and any that showed trace CD45 levels were discarded. The top 33 most abundantly expressed channelome transcripts included 10 channels previously reported in platelets. Of note, by far the most abundantly expressed was TMEM16F (2.685 ± 0.847 relative to GAPDH). Originally described in platelets as an anion channel (Suzuki et al, 2010, Nature, 468, 834), a recent study suggests this is a Ca^{2+}-permeable cation channel (Yang et al, 2012, Cell 151, 111). The order of expression of other known channelome genes was P2RX1 (0.529 ± 0.269) > KCNA3 (0.332 ± 0.083) > ORAI1 (0.165 ± 0.038) > ITPR2 (0.120 ± 0.055) > STIM1 (0.114 ± 0.030) > TPCN1 (0.076 ± 0.052) > TRPC6 (0.068 ± 0.042) > CLIC1 (0.041 ± 0.007) > ITPR1 (0.020 ± 0.002) relative to GAPDH. These results correlate closely with estimations of relative channel density reported in patch clamp recordings and/or relative importance of the channels in functional studies. In addition, we identified several transcripts that encode for ion channels or their regulators, which have not previously been reported in platelets.

We have developed an approach to ultra-purify platelet mRNA for the purpose of detecting transcripts for proteins that may play a role even at low levels of expression, such as ion channels. A channelome screen confirmed the expression of 10 channel-related proteins previously reported in the platelet or megakaryocyte and highlights the high expression of TMEM16F. Further ion channel-related proteins were also detected which require additional work to validate the presence of functional protein and potential roles in platelet/megakaryocyte function.

Funded by the British Heart Foundation (PG/11/56).

PB 2.26-6

Perturbations in local clot hemodynamics triggers intraluminal thrombus contraction

Muthard RW and Diamond SL

University of Pennsylvania, Philadelphia, PA, USA

Background: Hemodynamic conditions vary throughout the vasculature, creating diverse environments in which platelets must respond. To prevent blood loss, a growing platelet deposit must be assembled in the presence of fluid wall shear stress (t_w) and a transthrombus pressure gradient (ΔP) that drives bleeding.

Aims: Our aim was to investigate clot development and contraction in response to controlled perturbations in transthrombus pressure gradient and wall shear stress.

Methods: We designed a microfluidic device capable of side view visualization of a developing thrombus forming on collagen ± tissue factor (TF), while independently controlling ΔP and t_w. Unlike traditional *in vitro* clot contraction studies, this device incorporates the critical mechanical and biological properties that can only be obtained under flow conditions. Platelet deposits were formed at an arterial shear rate (1130/s) for 10 min while maintaining a physiologic transthrombus pressure gradient (ΔP = 0–23.4 mm Hg). Side view visualization of thrombosis with transthrombus permeation allowed for quantification of clot structure, height, and composition at various ΔP.

Results: When ΔP was increased from 20.8 to 23.4 mm Hg at constant arterial shear stress, clot height was reduced 20% on collagen/TF and 28% on collagen alone. Using a fluorescent reporter of thrombin production, we observed a 62% reduction in thrombin's ability to penetrate into the luminal side of the clot as ΔP was increased from 0 to 23.4 mm Hg. This was consistent with convective removal of thrombogenic solutes due to pressure-driven permeation. Following thrombus development, the clot was perturbed by either reducing or increasing flow. Unexpectedly, the 20-μm thick platelet layer underwent massive platelet retraction upon flow reduction. Contraction rates 1–2 min after flow reduction/cessation significantly increased by 6.5-fold (upstream region) and 4.6-fold (downstream region) ($P < 0.05$), compared to the rate before perturbation. In our rigid wall microfluidic device we added 1 μM SQ-29,548 (TXA_2 receptor antagonist) or 10 μM MRS-2179 and 50 μM 2-MeSAMP ($P2Y_1$ and $P2Y_{12}$ platelet receptors, respectively) to investigate the role of soluble autocrine mediators ADP and TXA_2. Both antagonists significantly reduced the total clot contraction as compared to buffer. ADP antagonists had the largest effect, reducing the total contraction nearly 75% over 7 min, whereas TXA_2 antagonist reduced the contraction by 44%. Interestingly, when flow was increased to pathophysiological shear rates (15,000/s), vWF mediated platelet aggregation resulted in clot structures exceeding 100 μm in height. These protruding deposits diverted flow from the downstream portion of the clot to allow rapid trailing edge retraction.

Summary/Conclusions: We have recently described a novel microfluidic platform that allows for side view visualization of thrombus growth in the presence of a transthrombus pressure gradient. Using this technique we report that small reductions in transthrombus pressure drop

(11%) result in significant increases in average clot height (20–28%). We observed that reducing flow causes a rapid clot contraction mediated by ADP and TXA_2. Flow dilution of these platelet autocrine mediators during intraluminal clotting balances the platelet contractile apparatus with prevailing hemodynamics, a newly defined flow sensing mechanism to regulate clot function.

PB2.27 – Platelets in Cardiovascular Disease

PB 2.27-1

Search for a predictive signature of coronary artery disease in platelet transcriptome

Camera M[1], Colombo GI[2], Brambilla M[2], Piacentini L[2], Rossetti L[2], Canzano P[2], Teruzzi G[2], De Metrio M[2] and Tremoli E[1]
[1]Università degli Studi di Milano, Milano; [2]Centro Cardiologico Monzino IRCCS, Milan, Italy

Background: Platelets retain a small but significant amount of functionally active megakaryocyte-derived mRNA as well as protein and molecular machinery necessary for translation. The platelet transcriptome may change in coronary artery disease (CAD). We previously showed that differentially expressed transcripts do exist in platelets from patients with non-ST elevation acute coronary syndrome (NSTE-ACS) compared to those with stable angina (SA), suggesting that ACS platelets are potentially preconditioned at the transcriptional level to a higher degree of reactivity, which eventually lead to the thrombotic event.
Aims: (i) To assess in the platelet transcriptome a predictive signature of the CAD type. (ii) To identify transcriptional variations related to the CAD type as compared to healthy subjects.
Methods: Total RNA was isolated from leukocyte-depleted platelets from 41 NSTE-ACS and 37 SA patients, age- and sex-matched and with no comorbidities (diabetes and kidney disease). Gene expression profiling was performed using the HumanHT v.12 BeadChips (Illumina). Data variance stabilizing transformation and robust spline normalization were conducted with the lumi R package. Genes were filtered out if < 10% of expression data have at least a 1.35-fold change in either direction from gene's median value, and statistical differences and prediction classifiers were assessed using the BRB-ArrayTools v.4.3.0-beta2 package. Functional annotation clustering was done using the DAVID v.6.7 Bioinformatics Resources. Platelet activation state was assessed by flow cytometry, using anti-CD41, CD62, PAC1, and Tissue factor antibodies.
Results: Microarray analysis identified 4000 ± 670 transcripts expressed in patients' platelets. Interestingly, the number of transcripts that passed the quality control criteria was lower in NSTE-ACS than in SA patients (3770 ± 598 and 4141 ± 733, respectively, $P < 0.02$). Differential analysis was performed on the 2687 transcripts expressed in all samples: 138 were found significant with a permutation P-value ≤ 0.001 and a FDR < 2% (121 decreased and 17 overexpressed in NSTE-ACS vs. SA platelet). Notably, 58 of these transcripts are unannotated genes. Functional annotation analysis of the remaining 73 unique genes revealed that the Gene Ontology classes 'Translation and Elongation' and the KEGG pathway 'Ribosome' were significantly enriched in NSTE-ACS downregulated transcripts (17 and 10 genes, respectively, adjusted P-value 2.36E-10 and 1.14E-08). Prediction analysis of microarray (PAM) identified a classifier composed of 17 unique genes: cross-validation, used to assess the performance of the PAM classifier, showed that it had a rate of correct classification of 70%.
Comparison with 10 age- and sex-matched healthy subjects and functional analysis showed that several biological processes and cell compartments are altered in CAD platelets (adjusted P-value < 0.05), e.g. 'Wound healing', 'Glycolysis', 'Regulation of metabolic processes', 'Membrane-bound vesicle', and 'Platelet alpha-granule' genes. Of interest, CD41 mRNA is overexpressed in NSTE-ACS compared to both SA and healthy platelets, and this is paralleled by the higher antigen level assessed by flow cytometry.
Conclusion: The observed decrease of translational elongation genes in NSTE-ACS might point out an exhausted capability of *de novo* protein synthesis, which has been already exploited to sustain the platelet hyperreactive state found in unstable patients. The partial predictive capacity of the PAM classifier suggests that other variables may act as confounders.

PB 2.27-2

Plasma-derived microparticles as a source of biomarkers in acute coronary syndromes: a proteomic study comparing ST-elevation myocardial infarction patients and stable coronary artery disease controls

Vélez P[1], Parguiña AF[1], Rosa I[1], Alonso-Orgaz S[2], De La Cuesta F[2], Grigorian L[3], Barderas MG[2], Moreu J[4], González-Juanatey JR[3] and García A[1]
[1]CIMUS, Universidad de Santiago de Compostela, Santiago de Compostela; [2]Hospital Nacional de Parapléjicos, Toledo; [3]Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela; [4]Hospital Virgen de la Salud, Toledo, Spain

1 Microparticles (MP) are cell-derived submicron size membrane vesicles known to be increased in the blood of patients with acute coronary syndromes [Mallat Z et al. (2000) Circulation 101:841–843]. They derive from various cells, most notably platelets, but also leucocytes, lymphocytes, erythrocytes and endothelial cells. MP are present in a small amount in the circulation of healthy individuals, but their levels increase in a high range of pathological conditions.
2 Our objective was to compare the proteome of plasma-derived microparticles from ST-elevation myocardial infarction (STEMI) patients and stable coronary artery disease (SCAD) controls. Our goal was to detect MP proteins differentially regulated that could serve as biomarkers for the acute event.
3 Plasma MP were isolated from 10 STEMI patients and 10 SCAD matched controls. We followed a standardized procedure to guarantee the purity of the microparticle population [Ramacciotti E et al. Thromb Res. 2010;125:e269-e274]. MPs were characterized by FACS with FITC-conjugated mouse anti-human CD41 monoclonal antibody, and by electron microscopy. Proteome analysis was based on two-dimensional differential in-gel electrophoresis (2D-DIGE) and mass spectrometry (MALDI-MS/MS and LC-MS/MS). For the DIGE analysis, CyDye-labeled proteins were separated by 24 cm 4–7 IPG strips for the first dimension, and 11% SDS-PAGE for the second. Image analysis was performed with Progenesis SameSpots software (NonLinear Dynamics). Validations were by 1D- and 2D-western blotting in an independent cohort of patients.
4 Due to the low amount of protein obtained from the patients, two pools were done, one for each condition (STEMI and SCAD). The DIGE analysis included four gels (technical replicates). Following image analysis, 1228 spots were detected per gel. The number of differentially regulated spots was of 115 (fold change ≥ 2 and $P < 0.05$). Form those, 71 were up-regulated in MP from STEMI patients, whereas 44 were up-regulated in MP from SCAD controls. So far we successfully analyzed 76 differentially regulated spots by mass spectrometry. Proteins identified include complement C4-A, fibrinogen, haptoglobin, apolipoprotein A-1, etc. Interestingly, alpha-2-macroglobulin and cardiotrophin-like cytokine factor 1 (CLCF1) were found to be up-regulated in STEMI samples. The former plays an important role in thrombogenesis and has been recently found to be up-regulated in plasma MP from deep venous thrombosis patients. The latter is a cytokine with B-cell stimulating capability that we recently found to be present in platelet-derived MP.

5 We performed the first high-resolution proteome analysis of MP from STEMI and SCAD patients. We provide a repertoire of proteins up-regulated in STEMI MP that could serve as biomarkers for the acute event. We believe our data open a new line of investigation that will allow a better understanding of the pathophysiological mechanisms underlying acute myocardial infarction. Our results demonstrate plasma-derived MP are a promising source of biomarkers for the acute event.

PB 2.27-3

P-selectin compared to other tests as a simple-to-use approach for assessing platelet function in cardiac patients

May JA, Fox SC, Johnson A, White AE, Glenn JR, Dovlatova N, Wijeyeratne Y and Heptinstall S

University of Nottingham, Nottingham, UK

Background: There are several tests of platelet function that are used to monitor the effects of antiplatelet agents, particularly aspirin and $P2Y_{12}$ antagonists, in patients with acute coronary syndromes. We have developed tests based on measurement of platelet surface-bound P-selectin following platelet stimulation. The tests differ from other approaches to measuring platelet function in that they are simple-to-use and measurements can be performed remotely, e.g. in GP's surgeries or in people's homes. Treated blood samples are stable for up to 9 days and are posted to a central laboratory for analysis. All tests, including the P-selectin tests, demonstrate that high residual platelet function in patients taking the $P2Y_{12}$ antagonist clopidogrel have a significantly increased risk of further thrombotic events.
Aim: The P-selectin test is being developed for commercial use by Platelet Solutions Ltd. The aim of this study was to compare the results obtained with other forms of platelet function testing in the same patients.
Methods: For measurement of P-selectin platelets in citrate anti-coagulated whole blood are activated and fixed after 5 min using a unique stabilising agent (patent applied for). We have compared the P-selectin aspirin and $P2Y_{12}$ tests with three aspirin and four $P2Y_{12}$ commercial tests including PRP aggregometry (PRP), Multiplate (MP), VerifyNow (VN) and Biocytex VASP (VASP). Blood samples were obtained from patients following treatment for 1 month with either aspirin plus clopidogrel ($n = 78$) or aspirin plus the more potent $P2Y_{12}$ antagonist, prasugrel ($n = 28$).
Results: All of the $P2Y_{12}$ tests demonstrated variability in the effectiveness of clopidogrel to inhibit platelet function while prasugrel treatment resulted in greater inhibition. Spearman correlations of P-selectin $P2Y_{12}$ test results compared with the other $P2Y_{12}$ tests were all good with r values of 0.5958 (PRP), 0.6268 (VN), 0.6227 (MP) and 0.4986 (VASP) all $P < 0.0001$. All of the aspirin tests consistently identified four patients as either non-responders or non compliant while all other patients demonstrated inhibition by aspirin using all tests.
Conclusions: The P-selectin tests, with their potential for remote testing, were at least as effective in determining the inhibitory effects of antiplatelet therapies as the other tests used in this study.

PB 2.27-4

Comparison of the optimul assay with light transmission aggregometry for the detection of aspirin resistance in patients with stable coronary artery disease

Floyd CN[1], Warner TD[2] and Ferro A[1]

[1]King's College London; [2]Barts & The London School of Medicine and Dentistry, London, UK

Background: Clinical studies into aspirin resistance (ASA-R) predominantly utilise point-of-care tests based on surrogate measures of platelet function, as light transmission aggregometry (LTA) which is widely considered the gold standard, is not suitable for clinical application. These surrogate tests demonstrate poor correlation with LTA and so the clinical need for an improved standardised test remains. The 96-well plate assay (Optimul) is based on LTA but requires less technical expertise and enables rapid testing at a range of agonist concentrations. In healthy subjects, it has demonstrated good ability to determine response (both *in vitro* and *in vivo*) to antiplatelet agents and good correlation with LTA in both healthy subjects and in patients with mild bleeding defects. ASA-R by LTA is generally defined as > 20% aggregation in response to 1.6 mM arachidonic acid (AA). No such criteria have been defined for the Optimul assay.
Aims:
1 To assess the correlation between LTA and Optimul following *in vivo* aspirin therapy in subjects with cardiovascular disease
2 To define criteria for ASA-R by Optimul
Methods: Whole blood was drawn into citrate (final concentration 0.32%) from patients with coronary artery disease receiving 75 mg aspirin daily ($n = 15$). Aggregation of platelet-rich plasma was performed by LTA in a PAP-8E aggregometer (Bio/Data) in response to 0.6, 1.0 and 1.6 mM AA (Sigma-Aldrich). Aggregation using the 96-well technique was performed using a plate reader (Tecan Sunrise) at absorbance 595 nm in response to 0.03, 0.1, 0.3, 0.6, 1.0 and 1.6 mM AA. Hundred percent aggregation was defined as the optical density of platelet-poor plasma.
Correlation of Optimul and LTA was performed using a Pearson correlation and paired t-test. Receiver operating characteristic (ROC) analysis curves were performed to assess the ability of 96-well aggregometry to identify ASA-R. Statistical analyses were performed using Prism 4 (GraphPad). Statistical significance was taken as $P < 0.05$. The study was approved by local ethics committee and all subjects provided informed consent.
Results: Optimul was found to be positively correlated to LTA for all AA concentrations tested (0.6 mM, r^2 0.59, $P < 0.001$; 1.0 mM, r^2 0.82, $P < 0.001$; 1.6 mM, r^2 0.81, $P < 0.001$). No significant difference was found between the two assays ($P = 0.1868$). ROC analysis using above the criteria to define ASA-R, yielded non-significance at all concentrations ($P > 0.05$). Modifying ASA-R criteria to > 30% aggregation by LTA improved significance, in particular at 1.6 mM AA (0.6 and 1.0 mM, AUC 0.91, 95%CI 0.75–1.01, $P = 0.063$; 1.6 mM, AUC 1.00, 95%CI 1.00–1.00, $P = 0.024$). For the 1.6 mM ROC at 30% LTA aggregation, a cut-off of < 27.73% yielded 100% sensitivity and specificity.
Summary/Conclusions: Optimul and LTA correlate well within patients with stable coronary artery disease, with no significant difference seen in results. ROC analysis trended to significance for all concentrations of agonist, but with significance only achieved following acceptance of a more stringent LTA definition of ASA-R. A degree of this discrepancy is likely to reflect measurement error from an imperfect gold standard. These findings suggest that the Optimul assay may be a suitable clinical tool for the detection of ASA-R.

PB 2.27-5

Role of platelets in driving the thrombotic risk and protective processes associated with exposure to diesel exhaust particles

Emerson M, Solomon A, Smyth E, Vydyanath A, Luther P and Tetley TD

Imperial College London, London, UK

Background: There is an established link between exposure to air born pollution and the incidence of respiratory and cardiovascular diseases. Inhalation of ambient particulate matter enhances the risk of platelet-driven cardiovascular diseases such as myocardial infarction in at-risk individuals. The nanoparticulate fraction of ambient air (i.e. particulate matter of diameter < 100 nm) is thought to be the most damaging

to health. Nanoparticles induce inflammation and cytotoxicity and have been shown to translocate the pulmonary epithelium to blood and internal organs. Urban ambient air is rich in nanoparticulate diesel exhaust particles (DEP) produced from industrial, public and private vehicular emissions.

Aims: We aimed to investigate the ability of DEP to interact physically and functionally with platelets as well as the ability of endothelial mediators to offer protection against DEP-induced platelet activation.

Methods: The interaction of DEP and carbon black (CB, which consists of the carbon core of DEP without the transmission metals and organic compounds associated with the surface of DEP) with platelets was examined by transmission electron microscopy, while the functional consequences of exposure were assessed by measuring *in vitro* and *in vivo* platelet aggregation using established methods.

Results: Electron microscopy revealed DEP and CB to be present in a mixture of individual, chained and agglomerated nanoparticles. Following exposure, both DEP and CB were internalised and seen in proximity with the open canalicular system in platelets. DEP induced concentration-dependent human platelet aggregation *in vitro* whereas CB had no effect. DEP induced Ca^{2+} release, dense granule secretion and surface P-selectin expression, but not toxicologic membrane disruption. Low concentrations of DEP potentiated agonist-induced platelet aggregation *in vitro* and *in vivo*. A nitric oxide donor was found to exert a similar inhibitory effect upon DEP-induced platelet aggregation to that occurring with a conventional platelet agonist.

Summary/Conclusions: DEP associate physically with platelets in parallel with a Ca^{2+}-mediated aggregation response displaying the conventional features of agonist-induced aggregation. The ability of DEP to enhance the aggregation response to platelet stimuli would be expected to increase the incidence of platelet-driven cardiovascular events should they be inhaled and translocate into the blood and provides a potential mechanism for the increased thrombotic risk associated with exposure to ambient particulate air pollution. Our study also suggests that the healthy vascular endothelium would be expected to provide protection against the platelet-mediated pro-thrombotic effects of DEP. A lack of endothelial-mediated inhibition of nanoparticle-induced platelet aggregation during endothelial dysfunction may provide a mechanism for the enhanced risk observed in individuals with underlying cardiovascular conditions upon exposure to particulate ambient pollution.

PB 2.27-6

Platelet and leukocyte ROS production and lipoperoxidation are associated with high platelet reactivity in acute coronary syndrome patients on dual antiplatelet treatment

Becatti M[1], Fiorillo C[1], Gori AM[1], Marcucci R[1], Paniccia R[1], Giusti B[1], Violi F[2], Pignatelli P[2], Gensini GF[1] and Abbate R[1]

[1]University of Florence, Florence; [2]Sapienza-University of Rome, Rome, Italy

High platelet reactivity (HPR) on dual antiplatelet therapy is a risk factor for adverse vascular events in acute coronary syndrome (ACS) patients.

Several studies have shown that reactive oxygen species (ROS) may be involved in modulating platelet function.

In ACS patients we investigated: (i) the relationship between the amount of ROS production/lipoperoxidation of cellular elements (by FACS analysis) and platelet activation through different pathways; (ii) the association of cellular ROS production with the presence of high platelet reactivity to ADP and arachidonic acid (AA) stimulation in ACS patients on dual antiplatelet therapy.

Significantly higher levels of platelet and leukocyte-derived ROS were detected in 49 dual HPR (with platelet aggregation by 1 mM AA $\geq$ 20% and by 10 μM ADP $\geq$ 70%) with respect to non-HPR patients (n = 49). Similarly, dual HPR patients had significantly higher platelet and leukocyte lipoperoxidation than non-HPR patients.

After adjustment for several potential confounders, platelet-, leukocyte-derived ROS and platelet and leukocyte lipoperoxidation remained significantly associated to dual HPR [platelet-ROS:2.53 (2.28–5.01), $P < 0.001$; leukocyte-ROS:1.13 (1.06–1.21), $P < 0.001$; platelet-lipoperoxidation:1.92 (1.10–1.35), $P < 0.001$; leukocyte lipoperoxidation: 1.59 (1.28–1.98), $P < 0.001$].

The significant predictors of ADP, AA, and collagen platelet aggregation at multiple linear regression analysis, after adjusting for age, cardiovascular risk factors, procedural parameter, medications, leukocyte number and MPV, were platelet-, leukocyte-derived ROS and platelet and leukocyte lipoperoxidation.

Our results demonstrate that in patients with ACS on dual antiplatelet therapy ROS production by and lipoperoxidation of platelets are strictly correlated to the different pathways of platelet aggregation and that ROS production and lipoperoxidation of platelets and leukocytes are predictors of nonresponsiveness to dual antiplatelet treatment.

PB2.28 – Platelet Activation: Miscellaneous – I

PB 2.28-1

Streptococcus pneumoniae triggers platelet activation and platelet-leucocyte complex formation in a strain dependent and toll-like receptor 2 independent manner

De Stoppelaar SF, Schaap MCL, Van Der Poll T, Nieuwland R and Van't Veer C

Academic Medical Center, Amsterdam, The Netherlands

Background: *Streptococcus pneumoniae* strains vary considerably in their ability to cause invasive disease, and this is associated with the capsular serotype. The *S. pneumoniae* capsule inhibits complement- and phagocyte-mediated immunity. Septic patients often develop thrombocytopenia, which is associated with higher mortality. Besides the role of platelets in hemostasis, platelets exert a role in the immune continuum through release of regulatory proteins, platelet-neutrophil complex formation, and secretion of antimicrobial peptides.

Aims: To determine how *S. pneumoniae* activates human platelets.

Methods: *Streptococcus pneumoniae* serotypes used: D39, TIGR4 and 6303 and mutant unencapsulated D39. Human platelet aggregation was measured in citrate-anticoagulated platelet rich plasma by light transmission aggregometry. Platelet degranulation and platelet-leukocyte complexes were measured by flow cytometry. Platelet and neutrophil killing capacity was determined in incubation experiments with *S. pneumoniae*.

Results: Unencapsulated *S. pneumoniae* induced platelet aggregation in a capsule-dependent manner; aggregation was not induced by encapsulated strains, or by direct toll-like receptor (TLR) ligands. Aggregation was inhibited by IgG receptor blocking antibody anti-FcγRII, but not by anti-TLR2. Whole blood incubation with all *S. pneumoniae* serotypes resulted platelet degranulation and platelet-granulocyte and platelet-monocyte complex formation. These reactions were inhibited by PGE1 but not by anti-FcγRII, anti-TLR2 and 4. Platelets had no antimicrobial effect on *S. pneumoniae*, nor did platelet-neutrophil complex formation enhance neutrophil killing capacity.

Conclusions: *Streptococcus pneumoniae* causes FcγRII mediated platelet aggregation through a mechanism that is inhibited by its capsule. All *S. pneumoniae* serotypes are potent inducers of platelet degranulation and platelet-leukocyte complex formation in a TLR2 independent manner.

PB 2.28-2

Multiple sites on *Streptococcus gordonii* surface protein PadA mediate outside-in signaling in platelets

Kerrigan SW[1], Keane C[1], Petersen H[2], Tilley T[1], Haworth J[2], Cox D[1] and Jenkinson HF[2]

[1]*Royal College of Surgeons in Ireland, Dublin, Ireland;* [2]*University of Bristol, Bristol, UK*

Background: Infective endocarditis (IE) is a life threatening disease caused by a bacterial infection of the endocardial surfaces of the heart. The oral pathogen, *Streptococcus gordonii* is amongst the most common pathogens isolated from IE patients. Previously we identified a novel cell wall protein expressed on *S. gordonii* called platelet adherence protein A (PadA). This protein interacts with platelet GPIIb/IIIa resulting in platelet adhesion, dense granule secretion and platelet spreading. Proteomic analysis of the PadA protein identified two short amino acid motifs (RGD and AGD) which have been previously shown to be important for fibrinogen binding to GPIIb/IIIa and contributing to the generation of outside-in signalling.

Aim: The aim of this project was to determine if either or both of these motifs found on S. gordonii PadA have any role in mediating outside in signalling in human platelets.

Methods: Bacteria were grown in Brain Heart Infusion Broth over night under static conditions. The regions encoding potential platelet interactive motifs AGD and RGT were subjected to alanine-substitution mutagenesis. Dense granule secretion was measured by luminometry using a luciferin/luciferase assay. Platelet interactions with immobilized bacteria under shear were assessed using a parallel flow chamber. Platelet spreading on native and mutated PadA was visualised by confocal microscopy with differential interference contrast or using an argon laser at 488 nm.

Results: Site directed mutagenesis on the PadA protein in which the $_{454}$AGD and $_{383}$RGT was substituted to AAA resulted in the RGT motif having no role in supporting platelet adhesion (P = NS) however plays a role in dense granule secretion ($P < 0.005$) and platelet spreading ($P < 0.005$). The AGD motif on the PadA protein however has no role to play in supporting firm platelet adhesion or dense granule secretion (P = NS) however plays a role in platelet spreading ($P < 0.01$).

Conclusions: The work presented here extends previous knowledge in *S. gordonii* platelet interactions by identifying two motifs on PadA that are similar to the known binding motifs in fibrinogen that recognise GPIIb/IIIa. Of particular interest is the role these motifs play in platelet function. It appears that the RGT motif has no role in supporting platelet adhesion however plays a role in dense granule secretion and platelet spreading. In contrast to this, AGD has no role in supporting platelet adhesion or dense granule secretion, however plays a role in platelet spreading. These results suggest for the first time that multiple sites on *S. gordonii* PadA generate outside in signals through GPIIb/IIIa to mediate platelet responses that likely contribute to the thrombotic complications of IE.

PB 2.28-4

Effects of high-amount high-intensity exercise on *in vivo* platelet activation: modulation by lipid peroxidation and AGE/RAGE axis

Santilli F, Vazzana N, Iodice P, Lattanzio S, Liani R, Bellomo R, Perego F, Saggini R and Davì G

University of Chieti, Chieti, Italy

Background: Physical activity is associated with cardiovascular risk reduction, but the effects of exercise on platelet activation remain controversial.

Aims: We investigated the effects of regular high-amount, high intensity aerobic exercise on *in vivo* thromboxane (TX)-dependent platelet activation and plasma levels of platelet-derived proteins, CD40L and P-selectin, and whether platelet variables changes may be related to changes in HDL and in the extent of oxidative stress and oxidative stress-related inflammation, as reflected by urinary isoprostane excretion and endogenous soluble receptor for advanced glycation end-products (esRAGE), respectively.

Methods: Urinary excretion of 11-dehydro-TXB_2 and 8-iso-prostaglandin (PG) F_{2a} and plasma levels of P-selectin, CD40L and esRAGE were measured before and after a 8-week standardized aerobic high-amount-high-intensity training program in 24 low-to-intermediate-risk sedentary subjects with low HDL cholesterol.

Results: Exercise training had a clear beneficial effect on HDL cholesterol (+11%, $P = 0.014$) and triglyceride (−27%, $P = 0.009$) concentration. In addition, a significant ($P < 0.0001$) decrease in urinary 11-dehydro-TXB_2 (27%), 8-iso-PGF_{2a} (22.4%), plasma P-selectin (29%), CD40L (35%) and a 61% increase in esRAGE were observed. Multiple regression analysis revealed that urinary 8-iso-$PGF_{2\alpha}$ [beta = 0.393, SEM = 73.4, $P = 0.004$] and esRAGE ($\beta = -0.30$, SEM = 48.2, $P = 0.024$) were the only significant predictors of urinary 11-dehydro-TXB_2 excretion rate over the training period.

Conclusions: Regular high-amount-high-intensity exercise training, with minimal weight change, in sedentary, low- or intermediate-risk people, together with increases in fitness (as measured by peak oxygen consumption), has broad beneficial effects on platelet activation markers, paralleled and possibly associated with changes in the lipoprotein profile and in markers of lipid peroxidation and AGE/RAGE axis. Our findings may help explaining why a similar amount of exercise exerts significant benefits in preventing cardiovascular events, and may guide the optimization of the exercise protocol in patients with different degrees of cardiovascular burden, including those with chronic ischemic heart disease, based on the effect on lipoprotein profile as well as on platelet activation and oxidative stress markers.

PB 2.28-5

Effect of hydrogen sulphide (H2S) on human platelet adhesion and clot retraction

Bermejo IE[1], Alberto MF[1], Saenz DA[2], Rosenstein RE[2] and Lazzari MA[1]

[1]*Haematological Research Institute of the National Academy of Medicine;* [2]*Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina*

Background: Hydrogen sulphide (H_2S) is increasingly recognized as a member of a growing family of 'gasotransmitters', together with its two counterparts, NO and CO. Actually, H_2S is emerging as an important endogenous modulator which exhibits beneficial effects on the cardiovascular system, without producing toxic metabolites.

Objective: The present work was designed *in vitro* to study the effect of H_2S on human blood platelets adhesion and clot retraction.

Methods: Tests were performed using platelet rich plasma (PRP) or washed platelets (WP) (300×10^9 plat/L). Sodium hydrogen sulfide (NaHS) was used as H_2S donor. A platelet suspension was treated with 10 mM NaHS or buffer.

Adhesion: Microplate wells were coated with 100 μL of fibrinogen solution (20 μg/mL) and blocked with 200 μL of BSA solution. WP (100 μL) preincubated with buffer or 10 mM NaHS were added to wells coated with fibrinogen and incubated at room temperature for 1 h. The wells were rapidly filled with 100 μL of 0.1 M citrate buffer, pH 5.4, containing 5 mM p-nitrophenyl phosphate and 1% Triton X-100 (v/v). After 60 min incubation at room temperature, the reaction was stopped by the addition of 70 μL of 2 M NaOH. The p-nitrophenol produced was measured with a microplate reader at 405 nm against a platelet-free blank.

The amount of platelets adherent to protein-coated wells was estimated by measurement of the platelet acid phosphatase activity using a calibration curve.

Clot retraction: PRP pre incubated with buffer or 10 mM NaHS. Plasma was induced to coagulate with 0.4 UI/mL thrombin. The clots were allowed to retract at 37 °C and were photographed at various times (15, 25, 35 and 45 min). Two-dimensional sizes of retracted clots on photographs were quantified using NIH ImageJ software, and retraction was expressed as percentage retraction [1 − (final clot size/initial clot size)].

Statistical significance was determined using Mann-Whitney test, control vs. H_2S ($n = 5$).

Results: H_2S significantly inhibited platelet adhesion to fibrinogen coated plates ($P < 0.01$). In clot retraction, no difference was observed at the end point (45 min). However PRP incubated with NaHS had a delay with statistical significance at 25 and 35 min ($P = 0.001$ and $P = 0.04$ respectively), changing from hyperbola to sigmoid the kinetic curve of clot retraction.

Conclusion: It has been demonstrated that ligand binding to integrin aIIbb3 induces outside-in signaling-mediated Rap1b. It is crucial for the activation of a second pool of Rac1, which is important for clot retraction and platelet spreading. Our results suggest that a pathway, such as CalDAG-GEFI/Rap1-Rac1, could be affected by H_2S. In conclusion, several evidences are accumulating to demonstrate that H_2S donor compounds exert significant effects on antiadhesive activity in prevention of thrombotic states.

PB 2.28-6

A novel real-time whole blood flow cytometric assay identifies a sub-population of platelets that rapidly bind Annexin-V upon stimulation

Jones CI[1], Garner SF[2] and Gibbins JM[1]

[1]University of Reading, Reading; [2]University of Cambridge, Cambridge, UK

Background: The rate of platelet activation may be critical in determining the dynamics of thrombus formation, yet the regulation of platelet kinetics has received less investigation than the maximum extent of platelet response.

Aims: Here we report the development a novel flow cytometric assay designed to measure the kinetics of platelet activation, with the aim of measuring makers of platelet activation that occur rapidly upon activation.

Methods: Whole citrated blood was diluted in Hepes buffered saline containing (i) Fluo4-NW (Invitrogen), or (ii) FITC-anti-fibrinogen antibodies (Dako), PE-anti-P-selectin antibodies (BD), and Cy5-Annexin-V (BD) in combination. All reagents were dialyzed prior to use. Samples, maintained at 37 °C during data acquisition, were stimulated with CRP-XL (1 μg/mL) together with $CaCl_2$ (2 mM) and gly-pro-arg-pro peptide (0.5 mg/mL) (Sigma). Data were acquired for 5 min at approximately one platelet per 1 ms. All data were analysed using R (www.r-project.org) by fitting LOESS curves to the raw data from which the maximum response, the rate and acceleration (rate at which the rate changes) of platelet response were derived.

Results: Coefficient of variation (CV) was below 10% for all assays except acceleration in P-selectin exposure (CV = 16%) which showed increased variability due to the slow rate of P-selectin exposure. No correlation existed between the maximum level and the rate or acceleration of calcium flux, fibrinogen binding, P-selectin exposure or Annexin-V binding ($n = 10$). This assay revealed a small (< 2%) population of platelets that bind Annexin-V rapidly following stimulation. This population is reduced at lower concentrations of CRP-XL, absent with $CaCl_2$ alone, they are small, have high levels of P-selectin exposure, and curiously show differential levels of fibrinogen binding.

Summary/Conclusions: We have developed a robust, reproducible and sensitive assay for the measurement of the kinetics of platelet activation, and identified a sub-population of platelets that bind Annexin-V rapidly after activation. It is intriguing to postulate how this negatively charged population of platelets appearing early in thrombus formation might alter thrombus growth and development.

Evaluation of endothelial dysfunction and regeneration in an elderly population: the Mugello Study

Gori AM[1], Cesari F[2], Vannetti F[3], Sereni A[1], Molino Lova R[3], Sofi F[1], Sticchi E[1], Abbate R[1], Gensini GF[1] and Macchi C[1]

[1]University of Florence; [2]Thrombosis Center; [3]Don Carlo Gnocchi Foundation, Florence, Italy

Background: The precise mechanisms underlying the relationship between increasing age and increased risk for vascular diseases are not completely elucidated.

Circulating progenitor cells (CPC), endothelial progenitor cells (EPCs), and circulating endothelial cells (CEC) may play a role in the development and progression of atherosclerosis.

Clinical studies have demonstrated in young and middle-aged population that EPCs inversely correlated with the presence of traditional cardiovascular risk factors and with circulating pro-inflammatory molecules, but scarce data in the elderly are available.

Aims: We used data from the Mugello Study, a prospective study which enrolled ultranonagenarian subjects, who lived in the Mugello Area to evaluate the relationship between EPC, CPC, CEC and advanced age.

Methods: Circulating CEC, CPCs and EPCs were assessed by flow cytometric analysis and were defined as CD146+/CD31+/CD45−/CD61− (CEC), CD34+, CD133+, CD34+/CD133+ (CPC) and CD34+/KDR+, CD133+/KDR+, CD34+/CD133+/KDR+ (EPC) respectively. We also evaluate circulating levels of C-reactive Protein (CRP) and white blood cell count.

Results: We enrolled 270 ultranonangenarians (198F/72M) with a median age of 92 (90–103) years.

Ultranonagenarians showed a significant higher number of CEC[3 (0–187) vs. 1 (0–23) cells/10^6 events, $P < 0.001$] and a lower number of EPC[CD34+/KDR+:2 (0–28) vs. 10 (3–43) cells/10^6 events; CD133+/KDR+:3 (0–23) vs. 10 (4–45) cells/10^6 events;CD34+/CD133+/KDR+:2 (0–23) vs. 9 (3–43) cells/10^6 events, $P < 0.001$] with respect to younger (median age 65 years, 45–78 years) control population. In elderly and younger subjects CPC number was similar [CD34+:340 (30–1030) cells/10^6 events vs. 336 (259–414) cells/10^6 events; CD133+:314 (30–1030) vs. 321 (246–396) cells/10^6 events; CD34+/CD133+:307 (30–1010) vs. 294 (224–364) cells/10^6 events].

In the Mugello population CEC, CPC and EPC number was not affected by traditional cardiovascular risk factors. Furthermore, we found a significant relationship between CPC and EPC and leukocyte number [CPC: CD34+:$r = -0.162$, CD133+: $r = -0.165$, $P = 0.005$; CD34+/CD133+:$r = -0.190$, $P < 0.01$; CD34+/KDR+:$r = -0.142$; CD133+/KDR+:$r = -0.148$; CD34+/CD133+/KDR+:$r = -0.144$, $P < 0.05$ respectively] and between CEC, EPC number and CRP serum levels [CEC: $r = 0.142$, $P = 0.050$; CD34+/KDR+: $r = -0.317$, $P < 0.001$; CD133+/KDR+: $r = -0.306$, $P < 0.001$; CD34+/CD133+/KDR+: $r = -0.312$, $P < 0.001$ respectively].

Conclusions: Our results demonstrate the presence of an endothelial dysfunction, as documented by high CEC and low EPC number in ultranonagenarians. Moreover the positive relationship between CEC and CRP and the negative relationship between EPC and CRP suggest that an inflammatory state, which is commonly present in the elderly, significantly affects the endothelial function by promoting vascular damage and by reducing the endothelial regenerative capacity.

PB 2.29-2

Adherence to lifestyles' modifications after a cardiac rehabilitation (CR) program and endothelial progenitor cells (EPCs): a 6-months follow-up study

Cesari F[1], Marcucci R[1], Gori AM[1], Burgisser C[2], Francini SM[2], Sofi F[1], Gensini G[1], Abbate R[1] and Fattirolli F[1]

[1]Azienda Ospedaliero-Universitaria Careggi, University of Florence; [2]Cardiac Rehabilitation Unit, University of Florence, Azienda Ospedaliero-Univers, Florence, Italy

Background: A significant increase of EPCs number among acute coronary syndrome (ACS) patients participating in a CR program has recently been reported, but no data on the impact of adherence to lifestyle recommendations provided during a CR program on EPCs number are available.

Aim: To investigate the effects of adherence to lifestyles' recommendations on EPCs, inflammatory and functional parameters after 6 months from a CR program in ACS patients.

Methods: One hundred-ten out of 112 ACS patients (90M/20 F; mean age 57.9 ± 9.4 years) completed the study. EPCs, high sensitivity C-reactive protein (hsCRP), NT-ProBNP levels, and cardiopulmonary testings were determined at the end of the program (T1) and at a 6 month follow-up (T2). At T2, a questionnaire assessing dietary habits and physical activity in the previous 6 months was obtained. EPCs were defined as CD34+KDR+, CD133+KDR+ and CD34+CD133+KDR+. hsCRP and NT-ProBNP were measured by nephelometric and immunometric method, respectively.

Results: At T2, we observed a significant decrease of all the three types of EPCs [CD34+KDR+ 10 (0–37) vs. 7 (0–43) $P = 0.01$; CD133+KDR+ 10 (0–33) vs. 7 (0–43) $P = 0.03$; CD34+CD133+KDR+ 10 (0–33) vs. 7 (0–43) $P = 0.03$], of CRP ($P = 0.009$) as well as of NT-ProBNP ($P < 0.0001$). On the basis of dietary habits and physical activity we divided patient population into three categories (no/low adherence to lifestyles' recommendations, moderate adherence; high adherence). An increased adherence to lifestyle recommendations associated to a significant increase in EPCs and Watt max variations between T1 and T2 was observed (Δ CD34+KDR+ p for trend = 0.04; Δ CD133+KDR+ p for trend = 0.02; Δ CD34+CD133+KDR+ P for trend = 0.02; Δ Watt max P for trend = 0.003).

Moreover, the group of patients who reported at the end of the CR program an increase of EPCs and baseline levels of CRP in the lowest tertile (< 2.2 mg/dL) showed, at a 6-month of follow-up, significant higher levels of EPCs ($P = 0.03$), Watt max ($P = 0.003$) and VO2max ($P = 0.002$) and significant lower CRP levels ($P = 0.01$).

Conclusions: Adherence to lifestyles recommendations provided during a CR program is able to influence variations of EPCs' and Watt max, at 6-month follow-up.

PB 2.29-3

Extracellular acidosis inhibits the proangiogenic responses and the tissue regeneration capacity of endothelial progenitor cells

Negrotto S[1], Fondevila C[2], Boisson-Vidal C[3] and Schattner M[1]

[1]Institute of Experimental Medicine; [2]Bazterrica Clinic, Buenos Aires, Argentina; [3]University of Paris Descartes, Paris, France

Background: We have previously demonstrated that extracellular acidosis, a characteristic feature of inflammation, induces apoptosis of hematopoietic progenitors (CD34+ cells). Endothelial progenitor cells (EPC) are a subpopulation within the CD34+ cells which are mobilized from the bone marrow after vascular damage to the site of injury and contribute to tissue revascularization.

Aims: To study the impact of acidosis on the proangiogenic responses and the tissue regeneration capacity of EPC.

Methods: EPC were seeded in EBM medium supplemented with fetal bovine serum, VEGF1, SDF1 and bFGF. The pH of the culture medium (normal value: 7.4) was adjusted at pH values of 7.0 and 6.6 by the addition of an isotonic solution of HCl ($n = 4$–5. *$P < 0.05$ vs. pH 7.4, ANOVA).

Results: We found that while the survival of EPC was not affected by pH, the exposure to acidic medium for 24 h inhibited the proliferation (18 ± 1 and 26 ± 1*% of inhibition at pH 7 and 6.6 respectively, pNPP assay), migration (55 ± 3* and 61 ± 6*%, Boyden chamber), wound repair (9 ± 1 and 69 ± 4*%, mechanical damage of the monolayer) and tubule formation (58 ± 2* and 77 ± 5*%, Matrigel). We also evaluated how acidosis influences the EPC contribution to tissue regeneration in a murine model of hind limb ischemia induced by ligation of the femoral artery. To this end, EPC were previously incubated for 24 h at pH 7.4 or 6.5 and then transplanted intravenously (5 h post-surgery). After 7 days, the percentage of blood flow recovery within the ischemic area was analyzed (Doppler scanning). While the percentage of flow recovery in non-transplanted mice was 49 ± 6%, in those transplanted with EPC grown at pH 7.4 the flow recovery was 78 ± 10*%. However, when the EPC were exposed at pH 6.6, the flow recovery was similar to the non-transplanted animals (48 ± 8%, $n = 4$ nude mice per group).

Summary/Conclusion: Our results suggest that extracellular acidosis inhibits EPC proangiogenic responses *in vitro* and the tissue regeneration capacity of EPC in a murine model of hind limb ischemia.

PB 2.29-4

Down-regulation of TIPE2 in peripheral blood mononuclear cells is associated with low levels of circulating endothelial progenitor cells in patients with type 2 DM

Xiong S, Wang Q, Zheng L and Bao J

Nanfang Hospital, Southern Medical University, Guangzhou, China

Backgroud: Activation of the innate immunity system and systemic inflammation are closely involved in the pathogenesis of diabetes and its vascular complications. Circulating endothelial progenitor cells (EPCs) play an important role in the neovasculogenesis and maintenance of vascular homeostasis. Tumor necrosis factor alpha induced protein-8 like-2 (TIPE2) is a very recently identified negative regulator of inflammation that maintains immune homeostasis.

Aims: This study was performed to investigate the relationship between peripheral blood mononuclear cells (PBMCs) TIPE2 and circulating EPCs number in Type 2 Diabetes Mellitus (T2DM).

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from 36 normal subjects and 31 patients with T2DM. Mononuclear cell TIPE2 was measured by real-time PCR. EPCs were defined by CD133(+)/CD34(+)/VEGFR2(+) and quantified by flow cytometry.

Results: The TIPE2 mRNA and the EPCs number in the T2DM group were significantly lower than those in normal controls ($P < 0.01$). The changes of TIPE2 showed significant correlation with the changes of EPC number ($r = 0.341$, $P = 0.003$). Furthermore, the urine albumin/creatinine ratio (UACR) negatively correlate with the TIPE2 mRNA levels ($r = -0.5221$, $P = 0.0013$) and the number of circulating EPCs ($r = 0.8441$, $P = 0.0003$) in all the T2DM patients.

Conclusion: TIPE2 and circulating EPCs number are closely related and could be considered as potential markers of inflammation and renal impairment in T2DM.

PB 2.29-5

Mechanistic study of the proangiogenic effect of osteoprotegerin

Benslimane-Ahmim Z[1], Poirier F[2], Delomenie C[3], Lokajczyk A[1], Galy-Fauroux I[1], Mohamadi A[1], Fischer AM[1], Heymann D[4], Lutomski D[2] and Boisson-Vidal C[1]

[1]Inserm UMR_765, Paris; [2]CNRS CSPBAT, LBPS, UFR SMBH, Bobigny; [3]IFR-141-IPSIT, Chatenay Malabry; [4]Inserm, UMR-S 957, Nantes, France

Background: Osteoprotegerin (OPG), a soluble tumour necrosis factor receptor family member, inhibits RANKL-mediated osteoclastogenesis. We have previously reported that OPG enhances the proangiogenic properties of endothelial colony-forming cells (ECFC) *in vitro*, and promotes vasculogenesis *in vivo*. Here we investigated how OPG promotes neovascularisation.

Methods: Umbilical cord blood samples were collected from consenting mothers. Endothelial cells were isolated from human umbilical cords and ECFC from human umbilical cord blood. One day before experiments, cells were growth-arrested for 18 h in EBM2, 3% FCS and released from growth arrest by adding EBM2, 5% FCS, with or without various concentrations (0–0.4 nM, 0–25 ng/mL) of OPG at 37 °C. Proteomic analysis was used to reveal and identify proteins that were differentially expressed in OPG-stimulated and control ECFC. Some of the proteins involved in angiogenesis were further validated and characterized by RT-qPCR, western blot and apoptosis experiments. *In vitro* angiogenesis assay and *in vivo* Matrigel plug assay were performed to validate OPG mechanism of action.

Results: Proteomic experiments showed that OPG pretreatment affected ECFC protein expression in two ways, 23 spots being downregulated and six upregulated. These spots corresponded to proteins involved in cell motility, adhesion, signal transduction and apoptosis. In keeping with these proteomic results, we found that OPG induced ECFC adhesion to activated endothelium in shear stress conditions, promoting intermediate but not focal adhesion to fibronectin and collagen. Treatment with OPG induced a reorganization of the ECFC cytoskeleton, with the emergence of cell protrusions characteristic of a migratory phenotype. These effects correlated with decreased FAK phosphorylation and enhanced integrin $\alpha_V\beta_3$ expression. OPG drastically reduced caspase-3/7 activities and maintained ECFC viability after 48 h of treatment. All these effects were significantly attenuated by ECFC incubation with the CXCR4 antagonist AMD-3100, and by prior heparan sulphate proteoglycan disruption. The proangiogenic properties of OPG appeared to be mediated by the proteoglycan syndecan-1, although OPG 1-194 lacking its heparin-binding domain still had pro-vasculogenic effects *in vitro* and *in vivo*.

Conclusion: These results suggest that OPG may interact with ECFC by binding to HSPGs/syndecan-1, thereby induce an anti-adhesive effect and promoting ECFC migration through a SDF-1/CXCR4 dependent pathway.

PB 2.29-6

Protease-activated receptor 1 and 2 stimulate endothelial colony forming cell vasculogenesis in a vascular endothelial growth factor- and extracellular signal-regulated kinase-dependent manner

Pula G[1], Fortunato T[1] and Wheeler-Jones C[2]

[1]University of Bath, Bath Spa; [2]The Royal Veterinary College, London, UK

Background: Endothelial cells line the inner side of blood vessels and perform critical physiological functions. Besides guaranteeing normal blood flow through the inhibition of platelets, endothelial cells also play a critical role in vascular repair and angiogenesis. Endothelial dysfunction is associated with atherosclerotic and ischemic syndromes of the cardiovascular system and is a critical cause of cardiovascular diseases. Endothelial progenitor cells (EPCs) are circulating stem-like cells able to differentiate into mature endothelial cells and replenish the endothelial lining at the sites of vascular damage. Their utilisation for cell therapies aiming to restore healthy endothelial lining of blood vessels and stimulate neovascularisation of ischemic tissues has been the object of intense investigation. Different types of EPCs exist depending on the isolation and culture procedure. In this study, we utilise the most recent and promising type of EPCs denominated endothelial colony-forming cells (ECFCs), which is characterised by the ability to proliferate efficiently *in vitro*, to differentiate into fully functional mature endothelial cells, and to form a vascular capillary network both *in vitro* and *in vivo*.

Aims: Following the identification of both protease-activated receptor (PAR) 1 and 2 in ECFCs, we investigated the role of these receptors in the regulation of proliferation, differentiation and tubulogenesis within this cell type.

Methods: The stimulation of PAR1 or PAR2 was obtained with selective activating peptides (H-Thr-Phe-Leu-Leu-Arg-NH2 and 2-Furoyl-Leu-Ile-Gly-Arg-Leu-Orn-NH2, respectively). The effect of PAR stimulation on ECFC proliferation was assessed using a metabolic tracer, while the effect on ECFC differentiation was assessed by immunoblotting for mature endothelial markers, such as platelet endothelial cell adhesion molecule (PECAM-1), vascular endothelial growth factor receptor 2 (VEGFR2), VE-cadherin and von Willebrand Factor (VWF). The effect on the vasculogenic activity of ECFCs was tested in a Matrigel[TRADEMARK]-based tube formation assay. Finally, the molecular mechanism underlying ECFC regulation by PAR1 and PAR2 was dissected using phospho-specific immunoblotting for active extracellular signal-regulated kinase (ERK) and by inhibiting either ERK (e.g. PD98059) or VEGF (e.g. VEGF inhibiting antibody) in different functional assays.

Result: ECFC proliferation was not affected by PAR1 or PAR2 stimulation. On the other hand, both PAR1 and PAR2 stimulation resulted in a significant increase of mature endothelial marker expression. In particular, VEGFR2 expression was between 2 and 4 times higher in ECFCs treated with PAR1- or PAR2-activating peptides compared to controls. This upregulation of VEGFR2 was abolished by the ERK inhibitor PD98059. The stimulation of either PARs also resulted in a significant increase in the activation of ERK and in a potentiation of the vasculogenic response of ECFCs cultured on Matrigel[TRADEMARK]. Interestingly, the inhibition of ERKs with pharmacological tools (e.g. PD98059) or the antibody-based inhibition of VEGF resulted in the ablation of the PAR-stimulated tube formation.

Summary/Conclusions: Taken together, PAR1/2 activation promotes the maturation of ECFCs and stimulates their vasculogenic activity in an ERK- and VEGFR2-dependent manner. Therefore, activating PAR1 and PAR2 either *in vivo* or *ex vivo* may represent a valid approach for the stimulation of ECFC-dependent vascular repair or ischemic tissue revascularisation.

PB2.30 – Microparticles and Disease – II

PB 2.30-1

Characterization of circulating microparticles in pancreatic and colorectal cancers and chronic inflammatory diseases

Mege D[1], Panicot-Dubois L[1], Ouaissi M[2], Robert S[1], Farge-Bancel D[3], Sastre B[2], Dignat-George F[1] and Dubois C[1]

[1]Inserm UMR 1076; [2]Digestive Surgical Department, Marseille; [3]GFTC, Paris, France

Background: Microparticles have intensively been described as potential biomarkers and biovectors in coagulation, inflammation and

cancer. Pancreatic and colorectal cancers (CRC) are known to have elevated annexin V-positive microparticles in the plasma. Procoagulant activity of microparticles seems also to be elevated in these two types of cancer and in an inflammatory context. However, to date, no study has compared the quantity and the repartition of circulating microparticles in cancer and chronic inflammatory diseases.

Aims: The aim of the present study was to compare the quantity and the origin of circulating microparticles between cancers associated with thrombosis and chronic inflammatory diseases.

Methods: A prospective cohort included patients with pancreatic adenocarcinoma ($n = 29$), CRC ($n = 83$), chronic pancreatitis ($n = 14$) and Crohn's disease ($n = 14$). Healthy controls ($n = 19$) were also included. Microparticles were isolated from blood samples. High-sensitivity flow cytometry using fluorescents beads with appropriate sizes was performed to identify and quantify annexin-V-, platelet-, endothelial-, erythrocyte- and leukocyte-derived microparticles.

Results: Patients with a pancreatic cancer had significantly increased levels of annexin-V positive microparticles compared to patients suffering from a CRC ($P < 0.001$). Surprisingly, we didn't observe significant difference in the level of annexin-V positive microparticles, between each cancer (pancreas and CRC) and its equivalent inflammatory state (chronic pancreatitis and Crohn's disease, respectively). Although the repartition of microparticles according to their origin was similar in pancreatic and CRC, there was a significant difference compared to chronic pancreatitis or Crohn's disease. Platelets-derived microparticles were significantly increased and endothelial cell-derived microparticles were significantly decreased in chronic inflammatory diseases in comparison with cancers ($P < 0.03$). Theses significant differences were amplified with healthy controls.

Conclusions: The repartition of cells-derived microparticles significantly differs between cancer, chronic inflammatory disease and healthy controls. This difference allows allocating a hallmark for the different pathologies.

PB 2.30-2

Increased microparticles activities as a marker of platelet activation after percutaneous coronary intervention

Setiabudy RD, Suryaatmadja M, Yuniardi Y and Salim AK
Faculty of Medicine, University of Indonesia, Jakarta Utara, Indonesia

Background: Percutaneous coronary intervention (PCI) is a procedure to open the occlusive coronary artery. It was reported that restenosis of coronary artery may occurred after PCI. Balloons pumping during PCI can cause de-endothelialisation that result in exposure of subendothelial tissue which may activates platelets. There are several biomarkers of platelet activation, among others is microparticle which is mainly consist of phospholipid with procoagulant activities.

Aims: To compare microparticles activities in coronary artery before and after percutaneous coronary intervention as an evidence of platelet activation due to de-endothelialisation.

Methods: Twenty three MCI patients consisted of seven female and 16 male who underwent PCI were enrolled in this study. Three mL of blood were withdrawn from coronary artery just before ballooning and immediately after stenting, and then mixed with sodium citrate as anticoagulant. Determination of microparticle or phospholipid (PPL) activities were done based on clotting time of a mixture of plasma sample and phospholipid deficient plasma with the addition of activated factor X and calsium ion. The result of PPL activities were expressed as PPL ratio, i.e. clotting time of patient plasma divided by average of clotting time in healthy subjects. The proposal of this study has been approved by the ethical committee of Harapan Kita Cardiac Center and all of the subjects has given informed consent.

Results: The median (range) of PPL ratio before PCI (ballooning) was 1.3 (0.7–3.1) while after PCI it was 1.1 (0.5–1.5). The difference was statistically significant. The clotting time after PCI was shorter compared with that before PCI indicated higher phospholipid activities in the plasma sample after PCI.

Conclusions: The microparticle activities after PCI was higher than that before PCI indicated platelet activation occurred during PCI.

PB 2.30-3

Microparticle detection in human plasma using nanoparticle tracking analysis and scanning ion occlusion sensing

Mørk M, Pedersen S, Nejlund S and Kristensen SR
Aalborg University Hospital, Aalborg, Denmark

Background: In recent years cell-derived microparticles (MPs) have attracted growing attention as possible contributors to a wide range of physiological and pathological processes in the human body, including coagulation and thrombogenesis. Although showing promising potential as biomarkers and therapeutic targets the diversity of the size and composition of MPs as well as their susceptibility to being affected by pre-analytical handling entail a major challenge when it comes to standardizing their measurement and interpreting the results.

Aims: We evaluate the ability of two recently developed methods applicable for detection of MPs at the lower end of the MP size range to perform precise particle size and concentration measurements as well as the influence of pre-analytical parameters and instrument settings on the results. In continuance we will establish preliminary reference intervals for MP concentrations for the two methods using defined instrument settings.

Methods: Within- and between-day variation, effect of freezing at −80 °C, storing and diluting (with DPBS buffer) plasma samples as well as the impact of collecting postprandial vs. fasting samples is assessed using nanoparticle tracking analysis (NTA; Nanosight®) and scanning ion occlusion sensing (SIOS; qNano®). Preliminary reference intervals for MP concentration in fasting as well as non-fasting individuals will be calculated from measurements performed on plasma samples from 20 healthy individuals.

Results: Whereas NTA and SIOS do not agree on the absolute MP concentrations and size distributions they separately exhibit a within- and between-day variation that suggests they will be applicable for plasma MP level measurements in studies of patients. For SIOS we find direct proportionality between the calculated and measured MP concentration within the examined range of dilution factors. Freezing significantly changes and generally increases MP levels but variably. Preliminary results show that postprandial samples have a significantly higher concentration of MPs compared to fasting samples, and with the rise of MP concentration as a result of food intake being of substantially varying magnitude the reference intervals for non-fasting individuals is expected to be considerably broader than for fasting individuals.

Conclusions: NTA and SIOS display promising abilities as methods for MP level detection in plasma samples and while they cannot be expected to provide exact absolute concentrations and size distributions over the whole range of MPs present in plasma they complement each other and existing methods for MP measurement such as flow cytometry in order to identify differences in MP levels between healthy persons and relevant patient populations. Based on our preliminary results we recommend MP measurements to be performed on fresh plasma samples from fasting individuals as results from non-fasting as well frozen samples should be interpreted with certain reservations.

PB 2.30-4

Microparticles do not modify the antithrombotic properties of brain microvascular cells

Faille D[1,2], Ollivier V[3], Huisse MG[1,2], Couraud PO[4], Jandrot-Perrus M[3], Mazighi M[5] and Ajzenberg N[1,2]

[1]Inserm U698, Université Paris Diderot; [2]Department of Hematology, Bichat Hospital; [3]Inserm U698; [4]Institut Cochin, CNRS UMR 8104-INSERM U567, Université René Descartes; [5]Department of Neurology, Bichat Hospital, Paris Cedex 18, France

Background: High levels of membrane-shed submicron microparticles (MP) circulate in the peripheral blood of patients with thrombotic diseases including ischemic stroke. While circulating MP are useful biomarkers of cell activation/apoptosis, their role in the development of thrombosis remains uncertain.

Aims: To study the potential effects of MP from ischemic stroke patients on the antithrombotic properties of brain microvascular compared to macrovascular endothelial cells focusing on the interactions between platelets and endothelial cells under static and flow conditions and on thrombin generation.

Methods: MP were purified from lipopolysaccharide-stimulated blood or from blood of patients with ischemic stroke ($n = 16$) or stroke mimics ($n = 8$). MP were then quantified and characterized by flow cytometry. After 24 h co-incubation of MP (3000 annexin V+/μL) with human brain microvascular endothelial cells (hCMEC/D3) or human umbilical vein endothelial cells (HUVEC), adhesion of platelets to endothelial cells under static conditions was quantified by fluorescent microscopy using a CD42b labelling. Platelet adhesion was also assessed under high shear stress (1800/s) in a parallel flow chamber and strings of von Willebrand factor covered by calcein-loaded platelets were quantified by fluorescence microscopy. Modulation of the antithrombotic properties of endothelial cells by MP was assessed by measuring thrombin generation at the cell surface by means of the Calibrated Automated Thrombography method in platelet-rich plasma in the absence of tissue factor.

Results: In resting conditions, platelet adhesion was less intense on hCMEC/D3 than on HUVEC under both static and flow conditions (covered surface: 0.3 ± 0.1 vs. 1.6 ± 0.5%, $P = 0.05$ and 0.9 ± 0.03 vs. 5.8 ± 1.9 arbitrary units, respectively). Platelet adhesion increased after agonist stimulation of HUVEC only (4.7 ± 1.4% vs. 1.6 ± 0.5%, $P = 0.09$ after stimulation with tumor necrosis factor/interferon-gamma for static experiments and 28.9 ± 11.6 vs. 5.8 ± 1.9 arbitrary units after stimulation with IBMX/forskolin for flow conditions). These differences could be related to the less intense expression of von Willebrand factor by hCMEC/D3 than by HUVEC. When preincubated with endothelial cells, MP from stimulated whole blood did not modify platelet adhesion on either hCMEC/D3 or HUVEC. To evaluate the modification of antithrombotic properties of the endothelium by MP, we measured thrombin generation at the endothelial cell surface. Under resting conditions, thrombin generation was higher at the surface of hCMECs/D3 compared to HUVEC (peak 47.9 ± 14.7 vs. 9.5 ± 4.3 nM, $P = 0.02$) but lower than in absence of endothelial cells (peak 60.4 ± 6.3). Incubation with whole blood-derived MP for 4 h prior to thrombin generation led to a slight but not significant increase in peak (18.8 ± 3.7 vs. 9.5 ± 4.3 nM, $P = 0.15$) and decrease of lagtime (17.3 ± 2.3 vs. 25.4 ± 6.2 min, $P = 0.2$) only on HUVEC. MP isolated from stroke patients or stroke mimics did not modify thrombin generation on both cell lines.

Conclusions: In this study, we found that MP isolated from stimulated whole blood or from stroke patients did not promote either platelet adhesion or thrombin generation on endothelial cells from brain microvascular (hCMEC/D3) or from macrovascular (HUVEC) origin. However, we provide evidence that these endothelial cells differ regarding their relation to haemostasis that could be useful in understanding the physiopathology of stroke.

PB 2.30-5

Circulating microparticles in patients with colorectal cancer

Chalabi M[1,2], Leers MPG[1] and Jie KSG[1]

[1]Atrium Medical Center, Heerlen; [2]Department of Internal Medicine, Maastricht, The Netherlands

Background: Microparticles (MPs) are subcellular fragments shed from cell membranes of different cell types through a process of vesiculation and are believed to play a role in thrombus formation *in vivo*. Numerous studies have found increased levels of microparticles in patients with solid and haematological malignancies. Few of these studies, however, have focused on patients with colorectal carcinoma (CRC).

Aim/Objective: In this prospective study we aimed to investigate whether levels of endothelial (EMPs; CD62+), platelets (PMPs; CD41+) and Tissue Factor-bearing MPs (TF + MPs) are elevated in patients with stage 1–3 CRC compared to healthy subjects and to determine whether these levels decrease significantly after surgical resection of the tumor.

Materials and Methods: MPs plasma levels were measured in 36 patients with colorectal cancer and 16 healthy controls, using a multiparameter flow cytometric assay. Blood samples were taken pre-operatively and during 5 months after surgery.

Results: When compared to controls, patients showed significantly higher median levels of PMPs (2268 and 280079 mp/L; $P < 0.0001$) and EMPs (2268 and 2807 mp/L; $P < 0.0001$). This was also the case for TF + MPs (1613 and 15028 mp/L; $P < 0.0001$). Patients with more advanced stages of cancer seemed to have higher levels of MPs, but no significant difference was found.

There was no significant decrease in any of the MPs levels during the 5 months after surgery. Subanalysis of groups with early and more advances stages of CRC did not change these results.

Conclusions: Our results show that patients with CRC have significantly higher levels of circulating MPs when compared to controls. No significant decrease in MPs levels were found In the 4 months after surgery.

PB 2.30-6

Biological markers in the progression of asymptomatic carotid stenosis

Martínez-Sales V, Vila V, Tembl J, Parkhutik V, Contreras T, Aguilera C and Lago A

Hospital Universitario y Politécnico la Fe, Valencia, Spain

Background: Asymptomatic carotid stenosis presents a high risk of suffering an ischemic stroke, and it is important to stratify said risk in order to select the cases that could benefit from preventive interventional treatment.

Aim: To determine biomarkers that relate to the progression of carotid stenosis.

Patients and Methods: We studied 40 patients with asymptomatic > 50% carotid stenosis and 40 healthy subjects. Circulating markers of endothelial damage (circulating endotelial cells, CECs; circulating microparticles, MPs; von Willebrand factor, vWF), inflammation (Interleukin-6, IL6; C-reactive protein, CRP; Fibrinogen, Fg) and tissue factor (TF) were determined.

Results are expressed as mean values ± standard deviations (SD). Data were analyzed using SPSS version 15.0., P-values < 0.05 were considered statistically significant. Statistical comparisons were performed using the Student's t test, and the analysis of variance (ANOVA) with Bonferroni *post hoc* analysis. Spearman's correlation test (IC 95%) was used.

Results: The levels of all markers studied were statistically higher in patients compared to controls: (i) endothelial damage markers, CECs (90 ± 61 vs. 10 ± 6 cell/mL, $P < 0.0001$), MPs (13344 ± 7944 vs.

8916 ± 5820 event/120s, $P < 0.05$) and vWF (220 ± 60 vs. 102 ± 29%, $P < 0.0001$); (ii) inflammatory markers: CRP (3.7 ± 5.3 vs. 1.1 ± 0.87 mg/dL, $P < 0.01$); Fg (316 ± 45 vs. 248 ± 37 mg/dL, $P < 0.0001$), and IL6 (2.5 ± 2.9 vs. 0.8 ± 0.7 pg/mL, $P < 0.02$).
MP levels showed a positive, significant correlation with TF ($r = 0.43$) and CRP ($r = 0.42$) ($P < 0.05$). Furthermore, levels of IL6 correlated with those of TF ($r = 0.61$; $P < 0.001$) and CRP ($r = 0.39$; $P < 0.5$), and Fg levels with CRP ($r = 0.42$; $P < 0.05$).
Conclusions: Asymptomatic carotid stenosis patients show elevated circulating markers of endothelial damage and inflammation. Our results indicate that markers of endothelial damage are those with the greatest increase, supporting, therefore, its role in carotid stenosis. We have presented initial data from a study whose purpose is to ascertain which set of biological markers and parenchymal or functional MRI findings can serve as predictive factors in asymptomatic carotid stenosis.
Supported by grant FIS PI10/00473.

PB2.31 – Endothelium and Disease

PB 2.31-1
Circulating endothelial cells in venous thromboembolism

Campos M[1], Torres C[1], Matos R[1], Morais S[1] and Lima M[2]
[1]Centro Hospitalar Porto; [2]Centro Hospitalar do Porto, Porto, Portugal

Background: The sequence of events leading to venous thrombosis is not well known. Recently it was suggested that activation of the coagulation system mediated by tissue factor precedes platelet activation in venous thrombosis. The source of tissue factor is not clear. Activated endothelial cells have been shown to express tissue factor *in vitro* and probably they may promote expression of tissue factor in intact venous endothelium.
Aims: To quantify CEC (circulating endothelial cells) and CEP (circulating endothelial progenitors) and evaluate soluble markers of endothelial activation levels in patients with venous thromboembolism (VTE). To characterize the CEC for the expression of activation (CD54, CD62E) and procoagulant (CD142) markers and investigate whether the expression of these markers correlates with other clinical and laboratorial data.
Methods: We recruited 16 patients with previous VTE (at least 1 month after the thrombosis) and 20 healthy individuals. The CEC were characterized and quantified by flow cytometry (FACS Calibur®, Becton Dickinson) using a single-platform method. The antibodies used were anti-CD146, anti-CD45, anti-CD133, anti-CD54, anti-CD62E and anti-CD142. CEC were identified as CD146 + CD45-CD133-. The soluble markers of endothelial activation evaluated by ELISA essays were: sP-selectin, sE-selectin, sICAM-1, sVCAM-1 (eBioscience); IMUNOBIND Tissue Factor (American Diagnostica Inc); vWF Ag (Siemens). We also collected the number of thrombosis episodes and the levels of fibrinogen, homocysteine, D-dimmers, FVIII, protein S, protein C and anti-thrombin.
Results: In VTE patients the number of CEC was increased ($P < 0.001$) and the number of CEP was decreased ($P = 0.029$). There was a statistically significant increase in the number of activation (CD54, CD62E) and procoagulant (CD142) markers, although the soluble markers levels (sICAM-1, sE-Selectin and sTF) weren't increased. There was a statistically significant increase in the levels of sVCAM-1 and vWF:Ag. The number of CD142+ CEC and the level of sTF were correlated with the number of thrombosis.
Conclusion: In our study, the number of CEC in patients with previous VTE is increased and they express activation and procoagulant markers. These results suggest that CEC are involved in the pathophysiology of venous thrombosis.

PB 2.31-2
Endotelial nitric-oxide synthase gene polymorphisms in early and late-onset severe preeclampsia

Alpoim PN[1], Carvalho Z[2], Carvalho Godoi L[2], Lemos Jardim L[2], Fernandes AP[2], Braga Gomes K[2] and Dusse LMS[2]
[1]Faculdade Farmácia da UFMG, Contagem; [2]Faculdade de Farmácia da UFMG, Belo Horizonte, Brazil

Backgound: Preeclampsia (PE) is a systemic syndrome that occurs in 3–5% of pregnant women and classically manifests as new-onset hypertension and/or proteinuria after 20 weeks of gestation. PE is a leading cause of maternal and neonatal morbidity and mortality. PE progresses with vasoconstriction, hipercoagulability and endothelial dysfunction, but the mechanisms are not fully understood. The L-arginine-NO pathway appears to play a central role in both normal pregnancy and PE. Several polymorphisms affecting endothelial nitric oxide synthase (eNOS) production levels or function were described, including G894T (Glu298Asp; exon 7), VNTR b/a (variable-number 27-bp tandem repeat; intron 4) and T-786C (promoter) polymorphisms in eNOS gene.
Aim: To investigate the frequency of these polymorphisms in early and late-onset severe preeclamptic and normotensive women.
Methods: This case-control study enrolled 53 women with early-onset severe PE, 45 women with late-onset severe PE and 103 nomotensive pregnant. DNA was extracted from whole blood using a mini Spin Kit. G894T (*Mbo*I) and T-786C (*Msp*I) genotyping was performed by PCR-RFLP analysis. The VNTR b/a polymorphism was detected by PCR allele specific. Statistical analysis was performed by qui square test (SPSS 13.0).
Results: The frequency of TT genotype (G894T) in the late-onset group (20%) was higher than control group (1.9%) ($P = 0.002$). The frequency of aa genotype (VNTR b/a) in the early-onset group (13.2%) was higher than late-onset group (2.2%) and control group (1.0%) ($P = 0.002$). No difference was observed for T-786C polymorphism among the groups.
Conclusion: Considering these genotypes frequencies, these results suggest that NO synthesis can be involved in vasoconstriction, hipercoagulability and endothelial dysfunction in PE cases, mainly in the late-onset form.
Keywords: Preeclampsia, nitric oxide, polymorphisms, endothelium.

PB 2.31-3
Evidence of endothelial dysfunction in patients with major depression: recovery after treatment with a selective serotonin reuptake inhibitor (SSRI)

Lopez-Vilchez I[1], Navarro V[2], Serra M[2], Molina P[1], Hernandez R[1], Diaz-Ricart M[1], Gasto C[2], Escolar G[1] and Galan AM[1]
[1]Department of Hemotherapy-Hemostasis, Hospital Clinic, CDB, IDIBAPS; [2]Clinic Psychiatry Institute, Hospital Clinic, Barcelona, Spain

Background: New emerging concepts suggest an association between major depression, inflammation and cardiovascular risk. Alterations of serotonergic mechanisms and its modulation could be involved not only in the enhanced cardiovascular risk in major depression, by promoting the activation of platelets and coagulation mechanisms, but also inducing endothelial dysfunction at the vascular level.
Aims: To investigate the possible association between major depression and endothelial dysfunction and the potential corrective effect of an antidepressive treatment with a selective serotonin reuptake inhibitor (SSRI).
Methods: To compare the degree of endothelial damage in samples from healthy subjects (CON) and major depressive patients at the time of diagnosis (P0), and after 8 (P8) and 24 weeks (P24) of treatment with a SSRI (S-citalopram), different markers were analyzed: (i) circu-

lating endothelial cells (CEC) and endothelial progenitor cells (EPC), by flow cytometry, (ii) soluble levels of von Willebrand factor (vWF) and VCAM-1 in plasma samples, by ELISA techniques; and (iii) changes in the expression of the adhesion receptor ICAM-1 on cultured endothelial cells (HUVEC) exposed to sera from both groups by immunofluorescence.

Results: Levels of CEC in P0 samples were increased with respect to healthy controls (99.9 ± 11.5 vs. 48.5 ± 7.2 CEC/mL, $P < 0.01$). Along the SSRI treatment, levels of CEC decreased progressively reaching values similar to controls (P8: 81.2 ± 15.6 and P24: 49.7 ± 7.5 CEC/mL, respectively). The EPC values were lower in P0 samples compared to healthy subjects, without reaching statistical significance. Plasma levels of VWF and VCAM-1 in P0 samples were increased vs. healthy controls (vWF: 126.5 ± 11.7% vs. 87.1 ± 8.1%, $P < 0.01$; and sVCAM-1: 768.7 ± 110.4 vs. 532.8 ± 31.2 ng/mL, $P < 0.05$ respectively), but no significant differences were observed during the SSRI treatment. The exposure of HUVEC to P0 sera samples resulted in an increment of the expression of ICAM-1 on the cell surface with respect to CON cells. Expression of ICAM-1 was normalized when HUVEC were exposed to samples from patients under SSRI treatment for 24 weeks (P24).

Conclusions: Our results confirm the presence of endothelial dysfunction associated with major depression and indicate that treatment with a selective serotonin reuptake inhibitor have a potential protective role in the modulation of the pro-inflammatory state developed in these patients.

PB 2.31-4

Endothelial activation in patients with superficial vein thrombosis (SVT) of the lower limbs

Falcinelli E[1], Cosmi B[2], Filippini M[2], Petito E[1], Legnani C[2], Cini M[2], Migliacci R[3], Gualtiero P[2] and Gresele P[1]

[1]University of Perugia, Perugia; [2]S.Orsola-Malpighi University Hospital, Bologna; [3]Ospedale della Valdichiana, S. Margherita, Cortona, Italy

Background: The association between venous thromboembolism (VTE) and arterial cardiovascular events has been confirmed by several epidemiologic and experimental studies in the last few years. We have previously shown that patients with spontaneous VTE present an endothelial dysfunction, suggesting that endothelium is the link between venous and arterial thrombosis. Superficial vein thrombosis (SVT) of the lower limbs has long been considered a benign disorder, but more recently several studies have demonstrated that SVT shares the same risk factors of VTE and carries a relevant risk of thromboembolic complications. As a result, it has been advocated that SVT should be considered the superficial venous manifestation of VTE. No data are available on SVT and endothelial function.

Aims: Aim of the present study was to establish whether patients with symptomatic SVT of the lower limbs have altered circulating markers of endothelial activation.

Methods: One hundred and twenty-four patients with SVT of the internal or external saphenous veins or their collaterals of at least 4 cm in length underwent blood sampling for measuring soluble P-selectin and von Willebrand factor antigen (vWFAg), markers associated with damage of the endothelium, on the day of diagnosis, before starting treatment. The severity of symptoms was also determined using the Visual Analogue Score (VAS) for pain.

One hundred and seventeen healthy controls, matched for sex and age (M/F:53/64, mean age 65), were simultaneously studied. A subgroup of SVT patients ($n = 22$) was reassessed at a subsequent time, distant from the event (2 months later).

Results: Soluble P-selectin was signficantly higher in SVT patients (M/F:56/68, mean age 66), than in controls (mean ± SD: 38 ± 13.4 ng/mL vs. 34 ± 25 ng/mL; $P = 0.029$). vWFAg was also higher in patients than in controls (mean ± SD: 209 ± 82% vs. 154 ± 75%; $P < 0.0001$). At follow up, P-selectin and vWFAg remained significantly higher in SVT patients than in controls (42.2 ± 3.2 ng/mL and 189.1 ± 8.2% respectively), without significant differences with the acute phase.

No correlation was observed between the levels of vWFAg or P-sel and the extension of SVT or the rate of subsequent recurrent SVT events.

sPsel levels, but not VWF:Ag levels, were significantly higher in patients with a Visual Analogue Score for pain > 5 (27.4 ± 2.5 ng/mL vs. 22 ± 2.55 ng/mL; $P = 0.047$).

Conclusions: Patients with symptomatic SVT of the lower limbs have a systemic perturbation of endothelial function, as revealed by significantly higher plasma levels of markers of endothelial activation. Endothelial dysfunction is not due to the inflammatory reaction accompanying acute SVT. Increased endothelial-activation markers do not seem to predict recurrent superficial events

PB 2.31-5

Toll-like receptor 4 and the inflammasome NALP3 mediate the activation and damage of endothelial cells in advance chronic kidney disease: protective effect of defibrotide

Martin S[1], Caballo C[1], Molina P[1], Gutiérrez G[1], Vera M[2], Cases A[2], Escolar G[1] and Diaz-Ricart M[1]

[1]Department of Hemotherapy-Hemostasis, Hospital Clinic, CDB, IDIBAPS; [2]Department of Nephrology, Hospital Clinic, IDIBAPS, Barcelona, Spain

Background/Aim: Endothelial dysfunction (ED) is a common pathologic condition for the development of atherothrombotic complications in many diseases. Our group has been able to reproduce *in vitro* and characterize the ED associated with chronic kidney disease (CKD). However, the relative contribution of the uremic environment, the impact of the substitutive therapies, and the precise molecular mechanisms involved are still under investigation. Involvement of the innate immunity receptor Toll like receptor (TLR) 4 and the inflammasome NALP3 in the inflammatory response of endothelial cells was explored.

Methods: Cultured endothelial cells were exposed to sera from three groups of CKD patients, under: conservative treatment (predialysis) (PreD), undergoing hemodialysis (HD) and peritoneal dialysis (PD). Activation of the inflammation related proteins p38MAPK, Akt, and the transcription factor NFkappaB, changes in the expression of TLR4 and ICAM1 and activation of the NALP3 components were evaluated in these cells. The effect of the novel pharmacological agent with pleiotropic actions on hemostasis, defibrotide, was also investigated in this *in-vitro* model.

Results: TLR4 was found to be expressed in EC both in the cytoplasm and at the surface. After exposure to the sera under study, there was an increase in the expression of TLR4 and a redistribution to their luminal surface in the three situations (PreD, HD and PD). This effect was paralleled by activation of the stress protein Akt and the transcription factor NFκB, together with a higher expression of ICAM1 at the EC surface, which was partially prevented by an antibody to TLR4. Exposure of EC to the sera from PreD, HD and PD groups led to the assembly of NALP3 and TXNIP proteins, with the activation of caspase-1 and release of IL-1β. This inflammatory response was observed in association with the three uremic groups, being more intense in response to the sera from dialyzed patients. Defibrotide was able to prevent these changes.

Conclusion: TLR4 and the multiprotein oligomer NALP3 inflammasome, two crucial elements of the innate immune response, were found to be associated with the development of endothelial activation and damage in response to chronic inflammation and oxidative stress. Further research is needed to explore their usefulness as potential targets to prevent the development of endothelial damage. In addition, defibrotide showed a preventive effect on the inflammatory reaction observed.

PB 2.31-6

Biomarkers of endothelial dysfunction in cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)

Cesari F[1], Pescini F[2], Gori AM[1], Giusti B[1], Donnini I[2], Zicari E[3], Federico A[3], Balestrino M[4], Abbate R[2] and Inzitari D[2]

[1]Azienda Ospedaliero-Universitaria Careggi, University of Florence; [2]University of Florence, Florence; [3]University of Siena, Siena; [4]University of Genoa, Genoa, Italy

Background: Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL), is an inherited disease due to cerebral microangiopathy presenting with variable pictures, including stroke, progressive cognitive impairment and disability. Among pathogenic processes, endothelial dysfunction has been hypothesized.

Aim: To evaluate the role of biomarkers of endothelial dysfunction (EPCs and CPCs, von Willebrand factor [vWF], and thrombomodulin [TM]) in a large CADASIL series.

Methods: Forty-five CADASIL patients and 33 sex and age-matched controls were enrolled. EPCs were measured by using flow cytometry and defined as positive for CD34/KDR, CD133/KDR and CD34/CD133/KDR; CPCs as positive for CD34, CD133 and CD34/CD133. vWF and TM were measured using commercially available ELISA kits.

Results: In comparison with controls, CADASIL patients presented significantly lower EPCs levels [CD34/KDR:0.07 vs. 0.1 cells/μL, $P = 0.009$; CD133/KDR:0.07 vs. 0.1 cells/μL, $P = 0.008$; CD34/CD133/KDR:0.05 vs. 0.1 cells/μL, $P = 0.002$], significantly higher vWF activity [130.2 vs. 91.7%, $P = 0.014$] and similar levels of TM [29.2 vs. 27.4 ng/mL, $P = 0.955$].

CPCs were not significantly lower in CADASIL, but patients with stroke or dementia had significantly reduced CPCs levels than patients without [CD34:1.85 vs. 2.83 cells/μL, $P = 0.014$; CD133:1.77 vs. 2.78 cells/μL, $P = 0.009$; CD34/CD133:1.77 vs. 2.73 cells/μL, $P = 0.009$]. Both vWF and TM were not significantly higher in the same subgroup of CADASIL patients with a more severe phenotype.

Conclusions: This is the largest series of CADASIL patients in which biomarkers of endothelial dysfunction have been studied. We confirmed the previously reported association between EPCs and CPCs and the disease, and we found an association with vWF, supporting the hypothesis of the presence of endothelial dysfunction in this disease and its potential role in modulating phenotype.

PB2.32 – Immune Thrombocytopenia Purpura – II

PB 2.32-1

Restrospective analysis of the incidence of refractory ITP and response to second line treatments. Experience in a single centre.

Gomez-del-Castillo MC

Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Background: Primary Immune Thrombocytopenia (ITP) is an acquired autoimmune disease. It is characterized by an accelerated destruction and an inadequate production of platelets. Corticosteroids are commonly used as first line treatment but the incidence of recurrent ITP and response to second line treatments is not well established.

Aims: The aim of this review is to analyze the incidence of recurrent ITP and its response to second-line treatments.

Methods: We conducted a retrospective, observational study based on the follow-up of patients diagnosed with ITP at our centre during the last 28 years. Patients were classified by first and second line treatment administrated and by the obtained response and its duration. We defined a complete response as platelet count > 100×10^9/L for more than 6 months without treatment and with no bleeding symptoms. Maintained response was defined as platelet count > 50×10^9/L, for more than 6 months without treatment and with no bleeding symptoms.

Results: Seventy-one patients were diagnosed with ITP, receiving treatment 90.1% (64 patients). Sixty-two of them (96.8%) were treated with corticosteroids as first line treatment. Global response was 74.2%, but only 11.3% could be classified as complete responses and 19.3% as maintained responses. The rest of the patients did not achieved response according to the criteria defined above. Average time of response were 48.5 months (8–156) and 58.1 months (16–156) for complete and maintained response respectively.

Most frequent second line treatments were romiplostim, rituximab and splenectomy. Twenty four patients (37.5%) received romiplostim, 70.1% of them as second line treatment. 8.3% obtained a complete response with an average duration of response of 18 months (10–26). Twenty-four percent of them (10 patients) obtained response but are still on treatment. A synergistic effect seems to exist in associating low dose corticosteroids and romiplostim, but this fact is not analyzed in this review due to short time follow-up.

Twelve patients (18.7%) received rituximab. Three of them (25%) achieved complete response, that lasted an average time of 62 months (25–80 months). One of them achieved a maintained response that lasted for 24 months.

A total of twenty one patients (32.8%) underwent splenectomy. 28.6% of them (six patients) reached complete response. Average time of response was 53 months (10–108). One patient reached a maintained response that lasted 14 months.

Conclusions: First-line treatment for ITP was corticosteroids in the majority of patients. However, the incidence of recurrent ITP is higher than expected, reaching 76%. Almost 20% of the patients reached a maintained response.

Second line treatments rescued 31.4%, all of them reaching long term complete responses. Rituximab and esplenectomy achieved the best durable responses.

It is too soon to analyze the incidence of long term complete responses related to romiplostim, although an 8.3% of the patients reached a complete response. It is an effective salvage therapy, although it is hard to discontinue treatment.

16.2% of the patients receiving second line treatments achieved a maintained response, concluding that 47% of refractory/recurrent patients were rescued with second line treatments

PB 2.32-2

Differential effects of All-Trans Retinoid on expansion of CD4+CD25+Foxp3 Treg subpopulations in patients with chronic immune thrombocytopenia

Dai L

Key Lab of Thrombosis and Hemostasis, Jiangsu Institute of Hematology, the First, Suzhou, China

Objective Immune thrombocytopenia (ITP) is an immune-mediated disorder. In addition, T-cell is also involved in platelet destruction or marrow suppression. During immune responses CD4+ T cells can differentiate into a range of cell types, including T helper type 17 (Th17) and regulatory T cells (Treg). The goal of the present study is to investigate the therapeutic effects of all-trans-retinoic acid (ATRA) plus prednisone treatment on adult refractory idiopathic thrombocytopenic purpura (RITP) and to further explore the underlying mechanisms.

Methods: The concentrations of the peripheral blood $CD4^+$ T cells (TH17,nTREG and mTREG) were analyzed by flow cytometry,the levels of IL-17, IL-10, TGF-β cytokines were confirmed by enzyme-linked immunoassay (ELISA), and the expression of RORγ, Foxp3 were detected by semiquantitative reverse-transcription polymerase chain reaction (RT-PCR) in 45 RITP patients before and after treatments, with 20 normal individuals as respective controls.

Results: The overall response rate of ATRA plus prednisone treatment in RITP patients was 48.9%, 22.2% ($n = 10$) of patients with a complete response and 26.7% ($n = 12$) of patients with a partial response. The levels of regulory T cells were significantly increased in patients after ATRA plus prednisone treatment,especially $CD31^{-}CD4^{+}CD25^{+}CD127^{+}CD45RO^{+}$ mTreg ($P < 0.05$); The concentrations of IL-10, TGF-β was increased ($P < 0.05$),whereas IL-17 factor showed no obvious change in the effective groups after treatment ($P > 0.05$). The expression levels of Foxp3 enhanced dramatically after treatment in real-time RT-PCR analysis ($P < 0.05$). However, the concentrations of ROR-γ showed no obvious change after the therapy in real-time RT-PCR analysis ($P > 0.05$).
Conclusions: Sixty percent of ARITP patients recovered after ATRA plus prednisone treatments. The therapeutic effects of ATRA plus prednisone may be involved in the increased levels of mTreg cells in peripheral blood.

PB 2.32-3
Nonclassical monocytes are expanded and involved in the pathogenesis of immune thrombocytopenia

Yang Y, Zhang D, Zhang X, Xuan M, Fu R, Xue F, Liu X, Zhang L and Yang R
Institute of Hematology and Hospital of Blood Diseases, Tianjin, China

Background: Human monocytes are heterogeneous and play an important role in the inflammatory and autoimmune response. CD16+ monocytes have been described to increase in active immune thrombocytopenia (ITP) patients. Recently, based on function and phenotype, monocytes are classified into three subsets, with the CD16+ subset further subdivided into the intermediate (CD14++CD16+) and the nonclassical (CD14+CD16++) group.
Aim: To investigate the distribution of monocyte subsets in ITP patients and their possible role in the pathogenesis of this disease.
Methods: Seventy-three patients diagnosed with ITP (47 females and 26 males, median age: 40 years; median platelet counts: 23×10^9/L) were enrolled in this study after informed consent obtained. This study was approved by the medical ethic committee of our hospital. All patients had not been treated for at least 1 month before sampling. The frequencies of monocyte subsets were determined by flow cytometry. Cytokine production from monocyte subsets was measured by ELISA. The sorted monocyte subsets were co-cultured with CD4+T cells and autologus platelets ($n = 12$) respectively. The proliferation of auto-reactive CD4+ T cells was determined by BRDU ELISA. To detect the relationship between monocyte subsets and T cell differention, the intracellular IL-17A, IFNG and IL-4 levels of T cells co-cultured with different monocyte subsets were analyzed by flow cytometry. Nonparametric statistic tests were used: Mann-Whitney U test or Wilcoxon test was performed for independent or related two-group analysis, respectively. $P < 0.05$ was considered significant and results were described as median [inter-quartile range].
Results: The frequency of nonclassical monocytes was significantly increased in active patients ($n = 73$) compared with controls ($n = 49$), (untreated ITP: 5.44% [7.52%] vs. Ctrl: 1.83% [2.34%] $P < 0.001$). In 23 patients, the monocyte subsets were reevaluated after treatment with glucocorticoids for 7 days, nonclassical monocytes were decreased markedly (untreated: 4.95% [4.7%] vs. treated: 0.96% [4.35%] $P < 0.001$). The frequency of intermediate monocytes was increased in active patients (untreated ITP: 10.54% [3.58%] vs. Ctrl: 7.6% [6.2%] $P < 0.001$) and remained stable after glucocorticoids therapy (untreated: 10% [4.2%] vs. treated: 9.79% [9.18%] $P = 0.798$). The frequency of classical monocytes was decreased in active patients (untreated ITP: 82.6% [7.21%] vs. Ctrl: 90.18% [7.31%] $P = 0.001$) but recovered after glucocorticoids therapy (untreated: 83.15% [9.32%] vs. treated: 88.62% [7.73%] $P = 0.019$). Compared to the controls, serum TNF-α ($P = 0.004$) and IL-1β ($P < 0.05$) levels in ITP patients were elevated. After stimulation with LPS for 20 h, nonclassical monocytes produced more TNF-α ($P < 0.05$) and IL-1β ($P = 0.057$) than the intermediate. However, the three subsets showed no difference in the proliferation of platelet reactive T cells. Further studies demonstrated that nonclassical monocytes skewed Th1/Th2 response (Th1/Th2: nonclassical 15.36 ± 4.25 vs. Ctrl 8.92 ± 3.67, $P < 0.05$) and promote the expansion of Th17 cells (nonclassical/T cells 1.26%[1.02%] vs. Ctrl 0.73% [0.67%], $P < 0.05$).
Conclusion: This study demonstrated that nonclassical monocytes may hallmark the activity of ITP and be involved in the immune disfunction of this disease.

PB 2.32-4
CXCL-10/IP-10 chemokine expression in patients with immune-mediated thrombocytopenia

Eissa DS, Shalaby NA, Ismail MA and Eissa DG
Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: Immune thrombocytopenic purpura (ITP) is a heterogeneous clinical syndrome characterized by immune-mediated increase in platelet clearance through the production of autoantibodies against platelet glycoproteins, resulting in enhanced Fc-mediated destruction of platelets by reticuloendothelial system macrophages. CXC chemokine ligand-10/interferon-γ-inducible protein-10 (CXCL-10/IP-10), the prototype of the CXC family, is a T-helper (Th) 1 cytokine that exhibits a chemotactic activity for activated Th1 cells and is suggested to be involved in various Th1-dominant autoimmune diseases including ITP.
Aims: This study aimed to evaluate the plasma level of CXCL-10/IP-10 in patients with ITP as well as investigate its role in the pathogenesis and diagnosis of the disease.
Methods: Plasma CXCL-10/IP-10 was evaluated using enzyme-linked immunosorbent assay (ELISA) in 90 patients with ITP; 60 with de-novo active untreated ITP and 30 with remitted ITP, compared with 20 healthy volunteers.
Results: Significantly higher levels of CXCL-10/IP-10 were detected in both active ($P < 0.001$) and remitted ($P = 0.01$) ITP compared with controls, and in active compared with remitted patients ($P < 0.001$). The best cut-off value of 120 and 70 pg/mL were able to sharply discriminate between active ITP and controls, and remitted ITP and controls, respectively. No significant correlation was found between CXCL-10/IP-10 and platelet counts of either active or remitted patient subgroups.
Conclusions: CXCL-10/IP-10 is significantly elevated in active ITP, consistent with the Th1 characterization of the disease, suggesting CXCL-10/IP-10 as a pathogenetic and diagnostic marker of ITP.

PB 2.32-5
Detection of autoantibodies against platelet glycoproteins in patients with idiopathic thrombocytopenic purpura by a flow cytometric bead array

He Y, Zhao YX, Zhu MQ and Ruan C
The First Affiliated Hospital Soochow University, Suzhou, China

Background: Idiopathic Thrombocytopenic Purpura (ITP) is an autoimmune disorder characterized by premature platelet destruction induced by autoantibodies directed against platelet glycoproteins. Despite being a clinically important disorder, ITP lacks a feasible diagnostic assay for routine clinical use.
Aims: The aim of this study is to establish a flow cytometric bead array (CBA) to detect autoantibodies against platelet glycoproteins (GPs) in patients with ITP.
Methods: Polystyrene beads of different fluorescent intensities were coated with monoclonal antibodies against human platelet GPs Ib/IX (SZ1), Ib (SZ2), IIIa (SZ21), GPIIb (SZ22), and P-selectin (SZ51), and

incubated with platelet lysates from patients with ITP or control individuals. The captured platelet antigen-autoantibody complexes were detected by an FITC-labeled goat anti-human IgG antibody by flow cytometry. The mean fluorescence intensity (MFI) in samples from 50 ITP patients, 37 non-ITP patients and 49 healthy controls was determined. The results were compared with that from the traditional monoclonal antibody immobilization of platelet antigen (MAIPA) technique.

Results: The newly established CBA was designed to detect five platelet-specific autoantibodies against GPIb/IX, GPIb, GPIIIa, GPIIb, and P-selectin simultaneously. Coefficients of variation (CVs) of intra-assay were 9.25%, 5.25%, 3.32%, 2.33% and 2.51%, respectively, and those of inter-assay were 10.89%, 6.58%, 8.65%, 7.12% and 7.98%, respectively. The MFI values of SZ1, SZ2, SZ21, SZ22 and SZ51 in ITP group were all higher than those in non-ITP or healthy groups (SZ1: 5.03 ± 3.90 vs. 1.91 ± 0.64 or 1.88 ± 0.84, $P < 0.01$; SZ2: 4.67 ± 3.66 vs. 2.36 ± 1.16 or 2.16 ± 0.93, $P < 0.01$; SZ21: 2.70 ± 1.31 vs. 1.08 ± 0.32 or 1.14 ± 0.41, $P < 0.01$; SZ22: 2.52 ± 1.19 vs. 1.10 ± 0.41 or 1.28 ± 0.57, $P < 0.01$; and SZ51: 2.33 ± 1.19 vs. 0.96 ± 0.40 or 1.06 ± 0.67, $P < 0.01$). In ROC analysis, with a cut-off value of 1.35, 0.60, 0.49, 0.48 and 0.63, respectively, the area under curve of the CBA was 0.84 (SZ1), 0.81 (SZ2), 0.89 (SZ21), 0.90 (SZ22) and 0.92 (SZ51). When the data of five antibodies were combined, the sensitivity of the CBA was 72.0% (36/50), significantly higher than that of MAIPA (48.0% (24/50), $c2 = 6.00$, $P < 0.05$).

Conclusion: We developed a CBA with five monoclonal antibodies to detect autoantibodies against human platelet GPs. Our results show that this assay was more sensitive than traditional methods, indicating that the assay may be used to improve the diagnosis of ITP.

PB2.33 – ADAMTS13: Clinical – II

PB 2.33-1

Importance of measuring circulating ADAMTS13 immune complexes in addition to free antibodies in patients with acquired TTP

Turecek PL, Ferrari S, Palavra K, Gruber B, Plaimauer B, Rottensteiner H and Scheiflinger F

Baxter Innovations GmbH, Vienna, Austria

Background: A functional deficiency of ADAMTS13 results in accumulation of uncleaved, highly adhesive Willebrand factor (VWF) multimers in plasma leading to increased platelet aggregation and thrombus formation in the microcirculation. Anti-ADAMTS13 autoantibodies are the main cause of severe ADAMTS13 deficiency in acquired thrombotic thrombocytopenic purpura (aTTP). Circulating ADAMTS13-specific immune complexes (IC) as a potential factor in disease pathogenesis have been described in the plasma of aTTP patients.

Aim: We analyzed plasma samples from a large cohort of patients with aTTP for the presence of circulating IC and correlated these data with free anti-ADAMTS13 antibodies, ADAMTS13 activity (ADAMTS13:Ac), ADAMTS13 antigen (ADAMTS13:Ag) and inhibitor.

Material and Methods: We developed an ELISA assay to specifically determine IC levels in which the antigen portion is captured by a polyclonal anti-ADAMTS13 IgG and the immunoglobulin component detected by a class-specific antibody. Co-immunoprecipitation of ADAMTS13 with total IgG was employed as an orthogonal method. All other ADAMTS13 parameters were determined by standard protocols.

Results: Eighty-eight patients were analyzed in the acute phase. Free and ADAMTS13-bound IgG anti-ADAMTS13 antibodies were detected in 94% and 96% of patients, respectively. In both instances, IgG4 was the most prevalent IgG subclass (free: 94%, complexed: 93%). ADAMTS13:Ac and ADAMTS13:Ag were undetectable in most patients or very low. In remission (25 patients, median length of remission 12 months), 80% of patients still had detectable free IgG antibodies, mainly IgG4 (70%) followed by IgG1 (50%). ADAMTS13-specific ICs were found in 96% of patients, with IgG4 being again the most prevalent subclass (92%). Importantly, in 20% of patients, ADAMTS13-IgG IC were detected in plasma although free IgG antibodies were absent.

A comparison of ADAMTS13:Ac and ADAMTS13:Ag levels between acute and remission phase samples showed a statistically significant increase in both parameters at remission, whereas ADAMTS13 inhibitor and IgG anti-ADAMTS13 (total and subclasses) antibody titers were decreased. A trend towards reduced or undetectable titers at remission was also observed for ADAMTS13-specific IC of the IgG1, IgG2 and IgG3 subclasses, but not for the IgG4 subclass.

Conclusions: Our analysis provided for the first time a complete picture of the autoantibody response in aTTP. ADAMTS13-specific IC were mainly of the IgG4 subclass and persisted for a long time, as they could be detected in plasma of aTTP patients not only in the acute phase but also in remission. Our study suggests that in addition to characterization of autoantibodies against ADAMTS13, ADAMTS13-specific IC also need to be determined at the time of diagnosis and during remission to obtain a full picture of disease status.

PB 2.33-2

Mutations and polymorphisms in adult onset pregnancy related TTP

Langley KM, Underwood M, Lane P, Lamb K, Scully M and Machin SJ

UCL, London, UK

Background: Thrombotic thrombocytopenia purpura (TTP) is a rare but potentially fatal microangiopathic haemolytic anaemia (MAHA) which afflicts approximately six individuals per million per year. It is characterised by a congenital, autoimmune or idiopathic reduction in ADAMTS13 (a disintegrin and metalloprotease with thrombospondin type 1 motif). Adult onset TTP is often precipitated by physiological stress and pregnancy related TTP is a subgroup which may represent up to one third of annual TTP cases. It can be difficult to diagnose and is characterised by recurrent foetal loss, maternal morbidity and mortality.

Aims: We examined the differences in the ADAMTS13 gene in our subjects compared to wild type, including intronic, silent and missense polymorphisms and mutations.

Method: DNAwas extracted from EDTA samples in 15 pregnancy related TTP subjects on the UK TTP Registry after informed consent. ADAMTS13 exons and exon- intron boundaries were amplified using polymerase chain reaction (PCR) and sequenced. Any variations between the ADAMTS13 genotype of patients from our reference sequence were recorded. The variations found were assessed for their frequency in the general population using the 1000 genome project and Hapmap.

Results: All 15 patients had an ADAMTS13 activity of < 5% (NR 66–120%) on admission. We found that our cohort had a number of ADAMTS13 variations in common which have a very low prevalence in the general population. For example the R7W polymorphism is present in 13% of the European population, but occurred in 11/15 (73%) of our patients. Each patient had at least two variations from wild type ADAMTS13. We focused on three variations which occur in exons 23 and 24: the A1033T SNP is often co-inherited with the R1060W mutation (which is associated with decreased ADAMTS13 activity due to decreased secretion); 12/15 (80%) of our cohort had both variations, where the general prevalence is 2% and < 1% respectively. None of our cohort had inherited one variation without the other. Upstream from this pairing, the V970V SNP was found in 9/15 (60%), but occurs at a frequency of 2% across all ethnic groups. Of the 12 patients who had inherited both A1033T and R1060W, 8/12 (67%) also had inherited V970V.

Conclusion: The potential impact of ADAMTS13 non synonymous polymorphisms has received little investigation and synonymous poly-

morphisms have been regarded as devoid of clinical significance. However both appear to occur far more often in the disease state than anticipated from general population frequencies. Some of these may potentially have a real effect on the secretion or activity of ADAMTS13 whereas others may be linked to the mutations responsible for the disease. Further investigation would be needed to determine if this is the case. It is of particular interest that patients with the R1060W mutation presented later on in life during pregnancy and that this mutation was found to occur frequently with the A1033T polymorphism and V970V synonymous polymorphism. This is something that should be considered for *in vitro* studies as there may be possible modulatory effects.

PB 2.33-3

Variability in measurement of ADAMTS13: a UK NEQAS multicentre exercise for ADAMTS13 assays

Jennings I[1], Mackie IJ[2], Fretwell R[3], Kitchen S[1], Kitchen D[1], Woods T[1] and Walker I[1]

[1]UK NEQAS (Blood Coagulation), Sheffield; [2]University College London Haemostasis Research Unit, London; [3]Sheffield Haemophilia and Thrombosis Centre, Sheffield, UK

Background: ADAMTS13 is a plasma metalloprotease which regulates the multimeric size of VWF by cleaving the protein at Tyr1605-Met1606. ADAMTS13 deficiency (acquired or congenital) is frequently observed in thrombotic thrombocytopenic purpura (TTP). This disease primarily requires a clinical diagnosis, but ADAMTS13 assays can provide confirmation, help characterise the phenotype of the deficiency, may be useful in monitoring treatment, and can be used to identify family members with ADAMTS13 deficiency.

Methods: We describe here a multicentre exercise for ADAMTS13 assays, in which 22UKand International centres performed assays on three lyophilised plasma samples. AD12:01 was a normal plasma sample; AD12:02 was from a 22 year old female diagnosed with TTP, who had received 8 days of plasma exchange and Rituximab; AD12:03 was from a 58 year old female with acquired TTP, who had 10 days of plasma exchange prior to sample collection.

Results: All centres performed activity assays, with six also performing antigen assays, and nine performing IgG anti-ADAMTS13 assays. Median (and range) ADAMTS13 activity in each sample was: AD12:01 78% (25.3–104.0), AD12:02 60.5% (33.0–71.5), and AD12:03 < 3% (0.0–37.1). All but one centre reported ADAMTS13 activity below 10% for sample AD12:03. However, two centres reported higher ADAMTS13 activity levels in sample AD12:02 than in sample AD12:01. One of these also reported a level of 37% activity in sample AD12:03. In total, three centres reported activity assay results on sample AD12:01 below the lower limit of their reference range. Seven centres reported results below their reference range for sample AD12:02. Results amongst centres using collagen binding assay (CBA)-based methods were lower than for centres using other methodologies by an average 46%. Nine centres used the Technozym ADAMTS-13 INH kit for anti-ADAMTS13 assays, assays (manufacturer's cut-off 15 μ****/mL), but agreement was suboptimal. Median (CV) anti-ADAMTS13 activity in each sample was: AD12:01 9 μ**/mL (37%), AD12:02 14.5 μ***/mL (29%), and AD12:03 26.7 μ***/mL (27%). Frequency of testing clinical samples in different centres varied markedly – two centres reported that they perform fewer than two assays per annum, with five centres reporting more than 100 assays each year.

Conclusions: Currently no international standards or any other external quality assessment programme are available for ADAMTS13 assays. Development of both will assist in standardisation and therefore improved clinical utility of these assays.

PB 2.33-4

Decreased ADAMTS13 activity and its clinical significance in patients with idiopathic portal hypertension

Takaya H, Uemura M, Fujimoto M, Ishii S, Morioka C, Kawaratani H, Hayakawa M, Matsumoto M, Fujimura Y and Fukui H

Nara Medical University, Kashihara, Nara, Japan

Background: Idiopathic portal hypertension (IPH) is characterized by a noncirrhotic portal hypertension with hypersplenism, but is distinctly different from liver cirrhosis (LC) with regenerative nodules. The characteristic hepatic lesions in IPH are the occulusive changes of intrahepatic portal branches and portal fibrosis, but its pathogenesis has not been fully clarified. Deficiency of ADAMTS13 activity (ADAMTS13:AC) results in the accumulation of unusually large von Willebrand factor multimers (UL-VWFM) and platelet thrombi formation. We demonstrated that an imbalance between the decreased ADAMTS13:AC and the increased substrates may reflect the predisposing state for platelet thrombi formation in advanced LC patients (Thromb Haemost, 2008; 99:1019).

Aims: The aim of this study was to analyze ADAMTS13:AC and its related parameters, and to explore the clinical significance in patients with IPH in comparisons with LC.

Methods: Patients studied were chronic hepatitis (CH) in 33, LC in 109 (Child A-LC in 35, Child B-LC in 33 and Child-LC in 41), and IPH in 15. The diagnosis of IPH was based on the definition and diagnostic criteria described in the Japan IPH Research Committee. Liver biopsy under laparoscopic examination and angiography were performed in all patients with IPH. Plasma ADAMTS13:AC was determined by both a classic VWFM assay and a chromogenic ELISA. VWF:Ag was measured by ELISA, and VWFM patterns were analyzed by SDS-0.9% agarose gel electrophoresis.

Results: The ADAMTS13:AC measured by ELISA strongly correlated with those determined by the VWFM assay. ADAMTS13:AC was 57% (mean) in IPH compared to 100% in healthy controls, 87% in CH, 79% in Child A-LC, 63% in Child B-LC, and 31% in Child C-LC. No patients with IPH whose ADAMTS13:AC showed severe deficiency (< 3% of controls) were found, while five end-stage LC had severe deficiency. VWF:Ag was 254% in IPH compared to 100% in normals, 245% in CH, 320% in Child A-LC, 436% in Child B-LC, and 486% in Child C-LC. As a result, the ratio of VWF:Ag to ADAMTS13:AC was 5.4 in IPH, 1.0 in normals, 2.9 in CH, 4.3 in Child A-LC, 13.3 in Child B-LC, and 43.2 in Child C-LC. UL-VWFM was not found in IPH, whereas it was detected in LC with the lowest ADAMTS13:AC (23%) and the highest values of Child-Pugh score (12.4), serum creatinine (2.4 mg/dL) and blood ammonia (144 μg/dL), which corresponded to 16% of LC patients whose ADAMTS13:AC showed < 50%. In IPH, ADAMTS13:AC decreased in patients with hepatic encephalopathy and severe liver atrophy than those without (41% vs. 67%, $P < 0.05$). The ratio of VWF:Ag to ADAMTS13:AC inversely correlated with platelet count ($r = -0.534$, $P < 0.05$), hemoglobin ($r = -0.501$, $P < 0.05$), and serum albumin ($r = -0.579$, $P < 0.05$).

Conclusions: In IPH, ADAMTS13:AC decreased to 57% of normals, the value of which corresponded to Child B-LC patients. VWF:Ag increased 2.5 times higher than normals. The imbalance of enzyme to substrate indicates platelet hyperaggregability, and may contribute to anemia, reduced functional liver capacity, and the occurrence of hepatic encephalopathy together with the development of liver atrophy in patients with IPH.

PB 2.33-5

An unbalance between von Willebrand Factor and its cleaving protease ADAMTS13 in acute liver failure: implications for hemostasis and correlations with clinical outcome

Hugenholtz GCG[1], Adelmeijer J[1], Meijers JC[2], Porte RJ[1], Stravitz TR[3] and Lisman T[1]

[1]*University Medical Center Groningen, Groningen;* [2]*Academic Medical Center Amsterdam, Amsterdam, The Netherlands;* [3]*Virginia Commonwealth University, Richmond, VA, USA*

Background: Liver diseases are frequently associated with substantial changes in the hemostatic system. Traditionally these changes were believed to result in a hypocoagulable state. Recent clinical and laboratory studies have challenged this concept an it has now been well established that patients with chronic liver diseases are in 'hemostatic rebalance', which results from a commensurate decline in pro- and antihemostatic drivers, and from the presence of compensatory mechanisms sustaining an appropriate hemostasic function. In acute liver failure (ALF), the net effect of all hemostatic changes is not clear, partly because these alterations in the hemostatic system in these patients have been less well defined when compared to those in patients with chronic liver failure. In an effort to elucidate this issue, we are systematically studying consequences of hemostatic defects in patients with ALF.

Aims: In the present study, we assessed levels and functionality of the platelet-adhesive protein von Willebrand factor (VWF) and its cleaving protease ADAMTS13 in plasma of patients with acute liver injury and acute liver failure (ALI/ALF). Furthermore, we explored possible associations between VWF, ADAMTS13 and disease outcome, as plasma levels of these molecules have been associated with progressive liver failure.

Methods: We measured functional parameters of VWF and ADAMTS13 in plasma of 50 patients taken on the day of admission for ALI/ALF. In addition, we investigated the ability of patient plasma to support platelet adhesion and aggregation in a flow-based model. Finally, we explored possible relationships between VWF/ADAMTS13 and ALI/ALF specific complications, frequency of liver transplantation, spontaneous survival and death rates. Plasma of 40 healthy volunteers served as controls.

Results: VWF antigen levels were highly elevated in patients with ALI/ALF. In contrast, the collagen binding activity as well as the VWF ristocetin cofactor activity/VWF antigen ratio were significantly decreased when compared to healthy controls. Also the proportion of high molecular weight VWF multimers was reduced, despite severely decreased ADAMTS13 levels, suggesting proteolysis of VWF by enzymes other than ADAMTS13. In spite of these functional defects, platelet adhesion and aggregation were better supported by plasma of patients with ALI/ALF when compared to control plasma. Low ADAMTS13 activity, but not high VWF antigen, was associated with poor outcome in patients with ALI/ALF as evidenced by higher grades of encephalopathy, higher transplantation rates and lower survival.

Summary/Conclusion: Strongly elevated levels of VWF in plasma of patients with ALI/ALF support platelet adhesion, despite a relative loss of function of the molecule, suggesting a rebalanced primary hemostatic function in ALF. Furthermore, low ADAMTS13 activity is associated with progressive liver failure in the patient cohort. An unbalance between VWF and ADAMTS13 has been shown to lead platelet-induced thrombosis, and intrahepatic thrombosis has been shown to accelerate liver failure progression. We therefore speculate that a substantially unbalanced VWF/ADAMTS13 ratio, as observed in the present study, results in the formation of platelet-rich microthrombi in the diseased liver and in turn adversely affects disease progression in patients with ALI/ALF.

PB 2.33-6

Relationship of von Willebrand factor, D-Dimer and ADAMTS13 with hypercoagulability in type 1 diabetic patients with and without nephropathy

Domingueti CCP[1], Fóscolo RB[2], Reis JS[3], Dusse LMS[4], Carvalho MG[4], Gomes KB[4] and Fernandes AP[4]

[1]*Universidade Federal de Minas Gerais, Belo Horizonte;* [2]*Faculdade de Medicina, Universidade Federal de Minas Gerais;* [3]*Instituto de Ensino e Pesquisa da Santa Casa de Belo Horizonte;* [4]*Faculdade de Farmácia, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

Background: Diabetic nephropathy is an important risk factor for cardiovascular complications. Some studies have shown that increased plasma levels of Von Willebrand factor (VWF) and reduced of ADAMTS13 are associated with diabetic nephropathy and an increased risk of cardiovascular events in type 2 diabetic patients. However, these relationships have not been investigated in type 1 diabetic patients and a better understanding of the role that these parameters play in type 1 diabetic patients is still lacking.

Aims: Evaluate plasma levels of VWF, ADAMTS13 and D-Dimer (DDi), and VWF/ADAMTS13 ratio in type 1 diabetic patients.

Methods: Patients were classified according to glomerular filtration rate (GRF) and urinary albumin excretion in three groups: without renal dysfunction (GFR $\geq$ 90 mL/min/1.73 m^2 and normoalbuminuria, $n = 49$), with mild renal dysfunction (GFR $\geq$ 60 and $<$ 90 mL/min/1.73 m^2 and/or microalbuminuria, $n = 35$) and with severe renal impairment (GFR $<$ 60 mL/min/1.73 m^2 and/or proteinuria, $n = 41$). A group of 35 individuals without diabetes or renal dysfunction was also included. Individuals undergoing hemodialysis and those with liver disease, alcoholism, coagulation disorder, cancer, history of renal transplantation and pregnancy were excluded. VWF, ADAMTS13 and DDi were measured by ELISA method. Statistical comparisons were performed by Mann-Whitney test. Differences were considered significant when $P < 0.05$.

Results: Diabetic patients without renal dysfunction had higher levels of VWF, 1031.600 mU/mL (778.100–1142.200 mU/mL), than individuals without diabetes, 730.800 mU/mL (575.600–962.600 mU/mL), $P = 0.002$. VWF levels increased with renal function impairment, being increased in diabetic patients with mild renal dysfunction, 1233.200 mU/mL (904.900–1486.400 mU/mL), compared with those without renal dysfunction, $P = 0.013$, and even higher in patients with severe renal impairment, 1358.000 mU/mL (1164.000–1751.600 mU/mL), $P = 0.029$. Levels of ADAMTS13 were reduced in patients without renal dysfunction, 296.760 ng/mL (221.335–440.415 ng/mL), compared to healthy subjects, 444.960 ng/mL (362.180–594.345 ng/mL), $P < 0.001$. However, an increase in ADAMTS13 levels was also detected in patients with mild, 502.600 ng/mL (293.730–601.975 ng/mL), and severe renal impairment, 567.640 ng/mL (363.050–654.365 ng/mL), compared to those without renal dysfunction, $P < 0.001$. Furthermore, VWF/ADAMTS13 ratio was increased in patients without renal dysfunction, 3.161 (2.028–4.204), and with mild, 2.569 (1.878–3.122), and severe renal dysfunction, 2.427 (1.908–3.454), compared to non-diabetic subjects, 1.653 (1.368–1.881), $P < 0.001$, but no significant differences were observed between diabetic patients with and without renal dysfunction. DDi levels were higher only in patients with severe renal impairment, 363.607 ng/mL (223.470–508.604 ng/mL), compared to other groups, 177.055 ng/mL (130.350–264.494 ng/mL), 176.845 ng/mL (131.935–259.828 ng/mL) and 217,251 ng/mL (142.361–297.972 ng/mL), $P < 0.001$.

Conclusion: The gradual increase in VWF levels as nephropathy progress suggests that endothelial dysfunction may contribute to the development and progression of vascular complications in type 1 diabetic patients. However, increased levels of VWF are accompanied by a concomitant increase in ADAMTS13 levels, the enzyme responsible for cleavage and inactivation of VWF, either as a compensatory mechanism or due to a compromised renal function that may affect the

renal excretion of these proteins. This hypothesis is corroborated by increased levels of DDi observed in the severe renal impairment group, indicating a hypercoagulable state in these patients.

PB2.34 – Fibrinolytic System: Basic – II

PB 2.34-1

Regulation of fibrinolysis by polyphosphate is dependent on the plasminogen activator

Whyte CS and Mutch NJ

University of Aberdeen, Aberdeen, UK

Background: The modes of action of the plasminogen activators (PA), tissue plasminogen activator (tPA) and urokinase (uPA) differ. Efficient tPA-mediated plasminogen activation requires binding to fibrin. In contrast, uPA is fibrin independent but is associated with its cellular receptor uPAR. We have previously shown that polyphosphate (polyP), a biomolecule released from platelet dense granules, alters fibrin structure and attenuates tPA and plasminogen binding to fibrin thereby down-regulating fibrinolysis.
Aims: The aim of this study is to determine if polyP-induced changes in fibrin structure influence uPA-mediated fibrinolysis
Methods: Fibrin clots were formed from fibrinogen (2.4 μM), glu-plasminogen (0.24 μM) and tPA (20 pM) or uPA (180 pM) ± $polyP_{65}$ (5 μM). Clotting was initiated by thrombin (0.25 U/mL) and $CaCl_2$ (5 mM) and fibrinolysis monitored at 340 nm. Fibrin degradation products (FDPs) were collected and analyzed by Western blotting using an anti-human fibrin(ogen) antibody. Plasmin generation in clots was quantified by incorporating the fluorogenic substrate D-VLK-AMC (excitation 360 nm emission 460 nm). Confocal microscopy was used to visualize fibrin structure and localization of proteins during fibrinolysis. Clots were prepared with fibrinogen (2.65 μM, 9% was DyLight 488-labelled), plasminogen (1.25 μM, 20% was DyLight 633-labelled), thrombin (0.25 U/mL), $CaCl_2$ (5 mM) and fibrinolysis initiated by exogenous PA (75 nM).
Results: As previously reported $polyP_{65}$ delayed tPA-mediated clot lysis (50% lysis times 102.6 ± 2.3 vs. 69.8 ± 1.9 min; $P < 0.001$). Plasmin generation during tPA-mediated fibrinolysis was delayed and reduced 1.3-fold in $polyP_{65}$ containing clots (1860 ± 82 vs. 2475 ± 155 average FU/min $P < 0.001$). Confocal microscopy also showed delayed tPA-mediated fibrinolysis in clots containing $polyP_{65}$. Plasminogen was visualized at the edge of the lysis front as a tight band. In marked contrast to tPA, uPA-mediated clot lysis was enhanced by $polyP_{65}$ (50% lysis times 64.5 ± 1.7 vs. 108.2 ± 3.8 min; $P < 0.001$). This was reflected as an increase in FDPs generated during uPA-mediated lysis of clots containing $polyP_{65}$ and a 1.6-fold increase in plasmin generation (3961 ± 73 vs. 2434 ± 123 average FU/min; $P < 0.0001$). Confocal microscopy also showed enhanced uPA-mediated lysis by $polyP_{65}$, with a broader zone of plasminogen visible compared to that observed with tPA. The signal of 633-plasminogen was unchanged upon conversion to plasmin, suggesting the observed differences result from accumulation of plasminogen on fibrin at the lysis front.
Varying the plasminogen concentration (0.125–1 μM) in clot lysis only marginally affected tPA-mediated fibrinolysis, conversely, uPA-mediated lysis was dramatically accelerated by increased plasminogen. The effect of $polyP_{65}$ on uPA-mediated fibrinolysis and plasmin generation was overcome by additional plasminogen, while the down-regulation of tPA-mediated lysis and plasmin generation was unaffected.
Summary: $PolyP_{65}$ has opposing effects on tPA- and uPA-mediated fibrinolysis. The cofactor function of fibrin in tPA-mediated plasminogen activation is attenuated by polyP. In contrast, as uPA does not bind fibrin, it is feasible that polyP may act as a template to facilitate the interaction between uPA and plasminogen thereby accelerating fibrinolysis.

PB 2.34-2

The expression of plasminogen activator inhibitor type-1 is post-transcriptionally regulated by sphingosine-1-phosphate and SERPINE1 mRNA binding protein

Fujii S[1], Iwaki S[1], Yamamura S[1], Sanagawa A[1], Asai M[1] and Sobel B[2]

[1]Nagoya City University, Nagoya, Japan; [2]University of Vermont, Burlington, VT, USA

Background: Plasminogen activator inhibitor type-1 (PAI-1), the major physiologic inhibitor of fibrinolysis and proteolysis produced in liver and vascular cells, is implicated in thrombosis and atherosclerosis. Sphingosine-1-phosphate (S1P) is a breakdown product of sphingosine released from platelets upon activation and regulates various gene expressions and alters PAI-1 expression in several cells. Nevertheless, posttranscriptional regulation of PAI-1 by S1P has not been elucidated.
Aims: We aimed to determine whether S1P is involved in posttranscriptional regulation of PAI-1 expression.
Methods: We analyzed the promoter activity, mRNA levels, 3′-untranslated region (UTR) activity and protein levels of PAI-1 using human liver derived HepG2 cells.
Results: S1P (500 nM) increased PAI-1 promoter activity by three fold (luciferase assay) and the expression of PAI-1 mRNA by two fold (RT-PCR) at 4 h. Transcriptional induction of PAI-1 by S1P was transient. S1P decreased expression of PAI-1 mRNA to 0.6 fold and inhibited the accumulation of PAI-1 protein into the conditioned media at 24 h (Western blot). Human PAI-1 mRNA exists in two subspecies (3.2 and 2.2 kb) and S1P decreased the baseline luciferase activity of 1 kb fragment of the 3′ terminus (+2177–3176 nt) of 3′-UTR of the 3.2 kb PAI-1 mRNA [3′-UTR (+2177–3176)]. Mutation of AU-rich element 3 (ARE3) inhibited the decreased activity of PAI-1 mRNA [3′-UTR (+2177–3176)] by S1P. S1P destabilized 3.2 kb PAI-1 mRNA (Northern blot), suggesting that S1P decreased the expression of PAI-1 protein by regulating PAI-1 expression at the posttranscriptional level and thereby affecting mRNA stability. S1P increased SERPINE1 mRNA binding protein (SERBP1) through $S1P_1$ receptor and facilitated binding of SERBP1 to PAI-1 mRNA (pull-down assay). Small interfering RNA against SERBP1 prevented the decrease of PAI-1 mRNA induced by S1P, suggesting that SERBP1 and ARE3 in the 3′-UTR were cooperatively involved in the posttranscriptional regulation by S1P.
Summary/Conclusion: Our data indicate that brief transcriptional induction of PAI-1 by S1P is followed by S1P-mediated destabilization of 3.2 kb PAI-1 mRNA mediated by specific effects on the 3′-UTR through SERBP1 and ARE3. These effects are associated with decreased expression of PAI-1 protein potentially leading to regulation of fibrinolysis.

PB 2.34-3

Investigation of possible exosite interactions between plasmin(ogen) and antiplasmin

Horvath AJ, Lu B, Law RHP and Coughlin PB

Monash University, Melbourne, Australia

The inhibition of plasmin by antiplasmin (AP) is usually understood as a two step-process; the binding of the C-terminal region of AP to the kringle domains of plasmin(ogen) followed by the inhibitory interaction between the AP reactive centre loop and active site of plasmin. Our previous work has shown that the binding affinity between α2-antiplasmin lacking the C-terminal region to active site-blocked plasmin remains strong, K_d = 50 nM. This raised the possibility that additional exosite region(s) may exist beyond the C-terminus/kringle domain interaction. To further explore this possibility we performed binding studies of AP with various plasminogen conformations (Glu and Lys-

plasminogen (PLG), active plasmin, micro-plasmin, active site-blocked plasmin and micro-plasmin). Binding of these plasmin(ogen) variants with full-length and C-terminally truncated antiplasmin was assessed by surface plasmon resonance. Our results show that in the closed, Glu-PLG conformation, where the kringle domains and protease active site are unavailable the binding affinity for AP(wt) remains high (K_D = 30 nM) and that this interaction is not influenced by the removal of the C-terminus of AP (K_D = 50 nM). As expected the binding affinity is increased in the open and active conformations (K_D = 7.8 nM and 1.6 nM) with Lys-PLG and active site blocked plasmin respectively. However, C-terminal truncation of AP resulted in a 20–30 fold decrease in binding affinity for Lys-PLG and active site blocked plasmin. A dramatic loss in binding affinity was observed for micro-PLG (K_D = ~1.4 μM) with both AP(wt) and AP(c-trunc). These results suggest that the high affinity interaction observed between AP and Glu-PLG may involve exosites within the AP core domain and the kringle domains of plasmin(ogen). This is further supported by the observation that there is a 3-fold loss in binding affinity of plasmin-CMK with AP(C-trunc) compared to micro-plasmin-CMK with AP (C-trunc). Mutagenesis of residues in β-sheet C of human α2-antiplasmin was also carried to further explore regions in AP involved in exosite interactions with plasmin(ogen).

PB 2.34-4

Comparison of thrombolytic efficacy of plasmin and rt-PA in an *in vitro* flow system

Bizjak N[1], Bajd F[1], Vidmar J[2], Blinc A[3], Marder VJ[4], Novokhatny V[5] and Serša I[1]

[1]Institute Jožef Stefan; [2]Institute of Physiology, Medical Faculty of Ljubljana; [3]University of Ljubljana Medical Centre, Ljubljana, Slovenia; [4]Division of Hematology/Medical Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Grifos, Inc., Triangle Research Park, NC, USA

Background: Plasmin, a directly acting thrombolytic agent has been recently tested in phase I clinical studies. While plasmin demonstrated a very favorable safety profile upon intra-arterial delivery to the clot site, its thrombolytic efficacy remains to be further assessed.
Aim: To test in a model system if there are differences in thrombolysis between clots exposed to equimolar concentrations of plasmin and rt-PA after partial vessel recanalization.
Methods: Model blood clots were prepared in a glass chamber enabling direct observation by dynamic optical microscopy. The incubation of clots with plasmin (2.4 mg/mL) or rt-PA (2.63 mg/mL), allowing for the initial biochemical clot degradation, was followed by 'flushing' the clots with tangentially directed plasma flow devoid of a thrombolytic agent, mimicking blood flow after partial vessel recanalization. The acquired images were analyzed for non-dissolved blood clot area as a function of time.
Results: With both thrombolytic agents, the relative clot area decreased rapidly in the first 30 s after initiation of perfusion due to 'flushing' the degraded clot fragments (after plasmin by 0.26 ± 0.22 and after rt-PA by 0.34 ± 0.21, P = 0.60). In the following minutes the clot size showed a linear time dependence: after incubation with plasmin the clot size did not change substantially any more, while after incubation with rt-PA the clot size continually decreased. The slopes of the regression lines differed significantly ($r_{pl} = -8.9 \times 10^{-3}$/min vs. $r_{rtPA} = -44.1 \times 10^{-3}$/min, $P < 0.01$).
Conclusion: The thrombolytic action of plasmin was terminated rapidly by contact with flowing blood plasma, while the thrombolytic action of rt-PA was prolonged.

PB 2.34-5

Antibody-engineered bispecific inhibitor against TAFI and PAI-1 with improved expression and efficacy

Wyseure T, Develter J, Tziarou E, Gils A and Declerck PJ

KU Leuven, Leuven, Belgium

Background: Targeting Thrombin Activatable Fibrinolysis Inhibitor (TAFI) and Plasminogen Activator Inhibitor-1 (PAI-1) constitutes a potential strategy to increase thrombolytic efficiency of plasminogen activators without aggravating safety concerns. Additionally, the synergistic profibrinolytic effect caused by dual targeting of human TAFI and PAI-1 has been demonstrated *in vitro* to be even more pronounced when using a diabody (Db) than the combined addition of the parental monoclonal antibodies (MA) (Develter et al., JTH, 2008). Db's are bispecific antibody fragments with a size of 58 kDa allowing better clot penetration. To evaluate this dual targeting strategy *in vivo*, a novel Db was generated from two potent MA's against rat TAFI and PAI-1. However, this Db encountered stability problems hampering further evaluation.
Aims: Improving the plasma stability of a bispecific Db against rat TAFI and PAI-1 by adding a stabilizing flexible linker (single-chain diabody, scDb) and by CDR-grafting on a stable scaffold in order to evaluate this dual targeting strategy *in vivo*.
Methods: Db and scDb were constructed by cloning and assembling the variable domains of MA-33H1F7 (inhibiting rat PAI-1) and MA-RT36A3F5 (destabilizing rat TAFIa), followed by expression in bacteria (Db) and HEK293T cells (scDb), and subsequent purification. Since instability of (sc)Db is caused by the variable domains of MA-RT36A3F5, CDR-grafted variants (CDR-Db and CDR-scDb) were constructed on a stabilized scaffold (scFv-4D5 derived from Herceptin, Kelley et al., Biochemistry 1992). Functional stability was determined through an ELISA assessing simultaneous binding to rat TAFI and PAI-1. Inhibitory properties against rat TAFI and PAI-1 were measured via chromogenic assays. An *in vitro* clot lysis assay was used to evaluate the profibrinolytic effect of parental MA (0.7 μM) or (sc) Db (1.4 μM, corresponding to an equal amount of binding sites as 0.7 μM MA) in rat plasma.
Results: CDR-grafting improved expression of CDR-Db in bacteria (three-fold increase vs. Db) and of CDR-scDb in HEK293T cells (10-fold increase vs. scDb). Upon incubation of Db for 3 h at 37 °C in citrated plasma, 13% residual binding capacity was observed. In contrast, residual binding capacity under these conditions was 44 ± 9%, 62 ± 10% and 88 ± 13% for scDb, CDR-Db and CDR-scDb, respectively. Inhibitory properties of the parental antibodies were preserved in Db, CDR-Db and CDR-scDb, but could not be determined for scDb due to insufficient production. The profibrinolytic effect of Db, CDR-Db and CDR-scDb was 2%, 46% and 85%, respectively, compared to that of MA-RT36A3F5 against TAFI. The contribution of the effect of the PAI-1 inhibiting moiety could not be evaluated in the plasma-based assay system due to the low baseline plasma levels of PAI-1.
Conclusion: Our efforts to increase the plasma stability of an unstable bispecific antibody-based inhibitor against rat TAFI and PAI-1 resulted in a CDR-scDb, exhibiting a seven-fold increased stability and a 43-fold increased profibrinolytic effect. In order to explore the full potential of the dual TAFI/PAI-1 inhibitor, *in vivo* thrombolysis experiments in which both TAFI and PAI-1 contribute, are in progress.

PB 2.34-6

Plasminogen alterations mediated by N-homocysteinylation processes

Genoud V[1], Sinito MA[2], Gionco S[2], Quintana I[3] and Lauricella AM[2]

[1]Quintana, Irene, Facultad de Ciencias Exactas y Naturales, UBA; [2]Facultad de Ciencias Exactas y Naturales, UBA; [3]Facultad de Agronomía, Universidad de Buenos Aires, Buenos Aires, Argentina

Background: Hyperhomocysteinemia is a risk factor for atherothrombosis. Plasma homocysteine exists in several chemical species such as protein bound, oxidized to form dimers, free reduced homocysteine and as its cyclic thioester homocysteine thiolactone (HTL). N-homocysteinilation reactions are mediated by HTL, which is N-linked to epsilon amino group of lysine residues resulting in modified proteins named HTL adducts.
Aim: To evaluate the effects of HTL on plaminogen (Plg) structure, activation kinetics and plasmin activity.
Methods: Human purified Plg (1.5 mg/mL) was incubated with HTL (molar ratio Plg:HTL = 1:150; 3 h 37 °C); saline solution was used as control. Samples were dialyzed to remove unreacted HTL. The homocysteinylated Plg (Plg-HTL) was analyzed by native and denaturing polyacrylamide gel electrophoresis (PAGE and SDS-PAGE), crossed immunoelectrophoresis (CIE) and capillary electrophoresis. Plg-HTL (0.3 μM) activation with tissue Plg activator (t-PA, 360 U/mL) was studied through kinetic amydolitic assays with chromogenic substrate S-2251 (0.5 mM), evaluating paranitroaniline release over time. Lysis activity of t-PA (11 U/mL) activated Plg-HTL over fibrin obtained in the presence of purified fibrinogen (2.6 mg/mL), thrombin (0.5 U/mL) and $CaCl_2$ (20 mM), was kinetically studied. All experiments were performed in quadruplicate.
Results: There were no significant differences in the electrophoretic profiles between Plg-HTL and control in PAGE, SDS-PAGE and capillary electrophoresis. However, CIE showed two fractions for Plg-HTL, one coinciding with the fraction of Plg control and another with a different displacement, related to the heterogeneity of the homocysteinylated protein. Amydolitic assays showed an increased activation time for Plg-HTL compared to control (41 ± 2 vs. 34 ± 1 min; $P = 0.01$) and a decreased enzyme activity (0.0053 ± 0.0002 vs. 0.0066 ± 0.0004/min; $P = 0.01$). In accordance, fibrin lysis times with Plg-HTL were significantly prolonged respect to control (51 ± 2 vs. 40 ± 1 min; $P < 0.05$).
Conclusions: Lysis of fibrin networks was diminished by N-homocysteinylated plasminogen. It can be suggested that Plg of patients with high homocysteine plasma levels would have less fibrinolytic activity and therefore, be associated to the prothrombotic state of hyperhomocysteinemia.

PB2.35 – Haemophilia A: Basic Research – II

PB 2.35-1

Prediction by cellular expression of impact of four novel F8 molecular variations identified in isolated female with low FVIII:C levels suspected of being haemophilia A carriers

Fretigny M[1], Nougier C[2], Talagrand E[1], Costa C[3], Roualdes O[1], Pellechia D[1], Negrier C[1] and Vinciguerra C[1]

[1]Hospices Civils de Lyon; [2]Universite Lyon 1, Lyon; [3]AP-HP, CHU Henri Mondor, Creteil, France

Background: Haemophilia A (HA) is an inherited X-linked disorder that typically affects males, while females are carriers. However, carrier status of HA may also be raised in females with low clotting factor VIII (FVIII) level and without HA family history once no alternative diagnosis can be retained.
Aim: The aim of the present study was to predict the carrier status in four female without family history of bleeding with decreased FVIII:C levels (< 50 IU/dL) in whom we identified unreported *F8* gene variation.
Methods: Prediction of the causal impact of these four novel molecular variations was studied by two strategies: bioinformatics approaches and site-directed mutagenesis followed by cellular expression. Molecular modelling was performed using Alamut®-Mutation Interpretation Software 2.1 and sequences alignments of the homologous FVIII (human, pig, canine, mouse and fish FV/FVIII). Mutant plasmids were generated through site-directed mutagenesis. Plasmid DNA of FVIII WT and FVIII mutants were transfected into COS-1 monkey cells. For each construct, three series of duplicate assays were performed. To evaluate specific activities, FVIII activity (FVIII:C) and FVIII antigen (FVIII:Ag) levels were measured in the conditioned media of COS-1 by using one-stage aPTT clotting assay and ELISA.
Results: We identified four novel nucleotide variations. Three were missense substitution: p.Pro521Leu, p.Ser577Tyr and p.Leu2032Pro and one was a duplication: p.Ala315dup. No other nucleotide change was found in the *F8* coding region or in exon-intron boundaries.
Analysis with molecular modelling tools showed that p.Pro521Leu and p.Ser577Tyr substitutions were probably damaging for the FVIII function. The p.Leu2032Pro substitution analysis led to discrepant results, but impact on splicing cannot be excluded. All novel missense changes were fully conserved among mammalian species. Specific activity of factor VIII mutants relative to WT showed that expression of FVIII mutant p.Leu2032Pro was similar to WT in COS-1 ($P = 0.69$) while FVIII mutants p.Pro521Leu, p.Ser577Tyr and p.Ala315dup led to a significant decrease ($P < 0.01$). FVIII activities were undetectable in conditioned media for FVIII mutant p.Ser557Tyr and p.Ala315dup while p.Pro521Leu variant displayed a mild impairment of WT FVIII activity (38% of WT FVIII:C).
Conclusion: In this study we identified four novel mutations detected in female with low FVIII level. The p.Pro521Leu substitutions could lead to a mild HA while p.Leu2032Pro could be considered as *F8* polymorphism. Both p.Ser577Tyr and p.Ala315dup lead to severe dysfunctions of FVIII. These two mutations could be responsive of severe HA. A prenatal diagnosis could be offered to carriers with these mutations.

PB 2.35-2

Cellular stress in synoviocytes, chondrocytes and osteoblasts and increased osteoclast activity induced by plasma derived factor VIII products *in vitro*

Brodde MF[1], Müller A[1] and Kehrel BE[2]

[1]OxProtect GmbH; [2]Universität Münster, Münster, Germany

Aim: By effective treatment of bleeding and thereby reducing blood induced joint damage factor concentrate replacement therapy has dramatically improved the quality of life of patients with haemophilia. However, plasmatic factor concentrates contain many co-purified proteins that might impact the influence of these blood products on joint cells after bleeding. As these products induce mild cellular stress in blood cells, we compared the effect of factor VIII products on joint cell viability and morphology.
Method: The effect of three different recombinant FVIII (rFVIII) products and four plasma derived FVIII (pdFVIII) products was investigated. Primary cells, straight from the human knee tissue (PromoCell, Heidelberg, Germany), were cultured and factor VIII concentrates were added to a final factor FVIII concentration of up to 1 IU/mL. Osteoclast formation was induced from human peripheral blood mononuclear cells. Cell viability was tested by cell viability assay (MTT) and cell counting. The influence of FVIII products on synoviocytes, chondrocytes, osteoblasts and osteoclasts was investigated in addition by microscopy.

Result: About 1 IU/mL of all different pdFVIII concentrates strongly increased human synoviocytes proliferation, while all different rFVIII concentrates (1 IU/mL) had no influence. The effect of the pdFVIII concentrates on chondrocytes and osteoblasts was dramatic. Twenty-four hours incubation with pdFVIII products induced cell membrane blebbing and cell shrinkage in many osteoblasts. The incubation of pdFVIII products induced detachment of many chondrocytes from the matrix. RFVIII products did not induce any of these effects. RFVIII treated osteoblasts and chondrocytes showed a typical picture of undisturbed human cells in culture with a 'smooth' membrane surface. Osteoclasts differentiated in the presence of plasma derived factor VIII concentrates showed after 7 days significantly more nuclei as osteoclasts that were differentiated in the presence of recombinant factor VIII concentrates.
Conclusion: Enhanced synoviocyte proliferation clearly indicates that the tested pd FVIII products, in contrast to the rFVIII products, might amplify the damaging effect of blood on synoviocytes. As chondrocytes produce all the components of cartilage and as bone destruction is induced by severely impaired osteoblast activity, chondrocyte and osteoblast destruction by the tested pdFVIII concentrates might lead to an enhanced destruction of the cartilage and bone, while the tested rFVIII concentrates do not. As a positive correlation between the number of nuclei per osteoclast and the volume of the pit (resorption bays) made has been described in the literature, this result again indicates a potential harmful effect of plasma derived factor VIII concentrate in comparison to recombinant factor VIII.

PB 2.35-3

An aberrant pattern for intron 1 inversion with concomitant large duplication and deletion within the F8 gene in a severe hemophilia A

Chi K and You G
Ruijin Hospital, Shanghai, China

Background: Hemophilia A (HA) is the most common X-linked recessive bleeding disorder and caused by mutations in the F8 gene, resulting in a quantitative and qualitative abnormality of coagulation factor VIII. There is a wide spectrum of mutations in the F8 gene causing HA. Inversion of intron 1 is responsible for about 2% of HA cases and results from intrachromosomal homologous recombination between a 1041 bp region (int1h-1) of intron 1 and an extragenic copy (int1h-2) approximately 140 kb telemetric to the F8 gene.
Aims: To disclose the complex molecular mechanism for the aberrant pattern of intron 1 inversion associated with gross genomic rearrangements causing severe HA.
Methods: All 26 exons and flanking intron/exon boundaries of F8 gene were amplified and sequenced directly. Intron 1 inversion was detected by long-fragment PCR described by Bagnall et al. (2002). We used the AccuCopy technology, a copy number variation (CNV) genotyping method based on multiplex competitive amplification, for quantitative analysis of copy number of all 26 exons in the F8 gene. Affymetrix CytoScan HD array was also applied to detect CNVs of the whole genome. Breakpoints of gross genomic rearrangements were identified by primer walking strategy and genome walking technique.
Results: No point mutation was identified in all 26 exons, flanking intron/exon boundaries, promoter, 5′ and 3′ regions of the F8 gene. An abnormal pattern of intron 1 inversion was detected in the index patient: one corresponding to the normal int1h-2 region (1191 bp) and the other corresponding to the band with the inversion of the int1h-2/1 sequence (1776 bp). AccuCopy showed normal dosage of all 26 exons in the F8 gene. Affymetrix CytoScan HD array revealed a duplicated region between F8A2 and int1h-2, which included three genes: VBP1, RAB39B and CLIC2. In addition, a deleted region between int1h-1 and exon 2 of F8 gene was detected. We successfully characterized the breakpoints of the deleted region, revealing that a genomic rearrangement occurred between the deleted region and the additional copy of the fragment between F8A2 and Int1h-2 in the process of intron 1 inversion.
Conclusions: We presented the case of a patient with an aberrant pattern of intron 1 inversion in the F8 gene causing severe HA and illustrated the complex molecular mechanism of the inversion associated with gross genomic rearrangements.

PB 2.35-4

Hemarthrosis-induced heme oxygenase-1 reduces the immune response to FVIII in hemophilic mice

Peyron I, Dimitrov JD, Delignat S, Kaveri SV and Lacroix-Desmazes S
Inserm U872, Paris, France

Background: Major bleedings in patients with hemophilia A are treated by on-demand administration of therapeutic FVIII. The role of bleeding severity has been evoked as a possible risk factor for the development of anti-FVIII 'inhibitory' antibodies. It remains unclear however whether the increased risk for inhibitor development is a direct consequence of bleeding, that presumable creates a local inflammatory microenvironment, or of the elevated dose of infused FVIII.
Aim: We evaluated the impact of induced hemarthrosis on the development of an anti-FVIII immune response in FVIII-deficient mice.
Methods: Hemarthrosis was induced in the left knee of 6–7-week old FVIII-deficient mice by intra-articular space insertion of a needle. One week later, mice received 1 IU FVIII once a week for 3 weeks. The levels of inhibitory anti-FVIII IgG titers were evaluated by ELISA and Bethesda assay. Induction of arthropathy was validated 3 weeks after injury by measuring knee diameters. Expression of heme oxygenase-1 (HO-1) was assessed by Western-blot in spleen, liver and knee joint extracts 1 week after hemarthrosis induction.
Results: Induction of hemarthrosis lead to the development of arthropathy 3 weeks after injury with knee diameters of 3.48 ± 0.08 mm in the injured left knee and 3.07 ± 0.02 mm in the untouched right knee ($P < 0.0001$). Unexpectedly, levels inhibitory anti-FVIII IgG were significantly lower in injured mice as compared with sham-treated mice after 3 weeks of FVIII administration, as measured by ELISA (mean ± SEM: 132 ± 32 vs. 334 ± 46 μg/mL, respectively, $P < 0.05$) and Bethesda assay (29 ± 8 vs. 111 ± 22 BU/mL, respectively, $P < 0.005$). We then assessed the induction of the heme detoxifying enzyme HO-1. Induction of hemarthrosis was associated with the induction of HO-1 in the injured knee, but not in the untouched knee, spleen or liver.
Conclusions: The induction of hemarthrosis in hemophilic mice reduces the intensity of the anti-FVIII immune response against exogenously administered FVIII. This reduction is associated with a local induction of HO-1 on week after injury, at the time of the first FVIII administration. Our previous data had shown that the systemic induction of HO-1 upon heme injection was able to drastically reduce the onset of the anti-FVIII immune response in experimental hemophilia A. The present data indicate that the local induction of HO-1 in a non-immunological compartment is sufficient to modulate the immune response to FVIII. Our results showing that major bleeds in mice, leading to extravascular blood release and hemolysis, induce HO-1, thus reducing the immune response to FVIII, are in contrast with empirical observations in hemophilia A patients. Indeed, in patients, major bleeds and the ensuing administration of large doses of FVIII, have been proposed as predisposing factors for inhibitor development. Of note, while patients are generally treated as soon as bleeding occurs, the mice received FVIII 1 week after injury. Whether differences in timing of bleeding induction and FVIII administration, or in the intrinsic capacity to induce HO-1 are responsible for the observed discrepancy, remains to be elucidated.

PB 2.35-5

The development and binding mechanism of FVIII Trp1707Ser related inhibitors

Lu Y

Ruijin Hospital affiliated to Medical College of JiaoTong University, Shanghai, China

Background: Haemophilia A is due to the mutations of F8 gene. The replacement of factor VIII is the most effective treatment now. But FVIII antibodies develop in approximately 20–50% of patients with HA, which complicates the management of hemorrhage.
Aims: To investigate the binding mechanism of inhibitors in FVIIITrp1707Ser missense mutation.
Methods: LD-PCR and PCR were adopted for the screening of the INV22 and INV1 respectively. The F8 coding and boundary sequences were analyzed by sequencing. Inhibitors were reacted with different segments of FVIII (Heavy chain, light chain, A1, A2, A3, C1, C2), and corrected test was used to measure the remaining FVIII:C(%) by adding pooled plasmas of normal persons. Inhibitors in plasma were purifed by affinity chromatography. After labeling purified inhibitors with biotin, wesern blot was used to further confirm the binding reactions between inhibitors and segments which employed each segment as an antigen and biotin-labeled inhibitors as antibodies.
Results: F8 gene direct sequencing showed that the HA patient with inhibitor had the missence mutation c.97223G>C in exon 14 of F8 gene (p.Trp1707Ser). Corrected method detected that the remaining FVIII:C were increased when inhibitors reacted with FVIII heavy chain and light chain, and the reaction with heavy chain was increased more obvious. The remaining FVIII:C were also increased in the A2 and C2 domain reactions, and the A2 domain reaction was increased more obvious. No significant differences were seen in the A1, A3 and C1 domain reactions. The western blot results further confirmed the previous results as bands were seen when degenerated B-domain deleted recombinant FVIII, heavy chain, light chain, A2 and C2 were used as antigens. The bands were more darker when heavy chain and A2 were used as antigens. No band was detected in the reaction with A1, A3 and C1 domain.
Conclusions: The binding sites of the FVIII Trp1707Ser related inhibitors were in the A2 domain of FVIII heavy chain and C2 domain of the light chain. The binding reaction was more intense with the A2 domain of the heavy chain. Inhibitors binding to A2 domain may affect FVIII to activate FIX as a cofactor, and inhibitors binding to C2 domain may block the interations between FVIII and phospholipids or VWF.

PB 2.35-6

Functional FVIII assays and bleeding phenotype in 13 patients with mild haemophilia A due to the p.Tyr365Cys mutation

Graves EA[1], Talks K[1], Sergeant K[2], Vowles J[1], Hanley J[1] and Biss T[1]

[1]Newcastle Upon Tyne Hospitals; [2]International Centre for Life, Newcastle Upon Tyne, UK

Aims: The aim of this study was to define the laboratory characteristics and bleeding phenotype of a cohort of individuals with an identified p.Tyr365Cys mutation.
Methods: The Institute of Genetic Medicine at the International Centre for Life, Newcastle upon Tyne, identified all individuals with the p.Tyr365Cys mutation registered on our North of England database. Their bleeding history was evaluated and historical one stage and chromogenic FVIII assays were recorded. Factor XI assay, von Willebrands disease screen and platelet aggregation studies were performed to rule out a coincidental additional bleeding disorder.
Results: Thirteen individuals had haemophilia A with the p.Tyr365Cys mutation. Median age at diagnosis was 34 years: range 1–69 years. Six were identified incidentally when coagulation screening showed a prolonged APTT, three were identified by family screening and three presented with bleeding symptoms. The route to diagnosis for one patient was unclear.
Recurrent severe epistaxis was reported by one individual; further investigation confirmed the co-existence of Type 2N von Willebrands disease. A second patient had recurrent spontaneous muscle haematomas and was found to have an additional F8 mutation associated with a moderate bleeding phenotype.
Prior to diagnosis six individuals experienced bleeding (five dental, four trauma-induced, one post-surgical); in only one case was this bleeding sufficient to prompt investigation and diagnosis of a bleeding disorder. Two of these patients had experienced haemostatic challenges (surgical and dental) at other time-points with no significant haemorrhage. Two individuals had undergone dental extraction as their only haemostatic challenge without any bleeding.
Median One Stage FVIII level was 33% (range: 8–46%) and Chromogenic assay 62% (range: 30–113%) with inverse discrepancy seen in all patients. FXI level and platelet aggregation studies were normal. One individual was found to have von Willebrands disease (type 2N).
Nine individuals received haemostatic treatments (DDAVP or FVIII concentrate) following diagnosis. In nine of thirteen treatment episodes the treatment was prophylactic: dental extraction (3), spinal surgery or regional anaesthesia (3), amputation of limb (1), orthopaedic surgery (2). Two individuals were treated following significant trauma and one was managed with FVIII concentrate for spontaneous haematomas (this patient had a second F8 mutation and moderate haemophilia A). No haemorrhagic complications occurred.
Conclusions: Our data support previous publications in which patients with the p.Tyr365Cys mutation are reported to have minimal bleeding symptoms and a significantly higher chromogenic FVIII concentration. Prophylactic haemostatic treatment prior to intervention may not be required and may represent unnecessary exposure to FVIII concentrate. In addition we can confirm the value of carefully investigating patients with significant bleeding in this patient group, as coexistent bleeding disorders are likely to be identified and will require specific treatment.

PB2.36 – Haemophilia A: Clinical Research – VI

PB 2.36-1

Low titre FVIII inhibitor assay may substitute the recovery and half-life measurements in detection of tolerance after immune tolerance induction therapy

Dardikh M[1], Gascoigne E[2], DiMichele D[3], Hay CRM[4], Van Heerde W[5] and Verbruggen B[6]

[1]University Medical Center Nijmegen (NL) & University Medical Center Goethe [D], Nijmegen, The Netherlands; [2]Bio Products Laboratory Ltd, Elstree, UK; [3]Weill Cornell Medical College, New York, NY, USA; [4]Manchester University, Manchester Royal Infirmary, Manchester, UK; [5]University Medical Center Nijmegen (NL), Nijmegen; [6]Jeroen Bosch Hospital, 'sHertogenbosch, The Netherlands

Background: Immune tolerance induction is so far the only proven method to eradicate FVIII inhibitors in patients with severe haemophilia A. Tolerance is currently defined as normalization of FVIII pharmacokinetic parameters after administration of FVIII, especially FVIII half-life and 30-minutes FVIII recovery. FVIII recovery below 66% and half-life < 6 h were taken as indicative of the presence of FVIII inhibitors in the International Immune Tolerance Study (I-ITI Study). However, pharmacokinetic evaluations in patients are burdensome because of the need for multiple blood samples.

Methods: In order to investigate whether inhibitors assays can be used as significant parameters to detect the state of tolerance, the Nijmegen assay (NA), the Bethesda assay (BA) and the Low titre assay (LTA) were performed on plasma samples from 13 pharmacokinetic studies on those subjects in the I-ITI study who had successfully achieved immune tolerance. Both the sensitivity and specificity of each FVIII inhibitor assays were investigated relative to the pharmacokinetic parameters. In addition, the usefulness of measuring FVIII-recovery within 30 min was explored.

Results: The inhibitor data were all within the normal range (0.0–0.2 BU/mL) using the NA but varied from 0.2 to 0.9 BU/mL with the BA including two subjects with abnormal inhibitor values (0.8 resp.0.9 BU/mL). The LTA varied between 0.00 and 0.18 BU/mL. Neither BA levels ($P = 0.70$) nor NA levels ($P = 0.91$) correlated significantly with FVIII half-life. In contrast, the LTA correlated significantly with the corresponding half-life ($P = 0.02$).

FVIII-recovery was normal in all patients and no correlation was detected between the half-life and recovery 30 min post-infusion. Furthermore, FVIII half-life of 7.0 h was established as the minimum normal half-life and was used for further analysis of the results. The Receiver Operating Characteristic (ROC) curves of the BA, the NA, LTA and FVIII recovery were calculated using a half-life of 7.0 h as inhibitor status criterion. The highest specificity (75%) combined with a sensitivity of 100% was observed for the LTA representing a cut off value of 0.04 BU/mL.

Conclusion: The low titre assay is a reliable tool to exclude the presence of low titre of FVIII inhibitors, and therefore, may represent a new and important parameter in the determination of successful immune tolerance induction outcome.

PB 2.36-2

A retrospective observational multicenter cohort study on peri-operative factor VIII consumption in hemophilia A ('OPTI-CLOT' studies)

Lock J[1], Hazendonk HCAM[1], Bouzariouh H[1], Fijnvandraat KJ[2], Peters M[2], Polinder S[3], De Wildt SN[1], Leebeek FWG[3], Mathôt RAA[4] and Cnossen MH[1]

[1]Erasmus Medical Center, Sophia Children's Hospital, Rotterdam; [2]Academic Medical Center, Emma Children's Hospital, Amsterdam; [3]Erasmus Medical Center, Rotterdam; [4]Academical Medical Center, Amsterdam, The Netherlands

Background: Hemophilia A is an X-linked bleeding disorder, caused by a deficiency of clotting factor VIII (FVIII). Treatment of hemophilia with coagulation factors is costly. Previous studies have demonstrated that FVIII consumption in prophylactic treatment can be significantly reduced by individualized dosing regimens. However, data on peri-operative FVIII consumption, clearance and modifying factors are scarce.

Aims: To evaluate peri-operative FVIII consumption and achieved FVIII levels in hemophilia A with attention to patient and surgical characteristics.

Patients and Methods: In this retrospective observational multicenter cohort study, we included patients with severe and moderate hemophilia A (FVIII levels < 0.05 IU/mL), without an inhibitor, undergoing elective, and low or medium risk surgery from January 2000 until July 2012, from three Dutch Hemophilia Treatment Centers. The study was not subject to the Medical Research Involving Human Subjects Act and was approved by the Medical Ethics Committee. FVIII concentrates were administered with the aim to achieve the following target levels advised by the Dutch Hemophilia Consensus: day 1: 0.8–1.0 IU/mL; day 2–5: 0.5–0.8 IU/mL; >day 6: 0.3–0.5 IU/mL. The achieved FVIII plasma levels were generally checked daily. Data were collected on clinical and surgical characteristics, peri-operative dose and mode (bolus infusion: BI or continuous infusion: CI) of FVIII concentrate administration, achieved FVIII levels and bleeding complications.

Results: A total of 176 surgical procedures was performed in 99 patients: 61 adults (123 surgeries; median age 43 years; median weight 80 kg) and 38 children (53 surgeries; median age 4 years; median weight 18 kg). In adults, mainly orthopedic surgeries were performed (46%), in children mainly intravenous catheters were inserted or removed (55%). Peri-operative bleeding complications were reported in 28 procedures (16%), not associated with low FVIII levels; in seven patients (4%) reoperation was required for persistent bleeding.

Median amount of infused FVIII concentrate during hospitalisation was 20,063 IU (443 IU/kg) per surgical procedure. Sixty-one percent of achieved peri-operative levels in steady state was above highest required levels (median +0.27 IU/mL) according to the Dutch Hemophilia Consensus. Only 25% was within target range and 14% of levels was below the target range (median −0.14 IU/mL).

CI was used more frequently (64%) than BI (36%), especially in children compared to adults (51% vs. 31%). CI and BI did not differ in bleeding complications or achieved FVIII levels. For adults the median amount of infused FVIII concentrate was significantly higher when treated by CI (445 IU/kg) compared to BI (161 IU/kg) ($P < 0.001$), after correction for duration of hospitalisation this difference did not persist; CI: 40 IU/day and BI: 38 IU/day ($P = 0.51$). Further analyses are ongoing to differentiate between indications for surgery.

Conclusion: Sixty-one percent of peri-operative FVIII levels was above the predefined target levels. These data support that there is room for improvement in the efficacy of peri-operative dosing. PK-guided dosing with iterative pharmacokinetic modelling in the peri-operative period is therefore promising.

PB 2.36-3

Bleeding frequency and consumption of FVIII concentrate during on-demand and prophylactic treatment with Human-cl rhFVIII in prospective clinical studies in adult patients with severe haemophilia A

Tiede A[1], Oldenburg J[2], Knaub S[3] and Bichler J[3]

[1]Hannover Medical School, Hannover; [2]University Clinic Bonn, Bonn, Germany; [3]Octapharma AG, Lachen, Switzerland

Background: There is ample evidence to support prophylactic treatment with factor VIII (FVIII) in children with severe haemophilia A (HA). Adults with severe HA, however, are often treated on-demand only and the potential benefit of regular prophylaxis is linked to a higher consumption of costly FVIII concentrates. During the clinical development of Human-cl rhFVIII, the first recombinant FVIII concentrate expressed in a human cell line, its efficacy and safety was evaluated in previously treated adult patients (PTPs) during on-demand treatment only (GENA-01) and prophylaxis (GENA-08). The two studies were similarly designed, e.g. regarding required study duration, and analyzed, e.g. regarding documenting, characterizing and treating bleeding episodes (BE).

Aims: To compare *post-hoc* the BE frequency and the use of FVIII concentrate in patients treated exclusively on-demand with those treated prophylactically.

Methods: Both prospective multi-centre studies were approved by the Ethics Committees of each participating institution and informed consent was obtained from the patient prior to any trial-related activity. In GENA-01, patients were to be treated on-demand for ≥ 6 months and ≥ 50 exposure days with protocol recommended doses ranging from 20 to 60 IU/kg, depending on the severity of the BE. In GENA-08, patients were to be treated prophylactically with Human-cl rhFVIII every other day with 30–40 IU/kg for ≥ 6 months. Human-cl rhFVIII was also to be used in case of breakthrough BEs using the same doses as in GENA-01.

Results: Twenty-two PTPs with severe HA were enrolled in GENA-01, and 32 in GENA-08. The study populations were reasonably well com-

parable to each other (GENA-01 vs. GENA-08), regarding age (39.6 ± 14.1 vs. 37.3 ± 13.6 years), BMI (23.9 ± 4.8 kg/m^2), haemophilia joint health score (38.4 ± 30.3 vs. 34.6 ± 32.2), race (> 80% White in both studies) and historical bleeding sites. In GENA-08, the majority of patients (65.6%) had been treated prophylactically prior to study entry. Their historical mean BE rate/month was 0.540, and their mean prophylactic dose/month was 293 IU/kg. The other patients who had been treated on-demand had a mean BE rate/month of 3.924. In GENA-01, all but two patients were treated on-demand prior to study entry. The historical mean BE rate/month of all GENA-01 patients was 4.07. During the studies, the GENA-08 patients experienced a mean of 0.19 ± 0.31 BEs per month, and the GENA-01 patients 4.77 ± 2.54 BEs per month. Their respective mean drug consumption was 475.5/kg/month (466.1 for prophylaxis, 9.4 IU/kg/month for treatment of breakthrough BEs) and 156.9 IU/kg/month, respectively.

Conclusion: The data suggest that regular prophylactic treatment with Human-cl rhFVIII in adult PTPs with severe HA results in an approximately 25-fold reduction of BE rate, and 4-fold increase of FVIII concentrate consumption.

PB 2.36-4

Atrial fibrillation in people with hemophilia: a cross-sectional evaluation in Europe

Schutgens REG[1], Klamroth R[2], Pabinger I[3], Malerba M[4] and Dolan G[5]

[1]UMC Utrecht, Utrecht, The Netherlands; [2]Vivantes-Klinikum, Berlin, Germany; [3]Medical University of Vienna, Vienna, Austria; [4]Ospedale Maggiore Policlinico, Milan, Italy; [5]Nottingham University Hospitals, Nottingham, UK

Background: With increasing life expectancy of people with hemophilia (PWH) in developed countries, the number of PWH affected with age-related diseases is also increasing. Atrial fibrillation is a common health problem in the general population, but in PWH, evidence-based guidelines for the management of AF are lacking.

Aims: The aim of this cross-sectional pan-European study is to analyze the prevalence of AF and risk factors for stroke in our adult hemophilia population and to document current anticoagulation practice.

Methods: The ADVANCE Working Group consists of members from 14 European hemophilia centers. Each center retrieved data on the number of PWH with AF in their hemophilia population, as well as their total number of adult PWH. For each person with AF, a case report form was completed.

Results: In total, 29 PWH with AF were documented of whom 25 (86%) with hemophilia A and 4 (14%) with hemophilia B. The mean age was 68.2 years (IQR 62–75.5). Hemophilia was severe in 6 (20.6%), moderate in 6 (20.6%) and mild in 17 (58.6%) patients. The prevalence in the total studied hemophilia population was 0.94% (29/3094) and increased with age; in patients > 40 years it was 1.7% (29/1723) and in patients > 60 years 3.6% (23/635). The median CHA_2DS_2-Vasc score was 1.0 (IQR 0–2). Hypertension was reported in 12 patients (41.4%), diabetes in 3 (10.3%), previous stroke or TIA in 1 (3.4%), peripheral vascular disease in 4 (13.8%). In 11 patients (37.9%), anticoagulation was started of whom nine low dose aspirin and two vitamin K antagonists. Of these 11 patients, nine had mild hemophilia, one moderate and one severe with FVIII prophylaxis. During follow-up after diagnosis (mean follow-up 52.9 months), there were no thrombotic events reported, nor increases in bleeding severity.

Conclusion: In this largest cohort of PWH with AF so far, the prevalence of AF in hemophilia increases with age and is predominantly present in mild hemophilia. Based on the population based CHA_2DS_2-Vasc risk scores, PWH have a low stroke risk that might be even lower considering the hypocoagulable state. Hemophilia doctors prescribe anticoagulation therapy approximately in half of their mild hemophilia patients and very few in moderate and severe.

PB 2.36-5

Beriate® P in the treatment of patients with haemophilia A: update of a long-term pharmacovigilance

Klamroth R[1], Heller C[2], Holzhauer S[3], Jürs M[4] and Kurnik K[5]

[1]Vivantes Klinikum in Friedrichshain, Berlin; [2]Comprehensive Care Center for Thrombosis and Haemostasis J.W.Goethe University, Frankfurt; [3]University Hospital Charité, Berlin; [4]CSL Behring GmbH, Marburg; [5]Dr. v. Haunersches Childrens' Hospital, University Hospital, Munich, Germany

Pharmacovigilance studies are effective tools to collect data on products in the post authorization period. This study assessed the long-term efficacy, tolerability and safety of a high purity plasma-derived FVIII concentrate, Beriate® P (CSL Behring GmbH, Marburg).

Previously untreated – and previously treated patients at any age with haemophilia A, who had received Beriate® P and who fulfilled the inclusion criteria were enrolled. Based on the proceeding at the centres, patients were routinely screened every 3–12 months. Parameters documented comprised efficacy-, safety-, pharmacoeconomic- and pharmacokinetic data.

Up to now, 86 patients were included into this study [median duration: 44 months (0–115)] and data from 809 visits were available for analysis. Seventy-one patients suffered from severe-, 10 patients from moderate- and four patients from mild haemophilia A. In one patient, the information on severity of haemophilia A was missing. There was no proven virus transmission for hepatitis A-, hepatitis B-, hepatitis C- or human immunodeficiency virus. Median patient age was 19.8 years (0.1–74.6).

Eighty-two percent of the patients (N = 68) received prophylaxis with at least one infusion per week. Median average number of bleeds per year was 3.23 (0–42.98) and a median of 2.0 infusion per bleeding was administered. Seventy-four percent of patients (N = 72) experienced no major bleeds and 11% experienced no bleed at all with regard to all sorts of bleeding. Efficacy of Beriate® P was assessed as good or excellent in 98.5% of patients with minor bleeds and 94% in patients with major bleeding.

Two cases of inhibitor development were reported; one inhibitor was transient and the second inhibitor was treated with immune tolerance therapy. The results included in this interim analysis confirm the very good efficacy, tolerability and safety of Beriate® P.

PB 2.36-6

Comorbidities in patients with haemophilia and other rare bleeding disorders: a cross sectional study

Marquardt N, Schwerdtfeger C, Goldmann G, Horneff S, Klein C, Ivaskevicius V, Brackmann H-H and Oldenburg J

University Clinic Bonn, Bonn, Germany

Background: Broad availability of virus-inactivated clotting factor concentrates and newer treatment options for HIV and HCV infected individuals has led to a near normal life expectancy in people with haemophilia (PWH) and other rare bleeding disorders (RBD). Thus, this patient cohort is facing comorbidities that are common in the general population but may pose a challenge to healthcare professionals due to the underlying bleeding disorder.

Aims: The aim of this study was to quantify comorbidities among PWH and patients with other RBD aged over 40 years who are regularly treated at the Haemophilia Center Bonn. The present sub-analysis focused on cardiovascular risk factors and diseases.

Methods: We conducted an observational, descriptive, cross-sectional study in PWH and patients with other RBD who were treated at the Haemophilia Center Bonn in 2011. We considered inclusion of patients with haemophilia A and B, type 2 and 3 von Willebrand disease (VWD) as well as patients with deficiency of clotting factors I,

VII, XI or XIII. Patients with type 1 VWD and carriers of haemophilia were excluded. Eligible patients were identified in our electronic patient database and comorbidity information was extracted from medical records.

Results: In total, 348 (42.8%) out of 814 patients were aged over 40 years. From these 348 patients 165 (47.4%) had severe forms of haemophilia or other RBD, 100 (28.7%) were moderate and 83 (23.9%) had a mild form of disease. One hundred and twenty-one (34.8%) patients had active HCV, 52 of these patients had mild to moderate liver fibrosis (F1-F2) and 43 patients had high-grade liver fibrosis or cirrhosis (F3-F4) as documented by transient elastography. HIV-infection was present in 87 (25%) patients over 40 years of age. Body mass index (BMI) was calculated in 343 out of 348 patients: four patients (1.2%) were underweight (BMI < 18.5 kg/m^2), 143 (41.7%) were of ideal body weight (BMI 18.5–25 kg/m^2), 152 (44.3%) were overweight (BMI 25–30 kg/m^2) and 44 (12.8%) were obese (BMI > 30 kg/m^2). The following cardiovascular diseases were identified: arterial hypertension in 109 (31.3%) patients, coronary heart disease in 19 (5.5%) patients, myocardial infarction in 8 (2.3%) patients, atrial fibrillation in 7 (2%) patients and apoplexy in 3 (0.9%) patients. Mean age at diagnosis of coronary heart disease was 63.12 years (42–83 years, standard deviation 11.93) and for atrial fibrillation 65.57 years (50–79 years, standard deviation 11.01).

Summary/Conclusion: Comorbidities, especially cardiovascular risk factors and diseases are present in a substantial proportion of patients with haemophilia and other RBD aged over 40 years. Careful assessment of comorbidities and guidance of affected patients is of increasing importance in haemophilia care.

PB 2.37-1

FXIII- a novel treatment in haemophilia

Rea CJ[1], Foley JH[2], Mickelson J[3], Monroe D[4] and Sorensen B[5]

[1]Haemostasis Research Unit, London, UK; [2]University of British Colombia, Vancouver, BC, Canada; [3]McAllister Heart Institute, UNC School of Medicine; [4]Hematology/Oncology, UNC School of Medicine, Chapel Hill, NC, USA; [5]University of Aarhus, Aarhus, Denmark

Background: Clot stability and structure are normalised if factor XIII (FXIII) is added to Factor VIII (FVIII) deficient plasma. FXIII could be an effective, novel therapy in haemophilia.

Aims: Investigate the effect of supra-physiological levels of FXIII in whole blood from patients with severe haemophilia A and evaluate the mechanisms of FXIII in haemophilia.

Methods: Six patients with severe haemophilia A and four healthy controls were included. Blood was drawn into citrate and CTI 30 μg/mL and spiked with rFVIII (0, 0.025, 0.05, 0.1, 1 IU/mL), plus FXIII (0, 0.5, 1 or 2 IU/mL). Clotting was triggered with tissue factor (TF, Innovin, 1:50000) plus calcium and measured using thromboelastometry. To assess clot stability the above assay was performed with t-Pa 1.5 nM. Area under the elasticity curve (AUEC) was the endpoint.

Thrombin generation (TG) was recorded in FVIII deficient plasma spiked with FVIII and FXIII as above using TF (1PM) and the CAT method (Thrombinoscope BV).

Effects of increasing concentrations of FXIII on FXIII activation were investigated using FXIIIa fluorogenic sustrate. TF (1:50000), Phospholipid (4 nM) and FXIIIa fluorogenic substrate peptide (A101, Zedira, 50 μM) were combined in microtiter wells. FVIII deficient plasma spiked with FVIII plus FXIII as above was added and coagulation triggered with calcium. FXIII activation was recorded as changes in the fluorescent signal.

A bleeding model in FIX deficient mice was used to see if infusion of FXIII (up to 50–200 IU/kg) could improve average time to haemostasis following saphenous vein incision compared to controls.

Results: FXIII added to whole blood resulted in a significant dose-dependent increase in clot stability at all concentrations of FVIII ($P < 0.05$, ANOVA). Mean clot stability in haemophilia patient samples could be normalised at low concentrations of FVIII when FXIII was administered as an adjunct as shown by a normalised AUEC with 0.08 IU/mL of FVIII plus FXIII 0.5 or 0.05 IU/mL FVIII combined with 2 IU/mL FXIII. FXIII had no significant effect of parameters of clot formation. FXIII significantly enhanced thrombin generation, shortening ttPeak and lagtime ($P < 0.05$). ELISA excluded FXIII contamination by FVIII.

The dynamic FXIII activation assay showed that addition of FXIII stoichiometrically regulates efficiency of conversion to FXIIIa, even at low FVIII concentrations.

The data from the mouse-bleeding model indicated that FXIII did not significantly change average time to haemostasis. Infusion of FXIII did not result in animal death.

Conclusion: The study shows that exogenous FXIII is able to normalise clot stability in whole blood samples from haemophilia patients. The failure to enhance haemostasis in the mouse model may reflect high endogenous FXIII and an inability to induce supra-physiological levels. FXIII enhances TG and this may provide a novel explanation for the clot modifying effects previously reported. We demonstrated that supra-physiological FXIII stoichiometrically enhances FXIII activation, providing a rational for the clot stabilising effects of FXIII in the presence of the abnormal thrombin generation of haemophilia. These results support the use of FXIII as a novel treatment in haemophilia and merits initiation of clinical trials.

PB 2.37-2

Bleeding pattern and median time interval between bleeding episodes amongst patients receiving on-demand and prophylaxis therapy

Valentino LA[1], Ewenstein BM[2], Guzmán-Becerra N[3], Wong WY[2], Schoenig-Diesing C[4] and Romanov V[4]

[1]Rush University Medical Center, Chicago, IL; [2]Baxter Healthcare, Research and Development; [3]Baxter Healthcare, Biostatistics Department; [4]Baxter Healthcare, Global Medical Affairs, Westlake Village, CA, USA

Background: Prophylaxis with factor VIII (FVIII) is considered the optimal treatment for the management of hemophilia A patients without inhibitors. The recently published ADVATE (rAHF-PFM) Prophylaxis Study[1] compared the efficacy of two prophylaxis regimens (pooled prophylaxis) and between on-demand and either standard or PK-tailored prophylaxis treatments. Previously on-demand-treated patients of median age 26 (range: 7–59 years; ($N = 53$ PP population) with FVIII levels ≤ 2% received 6 months of on-demand treatment and then were randomized to 12 months of either standard (20–40 IU/kg every other day) or pharmacokinetic (PK)-tailored (20–80 IU/kg every third day) prophylaxis, both intended to maintain FVIII trough levels ≥ 1%. Twenty-two (33.3%) patients on prophylaxis experienced no hemorrhages, whereas no patients treated on-demand were hemorrhage-free. The annual bleeding rate (ABR) for the two prophylaxis regimens were comparable, whereas differences between on-demand and either prophylaxis regimen were statistically significant ($P < 0.0001$).

Objectives: To evaluate the bleeding pattern and median bleed-free intervals (days) in patients who have taken part in the rAHF-PFM Prophylaxis Study[1].

Results: Herein, we report on an analysis of the joint bleeding and total hemorrhages among patients in the ADVATE (rAHF-PFM) Prophylaxis Study. Among all patients in the per protocol analysis set ($N = 53$), 1351 total hemorrhages occurred during the on-demand

phase, of which 1164 were hemarthroses. Seventy-seven hemorrhages (55 hemarthroses) occurred among patients randomized to the standard prophylaxis arm and 75 (72 hemarthroses) among patients in the PK prophylaxis arm ($P < 0.0001$ for both total and joint bleeding between either prophylaxis arm and on -demand).
The median differences in the interval (days) between bleeding events was significant comparing on-demand to either prophylaxis arm: with median time (days) between bleeding for on-demand of 6.3 days vs. 184.5 days in the standard prophylaxis arm and 183 days in the PK prophylaxis arm ($P < 0.0001$). When investigating the trough levels in the two prophylaxis arms the median trough levels differed: 2.5 IU/dL in the standard prophylaxis arm ($N = 24$) and 1.0 IU/dL in the PK prophylaxis arm ($N = 23$). It appears that trough level of 1.0 IU/dL in the PK prophylaxis arm was enough to achieve 1 ABR in this study.
No deaths, inhibitors or cases of hypersensitivity related to rAHF-PFM occurred during the conduct of this study.
Conclusions: These results provide additional evidence for the superiority of prophylaxis compared to on-demand treatment in severe hemophilia A and further indicate that a PK-tailored regimen may be effectively administered every third day.

PB 2.37-3

AURIGA: study of adherence to prophylaxis in patients with severe haemophilia A

García-Dasí M[1], Aznar JA[1], Jiménez Yuste V[2], Mingot E[3], Lucía F[4], Altisent C[5], Jiménez F[6], López F[7], Marco P[8], Pérez R[9], Fernández A[10], Paloma J[11], Galmes B[12], Herrero S[13] and García-Talavera JA[14]

[1]Hospital Universitario y Politécnico La Fe, Valencia; [2]Hospital La Paz, Madrid; [3]Hospital Carlos Haya, Málaga; [4]Hospital Miguel Servet, Zaragoza; [5]Hospital Vall d'Hebron, Barcelona; [6]Hospital Torrecárdenas, Almería; [7]Hospital Juan Canalejo, A Coruña; [8]Hospital General de Alicante, Alicante; [9]Hospital Virgen del Rocío, Sevilla; [10]Hospital Central de Asturias, Asturias; [11]Hospital Virgen del Camino, Pamplona; [12]Hospital Son Espases, Mallorca; [13]Hospital General de Guadalajara, Guadalajara; [14]Hospital de la Candelaria, Tenerife, Spain

Background: An international study performed in 18 countries showed reduced adherence to prophylaxis in adolescent patients compared with patients aged < 12 years (Geraghty et al. *Haemophilia*. 2006;12:75–81).
Aim: To assess adherence to prophylaxis with factor VIII (FVIII) in patients with severe haemophilia A aged 6–21 years.
Methods: We assessed adherence to prophylaxis by comparing the amount of FVIII administered by the patient with the amount prescribed by their physician over a 2-year period. To evaluate adherence from the patient's perspective, we developed a questionnaire ad hoc to assess the benefits of prophylaxis, barriers to adherence, patient perception of self-efficacy (patient's belief that he is able to self-administer the treatment and take care of his own health), and self-care practices. The Haemo-QoL questionnaire was administered to assess patient quality of life. The study was approved by the medical ethics committees of participating hospitals. Informed consent was obtained of each patient.
Results: Seventy-six patients were recruited from 14 centres in Spain between November 2011-November 2012. Patient data were retrospectively collected over a 2-year period before the date of inclusion in the study. Patient adherence ranged from 35.6% to 100%, with a mean (SD) of 95.0% (11.5%). Children aged < 12 years had a slightly higher adherence rate (95.7%) than adolescents (94.9%) ($P = 0.64$). Adherence scores ranged from 25 to 119 (mean, 87.3; higher scores indicate better adherence). The mean score for patients aged ≤ 7 years was 88.9; for patients aged 8–12 years, 86.4; for patients aged 13–16 years, 85.6; and for patients aged ≥ 17 years, 80.9 ($P = 0.18$). Adherence was higher when parents were responsible for administration (95.7%) than when patients self-infused (93.8%) ($P = 0.50$). Patients with lower adherence had more joint problems than those with better adherence ($P > 0.01$). The average Haemo-QoL score for patients aged ≤ 7 years was 74.5; for patients aged 8–12 years, 77.9; for patients aged 13–16 years, 78.8; and for patients aged ≥ 17 years, 89.0 ($P < 0.05$). The quality of life reported by patients (77.6) was higher than that reported by their parents (73.8) ($P = 0.03$).
Conclusions: Minimal differences in adherence between age groups were observed in Spanish patients with haemophilia A, unlike studies published in other European countries, in which adherence dramatically decreased during adolescence. This may be because in Spain, the transfer of responsibility for treatment from the parent to the child does not occur until early adulthood. Regarding the influence of psychological variables, patient-reported scores on the adherence questionnaire indicate that, as patients become older, they perceive more barriers to continuing treatment (time, effort, and day-to-day interferences), fewer benefits of prophylaxis, and less self-efficacy (ie, they believe they are less able to take care of their own health). If this trend continues, it could lead to adherence issues in adulthood. As expected, patients with lower adherence had more joint problems and, therefore, worse general health. The improvement in quality of life seen with patient age may reflect that patients are better able to accept and adapt to haemophilia as they get older.

PB 2.37-4

Major surgery in severe haemophilia A with inhibitors using a recombinant factor VIIa/activated prothrombin complex concentrate hybrid regimen

Van Veen J[1], Maclean RM[1], Hamer A[2], Hampton K[2] and Makris M[1]

[1]Sheffield Haemophilia and Thrombosis Centre; [2]Sheffield Teaching Hospitals NHS Trust, Sheffield, UK

Background and Aim: Major surgery in haemophilia A and inhibitors is increasingly performed with recombinant FVIIa (rFVIIa) or activated prothrombin concentrate (APCC). Evidence of superiority of one agent over the other is lacking. Dosing recommendations are available but the optimal regimen remains unclear. We report a hybrid regimen of rFVIIa and APCC (FEIBA®) in six total knee replacements (TKR), one emergency orchidectomy and one emergency open appendectomy in four patients with haemophilia A and inhibitors performed at our centre.
Methods: All patients received rFVIIa 90 μg/kg 2 hourly for at least 48 h and switched to FEIBA between days 2 and 5. RFVIIa was reduced to 90 μg/kg 3 hourly on the days 2 and 3 and 90 μg/kg 4 hourly on days 4 and 5. All received tranexamic acid 1gram QDS and this was stopped 12 h before switching to FEIBA®. FEIBA® 200 U/kg/day in three divided doses was given when switched up to day 5 and 100–150 U/kg/day in two divided doses thereafter.
Results: The joint functionality was excellent after all TKR at 1 year. In three (patients 1 and 4) there were no haematological bleeding complications (one had a surgical bleed that stopped immediately after ligation of a spurting vessel). Patient 2 developed a possible muscle bleed on day 5 following a TKR on 150 U/kg/day FEIBA® and was switched back to rFVIIa, 90 μg/kg 2 hourly for 24 h after which FEIBA® was resumed without further complications. Patient 3 developed a quadriceps haematoma on day 6 after a TKR whilst on 100 U/kg/day FEIBA®. He was switched to rFVIIa in reducing frequency for the remainder of his treatment without further complications. Patient 4 had three other procedures. An emergency orchidectomy was complicated by a large hemiscrotum haematoma on day 10 after stopping treatment with FEIBA® on day 9. An emergency open appendectomy was complicated by a large intra-abdominal haematoma on day 1 on 2 hourly rFVIIa 90 μg/kg. This settled on increasing doses, 150 μg/kg 2 hourly for eight doses, after which he was switched to FEIBA® without further complications. Finally, wound site bleeding developed on day 1 after a second TKR on 2 hourly rFVIIa 90 μg/kg, unresponsive

to increased doses of rFVIIa, but settled after switching to FEIBA® 200 U/kg/day. He rebled on day 6, on the same dose of FEIBA®. Sequential treatment with rFVIIa (105 μg/kg 2 hourly and FEIBA® 62.5 U/kg 12 hourly) was given for 12 h. The bleeding settled and treatment with FEIBA® was continued.

Conclusion: We report a hybrid regimen of rFVIIa and APCC in major surgery. There was bleeding in two patients (five procedures, including one surgical bleed). There were no long term sequelae and joint functionality after TKR was excellent. To our knowledge there have been no reports of the systematic use of a hybrid regimen combining the flexibility of rapid dose changes of rFVIIa and less frequent dosing with APCC. A further advantage is a significant cost saving compared to the use of monotherapy with rFVIIa.

PB 2.37-5

Helixate® NexGen for the treatment of hemophilia A: update of a long-term pharmacovigilance project

Oldenburg J[1], Auerswald G[2], Petrini P[3], Faradji A[4], Pabinger I[1], Niekrens C[5], Stockschläder M[6], Gutowski-Eckel Z[6] and Staritz P[7]

[1]University Hospital, Bonn; [2]Prof. Hess Childrens Hospital, Klinikum Bremen-Mitte, Bremen, Germany; [3]Karolinska Sjukhuset, Stockholm, Sweden; [4]CHU de Hautepierre, Strasbourg, France; [5]Klinikum Delmenhorst gGmbH, Delmenhorst; [6]CSL Behring GmbH, Marburg; [7]Hemophilia Center SRH, Heidelberg, Germany

This multinational (Austria, France, Germany, Italy, Sweden) project is assessing the long-term efficacy, tolerability and safety of Helixate® NexGen (CSL Behring, Marburg), a recombinant FVIII concentrate, in the post authorization period.

PUPs and PTPs with hemophilia A at any age treated with Helixate® NexGen are eligible for enrollment. Patients are routinely screened every 3–12 months.The following parameters, as determined routinely for these patients (non-interventional design), were documented: overall clinical response, bleeding events, adverse drug reactions including the incidence of inhibitors, laboratory safety and virus safety parameters, relevant concomitant diseases, relevant concomitant medication. Pharmacokinetic data were also collected if available. Treatment modalities with Helixate® NexGen, including average factor consumption per month and exposure days were recorded.

Data from a total of 223 patients with a total of 2306 visits were available for this update. The majority of the patients (82%) had severe hemophilia A. The median age was 23.0 years (range: 15 days–68 years). Median time between visits to the respective center was 4 months (range: 0–48 months).

The majority of patients are under prophylactic treatment (83%). The most common prophylaxis regimen was 2–3 infusion (64.5%) per week. The median number of bleeds per year was 2.57 per patient. A median number of two infusions were administered per bleeding. Eighty-two percent of the patients had no major bleeding and 14% experienced no bleed at all. During the up to 11-year observation period only three cases of inhibitor development were reported.

Efficacy of Helixate® NexGen in the treatment of bleeding was assessed as good or excellent in 97% of all documented bleeds. The results included in this interim analysis confirm the excellent efficacy, tolerability and safety of Helixate® NexGen.

PB 2.37-6

Applicability of the ESC guidelines on management of acute coronary syndromes to people with haemophilia – an assessment by the ADVANCE Working Group

Staritz P[1], De Moerloose Ph[2], Schutgens REG[3], Huth-Kuehne A[4] and Dolan G[5]

[1]SRH Kurpfalzkrankenhaus Heidelberg, Heidelberg, Germany; [2]Faculty of Medicine of Geneva, University Hospitals, Geneva, Switzerland; [3]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, The Netherlands; [4]SRH Kurpfalzkrankenhaus, Heidelberg, Germany; [5]Nottingham University Hospitals, Queens Medical Centre, Nottingham, UK

Background: There are no evidence-based guidelines for antithrombotic management in people with haemophilia (PWH) presenting with acute coronary syndrome (ACS)

Aim: Review of current European Society of Cardiology guidelines, and to consider how best they should be adapted for PWH.

Methods: Structured communication techniques based on a Delphi-like methodology were used to achieve expert consensus on key aspects of clinical management.

Results: The main final statements are: a) ACS and myocardial revascularization should be managed promptly by a multidisciplinary team that includes a haemophilia expert, b) Each comprehensive care centre for adult PWH should have a link to a cardiology centre with an emergency unit and 24 h availability of PCI, c) PCI should be performed as soon as possible under adequate clotting factor protection, d) Bare metal stents are preferred to drug eluting stents, e) Anticoagulants should only be used in PWH after replacement therapy, f) Minimum trough levels should not fall below 5–15% in PWH on dual antiplatelet therapy, g) The duration of dual antiplatelet therapy after ACS and PCI should be limited to a minimum, h) PWH receiving antiplatelet therapy should be offered gastric protection, i) The use of GPIIb-IIIa inhibitors is not recommended in PWH other than in exceptional circumstances, j) The use of fibrinolysis may be justified in PWH when primary PCI (within 90 min) is not available ideally under adequate clotting factor management.

Conclusion: It is hoped that the results of this initiative will help to guide optimal management of ACS in PWH.

PB 2.38-1

Heterogeneity of bleeding classification among randomized studies in hemophilic patients

Chan HW[1], Li C[2], Chan N[3], Lau K[1] and Chan AK[1]

[1]McMaster University, Hamilton, ON; [2]Western Ontario University, London, ON; [3]University of Waterloo, Waterloo, ON, Canada

Background: Bleeding in patients with hemophilia includes intraarticular bleeding, intramuscular bleeding, and mucocutaneous bleeding. Bleeding classifications, as defined by EMEA and ISTH, do not correlate well with the type of bleeding as experienced by patients with hemophilia. This makes it difficult, if not impossible, to make clear comparisons between studies evaluating bleeding events in this population.

Aim: This is a systematic review to determine the degree of homogeneity of bleeding classifications among randomized interventional studies for patients with hemophilia.

Methods: A literature search was conducted utilizing Pubmed database, retrieving the publications between 1981 and 2012 using 'hemophilia' 'bleeding' and 'randomized' as keywords. Only original randomized studies were included in the final review. Meta-analyses,

antiviral studies and studies that did not define bleeding as the end point of the study or did not include details regarding bleeding definition were excluded. Data regarding the definition of bleeding in hemophilic patients were extracted and classified into two major categories: those defining the location of bleeding and those defining the severity of bleeding. The I^2 statistic was used to assess the heterogeneity of bleeding classifications. An I^2 index of > 50% was considered as large heterogeneity.

Results: Two hundred and twenty-nine publications were found in the primary search and 28 eligible trials were identified. There were three studies on perioperative managements and 25 studies on non-operative hemophilic patients. Thirteen studies used nominal data, nine used ordinal data and one used combined data to analyze bleeding. The I^2 statistic index for perioperative studies and non-operative studies was 50% and 77.5% respectively. Even among the definitions regarding joint bleeding, the I^2 index was as high as 79%.

Summary/Conclusion: Among the randomized studies on hemophilic patients, highly variable characteristics were used to report bleeding. Although bleeding into the joints is the most common hemorrhagic complication in these patients, the studies did not have universal and objective criteria when describing its symptoms or signs, disallowing commensurable analysis. Various scoring systems have been developed to evaluate chronic joint deformity, but acute hemorrhage into the joint is usually dependent on subjective, self-reporting mechanisms. The data in this systematic review serves as a call for collaboration in our community to reach a consensus so that a reproducible evaluating system for haemorrhages in patients with hemophilia can be established.

PB 2.38-2

Combined T- and B-cell immunomodulatory therapy for immune tolerance induction in four hemophilia patients with poor risk inhibitors

Buckner TW, Nielsen B, Weston B and Monahan P
University of North Carolina, Chapel Hill, NC, USA

Background: Development of inhibitory antibodies in patients with hemophilia remains the most significant complication of treatment with coagulation factor concentrates. Immune tolerance induction (ITI) using high-dose factor VIII (FVIII) or factor IX (FIX) is now considered the standard of care for children with inhibitors. However, ITI is associated with a failure rate of ~30% in hemophilia A and up to 70% in hemophilia B. Individuals with factor IX inhibitors (who have a risk of anaphylaxis and nephrotic syndrome with standard ITI) and individuals with factor VIII inhibitors who have failed tolerance attempts with high dose clotting factor and anti-CD20+ are unlikely to gain tolerance without immunomodulation (altering the T cell interaction with B cells).

Aim: To describe four consecutive patients with high-titer inhibitors treated with ITI and combined immunomodulatory therapy.

Methods: Patients were treated with high-dose daily FVIII/IX plus the combined immunomodulatory (IP) regimen described by Beutal (*Haemostaseologie*, 2009): rituximab 375 mg/m^2/dose × 4 doses, mycophenolate mofetil (MMF) 300 mg/m^2/dose b.i.d × 50 days, dexamethasone 12 mg/m^2/day divided b.i.d for 4 days in weeks 2, 4, and 7, and intravenous immunoglobulin (IVIg) 1 g/kg/day × 2 doses with each dexamethasone pulse. Hemophilia B patients with inhibitors were started on IP simultaneously with ITI, whereas only those hemophilia A patients who were refractory to standard ITI plus rituximab received ITI + IP.

Results: *Patient 1* is a 33-month old boy with severe hemophilia B due to whole gene deletion. ITI + IP resulted in complete remission of inhibitor that persists 10 months later, after full recovery of CD20+ cells. He currently receives FIX 100 unit/kg q.o.d. *Patient 2* is a 5 year old boy with severe hemophilia B due to a frameshift mutation (F9 c.97delT (p.Leu-24HisfsX10)). ITI + IP resulted in complete remission of inhibitor that persists 4 months later, with partial recovery of CD20+ cells. He receives daily FIX 60 units/kg. *Patient 3* is a 5 year old boy with severe hemophilia A due to intron 22 inversion who failed ITI plus rituximab. ITI + IP resulted in partial remission of inhibitor (inhibitor titer: 1 BU); CD20+ testing is pending. He receives daily MMF and FVIII 200 units/kg q.o.d. *Patient 4* is a 6 year old boy with severe hemophilia A due to intron 22 inversion who had failed ITI plus rituximab. ITI + IP resulted in complete remission of inhibitor that persists 1 month later, with no recovery of CD20+ cells. He receives daily MMF and FVIII 40 unit/kg q.o.d. Patient #2 had a single episode of hypersensitivity to FIX, treated with antihistamine. No patient exhibited nephrotic syndrome during therapy.

Summary/Conclusion: ITI + IP resulted in marked improvement in quality of life for all patients. Durability of the remissions is yet to be determined, as only one patient has demonstrated full recovery of CD20+ cells. Successful eradication of inhibitors in these patients, all at high risk of treatment failure, suggests that modulating the interaction of B- and T-cells plays an important role in ITI for select patients. The IP regimen described should be considered for further study in clinical trials.

PB 2.38-3

On-demand treatment costs of Italian haemophilia patients with inhibitors: an exploratory lifetime economic model

Weatherall JH[1], Lee W[2], Petrilla AC[2], Bilir P[2] and Trochlil K[2]
[1]*Novo Nordisk A/S, Soeborg, Denmark;* [2]*IMS, Falls Church, VA, USA*

Background: Quantifying the health economic and the health related and quality of life (HRQoL) impact of on-demand (OD) treatment of bleeding episodes has not been done in Italian haemophilia patients with inhibitors.

Aims: this study estimated lifetime OD costs and HRQoL associated with recombinant activated Factor VIIa (rFVIIa) and plasma-derived activated prothrombin complex concentrate (pd-aPCC) from the Italian payer perspective.

Methods: A lifetime semi-Markov cohort model, reflecting 2-year old male haemophilia patients with high-responding inhibitors, was used to calculate outcomes associated with OD treatment of bleeds with rFVIIa or pd-aPCC. Using a 3-month cycle length, the model simulates patient transitions through eight health states: pre-ITI, delayed ITI, low-dose ITI, high-dose ITI, tolerised, partially-tolerised, non-tolerised, and death. Throughout the model, patients can experience mild-to-moderate bleeds (treated initially at home) and major bleeds, which require hospitalisation. Published international studies informed efficacy, utility, and other clinical inputs, while Italian cost schedules informed cost parameter values. Outcomes include life expectancy, quality-adjusted life expectancy, cost per bleeding episode, and direct treatment costs over time. Costs and effects were discounted at 3% in the base case analysis.

Results: Default analysis showed lower lifetime and per-bleed costs with rFVIIa compared with pd-aPCC (lifetime:€4,583,205 vs. €5,366,519 and per-bleed:€23,477 vs. €24,406, respectively). Hospitalisation length of stay is important for non-drug costs as length of stay for less than a day, costs €387 whereas stays of > 1 day costs were €4241. Patients treated with rFVIIa also had slightly higher quality-adjusted life expectancy, by 0.07 QALYs in base case analysis; this value may rise as high from 0.92 to 3.48 QALYs if pain relief from earlier bleed resolution improves underlying utility value by 5–20% compared to pd-aPCC.

Summary/Conclusion: Treatment with rFVIIa can lead to lower costs, with the difference attributable to lower costs of ITI, a less expensive dosing schedule, and improved bleed resolution, which reduces hospitalizations. If faster bleed resolution leads to earlier pain relief, rFVIIa treatment may improve quality-adjusted survival as well.

PB 2.38-4

Multi-centre Australia wide study comparing FVIII assay variation in haemophilia A patients receiving two different recombinant FVIII products using the one stage and chromogenic assays

Khoo TL[1], Kershaw G[1], Matthews S[1], Clare W[1], Bowyer A[2], Kitchen S[2] and Dunkley S[1]

[1]Institute of Haematology, Sydney, Australia; [2]Royal Hallamshire Hospital, Sheffield, UK

Background: In Australia, Xyntha (B domain deleted) and Kogenate (full length) are the two recombinant antihaemophilic factor VIII products available. Two common assays, chromogenic assay (FVIII:Chr) and one stage assay (FVIII:1S) are used to measure Factor VIII replacement levels (FVIII IU/dL) in patients with haemophilia A (HA). Discrepancies in FVIII IU/dL levels have been reported between these assays. Furthermore, it is uncertain how these different recombinant FVIII products could potentially affect the measurement of FVIII IU/dL levels by the FVIII:1S method. This has created an uncertainty in clinical practice for accurate replacement of FVIII in HA patients.

Aims: This multi-centre study aimed to evaluate the (i) inter-laboratory variability in the FVIII:1S assay and (ii) discrepancies between FVIII:1S and FVIII:Chr in severe HA patients receiving either Xyntha or Kogenate.

Methods: Fifteen Australian laboratories and one international laboratory (Sheffield UK) participated in this study. Samples from five patients receiving Xyntha and four patients receiving Kogenate were evaluated. Samples were collected between 1 and 20 h post FVIII treatment. All laboratories performed FVIII assays on the samples provided using their standard reagents and instrumentation. All assays were calibrated with commercially available human plasma standards. Fifteen laboratories performed the FVIII:1S assay and five performed the additional FVIII:Chr assay. A Bland and Altman difference analysis was also performed to assess bias and differences when comparing FVIII IU/dL levels using the FVIII:1S and FVIII:Chr assays.

Results: The mean FVIII level in the nine patient samples ranged from 16 to 124 IU/dL (FVIII:1S) and 22–187 IU/dL (FVIII:Chr). There was good inter-laboratory agreement in the results. The co-efficient of variation (CV%) for FVIII:1S ranged from 14.1% to 20.1% (Xyntha); and 10.4% to 12.5% (Kogenate). The CV% for FVIII:Chr ranged from 8.7% to 14.4% (Xyntha); and 4.2% to 6.9% (Kogenate). The FVIII:Chr method measured higher FVIII results compared to the FVIII:1S with a 1.5 times (range 1.5–1.7) increase in FVIII levels (Xyntha) but only a 1.2 times (range 1.0–1.3) increase in FVIII levels (Kogenate). The degree of agreement between FVIII:1S and FVIII:Chr when assessed using the Bland Altman analysis showed the FVIII:Chr assay had a positive bias of 42, standard deviation (SD) of bias = 31 (Xyntha); and a positive bias of 25, SD of bias = 13 (Kogenate).

Conclusion: There is a wider range of variation (CV%) when measuring FVIII levels in patients on Xyntha replacement compared to patients on Kogenate when using the FVIII:1S method. FVIII levels measured using the FVIII:Chr method resulted in an average 1.5 times higher level compared to FVIII:1S in patients on Xyntha replacement. This study highlights the challenges in measuring FVIII levels in patients on the two available FVIII replacement products available in Australia. Thus, depending upon the assay used, a patient with HA may receive vastly different quantities of FVIII replacement therapy. A product specific concentrate standard may be useful in standardizing FVIII measurements and allow the appropriate dose of FVIII to be administered to HA patients.

PB 2.38-5

Introducing the KAPPA prospective registry in hemophilia A: design, objectives and progress

Osooli M[1], Astermark J[2], Baghaei F[3], Holmstrom M[4], Lindvall K[2], Steen Carlsson K[5] and Berntorp E[2]

[1]Lund University; [2]Skane University Hospital, Malmo; [3]Sahlgrenska University, Gothenburg; [4]Karolinska Institute, Stockholm; [5]Faculty of Medicine, Lund University, Malmo, Sweden

Background: A recent Swedish health technology assessment of replacement treatment strategies in moderate and severe haemophilia, highlighted the lack of suitable data available for analyzing comparative effectiveness and cost-effectiveness. As a consequence, studies published to date have been limited by retrospective and incomplete data, small sample size, lack of generalization due to specific and narrow target populations, and sometimes inappropriate design. Notably, there is a paucity of data on outcomes of on-demand treatment, which is the only treatment available for many patients in a global perspective.

Aims: To introduce and present the aims, design and progress of the KAPPA (Key Aspects of medical Practice in Patients with haemophilia A) registry

Methods: Lund University (LU) has initiated the KAPPA project to collect valid evidence on the impact of treatment regiments on Health Related Quality of Life (HRQL) of haemophilia A patients. We will enrol 1000 patients from eight different centres in Algeria, Denmark, Norway, Latvia, Lithuania, Sweden, Tunisia and Turkey between February 2013 and January 2016. We use an online Electronic Data Capturing (EDC) system for data collection and storage. KAPPA database is in English and includes questions encompassing the following: socio-demographics, treatment, bleeds, HRQL, Haemophilia Joint Health Score (HJHS), co-morbidities and adverse reactions. Physicians will consecutively enrol eligible patients as they visit the centre. Eligibility criteria include: a Factor VIII activity at diagnosis equal to or < 5%, the patient must visit the centre at least once a year and provide informed consent. Clinicians have access to their patients' identifying information for treatment's follow-up, however we will transfer anonymous data for the study. The Ethics Committee (EC) of LU approved the study and separate permissions from EC in each participating country will be obtained. In a multivariate model, we will predict the utility of treatment after adjustment for age, socio-economic status and co-morbidities.

Results: As of January 2013, we have assessed and confirmed the feasibility of performing the study in each centre, prepared the EDC, and have submitted ethics proposals in the pilot sites. We will implement the pilot study between February and March 2013 with the aim of testing the database's functions and the study's training package as well as communication process between the centres and study teams. An interim report will be prepared at the end of 2013.

Summary/Conclusion: Prospective registries are the best choice for collecting evidence for research as well as recording patients' data for better clinical decisions. By providing the infra-structure for collecting and summarizing real world patient data, the KAPPA registry will also assist patients, clinicians and health decision makers. It enables clinicians to develop and maintain a comprehensive and secure haemophilia database for use in the clinic and for future research. Better decisions can be made by clinicians through access to patients' treatment history. Finally, the final report of KAPPA will enable health decision makers to be better informed when having to make decisions on resource utilization and budget allocation for the haemophilia A treatment.

PB 2.38-6

Social status of adult haemophilia patients: preliminary results of a comparative single-centre cohort study with thrombophilia patients

Von Mackensen S, Holstein K, Gässler J, Lentz B, Bokemeyer C and Langer F

University Medical Centre Hamburg-Eppendorf, Hamburg, Germany

Background: The impact of the disease on the social status of haemophilia patients is not well established. Joint bleeds may lead to arthropathy with potential effects on school education and professional career. Recent studies on social status in adult haemophilia patients showed a higher rate of unemployment and occupational disability compared to the general male population in the Netherlands or to age- and sex-matched controls. With the introduction of prophylactic factor replacement, younger haemophilia patients have less joint damage, but it is unclear how this affects their social status.
Aim: We therefore explored the social status of patients with haemophilia (PWH) from our centre in comparison to an age- and sex-matched group of patients with thrombophilia (PWT).
Methods: PWH routinely visiting the Haemophilia Treatment Centre completed a questionnaire including socio-demographic data, questions regarding social status and a generic quality of life questionnaire (SF-36) as did PWT. Social status is usually defined through education, employment and income; quality of life (QoL) assessment provides insight into social and role functioning. In addition, clinical data were collected from patient files in both groups.
Results: So far, data from 40 PWH (27 severely affected) and 40 PWT have been analysed. The majority of PWH received on-demand treatment (61.5%). PWH had a mean number of 8.03 + 10.3 bleeds, a median number of target joints of 0 (0–3) and a mean orthopaedic joint score of 9.61 + 9.0. Mean age of PWH and PWT was 43.8 + 14.8 and 45.2 + 13.4 years, respectively. There was no significant difference concerning partnership, number of children and school or professional education between the groups. However, there was a trend towards higher graduation in PWT. By contrast, more PWT ($P < 0.02$) were actually working (85.0%) compared to PWH (62.5%); similar proportions of PWT and PWH were retired ($P = 0.057$), while only PWH were either retired due to their disease ($n = 6$) or unemployed ($n = 3$). No difference was found with regard to the amount of working time (full-time vs. part-time) and the type of occupation. Monthly income was lower in PWH ($P < 0.027$). With regard to QoL, PWH reported worse values in the domains 'physical functioning', 'pain' and 'general health' of the SF-36 compared to PWT; the physical summary score (PCS) was significantly worse as well ($P < 0.001$)
Conclusions: Despite the availability of factor concentrate for bleeding prophylaxis and treatment, PWH still have a lower social status with respect to employment and income compared to an age- and sex-matched group of PWT.

PB2.39 – Acquired Coagulation Disorders – II

PB 2.39-1

Heat treatment and immunological testing substantially improves the detection of factor VIII antibodies in acquired haemophilia A

Platton SJ[1], Batty P[2], Bowles L[1], Pasi J[2] and Hart DP[2]

[1]Barts Health NHS Trust; [2]Barts and the London School of Medicine and Dentistry, QMUL, London, UK

Background: Acquired haemophilia A is a rare bleeding disorder resulting from the development of auto-antibodies to the factor VIII (FVIII) pro-coagulant protein. Although good response rates are seen to conventional immunosuppressive treatment, it is associated with significant morbidity and mortality. The laboratory monitoring of treatment response is guided by the Bethesda assay despite samples often having significant amounts of residual FVIII present. In congenital haemophilia A, a FVIII ELISA kit (Hologic, previously GTI Diagnostics) and a modification (heat treatment) to the Bethesda assay have been described previously for the detection of FVIII antibodies. These techniques do not form a part of routine laboratory practice in the United Kingdom. We describe the application of these techniques in the setting of acquired haemophilia A.
Aims: To compare the Bethesda assay with a FVIII ELISA and to investigate the effect of heat treatment in the detection of FVIII antibodies in acquired haemophilia A.
Methods: Plasma samples sent for routine inhibitor testing from patients with acquired haemophilia A were tested using the Bethesda assay in parallel with the FVIII ELISA before and after heat treatment at 58 °C for 90 min.
Results: Thirty-nine samples from eight patients were tested in parallel by the Bethesda assay and FVIII ELISA before and after heat treatment. In the untreated samples, only two samples (5.1%) were positive by the Bethesda assay with 11 samples (28.2%) being positive by ELISA. Following heat treatment 20 samples (51.2%) were positive by the Bethesda assay and 16 (41.0%) positive by ELISA. If both tests were used in parallel, 12 samples (30.8%) were positive without heat treatment and 24 samples (61.5%) were positive following heat treatment by one or more technique. All samples that were positive following heat treatment showed significant levels of FVIII in the sample prior to this step (median FVIII:C 61.25 IU/dL, range 24.1–362.4 IU/dL). Of the eight patients tested, a change from negative to positive would have occurred in one or more samples from six of the patients if these tests had been part of routine clinical care.
Conclusions: The results of this study suggest the Bethesda assay in isolation may significantly underestimate the presence of FVIII auto-antibodies in acquired haemophilia A, with potential clinical repercussions. The relevance and clinical utility of FVIII antibody detection using these methods would ideally require further exploration in collaborative trials.

PB 2.39-2

FEIBHAC study: prospective clinical and biological evaluation of antihemorrhagic treatment with aPPCs (Factor eight inhibitor bypassing activity) in Acquired Hemophilia A (AHA)

Borg J-Y[1], Négrier C[2], Durieu I[3], Lévesque H[4], Dolimier E[5] and Villette B[5]

[1]Haemophilia Treatment Centre, Rouen University Hospital, Rouen; [2]Haemophilia Treatment Centre, Edouard Herriot Hospital, Lyon; [3]Department of Internal Medicine, Edouard Herriot Hospital, Lyon; [4]Department of Internal Medicine, Rouen University Hospital, Rouen; [5]Baxter Healthcare Corporation, Maurepas, France

Background: AHA is a rare disease due to autoantibodies anti FVIII, characterized by bleeds. Recommended as first line treatment for the severe acute bleed, rFVIIa and aPPCs (FEIBA) have a similar efficacy and tolerability.
Aim: To assess FEIBA posology according to the haemostatic efficacy in patients with AHA and bleed treated by FEIBA in first or second line therapy.
Method: French prospective observational multicenter longitudinal (3 months) registry for 3 years. The bleed characteristics, the physician evaluation of FEIBA efficacy and its consequences on the posology, the reasons for initiating haemostatic treatment and choosing FEIBA, the anamnestic response, the adverse events (AEs) related to FEIBA and fatal outcome were analyzed.

Results: Thirty-three patients were evaluated: median age: 83 years [IQ 76–87]; sex ratio H/F: 1/1.54. AHA had already been known in five patients. At Inclusion: median FVIII: 2.00% (IQ 1.00–3.00), median INH titre: 15 BU/mL (IQ 8–60). Among the 28 patients without AHA known before, the delay in diagnosis after the bleed onset was 3 days (IQ 1.00–14); this delay had a significant impact on the interval between the bleeding onset and the start of FEIBA ($P < 0.001$). Approximately 75% of the haemorrhages were spontaneous and tissular (muscular hematomas with or without ecchymosis in 45%). The severe score of bleeding was independent of the FVIII level and INH titre. In 87.5%, the bleed was the reason for the treatment. In 85%, FEIBA was prescribed in 1st line therapy. The initial median posology was 76 U/kg, every 12 h in 54.5% and 8 h in 33.4%; it was independent of the severity score of bleeding. After 24 h, 10.7% of the haemorrhages were controlled, 75% stabilized or improved. When the physician concluded in stabilization, dosage and frequency weren't modified; in case of aggravation or improvement, the frequency was changed in 27%. The total mean duration was 8.5 days; the mean delay between the start of FEIBA and the disappearance of the active sites (7.6 days) rose with the increase of the duration of the treatment ($P < 0.001$).The delay between the disappearance of the active sites and the stop of FEIBA (2.46 days) rose with the duration of the treatment ($P = 0.084$). In three patients, FEIBA was stopped.

There were no anamnestic response; one non serious AE was related to FEIBA (lack of efficacy), six serious AEs were possibly related to FEIBA (two biological DIC, two venous thrombosis (one deep) in the same patient and two fibrinogen decreased in the same patient); six deaths were reported and one possible related to FEIBA (Acute coronary syndrome). Per protocol, all unrelated serious and non serious AEs (exception of fatal outcome) were not collected.

Conclusion: AHA is still diagnosed with delay and this has a negative impact on the start of the hemostatic treatment. The FEIBA posology was relatively stable during the treatment whatever the physician evaluation, and independent of the severity score of bleeding. FEIBA prescription is often continued for a few days while the active sites have disappeared. FEIBA was efficient and tolerated in this elderly population.

PB 2.39-3

Treatment characteristics and associated costs of factor replacement and immunosuppressive therapy among patients with acquired hemophilia A

Escobar MA[1], Chong K[2] and Khleif A[1]

[1]Gulf States Hemophilia and Thrombophilia Center; [2]Memorial Hermann Hospital, Texas Medical Center, Houston, TX, USA

Background: Acquired hemophilia A (AHA) is a rare, potentially life-threatening hemostatic disorder caused by autoantibodies against coagulation factor VIII (FVIII). The management strategy for patients diagnosed with AHA requires a two-step approach, the first directed at controlling the bleeding and the second aimed at inhibitor elimination. Standard therapeutic agents used for bleed treatment include recombinant activated FVII (rFVIIa) and FVIII inhibitory bypassing activity (FEIBA), while treatments for inhibitor eradication are more varied and include the use of different immunosuppressive agents. Due to the rarity and limited number of AHA diagnoses, it is nearly impossible to determine the relative value of each of these different treatment strategies, however the therapeutic agents used to care for persons diagnosed with AHA are incredibly expensive and early detection and prompt diagnosis are essential in ensuring improved health outcomes.

Aims: The primary objectives of this study were to evaluate treatment characteristics and assess the costs associated with factor replacement and immunosuppressive therapy among persons with AHA.

Methods: Eligibility was limited to patients with a clinical diagnosis of AHA, who received care at the Gulf States Hemophilia and Thrombophilia Center between 2002 and 2012. We conducted a retrospective study, and data were obtained from the patients' medical charts, and pharmacy and hospital records. Medicare reimbursement rates were used to calculate the per-unit cost of factor and immunosuppressive therapy as well as associated hospital physician fees.

Results: During the observation period, 15 patients were diagnosed with AHA, however complete data were only available for 12 of these patients. The majority of the sample were women (58%), were > 60 years of age (67%), and were followed for an average of 68.4 weeks. Inhibitor levels ranged from 19 to 11,000 BU (mean 1352 BU). Complete remission was achieved in 50% of the patients. Two deaths occurred (bleeding contributed to one), giving an overall mortality rate of 17%. Conditions associated with AHA were identified at diagnosis or subsequent follow-up and included autoimmune diseases (25%) and malignancies (17%). Roughly 58% of cases were idiopathic. Bleeding episodes were treated with rFVIIa and/or FEIBA (one patient also received FVIII), and all patients received a single agent or a combination of cyclophosphamide, rituximab, and/or prednisolone for inhibitor treatment (42% of patients received combination therapy). A total of $3.3 million USD was spent by 12 patients during the observation period (mean $277,000 per patient). The greatest costs were associated with factor replacement therapy $3,000,000 (over 2 million units dispensed) followed by immunosuppressive treatment, which accounted for approximately $283,000. Patients stayed an average of 24 nights in the hospital due to AHA related complications and the physician fee associated with their stay accounted for roughly $36,000.

Conclusions: While over $3 million was spent to treat 12 AHA patients, this figure only represents the cost of factor, immunosuppressive therapy, and physician fees, and does not take into account any other costs including hospital, laboratory, and pharmacy costs. To the author's knowledge, this is the first study to examine the costs associated with AHA treatment.

PB 2.39-4

Enzyme-linked immunosorbent assay (ELISA) detecting antibodies to von Willebrand factor in patients with Acquired von Willebrand Syndrome (AVWS): clinical significance

Franchi F[1], Stufano F[2], Canciani MT[2], Cozzi G[2], Baronciani L[2], Siboni SM[2], Mistretta C[2], Biguzzi E[2] and Peyvandi F[1]

[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, University of Milan; [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Gra, Milano, Italy

Background: Acquired von Willebrand Syndrome (AVWS) is a rare bleeding disorder, similar to the congenital disease in terms of laboratory findings. However, unlike congenital VWD, it arises in individuals with no personal or family history of bleeding. The disease displays bleeding tendency, with bleeding episodes typically affecting mucocutaneous or gastrointestinal districts. AVWS is usually associated with a variety of underlying conditions, including lynphoproliferative and myeloproliferative disorders (45–60%), solid tumours, immunological and cardiovascular disorders. As regards the lynphoproliferative disorders, monoclonal gammopathy of undetermined significance (MGUS) is the condition most frequently associated with AVWS. The prevalence of autoantibodies against VWF in patients with gammopathy varies from 18% to 66%.

Aim of the Study: To develop a sensitive ELISA assay to detect IgG and IgM antibodies against VWF and to verify the prevalence of autoantibodies in AVWS.

Methods: We developed an ELISA assay using recombinant VWF protein immobilized on polystyrene plates and sheep/goat polyclonal anti-human IgG or IgM labelled with peroxidase. AVWS was defined as follows: VWF below normal range, negative personal or family history

of bleeding diathesis, late onset of bleeding symptoms (spontaneous or after challenge). Twenty-three consecutive patients (12 males, 11 females) affected by AVWS, who referred to the Angelo Bianchi Bonomi Hemophilia and Thrombosis Center (Milan, Italy) between 2006 and 2012, were enrolled. A group of 40 healthy subjects (20 males and 20 females) was also tested in order to calculate the cut point value and the Normalization Factor during pre-study validation. This enabled us, during analytical study, to calculate a floating cut point: samples with OD above the floating cut point were considered positive for antibodies to VWF.

Results: The median age was 66 years (interquartile range [IQR]: 55–72 years). Twenty-one patients (93%) had an associated disease: 13 (57%) monoclonal gammopathy (11 monoclonal gammopathy of undetermined significance, one Waldestrom disease, one chronic lymphocytic leukemia), one Crohn's disease, two cardiovascular disorders, one lung cancer, four thrombocythemia. Two patients presented idiopathic AVWS. With our ELISA assay we detected auto-antibodies in 10 patients out of 23 (43%) (eight patients positive for both IgG and IgM, one patient positive only for IgG and one patient positive only for IgM). Twelve patients (52%) had VWF:RCo < 10%: of these, nine (75%) had IgG or IgM monoclonal component. Four (44%) of these nine patients were positive for autoantibodies to VWF (both IgG and IgM). Three more patients with VWF:RCo < 10% and other associated diseases (Crohn's disease, cardiovascular disease and cancer) were positive for anti-VWF autoantibodies. Three patients with VWF: RCo ≥ 10% were positive for autoantibodies to VWF.

Conclusion: The identification of anti VWF autoantibodies might help to diagnose patients affected by AVWS. With the present ELISA assay 10 patients out of 23 were positive for antibodies to VWF.

PB 2.39-5

Haemostatic changes following military trauma and major blood loss

Hunt BJ[1], Woolley T[2], Parmar K[1], Midwinter M[2], Pribul V[2], Peach C[2], Watts S[3], Bishop J[4] and Kirkman E[3]

[1]Guy's & St Thomas' NHS Foundation Trust, London; [2]Royal Centre for Defence Medicine, Birmingham; [3]Defence Science and Technology Laboratory, Salisbury; [4]University of Birmingham, Birmingham, UK

Background: Military trauma in Afghanistan is predominantly blast and high velocity gunshot wounds with associated high degree of soft tissue disruption and major haemorrhage.

Haemorrhage is controlled immediately at the point of wounding, often with tourniquets. Evacuation is usually via helicopter where prehospital administration of tranexamic acid and blood products occurs where appropriate before reaching the hospital. The effect of military trauma on haemostasis has not previously been studied and understanding the defect would help improve management.

Aims: To assess haemostatic changes in individuals with major military trauma received at Joint Force Hospital, Camp Bastion, Afghanistan.

Methods: Thirty-three sequential patients with blast and gunshot injuries with major blood loss presenting to the hospital, and who survived into their first surgery, were assessed and blood taken on admission for haemostatic studies. An injury severity score (ISS) of > 15 signifies major trauma.

Samples were collected in a ratio of 9:1 in 0.102M citrate & processed and frozen locally, then shipped back by a cold chain to the United Kingdom where they were stored at −80 °C. For each assay samples were analysed together to prevent interassay variability.

Results: Thirty-two out of 33 patients were male, with a median (range) age of 25 (19–35), On admission, pulse rate 110 (0–176) bpm, pH 7.17 (6.68–7.32), base deficit 7 (27–5), Injury severity score 27 (1–75). In the first 24 h total median (range) PRBC 10 (0–39), FFP 8 (0–36), Platelets 2 (0–12) cryoprecipitate 1 (0–11). Two patients received fresh whole blood (2 and 3 units respectively). Fifty-eight percent had received tranexamic acid prior to admission.

Admission haemostatic values showed median (range) [normal range] values of Platelet count 235 (178–298) [150–450] × 10^9/L; Clauss fibrinogen 1.56 (0.57–2.2) [1.5–4] g/L; PT 19.9 (13.8–30.9) [12–15.9]sec; prothrombin Fragment1 + 2 1382 (129–2380) [200–1200] pM; soluble tissue factor 216 (102–589) [40–300] pg/mL; D-dimer 3106 (536–6001) [< 145] ng/mL; t-PA antigen15 (4–108) [1–15] ng/mL; PAI-1 activity 34 (11–119) [0–33] ng/mL; Plasmin-antiplasmin complexes 6980 (1041–45,200) [150–800] ug/L; prothrombin levels 0.69 (0.37–1.16) [0.5–1.5] iu/mL; factor X 0.68 (0.33–1.09) [0.5–1.5] iu/mL; factor VII 0.66 (0.31–1.63) [0.5–1.5] iu/mL; Factor V 0.51 (0.08–1.06) [0.5–1.5] iu/mL.

Summary/Conclusions: Patients are coagulopathic with markedly reduced fibrinogen and factor V levels, with a lesser reduction of other coagulation factors. Markers of fibrinolysis (t-PA, PAP and D-dimers) are greatly increased with evidence of good thrombin generation (elevated PF 1 + 2). The study is ongoing.

PB 2.39-6

Long term follow-up in patients with acquired hemophilia: the role of immunosuppressive therapy

Saccullo G, Malato A, Santoro M, Napolitano M, Vaccarella G and Siragusa S

Policlinico Paolo Giaccone, Palermo, Italy

Background: Acquired hemophilia is a rare but potentially life-threatening bleeding disorder caused by development of auto-antibodies against FVIII. Recent data of European registry (EACH 2) and from United States (Boles et. al) confirm the efficacy of immunosuppressive therapy with corticosteroid alone or in association with Rituximab at standard regimen (375 mg/m^2 1 dose per week for 4 weeks) to obtain complete remission (CR) of AHA (defined as the proportion of patients who are in CR without relapse during follow-up). However, the reported duration of patients' follow-up (< 2 years) does not allow to make firm conclusions about the long-term effect of such therapy. Now we report data on AHA patients followed-up for a median time of 3.4 years.

Aims: To assess the long-term response after immunosuppressive therapy.

Patients and Methods: We retrospectively analyzed data from 15 consecutive patients diagnosed with idiopathic and secondary AHA, evaluated between June 2001 and December 2012. Primary objective was to assess the role of immunosuppressive drugs (steroids with or without Rituximab) after a follow-up of at least 3 years, by comparing its effectiveness with published data. All patients was treated first with steroids regimen while Rituximab was added in refractory cases. Refractory has been defined as the lack of clinical response, maintenance of severe FVIII deficiency (< 1%) and inhibitor.

Results: Among our population, the median follow-up was 3.4 years; detailed data of main outcomes are reported in Table 1. Two patients (13%) had spontaneously inhibitor disappearance, without immunosuppressive treatment, 5 (33%) were treated with regimens containing rituximab (in combination with steroids), 8 (53%) with steroids alone. Rituximab was administered according to the standard regimen above reported. All Rituximab-based regimens obtained CR as well as steroids-based regimes. However, the average time to obtain the CR was shorter in steroids-based regimen than that in rituximab-based regimes (4.8 vs. 1.5 months, respectively). The rate of relapse of patients treated with rituximab was similar to that of patients treated with steroids (60% vs. 50%, respectively). Seven (46.6%) patients (three treated with Rituximab, four with steroid alone) have experienced relapse after a mean time of 2.6 years. All relapsed patients had idiopathic AHA.

Conclusions: In our population, refractory patients treated with Rituximab based regimes, obtain a CR in all cases. This is clinical relevant since our median follow-up is much longer than previously reported (1232 vs. 262 days of EACH2 registry). However, this response was not maintained in long-term follow-up.

With a median time to relapse of 708 days, 60% of patients treated with rituximab experienced a relapse. The efficacy of subsequent rituximab after the first relapse deserve further and appropriate investigations.

PB2.40 – Heparin-Induced Thrombocytopenia (HIT): Basic

PB 2.40-1

Staphylococcal panton-valentine leukocidin activates platelets via neutrophil secretion products

Bertling A[1], Schlott B[2], Peters G[3], Heilmann C[3], Löffler B[3] and Kehrel BE[4]

[1]University Hospital Muenster, Muenster; [2]Leibnitz Institute for Age Research, Jena; [3]Institute of Medical Microbiology, University Hospital Muenster; [4]Anaesthesiology, University Hospital Muenster, Muenster, Germany

Background and Aims: Expression of the toxin Panton-Valentine Leukocidin (PVL) by *Staphylococcus aureus* has been linked to severe life-threatening, necrotizing haemorrhagic pneumonia and fulminant septicemia with poor prognosis especially in young, immunocompetent patients. These complications are often accompanied by thrombotic events. We therefore tested the effect of PVL on human platelets in the presence and absence of isolated human neutrophils.
Methods: Human neutrophils were isolated from citrate anticoagulated whole blood using Percoll gradients. The effect of recombinant PVL on platelet activation and microparticle formation in the presence or absence of autologous neutrophils was measured by flow cytometry. PVL induced lysis of neutrophils was assessed by propidium iodid staining. Release of neutrophil myeloperoxidase and defensins was detected by ELISA technique.
Results: PVL strongly induced platelet activation, but only in the presence of human neutrophils. In the presence of neutrophils, PVL treatment induced fibrinogen binding to human platelets as well as microparticle formation. PVL induced neutrophil lysis and release of defensins and myeloperoxidase, known mediators of platelet activation. PVL-induced platelet activation in the presence of neutrophils was inhibited by known defensin inhibitors as well as by the antioxidants resveratrol and glutathione (GSH).
Conclusions: PVL activated human platelet not directly, but indirectly via human neutrophils. This was elicited by binding to neutrophils, cell lysis and release of defensins and myeloperoxidase. Inhibitors of defensin and myeloperoxidase/HOCl modified protein induced platelet activation inhibited the action of PVL. Platelet activation by PVL-treated neutrophils is therefore likely to depend on HNP release and HOCl formation. These findings might help to combat complications associated with PVL-expressing *S. aureus* strains.

PB 2.40-2

Fibronectin inhibits anti-PF4/heparin antibody induced platelet activation and low fibronectin levels are a potential risk factor for developing clinical HIT

Krauel K, Valentin P, Fürll B, Hammer E, Brandt S, Jensch I, Kreimann M and Greinacher A

Ernst-Moritz-Arndt-Universität Greifswald, Greifswald, Germany

Background: In heparin-induced thrombocytopenia (HIT) immunoglobulin G (IgG) antibodies against complexes of the positively charged chemokine platelet factor 4 (PF4) and the negatively charged anticoagulant heparin activate platelets which can lead to thrombocytopenia and life-threatening thrombotic disorders. Not all patients with anti-PF4/heparin antibodies develop clinical HIT. As diagnostic assays using washed platelets are more sensitive than assays using platelet-rich plasma (PRP), plasma factors may influence platelet activation by anti-PF4/heparin antibodies.
Aims: The aim was to determine a risk factor contributing to clinical breakthrough of HIT.
Methods: Different plasma fractions were analyzed for inhibiting: (i) PF4 binding of gel-filtered platelets by flow cytometry, (ii) antibody binding to PF4/heparin complexes by ELISA, and (iii) antibody induced platelet activation using the heparin-induced platelet activation test (HIPA). The inhibitory mechanisms were further characterized by surface plasmon resonance (SPR) and photon correlation spectroscopy (PCS). Sera from patients with serologically- and clinically-confirmed HIT and from patients with serologically-confirmed HIT without thrombotic complications were compared concerning the levels of highly potential risk factors.
Results: Plasma and serum had the same inhibitory effect on PF4 binding to platelets. After affinity chromatography the inhibitory activity of serum disappeared. Among others the chromatographic matrix adsorbed IgG, complement factors, alpha-2-macroglobulin, vitronectin and fibronectin. Fibronectin was the only serum factor showing inhibition in all assays tested which was due to direct interaction with PF4/heparin complexes leading to their disruption. Fibronectin serum levels were higher in patients without clinical HIT compared to patients with clinical breakthrough.
Conclusions: Fibronectin protects from platelet activation induced by anti-PF4/heparin antibodies. This might be an explanation for the higher sensitivity of washed platelet assays. As a diagnostic tool eliminating fibronectin from PRP could be a faster and easier alternative to the washing procedure. More importantly, reduced fibronectin plasma levels seem to bear a risk for clinical breakthrough of HIT and might be useful as a prognostic marker.

PB 2.40-3

Usefulness of a murine monoclonal antibody against human platelet factor 4/heparin complexes to select donor platelets in platelet activation assays for diagnosis of heparin- induced thrombocytopenia

Asada R[1], Wanaka K[2], Miyashita K[2], Kaneko C[2], Hoshino N[3], Oosawa M[3], Okamoto U[2] and Matsuo M[1]

[1]Hyogo Cancer Center, Akashi; [2]Kobe Research Projects on Thrombosis and Haemostasis, Kobe; [3]Mitsubishi Chemical Medience Corporation, Chiba, Japan

Background: Platelet activation assays are extremely useful for detecting anti-platelet factor 4 (PF4)/heparin complex antibodies (HIT antibodies) that cause heparin-induced thrombocytopenia (HIT). The sensitivity of platelet activation assays depends on the reactivity of donor platelets to HIT antibodies. Therefore, selection of donor platelets is very important. However, it is difficult to evaluate the reactivity of donor platelet to HIT antibodies because sufficient quantities of plasma cannot be collected from HIT patients. We developed a murine monoclonal antibody against human PF4/heparin complexes (HIT-MoAb) and reported that HIT-MoAb-induced platelet activation possesses characteristics comparable to human HIT antibody-induced platelet activation.
Aims: We examined whether the reactivity of HIT-MoAb with donor platelets could be used as an index to select donor platelets, which are highly reactive with HIT antibodies.
Methods: HIT-MoAb was prepared by the ordinal polyethylene glycol method. Human HIT antibody immunoglobulin-G (HIT-IgG) was purified from HIT patient serum using a protein A column. The platelet aggregation test (PAT) was used to investigate platelet activation. HIT-MoAb or HIT-IgG was mixed with donor platelet-rich plasma (PRP) in a 1:1 ratio and incubated at 37 °C for 10 min. Subsequently platelet aggregation was measured by adding heparin (final concentration, 1 U/mL). Both HIT-MoAb and HIT-IgG were used in concentrations of 60, 120, and 200 μg/mL. A maximum aggregation rate of

≥ 20% was considered to be positive aggregation. The area under the curve (AUC) was calculated from the platelet aggregation response curve. The AUC value was used to evaluate the reactivity of donor platelets because AUC is considered to indicate platelet aggregation strength.

Results: PAT with HIT-MoAb (60, 120, and 200 μg/mL) was performed using donor PRPs (n = 11). As a result, 9.1% PRP (1/11) and 63.6% PRP (7/11) showed positive aggregation at ≥ 60 μg/mL and ≥ 120 μg/mL, respectively, whereas, 27.3% PRP (3/11) showed negative aggregation at all concentrations tested. These results indicated that the degree of HIT-MoAb-induced platelet aggregation varied among donor platelets. The total AUC (sum of AUC values at 60, 120, and 200 μg/mL), which is considered as the reactivity of donor platelets, was used to rank donor PRPs from high to low values. The relationship between the reactivity of donor platelets to HIT-MoAb and HIT-IgG was investigated. The ratio of positive aggregation with HIT-IgG was higher when the higher ranked donor PRP was used. Moreover, the total AUCs for HIT-MoAb and HIT-IgG were significantly correlated (Spearman's rank correlation: rs = 0.973; P = 0.0021).

Conclusion: Donor platelets showing high reactivity to HIT-MoAb also exhibited high reactivity to human HIT antibodies, indicating that HIT-MoAb would be useful for evaluating and selecting donor platelets in platelet activation assays for HIT diagnosis.

PB 2.40-4

Evaluation of three new fully automated quantitative immunoassays on diagnosis of heparin-induced thrombocytopenia

Miyashita K[1], Wanaka K[1], Kaneko C[1], Walenga JM[2], Prechel M[2], Escalante V[2], Asada R[3], Matsuo M[3] and Okamoto U[1]

[1]Kobe Research Projects on Thrombosis and Haemostasis, Kobe, Japan; [2]Loyola University Medical Center, IL, USA; [3]Hyogo Cancer Center, Akashi, Japan

Background: The cause of heparin-induced thrombocytopenia (HIT) is the generation of anti-platelet factor 4 (PF4)-heparin antibodies (HIT antibodies). HIT is a clinicopathologic syndrome, implying that diagnosis of HIT depends on both clinical and pathologic criteria being present. Functional and immunologic assays for detecting HIT antibodies are available. ^{14}C serotonin release assay (SRA) is still considered to be the gold-standard. However, unfortunately, it is done only in a few laboratories. Conversely, the enzyme immunoassays are widely used. Recently, three new fully automated quantitative immunoassays, the HemosIL® AcuStar HIT-IgG$_{(PF4-H)}$, specific for IgG, and the HemosIL® AcuStar HIT-Ab$_{(PF4-H)}$ and HemosIL® HIT-Ab$_{(PF4-H)}$, detecting IgG, IgM and IgA of HIT antibodies were introduced into the market by Instrumentation Laboratory Co Ltd. The HemosIL® AcuStar HIT-IgG$_{(PF4-H)}$ and HemosIL® AcuStar HIT-Ab$_{(PF4-H)}$ are based on a chemiluminescent immunoassay, and HemosIL® HIT-Ab$_{(PF4-H)}$ is based on a latex particle enhanced immnunoturbidimetric assay. In this study, we compared the performance among the SRA, the ELISA kit (PF4 Enhanced®, GTI) and the three new immunological assays.

Subjects/Methods: We measured HIT antibodies in 112 HIT suspected patients and 10 healthy normal subjects by using (A) PF4 Enhanced®, (B) HemosIL® AcuStar HIT-Ab$_{(PF4-H)}$, (C) HemosIL® AcuStar HIT-IgG$_{(PF4-H)}$, and (D) HemosIL® HIT-Ab$_{(PF4-H)}$. We used 0.4 OD units for (A), 1.0 U/mL for (B), (C) and (D), and 50% for SRA as a cut-off value, respectively.

Results: Co-positivity with SRA in four immunological assays (A, B, C, D) was 100%, 100%, 82% and 92%, and that of co-negativity was 63%, 66%, 73% and 66%, respectively. Spearman's rank correlation coefficient of (A) with each of the three immunological assays (B, C, D) was 0.924 (P < 0.001), 0.912 (P < 0.001) and 0.803 (P < 0.001), respectively. Furthermore, the correlation coefficients between (B) and (C), and (B) and (D) were also significant (0.954 and 0.865, respectively). Co-positivity and co-negativity between (A) and (B) were 95% and 98%, respectively. These values were higher than co-positivity (84%) and co-negativity (85%) between (A) and (D).

Conclusion: Co-positivity and co-negativity of the SRA with each of the three new immunological assays were similar to those of the SRA with PF4 Enhanced®, especially the HemosIL® AcuStar HIT-Ab$_{(PF4-H)}$ showed the most agreement among the assays. Furthermore, the PF4 Enhanced®correlated more significantly with HemosIL® AcuStar HIT-Ab$_{(PF4-H)}$ than with HemosIL® HIT-Ab$_{(PF4-H)}$. These results show that the performances of the three new fully automated quantitative immunoassays are comparable to the PF4 Enhanced®. However, further investigation is needed to clarify clinical significance of these assays on HIT diagnosis.

PB 2.40-5

Significance of the measurement of HIT antibodies on diagnosis of heparin-induced thrombocytopenia in the patients with hemodialysis

Wanaka K[1], Miyashita K[1], Kaneko C[1], Walenga JM[2], Prechel M[2], Asada R[3], Matsuo M[3] and Okamoto U[1]

[1]Kobe Rearch Projects on Thrombosis and Haemostasis, Kobe, Japan; [2]Loyola University Medical Center, IL, USA; [3]Hyogo Cancer Center, Akashi, Japan

Introduction: Heparin-induced thrombocytopenia (HIT) is a side effect of heparin characterized by thrombocytopenia and thrombus formation (blood clotting in the dialysis circuit is frequently observed in the hemodialysis patients with HIT). HIT is caused by the appearance of antibodies to platelet factor 4 (PF4)/heparin complex (HIT antibodies). Therefore, the detection of HIT antibodies as well as clinical findings including thrombocytopenia is an important point for the diagnosis of HIT. The diagnosis of HIT is confirmed if the results of functional and immunological assays are both positive, and excluded if they are both negative. However, the diagnosis is controversial if only one is positive. Therefore, we studied the relationship between HIT antibodies and clinical findings, and evaluated the significance of the measurement of HIT antibodies in the diagnosis of HIT.

Methods: The subjects were 165 patients (96 males and 69 females with a mean age of 67.9 ± 14.0 years) for whom the measurement of HIT antibodies was requested due to suspected HIT in 2003–2008. The HIT antibody level was measured using the ^{14}C-serotonin release assay (SRA) and ELISA (PF-4 Enhanced®, GTI; Waukesha, WI, USA). A release rate of 50% or higher on SRA and an OD value of 0.4 or higher on ELISA were judged to be positive.

Results: The patients were classified on the basis of the results of HIT antibody measurements into four groups: Groups A [SRA(+)/ELISA(+)] (n = 45), B [SRA(+)/ELISA(-)] (n = 9), C [SRA(-)/ELISA(+)] (n = 48), and D [SRA(-)/ELISA(-)] (n = 63), and the rate of reduction in the platelet count, timing of thrombocytopenia, the presence or absence of thrombosis, acute reactions, clotting in the dialysis circuit, and the presence or absence of other causes were evaluated. No significant difference was observed among the four groups in the rate of reduction in the platelet count (A: 62 ± 26%, B: 62 ± 16%, C: 52 ± 25%, D: 54 ± 28%), timing of thrombocytopenia (A: 15 ± 13 days, B: 14 ± 10 days, C: 19 ± 20 days, D: 22 ± 23 days), the presence or absence of thrombosis, or acute reactions. Clotting in the dialysis circuit was observed in 87% (39/45) in Group A, 56% (5/9) in Group B, 81% (39/48) in Group C, and 41% (26/63) in Group D, and its frequency was significantly higher in the ELISA(+) than in ELISA(-) groups. Other causes were noted in 11% of the patients in Group A, 33% in Group B, 13% in Group C, and 43% in Group D, and their frequency was significantly lower in Groups A and C than in Group D. Therefore, the risk of HIT is considered to be high in Group C as well as Group A. In Group B, four patients were positive for another ELISA (antigen: r-PF4/heparin, IgG only), suggesting the presence of

HIT antibodies not detected by the ELISA (antigen: PF4/PVS) used in this study.
Conclusion: The possibility of HIT is considered to be high in hemodialysis patients with clinical findings of HIT (thrombocytopenia, clotting in dialysis circuit, etc.) if HIT antibodies are detected on either functional or immunological assays.

PB 2.40-6
In-vitro inhibition of thrombin generation in heparin induced thrombocytopenia by dabigatran and rivaroxaban

Gregor H, Alena S, Thomas T and Greinacher A
Universitätsmedizin Greifswald, Greifswald, Germany

Background: In heparin induced thrombocytopenia (HIT), platelet activating antibodies cause increased thrombin generation despite the presence of the thrombin inhibitor heparin. Currently approved thrombin inhibtors such as danaparoid or lepirudin were recently shown to decrease thrombin generation in HIT.
Aims: To evaluate the effect the novel coagulation inhibitors dabigatran and rivaroxaban on *in vitro* thrombin generation in HIT.
Methods: To determine degree of thrombin generation inhibition, the final *in vitro* concentration of dabigatran or rivaroxaban was diluted to low (5%), intermediate (50%), or high (95%) levels of the respective drug's *in vivo* concentration. Samples from five patients with platelet activating antibodies were mixed with platelet rich plasma from healthy donors, unfractionated heparin at 0.2 U/mL, and dabigatran or rivaroxaban at the different concentrations. Thrombin generation was measured by Calibrated Automated Thrombinogram with the endogenous thrombin potential (ETP) as primary parameter.
Results: At high and intermediate dabigatran concentrations, ETP was significantly decreased (48 nM [15–51] and 162 [96–360] vs. 511 nM [400–860], $P = 0.002$ and $P = 0.02$, respectively). The low concentrations of dabigatran did not significantly reduce the ETP (265 [183–723] vs. 511 nM [400–860], $P = 0.18$). A high concentration of rivaroxaban significantly decreased median ETP (15 nM [10–133] vs. 511 nM [400–860], $P = 0.004$). The intermediate and low final concentrations of rivaroxaban did not significantly reduce the ETP, but showed a trend towards a lower thrombin generation (128 [35–398], $P = 0.05$ and 239 [176–731], $P = 0.13$, respectively).
Conclusion: Both dabigatran and rivaroxaban decreased *in vitro* thrombin generation in HIT. As the high concentrations of both drugs reduced thrombin generation more efficiently than lower concentrations, high concentrations may be required to treat HIT *in vivo*.

PB2.41 – Rare Bleeding Disorders – III

PB 2.41-1
Investigation of medical indications for PNH screening experiment by flow cytometry

Zhu M, Chen L, Shen W, Dai L and Ruan C
The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder leading to a partial or absolute deficiency of all glycophosphatidyl-inositol (GPI)-linked proteins. The classical approach to diagnosis of PNH by cytometry involves the loss of at least two GPI-linked antigens on RBCs and neutrophils. Flow cytometry (FCM) is firmly established as the method of choice for screening of PNH. In 2010, technical guidelines were published in order to standardize the diagnosis of PNH by mutiparameter FCM. But there is not a uniform consensus about the medical indications for PNH clone testing by FCM.
Methods: Three thousand and thirty-seven individuals were submitted for diagnostic screening of PNH. CD59 was used for RBC analysis based upon physical parameters. We combined FLAER with CD45, CD24, allowing the simultaneous analysis of FLAER and the GPI-linked CD24 on neutrophil and monocyte lineages by CD45 vs. side scatter.
Results: PNH clone cells were found in 189/3037 (6.2%) cases. Most commonly individuals were screened because of hemoglobinuria (730/3037,24.0%), followed by aplastic anemia (486/3037,16.0%), MDS (448/3037,14.8%), pancytopenia (395/3037,13.0%), hemolytic anemia (298/3037,9.8%), bone marrow failure (211/3037,6.9%), atypical venous thrombosis (64/3037,2.1%), other (405/3037,13.3%). Essentially all patients with classic PNH (95/189,50.3%) report gross hemoglobinuria at some point during the course of their illness. This symptom were absent in patients with PNH-subclincal (e.g. PNH/aplastic anemia or PNH/MDS) (9/189,4.8%) because the clone size is often relatively small. PNH clone cell often were found in PNH combined with another specified bone marrow disorder, including AA (58/189) MDS (23/189) pancytopenia (4/189).
Conclusion: Analysis of the different clinical and biological findings that may contribute to better selection of cases for PNH screening experiment by FCM. The FCM screening of GPI-deficient cells shows that the rate of positive results is higher when cases were tested because of hemoglobinuria, anemia, thrombosis and pancytopenia, and much higher in cases previously diagnosed of aplastic anemia or MDS, and therefore screening for PNH in patients with aplastic anemia, or MDS even in the absence of clinical evidence of hemolysis, is recommended at diagnosis and at least yearly during follow-up.

PB 2.41-2
Genotype and phenotype relationships in 10 unrelated Pakistani patients with inherited FVII deficiency

Borhany M[1], Boijout H[2], Pellequer J-L[3], Shamsi T[1], Fatima H[1], Moulis G[2], Schved J-F[2] and Blaizot M[2]
[1]National Institute of Blood Disease, Karachi, Pakistan; [2]CHU Montpellier, Département d'Hématologie biologique, Hôpital Saint-Eloi, Montpellier; [3]CEA, iBEB, Service de Biochimie et Toxicologie Nucléaire, F-30207 Bagnols sur Cè, Bagnols sur Cèze, France

Background: Inherited factor VII (FVII) deficiency is one of the commonest rare bleeding disorders (RBD). It is characterized by a wide molecular and clinical heterogeneity and an autosomal recessive pattern of inheritance.
Aims: FVII deficient patients are still scarcely explored in Pakistan albeit rare bleeding disorders became quite common as a result of traditional consanguineous marriages. This study aims to give a first insight of *F7* gene mutations in Pakistani population.
Material and Methods: The study was conducted in 10 unrelated patients with inherited FVII deficiency living in Pakistan. A clinical questionnaire was filled out for each patient who was then graded according to two previously published classifications for RBD (Maraini *et al* 2005, and Peyvandi *et al* 2012) and a bleeding score (Tosetto *et al* 2006). The FVII: C and FVII:Ag levels were determined using a human recombinant thromboplastin (RecombiPlastin 2G, IL) and an ELISA (Asserachrom FVIIAg Diagnostica Stago) respectively. Direct sequencing was performed on the coding regions, intron/exon boundaries and 5′ and 3′ untranslated regions of the *F7* gene.
Results: Ten unrelated FVII-deficient Pakistani patients (median FVII: C = 2%; ranges = 2–37%) were investigated. Molecular analysis allowed us to identify nine different mutations; among these, five were novel: (c.-57 C>T, p.Cys82Tyr, p.Cys322Ser, p.Leu357Phe, p.Thr410Ala). Only one mutation was located within the *F7* promoter (c.-57C>T) and is predicted to alter the binding site of transcription factor HNF-4. Quantitative deficiency is expected, due to decrease in mRNA transcription. Both p.Cys82Tyr and p.Cys322Ser mutations involved essential disulfide bridges either forming a loop in the Gla

domain or linking both heavy and light chains of activated FVII, respectively. The Leu 357 is located in an external loop of the catalytic domain, involved in the interaction between FVII and its substrate, but also in the catalytic conversion of FVII. The remaining novel p.Thr410Ala mutation changed a polar residue into an Alanine with hydrophobic side chain presumably leading to a pathogenic impact on the FVII molecule. Six out of seven patients with FVII:C levels below 10% were homozygous in connection with the high percentage of consanguinity in our series. Comparison of the three previously published classifications showed that both clinical classifications were corroborating in our small series. Conversely the bleeding score appears to better qualify the bleeding tendency when comparing the three patients with the same *F7* genotype.

Conclusion: Molecular analysis of an even small series of 10 FVII-deficient patients allowed us to report five novel mutations. The p.Cys82Arg mutation was the most frequent in our series. Moreover, the use of the Tosetto's bleeding score can be a promising tool to classify patients with rare bleeding disorders.

PB 2.41-3

Mild fibrinogen disorders: correlation between genotype and phenotype

Castaman G[1], Giacomelli S[1], Biasoli C[2], Veneri D[3], Radossi P[4], Borchiellini A[5] and Tosetto A[1]

[1]San Bortolo Hospital, Vicenza; [2]Bufalini General Hospital, Cesena; [3]University of Verona, Verona; [4]General Hospital, Castelfranco Veneto; [5]Molinette Hospital, Torino, Italy

Background: Fibrinogen is a complex dimeric protein of 340 kD, synthesized in hepatocytes as a hexamer composed of three pairs of non identical polypeptides (Aα, Bβ and γ chains, identified by a different gene *FGA*, *FGB* and *FGG*). Inherited fibrinogen disorders are classified according to a complete (afibrinogenemia) or partial (hypofibrinogenemia) fibrinogen deficiency and to an abnormal circulating molecule (dysfibrinogenemia) in plasma. The risk of bleeding or thrombosis conferred by partial deficiency or qualitative abnormality remains unclear.

Aim of the Study: We evaluated the clinical manifestations and the genotype of 24 families (54 patients) showing laboratory mild fibrinogen abnormalities.

Results: Abnormalities at thrombin-cleavage site in alfa chain (Arg16Cys, Arg16His and Arg19Gly) did not cause bleeding, while thrombotic events can be associated with Bbeta mutations at the same site (Arg14Cys). A significant bleeding tendency with impaired wound healing was reported with a novel Ile105Thr mutation in gamma chain. Overall, bleeding tendency was usually very mild and most patients did not require specific treatment. A woman with partial hypofibrinogenemia (fibrinogen 45 mg/dL) associated with a novel Leu344Phe mutation in gamma chain was treated prophylactically with fibrinogen concentrate during pregnancy because of an early placenta detachment with uterine bleeding. Familial increased risk of venous thromboembolism was associated with a novel Trp208Arg mutation in gamma chain. Four additional novel mutations (Arg57Lys in alfa, IVS5 + 2T>A and Ter462Gln in beta, and Cys339-Ser in gamma chain) were also detected.

Conclusions: Mild disorders of fibrinogen concentration and function are important to establish the structure-function relationships and clinical correlates of different mutations.

PB 2.41-4

Characterization of adult patients with a mild to moderate bleeding phenotype from the Vienna Bleeding Biobank

Haselböck J, Panzer S, Janig F, Kepa S, Mannhalter C and Pabinger I

Medical University Vienna, Vienna, Austria

Background: Mild bleeding disorders (MBDs) manifest in a variety of clinical symptoms and are a common cause for thorough hemostaseological investigation in adults. Still, no diagnosis can be established in the majority of patients.

Aim: Establishment of a Biobank of clinically extensively characterized patients with MBD for identification of underlying causes.

Methods: Patients aged > 18 years were consecutively enrolled after giving written informed consent. The severity of bleeding was estimated using a standardized bleeding score (Rodeghiero, J.Thromb.Hameost.2005:3:2619). Routine coagulation tests, von Willebrand factor antigen (vWF:Ag) and activity (vWF:RCo), single clotting factors, and platelet function, assessed by platelet function analyzer (PFA-100), aggregometry, and glycoprotein expression were performed.

Von Willebrand syndrom (vWS) was considered as definite when vWF:RCo was < 30%, and as possible vWS when vWF:RCo was between 30% and 50%. When platelet function tests revealed repeatedly abnormal results definite thrombocytopathy was diagnosed; possible thrombocytopathy was diagnosed when results were abnormal in only one available investigation.

Results: From 11 to 2009 until 12 to 2012 215 patients (female = 176, 82%) were enrolled. Seventy-three patients (34%) had a positive family history for bleeding. Median age [Interquartile (IQR) range] was 41 [29–54] years. There was no age difference between female and male patients. Patients with MBDs had a median bleeding score of 4 (IQR 2–6). We observed no difference in the severity of bleeding between male and female patients.

Common bleeding symptoms comprised skin manifestations in 66%, post-surgical bleeds in 51%, of which 53% demanded revision. Further manifestations were bleeding after tooth extraction in 33%, repeated episodes of epistaxis in 28%, small wound bleeding in 28%, and oral cavity bleeding in 11%. Nine percent of patients had gastrointestinal bleeding, one patient reported muscle and two joint bleeding. Twenty-five percent women suffered from hypermenorrhagia, and 13% of the women, who had given birth, reported postpartum bleeding.

In five patients (2%) definite vWS was diagnosed and in 13 patients (6%) vWS was considered possible. A not further characterized definite thrombocytopathy was confirmed in 11 patients (5%), in 27 patients (13%) a platelet function disorder was suspected (possible thrombocytopathy). Six patients (3%, female = 1) had factor VIII deficiency with levels of < 50% (< 30% in three of them), excluding those with vWS type Normandie. In one patient dysfibrinogenemia was diagnosed. Of patients without an established diagnosis, one each had repeated prolongations of APTT and PFA measurements of unknown cause; further six had deficiency of one or two single clotting factors, which could not be attributed to a bleeding tendency. In 151 (female = 129) patients (70%) all tests showed normal results and no diagnosis could be established. The median bleeding score was 4 (IQR 2–6) in patients with a definite or assumed diagnosis and 3 (2–5) in those without any identified abnormality ($P = 0.25$).

Summary: Like in previous studies, a definite or possible diagnosis explaining the bleeding tendency could be established in only 30% of patients with MBDs. The severity of bleeding, however, was almost equal in patients with an established diagnosis as in those without. Further mechanisms responsible for MBDs still have to be identified.

PB 2.41-5

Long-term prophylaxis in patients with severe factor VII deficiency

Siboni SM[1], Biguzzi E[2], Mistretta C[2], Garagiola I[3] and Peyvandi F[3]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan; [2]A Bianchi Bonomi, Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinico; [3]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, University of Milan, Milan, Italy

Introduction: According to the recent paper by the European Network of Rare Bleeding Disorders, there is a weak association between FVII levels and bleeding manifestations. In patients with a previous episode of intracranial bleeding, prophylaxis is generally initiated to prevent subsequent cerebral bleeding episodes.
Aim of the Study and Methods: To describe two patients on long-term prophylaxis with plasma-derived factor VII concentrate
Results: Case 1: A 53-years-old woman affected by severe congenital FVII deficiency (< 1%) presented a significant bleeding history (easy bruising, severe epistaxis, recurrent spontaneous hemartrosis, bleeding after tooth extractions, severe menorrhagia requiring treatment) from childhood, but the hemorrhagic disorder was diagnosed only when she was 18-years-old. Between 43 and 50 years, she presented several episodes of gastrointestinal bleeding (due to angiodysplasia), that required hospitalization. Long-term prophylaxis was started at the age of 50, because of the gastrointestinal bleeding. She was treated with plasma-derived FVII concentrate (pdFVII) twice a week (600U; 12 U/kg). The patient had no bleeding episodes for 3 years and did not require any additional treatment with pdFVII (except for surgical procedures). After 3 years, prophylaxis was interrupted for 1 month (due to the unavailability of the drug). During this period the patient presented another severe episode of gastrointestinal bleeding requiring hospitalization and treatment with activated recombinant FVII (rFVIIa) and red blood cells transfusion. After this episode the patient started again the prophylaxis with pdFVII (same dosage as before). The molecular analysis of factor VII gene showed compound heterozygosity: C.430 + 1 G/A; VS7 + 7 A>G; Thr419Met.
Case 2: A 23-year-old young woman affected by severe congenital FVII deficiency (< 1%) was diagnosed 4 days after birth, because of melena and extensive bruising that required treatment with fresh frozen plasma. In the first 7 years of life the patient had several episodes of spontaneous and post-traumatic hemartrosis/hematomas and four episodes of intracranial bleeding (the first at the age of 3 months, after which surgery was performed and a cerebral ventriculo-peritoneal shunt was positioned) treated with infusion of pdFVII every 6 h. At the age of 7 years, she started the long-term prophylaxis with daily infusions of pdFVII (50 U/kg; actually 3000 U). Since then (follow-up 16 years) the patient did not present any bleeding episodes that needed any more treatment. The molecular analysis of factor VII gene showed compound heterozygosity: Cys135Arg; 17 bp deletion at nucleotide 10585.
Discussion: Prospective studies that evaluate the efficacy of long-term prophylaxis are not available, as well as data regarding the prevalence of patients on prophylaxis with pdFVII or with rFVIIa. The theoretic advantage of pdFVII should be the longer half-life of the drug (and consequentially the less frequent administrations), but recently patients using successfully only one weekly infusion of rFVIIa were described. In this report we described two patients on long-term prophylaxis with pdFVII; in the two patients, a different dose regimen was used because of the different indication and because no evidence based guidelines are available on the minimal treatment to successfully avoid life-threatening hemorrhages in factor VII deficient patients

PB 2.41-6

Survey of practices: difficulty of venipuncture practice and contribution of a vein locating device in patients requiring multiple peripheral venipunctures

Guillon P[1], Makhlouifi M[2], Baillie S[3], Roucoulet C[4], Dolimier E[5] and Villette B[5]
[1]Haemophilia Treatment Center, Caen University Hospital, Caen; [2]Haemophilia Treatment Center, Necker Hospital- Enfant malades, APHP, Paris; [3]Haemophilia Treatment Center, Lille University Hospital, Lille; [4]Haemophilia Treatment Center, Maison Blanche Hospital, Reims; [5]Baxter Healthcare Corporation, Maurepas, France

Background: As part of the treatment or monitoring of their disease, a significant number of patients may have multiple venipunctures. This is the case, in particular, for patients with clotting disorders, who undergo regular punctures as well as self-treatments. These repeated punctures may result in weakening of the veins, making venous access difficult and inducing a negative feeling for the patient (increased pain and stress).
The existence of a peripheral vein locating device 'AccuVein®' in this context could facilitate the practice of venipunctures and provide us with the opportunity to assess the venipuncture practices and the interest of this device in this population.
Aim: To describe practices for venipunctures and their difficulty for patients with multiple peripheral venipunctures and the contribution of a peripheral vein locating device 'AccuVein®'.
Methods: French, pilot, survey of practices carried out in France, in four university hospital units (CHU Caen, Paris, Lille and Reims).
According to the use or not of the device, the nurses collected the numbers of attempted punctures, the pain and the stress of patients before and during the punction and the stress of the nurses as well.
Results: To date 150 patients have been analyzed:For the group without venous difficulty with or without device (AccuVein®): no difference in the number of attempts (0 in median for the two sub-groups), or in the pain and stress of the patient. For the group with venous difficulty with or without device (AccuVein®): median number of puncture attempts −0.5 (the device) and 0 (without the device), a trend in favor of the device.
In the subgroup with AccuVein®: less stress for the patient ($P = 0.055$), a reduction in pain ($P = 0.003$). The main reason for using AccuVein® was to locate the vein immediately.
Conclusion: The device 'AccuVein®' seems to bring an interest to the practice for venipuncture in patients with difficult venous access with a decrease in the number of attempted puncture, pain and stress.

PB2.42 – Von Willebrand Disease: Clinical – III

PB 2.42-1

Molecular characterisation and discrimination of patients with Type 2 Von Willebrand disease

Jenkins VP[1], Byrne MB[1], Keenan C[1], Holden F[1], Nolan B[2], O'Connell N[1] and O'Donnell JS[3]
[1]St. James's Hospital; [2]Our Lady's Childrens Hospital; [3]Trinity College, Dublin, Ireland

Background: Diagnosis of von Willebrand disease (VWD) sub-type is important in guiding patient treatment and genetic counselling. VWD discrimination is based on laboratory analysis of VWF levels and function. However mutation analysis of the *VWF* gene complements laboratory measurement and aids in distinguishing qualitative (Type 2) and quantitative (Types 1 and 3) deficiency of VWF. Most mutations associated with types 2A, 2B and 2M VWD occur in *VWF* exon 28 which encodes the functionally important VWF-A1 and A2 domains.

Therefore a targeted approach to mutation analysis allows detection of most mutations associated with these sub-types.
Aims: To screen and identify mutations associated with Type 2 VWD in a cohort of Irish patients with VWD.
Methods: Samples were collected from patients with a diagnosis of VWD and prior VWF:RCo/VWF:Ag ratio of ≤ 0.7. VWF:Ag was measured by an immuno-turbidometric method, VWF collagen binding (VWF:CB) was measured by ELISA, and VWF:RCo levels determined by platelet aggregometry. VWF multimers were analysed by discontinuous slab agarose gel electrophoresis. *VWF* exon 28 was amplified in four separate overlapping PCR reactions and the resulting product sequenced by standard di-deoxysequencing methods. Analysis of *GP1B* was also performed in a single kindred. In-silico structural analysis was also performed.
Results: Twenty-six discrete mutations were detected in *VWF* exon 28 in a total of 42 kindred, comprising 61 patients analysed. Twenty-three of the 26 mutations were associated with Type 2 VWD and a dominant family history. Six different mutations associated with 2A VWD were detected in 10 kindred comprising 14 patients. A novel candidate mutation was detected in three apparently unrelated kindred (p.Gln1541Arg). All patients were heterozygous for mutations that predicted amino-acid substitutions in the A2 domain. Four mutations associated with 2B VWD were detected in five kindred, an additional family had a mutation in *GP1B* (p.Gly249Val) causing platelet-type VWD. Ten different mutations causing 12 amino-acid substitutions were associated with definite 2M VWD. VWF:RCo/Ag ratios varied from 0.24 to 0.64 whereas VWF:CB/Ag ratios varied from 0.67 to 0.96 and HMW multimers were present. Notably two candidate gene conversion events between pseudogene and VWF exon 28 were associated with 2M VWD. One event predicting the amino-acid substitutions p.Pro1266Leu; p.Val1279Ile in the A1 domain was detected in three apparently unrelated kindred. A second candidate gene conversion event that predicted p.Val1229Gly and Asn1231Thr was detected in two unrelated patients. This has been previously associated with Type 1 VWD. Mutations predicting p.Arg1374Cys/His/Leu in the A1 domain were detected in six kindred. Mutation at this residue reduces VWF:Ag (0.14–0.25 IU/mL) and further reduces VWF:RCo (< 0.1–0.12 IU/mL). The mutations also affects VWF:CB (ratio 0.5–0.7) with a modest reduction of HMW multimers, thus classification of these patients is difficult. In additional two novel mutations; resulting in type 1 quantitative deficiency were detected: c.3675-1G>A splice site mutation, and p.Arg1566*. The latter mutation was also present in trans with the modifying polymorphism p.Tyr1584Cys.
Conclusions: Novel candidate mutations with unique molecular mechanisms were identified as causing type 2VWD. Molecular analysis complements laboratory measurement and provides further insight into the basis of VWD.

PB 2.42-2
Use of double virally inactivated FVII/vWF in 30 children and young people with von Willebrands disease – a single centre experience

Khair K, Efford J, Mathias M and Liesner R
Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK

Background: Children and young people (CYP) with von Willebrands disease (vWD) have mild to severe bleeding manifestations which appear spontaneously or following trauma or surgical intervention. Treatment is given to prevent or treat bleeding; for some this requires treatment with plasma derived concentrates. UK treatment guidelines recommend using plasma products which have been manufactured to the highest standards to limit exposure to potential blood borne viral disease.
Aims: A double virally inactivated FVIII/vWF concentrate was licensed for use in the UK in September 2009. All children treated at this centre since then have received this new product. A prospective monitoring record documenting safety and efficacy and outcomes of treatment was established, recording dose frequency, response to treatment and adverse events.
Methods: Since introduction of the new product, treatment of CYP, unresponsive to Desmopressin, has been recorded on a central database. All treatments are recorded including reason for treatment, dose, and response to treatment: bleed resolution, breakthrough bleeds for those on prophylaxis, surgical outcomes and adverse events.
The data is analysed regularly to assess results of treatment, adverse events and treatment outcomes.
Results: To date 30 CYP (14 girls:16 boys, 21 type 1, 1 type 2M, 6 type 3 vWD, 2 acquired) aged 1 day to 17.8 years have been treated either on demand for bleeds (four subjects for 23 bleeds, four have had continuous prophylaxis and 27 subjects have undergone 35 surgical procedures).
Surgical procedures varied from minor to major surgery (dental extractions to spinal, cardiac and neurosurgery) treatment was administered for 1–5 days. For major procedures FVIII and vWF levels were monitored to ensure adequate haemostatsis without any evidence of accumulation of vWF postoperatively.
No postoperative bleeding, complications or adverse events were seen. The CYP treated prophylactically have experienced no breakthrough bleeds on a dose regimen of 28–53 iu/kg/dose, administered at home every 48–72 h maintaining a 48 h trough > 1 iu/dL.
CYP treated on demand have responded to a single dose of ~50 iu/kg.
Summary/Conclusion: This study, of a heterogeneous group of CYP with vWD confirms data obtained in clinical trials that this product is efficacious, safe and well tolerated. Bleed resolution or prevention is 100% in this cohort. For CYP on home treatment ease of reconstitution and infusion and absence of breakthrough bleeding promotes treatment concordance.

PB 2.42-3
Results of a prospective, non-interventional clinical study in 170 VWD patients with a new generation of VWF/FVIII concentrate in Germany

Von Depka M[1], Feddern J[2], Halimeh S[3], Kadar J[4], Miesbach W[5], Nowak-Göttl U[6] and Scharrer I[7]
[1]Werlhof Institut, Hannover; [2]Octapharma GmbH, Langenfeld; [3]Coagulation Centre Rhein-Ruhr, Duisburg; [4]Laboratory and Medical practice for Transfusion Medicine, Köln; [5]Hemophilia Center Frankfurt, Frankfurt; [6]Institute of Clinical Chemistry, Kiel; [7]Johannes Gutenberg-University Medical Center, Mainz, Germany

Background: With marketing authorisation in 2005, a non-interventional study (SET = Surveillance of Efficacy and Tolerability) with a double virus inactivated VWF/FVIII concentrate (Wilate) was initiated in Germany. After duration of 7 years, the inclusion of patient documentation was terminated to finally evaluate the study data. At data lock point, 170 patients suffering from von Willebrand's disease (VWD) had been included. Some of the results from the final evaluation regarding safety and efficacy will be presented.
Aim: The presented study was performed to evaluate the haemostatic efficacy and safety of a newly introduced VWF/FVIII product in the treatment of all types of VWD patients in every day clinical setting and to validate the results from pivotal clinical trials.
Methods: Patients of any age suffering from hereditary or acquired VWD requiring replacement therapy were included. Apart from demographic and anamnestic data, details of all injections for treatment of bleeding episodes, surgeries and prophylactic treatment were documented. Clinical efficacy and tolerability were rated by the treating physician using four-point verbal scales. All data underwent a predefined data management process including double data entry and plausibility checks by an independent statistical institute.

Results: Twenty-six treatment centres provided data of 170 patients suffering from VWD reflecting the broad spectrum of disease severity. About two thirds of the patients are female; the age ranges from 1 to 85 years at study entry. Six cases of acquired VWD and 7 type 3 VWD were included. Type 2 of various subtypes accounts for about 30% of the patients and the remainder suffers from type 1 VWD. One hundred and eight surgical procedures in 82 patients were documented. In all rated surgical procedures, the efficacy of the concentrate was assessed to be 'excellent' or 'good'. Efficacy in 156 bleeding episodes was assessed as 'excellent/good' in 95.2% of ratings. Prophylactic treatment of 13 patients resulted in a drop of bleeding frequency of under 1 bleed per month. Five patients had experienced suspected adverse drug reactions – all without sequelae. The ADR rate per injection was as low as 0.1%.
Conclusion: The results, reflecting the experience of routine use in all types of VWD in all types of clinical settings, confirm the excellent efficacy and tolerability which had been demonstrated during the extensive panel of clinical trials.

PB 2.42-4
Thrombin generation in platelet-rich plasma is sensitive for the activation status of Von Willebrand Factor

Kelchtermans H[1], Pelkmans L[2], Miszta A[1], Al Dieri R[1] and De Laat B[2]

[1]Synapse BV, Cardiovascular Research Institute Maastricht, Maastricht University; [2]Department of Biochemistry, Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands

Background: Von Willebrand Factor (VWF), a multimeric protein, plays a key role in hemostasis through its interactions with platelet glycoprotein Ib (GPIb), Factor (F) VIII and subendothelial collagen. VWF in plasma is unable to interact with GPIb, unless it is structurally modified by binding for example to subendothelial collagen. More recently, evidence exists that under flow conditions VWF can bind to formed fibrin and subsequently GPIb, thereby activating platelets. Von Willebrand Factor disease (VWD), the most common inherited bleeding disorder in humans, results from deficits in the quantity (Type I; reduced levels of normal functional VWF/Type III; complete absence of VWF) or function (Type II) of VWF. Type IIA VWD is characterized by a loss of high molecular weight VWF, due to faulty assembly or enhanced proteolysis, while in type IIB VWD a mutation in VWF results in its spontaneous binding to GPIb. Type IIN VWD represents an inherent VWF defect causing defective FVIII binding.
Aims: In this study we have investigated the impact of the quantity and activation status of VWF on the thrombin generation in platelet-rich plasma (PRP).
Methods: Thrombin generation (TG) was determined by calibrated automated thrombography in platelet poor vs. rich plasma of healthy controls (HCs; $N = 9$) and of patients with VWD type IIA ($N = 5$), IIB ($N = 5$), IIN ($N = 3$) and type III (simulated by VWF deficient plasma). PRP samples were prepared from platelet-poor plasma (PPP) by adding washed platelets from a HC sample, to a final concentration of 3×10^8 platelets/mL. TG was initiated with 1 pM TF and 4 μM phospholipids (PPP only). Both in PPP and PRP, all results were normalized to the average of the HC samples. Subsequently the ratio of PRP/PPP was determined for the four parameters of the TG (lag time, time to peak (ttP), endogenous thrombin potential (ETP) and peak).
Results: In most samples of VWD patients, thrombin generation in PPP was found to be lower compared to the HCs, probably because of the reduced FVIII levels present in the samples. The ratios for the lag time and ttP were not significantly affected in VWD samples compared to HCs, apart from a small increase in type III VWD. However, a significant increase in the ratio PRP/PPP was observed for both the ETP and peak in type IIB patients compared to HCs. This increase was not found in type IIA or type III samples, and only marginally in type IIN samples. This increase is likely to be explained by the spontaneous interaction of the mutated VWF in type IIB patients with GPIb, inducing the activation of platelets.
Conclusion: By comparing TG in PRP and PPP from different VWD patient samples, we have demonstrated that the TG is sensitive to the activation status of VWF.

PB 2.42-5
Comprehensive classification of patients with von Willebrand Disease after systematic genotypic analysis

Schoormans S, Van Duren C, Diekstra A, Hoefsloot L and Van Heerde WL

Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Background: Von Willebrand disease (vWD) is a bleeding disorder caused by abnormalities in Willebrand factor concentration and/or function. The prevalence is 1: 100, but only 1:10,000 cases have a clinical significant bleeding tendency. VWD can be divided in three different subclasses, but classification remains difficult if based on well-standardized laboratory assays.
Aims: Since classification is still a challenge we initiated a national reference centre for von Willebrand factor genomic analysis. The aim of this center is to improve vWF classification. To do so, genetic abnormalities in the vWF gene in patient suspected to suffer from vWD will be correlated to the other vWF parameters.
Methods: DNA of patients suffering from vWD was analyzed by Sanger sequencing the coding regions including the intron-exon boundaries of the vWF gene. Large deletions and duplications in the vWF gene were detected by MLPA.
Results: Up to December 2012, 186 patients were analyzed. One hundred and eight patients had a genetic abnormality. The mutations found were eight nonsense mutations, 105 missense mutations, nine small deletions, four duplications, and four large deletions detected by MLPA. In 78 patients no mutations were found. Of all mutation detected 104 were reported previously and 16 were novel. Thirteen of the novel mutations were missense mutations, one nonsense and two small deletions. Twenty-nine patients were carrying the D1472H polymorphism affecting the von Willebrand Factor Ristocetin cofactor activity as reported by Flood et al, Blood, 2010. The *de novo* mutations were further analyzed by in silico analysis.
Summary/Conclusions: Our systematic genotypic approach resulted in 58% of the cases in a confirmation of von Willebrand disease. Furthermore, we were able to confirm in 90% of the cases a vWD classification. Finally, we expect that our approach will result in the identification of specific haplotypes since the rate of polymorphisms in von Willebrand factor is high. The results of our analyses will be included in the appropriate ISTH/WFH-related registries.

PB 2.42-6
Evaluation and clinical application of von Willebrand factor antigen and ristocetin cofactor by chemioliminiscence in a new analyzer ACL AcuStar in the diagnosis of von Willebrand disease

Costa-Pinto MJ, Gomez-del-Castillo M, Perez-Rodriguez A, Galego A, Lourés E, Rodriguez-Trillo A, Martinez-Marini T, Iglesias T, Batlle J and López-Fernández MF

Complejo Hospitalario Universitario A Coruña, La Coruña, Spain

Background: Von Willebrand disease (VWD) is the most common congenital bleeding disorder, caused by inherited quantitative and qualitative defects of the von Willebrand factor (VWF). An effective diagnosis of VWD includes assessment of FVIII coagulant activity,

VWF antigen (VWF:Ag) determined usually by ELISA, and VWF ristocetin cofactor (VWF:RCo) by aggregometry. Since its introduction, various modifications of VWF:RCo were proposed due to complexity, performance time, poor reproducibility and poor sensitivity to low levels of VWF. The ACL Acustar is the first analyzer that introduces chemioluminiscence technology in the detection of VWD. This new instrument allows to perform automated quantitative assays of VWF:Ag and VWF:RCo.

Aims: Comparison of the results of VWF:Ag and VWF:RCo obtained by conventional methods with the ones by new automatic analyzer ACL Acustar, in normal subjects and in patients with VWD. Evaluation of the performance of ACL Acustar in terms of imprecision, sensibility, specificity and probability to make a correct VWD diagnosis.

Methods: Citrated plasma samples were obtained from $n = 146$ patients with previously diagnosed congenital VWD (Type 1, $n = 51$; Type2A, $n = 35$; Type 2B, $n = 16$; Type 2M, $n = 30$; Type 2N, $n = 5$; Type 3, $n = 9$) and $n = 30$ healthy normal subjects. The VWF levels were analyzed by ELISA (VWF:Ag-ELISA) (DG-EIA VWF, Diagnostic Grifols), by light transmission aggregometry with lyophilized fixed platelets and ristocetin (VWF:RCo-LTA) (Helena Biosciences), and in the ACL AcuStar were tested reagents HemosIL® Acustar VWF:Ag (VWF:Ag-IL) and HemosIL® Acustar VWF:RCo (VWF:RCo-IL) (Instrumentation Laboratory). VWF:RCo/VWF:Ag ratio and multimeric distribution (SDS-agarose gel) of VWF were determinated in all samples VWD and genetic analysis in 77/146. Statistical analysis performed with Analyse-It v2.30.

Results: Normal ranges were: VWF:Ag-ELISA 41–156 U/dL, VWF:RCo-LTA 50–158 U/dL, VWF:Ag-IL 41–156 U/dL and VWF:RCo-IL 50–158 U/dL. The lower limit level detected of VWF:RCo-LTA in our laboratory is 4U/dL. Diagnosis algorithm considered VWF levels lower than 30 U/dL for the diagnosis of type 1 VWD and a cut-off of ratio VWF:RCo/VWF:Ag 0.7. ACL Acustar methods showed low levels of intra-assay and inter-assay imprecision (CV < 10%). Passing Bablok regression comparing VWF:Ag-ELISA and VWF:Ag-IL methods, yielded a slope of 1.07 (95% CI: 1.04–1.11), intercept of 1.49 (95% CI: 0.58–2.29). Comparing VWF:RCo-LTA and VWF:RCo-IL, slope was 1.18 (95% CI: 1.13–1.24), intercept 0.09 (95% CI: −0.23–1.24). Pearson r was 0.98 (95% CI: 0.94–0.99) comparing VWF:Ag methods and 0.97 (95% CI: 0.96–0.98) comparing VWF:RCo methods. Kappa test between original diagnosis and found diagnosis with both methods was > 0.8, being higher with ACL Acustar methods. A 3.4% (5/146) diagnosis discrepancies between two methods can be explained by limitations in sensitivity of VWF:RCo-LTA. Discrepancies between original and new method based diagnosis were 2.7% (4/146). Multimeric and genetic analysis were of help in clarifying these discrepancies.

Conclusion: New chemioliminiscence methods analyzed in ACL AcuStar can detect VWD and discriminate between type 1, 3, and variant forms. They offer a automated, faster, reproducible, more sensitive and less cumbersome alternative to conventional assays, specially VWF:RCo-LTA. In conjunction with multimer analysis and genotype they are reliable methods for the laboratory diagnosis of VWD.

PB 2.43-1

Dextran sulfate blocks assembly of UL-VWF strings on the surface of endothelial cells

Dragt BS[1], Kragten A[1], Hofman M[1], De Laat B[2] and Voorberg J[1]
[1]Sanquin Research, Amsterdam; [2]CARIM, Maastricht, The Netherlands

Background: Vascular endothelial cells (ECs) provide a highly interactive barrier between blood and the underlying tissues and are of vital importance in maintaining vascular homeostasis. ECs contain specific cigar-shaped storage organelles, designated Weibel-Palade bodies (WPBs), which upon stimulation release various components into the bloodstream. The main protein stored in WPBs is von Willebrand factor (VWF), a multimeric glycoprotein which is crucial for binding of platelets under shear stress. Upon exocytosis of WPBs VWF multimers assemble into ultra large VWF (UL-VWF) strings that remain anchored to the surface of endothelial cells. Our current knowledge on the conversion of VWF tubules as stored in WPBs into UL-VWF strings is limited.

Aim: In this study we investigated the ability of different pharmacological compounds to interfere with assembly of UL-VWF strings on the surface of endothelial cells.

Methods: Human umbilical vein endothelial cells were cultured in flowchambers, pre-incubated with various pharmacological inhibitors and stimulated with histamine or ionomycin under flow (2.5 dyn/cm^2) to release UL-VWF strings. UL-VWF strings were visualized by perfusion of beads coated with a monoclonal or polyclonal anti-VWF antibody or washed platelets. Images were taken of 20 randomly chosen optical fields and analyzed for number and length of VWF strings. VWF and VWF propeptide release was measured in medium from statically stimulated cells with or without pharmacological inhibitors by ELISA. Confocal microscopy of histamine-treated HUVEC employing an Alexa488 labeled polyclonal antibody was used to visually monitor the effects of the different inhibitors.

Results: The effect of different pharmacological inhibitors on assembly of UL-VWF strings was evaluated. Increasing concentrations of heparin (50–250 μg/mL) did not prohibit the number and length of UL-VWF strings (ranging from 50 to over 400 μm) on endothelial cells following stimulation with histamine. Also mannan (0.5–5 mg/mL) did not affect UL-VWF string formation, indicating that mannan-sensitive C-type lectins do not contribute to formation of UL-VWF strings. Incubation with the sulfated poly-anion dextran sulfate (at concentrations of 50–250 μg/mL) completely abolished histamine-induced formation of UL-VWF strings on the surface of endothelial cells. Also, ionomycin induced formation of UL-VWF strings was impaired under these conditions indicating that the dextran sulfate did not block the interaction of histamine with its receptor. We subsequently monitored whether dextran sulfate blocked release of WPBs under static conditions. Dextran sulfate showed a marked inhibition of histamine- and ionomycin -induced VWF release. Strikingly, release of VWF propeptide was not affected by dextran sulfate. Confocal microscopy revealed that VWF containing clusters, most likely originating from fused WPBs, were present on the plasma membrane of cells stimulated in the presence of dextran sulfate. In control cells stimulated with histamine in the absence of dextran sulfate these structures were not observed.

Summary/Conclusions: Our findings show that anionic dextran sulfate polymers interfere with assembly of UL-VWF strings on the surface of endothelial cells. Confocal microscopy suggests that dextran sulfate prevents the conversion of newly released VWF multimers into UL-VWF strings following fusion of WPBs with the plasma membrane.

PB 2.43-2

Platelet aggregates developed at high shear rate grow rapidly, are unstable, and incorporate vWF

Colace TV and Diamond SL
University of Pennsylvania, Philadelphia, PA, USA

Background: At sites of vascular injury, von Willebrand factor (vWF), a large multimeric protein, aids in the arrest and aggregation of platelets. We have demonstrated that vWF can form large fibril aggregates (> 100 μm in length) when perfused over immobilized collagen type I surfaces under elevated shear rate conditions. In platelet free plasma (PFP) we observed a threshold shear rate of 30,000/s, while we found a threshold of 10,000/s in whole blood (WB). We believe that the fibril aggregates consist of many cross-linked vWF molecules based on their long length and width (~300 nm). Here we report that exposure of soluble vWF to high shear rates in whole blood enhances the incorporation of vWF into growing platelet aggregates resulting in rapid and embolic platelet adhesion.

Aim: We sought to investigate the role of soluble vWF in the process of platelet deposition onto a collagen type I surface under elevated shear rates mimicking those found in stenosed coronary arteries.
Methods: Whole blood from healthy donors was collected into 100 μM PPACK to inhibit the generation of thrombin. Samples were perfused through a microfluidic channel via syringe pump over a collagen type I surface. Platelet and vWF deposition was visualized using fluorescently labeled antibodies and epifluorescence microscopy.
Results: Perfusion of WB at 200/s over a collagen type I surface resulted in platelet adhesion which reached steady state after ~20 min and incorporated no detectable vWF. These aggregates represented the balance between the activating forces (ADP and Thromboxane A2) aiding the capture of flowing platelets and shear forces which mechanically remove adhered platelets. Based on our previous efforts to model shear rate as a function of aggregate growth we estimate this value to be ~1000–2000/s. Counterintuitively, we found that platelet adhesion was restored by increasing the local wall shear rate (> 10,000/s) after steady state was achieved. The resulting aggregates grew rapidly (~5-fold faster), were embolic, and incorporated vWF. We believe that the enhanced deposition of vWF onto the aggregate resulted in elongated platelet contact times with the steady state deposit. We have previously demonstrated that fibril aggregates of vWF form on these surfaces of platelets under plasma perfusion. Rapid and embolic platelet adhesion (at > 10,000/s) could also be achieved from surfaces of collagen and required $\alpha_{IIb}\beta_3$ as well as Gp1b. In addition, sharp transitions in the adhesive mechanism (with incorporation of vWF) were observed starting with intermediate bulk shear rates (1000–2000/s). Approximately 50–60% of channel occlusion starting from these conditions resulted in shear rates above the critical value (~10,000/s).
Conclusions Under conditions of high shear rate that mimick coronary stenosis, vWF can form long fibril aggregates on surfaces of collagen and platelets. These aggregates appeared to be the nucleating event for rapid and embolic platelet deposition under WB flow in microfluidic channels. This vWF mediated mechanism of platelet adhesion may underlie ischemic events that result from full vessel occlusion or embolus.

PB 2.43-3
Functional role of von Willebrand factor (VWF) triplet bands in glycoprotein Ib-mediated platelet adhesion and thrombus formation under flow

Fuchs B[1], De Witt SM[2], Solecka BA[1], Kröning M[1], Obser T[3], Cosemans JMEM[2], Schneppenheim R[3], Heemskerk JWM[2] and Kannicht C[1]
[1]Octapharma R&D, Berlin, Germany; [2]Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, The Netherlands; [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Multimeric glycoprotein von Willebrand factor (VWF) exhibits a unique triplet structure of individual oligomers, resulting from ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motifs 13) cleavage. The faster and slower migrating triplet bands of a given VWF multimer have one shorter or longer N-terminal peptide sequence, respectively. Within this peptide sequence, the A1 domain regulates interaction of VWF to platelet glycoprotein (GP)Ib.
Aim: Distribution of VWF triplet bands is significantly altered in some types of von Willebrand's disease (VWD). Since the properties of individual VWF triplet bands have not been investigated so far, we analyzed platelet-adhesive function of VWF preparations with different triplet composition with regard to differential functional activities.
Methods: Two VWF preparations with similar multimeric distribution but different triplet composition obtained by size exclusion in addition to heparin affinity chromatography were investigated. Preparation A was enriched in intermediate triplet bands, while preparation B predominantly contained larger triplet bands, which was confirmed by VWF multimer analysis. Collagen- and GPIb-binding was determined by surface plasmon resonance (SPR). Platelet adhesion under flow using either reconstituted blood or blood from a type 2A VWD patient was determined using parallel-plate flow chamber models.
Results: Binding studies revealed that preparation A displayed a reduced affinity for recombinant GPIb, but an unchanged affinity for collagen type III, when compared to preparation B. Under high-shear flow conditions, preparation A was less active in recruiting platelets to collagen type III. Furthermore, when added to blood from patients with (VWD), defective thrombus formation was less restored.
Conclusion: Thus, VWF forms lacking larger size triplet bands appear to have a decreased potential to recruit platelets to collagen-bound VWF under arterial flow conditions. By implication, changes in triplet band distribution observed in patients with VWD may result in altered platelet adhesion at high-shear flow.

PB 2.43-4
Characterization of recombinant VWF73 peptide in different prokaryotic expression systems

Jian S, Xia B, ZhenNi M and Changgeng R
The 1st Affiliated Hospital of Suzhou, Suzhou, China

Background: VWF73 peptide, the well known susbtrate of ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin motif 13), has been modified by attachment of fluorescein moities to assay ADAMTS13 activity widely in clinic.
Aims: To probe its production in different prokaryotic expression systems and to compare its FRET(fluorescence resonance energy transfer)effect by modification in different specific amino acid, we set out to commit this experiment.
Methods: The wild sequence of VWF73 was amplified using the pSVHVWF1 plasmid (provided by Professor J. Evan. Sadler) as the template and the primers containing BamHI and Hind III plus stop codon in the 5′and 3′ end respectively. The PCR product was cloned into the pQE30 and PET-20b plasmid.
Regarding to the pQE30 plasmid containing wild VWF73, a pair of cysteine (Q1599C + N1610C/Q1599C + P1611C) was introduced to the VWF73 sequence using site-directed mutagenesis, meanwhile, the BamHI cleavage site was removed by deletion mutagenesis, and the final product expressed by pQE30 plasmid was as follows: MRGSHHHHHH plus the VWF73 sequence (Q1599C + N1610C/Q1599C + P1611C). The modified pQE30 plasmid was transformed to the M15 *E. coli* and the corresponding peptide was induced using 1 mM IPTG overnight at 30 °C, and the induced peptide was confirmed by Western-Blot using anti-His antibody-HRP. The expressed peptide was purified by Ni column and treated by TCEP followed by attachment with M-5-F (fluorecein-5-Maleimide) in pH 7.0 condition. The fluorescein-attached VWF peptide was dialyzed against Tris-HCL buffer (pH8.0) thoroughly to remove unattached M-5-F. And the FRET effects of two fluorescein version of VWF (Q1599C + N1610C/Q1599C + P1611C) were assayed using the sequentially diluted normal plasma as the source of ADAMTS13 in Bis-Tris buffer containing CaCl2.
The PET-20b plasmid containing wild VWF73 sequence was modified by several rounds of mutagenesis and the final product sequence expressed by PET-20b was the same as the peptide expressed by the pQE30 plasmid, i.e., MRGSHHHHHH plus the VWF73 sequence (Q1599C + N1610C/Q1599C + P1611C). The modified PET-20b plasmid was transformed to the *E. coli* B.L21 (DE3) and the corresponding peptide was induced using 1 mM IPTG overnight at 30 °C, and the induced peptide was confirmed by Western-Blot using anti-His antibody-HRP.
Results: The modified pQE30 and PET-20b plasmid containing VWF was confirmed by DNA sequencing. Western-Blot domenstrated an

intact one band existed regarding to the pQE30/M15 expression system. However, there existed two bands regarding to the PET20-b/DE3 expression system, implying that certain enzyme (enzymes) lurked in the *E. coli* B.L21, which could specifically/unspecifically cleave the VWF peptide. the FRET effects of two fluorescein version of VWF (Q1599C + N1610C/Q1599C + P1611C) derived from the pQE30/M15 expression system showed that fluorescence release from the peptide of Q1599C + N1610C was approximately two fold compared to the fluorescence release from the peptide of Q1599C + P1611C when the same amount of ADAMTS13 was used.

Conclusion: PET20-b/DE3 expression system is not suitable for the expression of VWF73 peptide while pQE30/M15 expression system is feasible for this expression purpose. And the VWF peptide modified at Q1599C plus N1610C is better than the peptide modified at Q1599C plus P1611C cause the FRET effect of former is almost two fold compared to the latter.

PB 2.43-5

Von willebrand factor levels are strongly associated with atherosclerosis in patients with ischemic stroke

Sonneveld MAH, Van Dijk AC, Van Den Herik EG, Van Loon JE, De Lau ML, Van Der Lugt A, Koudstaal PJ, De Maat PM and Leebeek FWG

Erasmus University Medical Center, Rotterdam, The Netherlands

Background: Increased von Willebrand Factor (VWF) levels are associated with an increased risk of ischemic stroke. As VWF levels are known to be associated with endothelial dysfunction, atherosclerosis is expected to play a role in this association. It is yet unknown what the association between VWF and atherosclerosis is in ischemic stroke patients.

Aims: We investigated the relationship between atherosclerosis and VWF antigen (VWF:Ag) levels in 925 consecutive patients with transient ischemic attack (TIA) or ischemic stroke, using an advanced measurement of atherosclerosis.

Methods: Calcification volumes (mm^3) were scored in the aortic arch and both carotid arteries using multidetector computed tomography (CT) angiography of the craniocervical vessels. VWF antigen (VWF:Ag) levels were measured using ELISA technique. Underlying ischemic events in the patients were classified according to the TOAST criteria. The associations between the calcium volumes and VWF:Ag levels were assessed using linear regression analysis and adjusted for potential confounders.

Informed consent was obtained and the study was approved by a recognised medical ethics committee.

Results: Mean VWF:Ag levels were significantly higher in the presence of calcification in either the aortic arch (1.54 vs. 1.26 IU/mL [$P < 0.0001$]) or the carotid arteries (1.56 vs. 1.27 IU/mL [$P < 0.0001$]). Levels of VWF:Ag rose with increasing aortic arch ($P = 0.005$ for trend) and carotid calcification volume ($P < 0.0001$ for trend). Patients with a small vessel TIA or ischemic stroke had significantly lower VWF:Ag levels compared with the other TOAST subtypes ($P = 0.003$). High VWF:Ag levels were significantly associated with an unfavorable outcome (modified Rankin Scale > 2 vs. ≤ 2; 1.70 vs. 1.40 IU/mL, [$P < 0.0001$]).

Summary/Conclusion: Our study showed a strong association between atherosclerosis in either the aortic arch or the carotid arteries and high VWF levels in patients with TIA or ischemic stroke. This finding supports the hypothesis of a pathophysiologic role of VWF in ischemic stroke which seems to be influenced by the extent of atherosclerosis and could therefore have a prognostic value.

PB 2.43-6

A comparative evaluation of two new automated assays for von Willebrand factor ristocetin cofactor activity and von Willebrand factor antigen

Stufano F[1], Lawrie AS[2], La Marca S[1], Canciani MT[1], Franchi F[3], Cozzi G[1], Baronciani L[1] and Peyvandi F[3]

[1]Angelo Bianchi Bonomi Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinic, Milano, Italy; [2]University College London, London, UK; [3]University of Milan, Milano, Italy

Background: von Willebrand's disease (VWD) is the most common congenital bleeding disorder caused by a quantitative or qualitative plasma deficiency of the von Willebrand factor (VWF). The initial laboratory classification of VWD is dependent on the measurement of von Willebrand Factor Antigen (VWF:Ag) and VWF activity, usually by ristocetin cofactor activity assay (VWF:RCo).

Aim: To compare the performance of two new automated VWF:Ag and VWF:RCo assays systems from Instrumentation Laboratory (IL, Bedford, USA).

Methods: One hundred and seventy-one healthy normal subjects and 72 patients with VWD (14 type 1, 52 type 2, 6 type 3) were evaluated. VWD patients have been previously characterized, according to the ISTH-SSC guidelines, using a home-made ELISA VWF:Ag determination and a platelet-based VWF:RCo assay on an ACL-9000 (Lattuada *et al*, 2004), as reference first-level tests. All samples were obtained after informed consent. VWF:Ag and VWF:RCo were performed using fully automated assays that utilised different principles: immunoturbidimetric assays (HemosIL VWF:RCo and HemosIL VWF:Ag) were performed on an ACL TOP analyser and chemiluminescent assays (AcuStar VWF:RCo* and AcuStar VWF:Ag*) were performed on an ACL AcuStar instrument. Both HemosIL VWF:RCo and AcuStar VWF:RCo assays use recombinant GPIb in the presence of ristocetin. Assay imprecision was assessed using commercial control plasmas. All reagents and analysers were from IL.

Results: VWF:Ag and VWF:RCo determination performed on the ACL AcuStar exhibited low levels of intra- and inter-assay imprecision for normal and pathological control plasmas (CV% range 3.3–6.9). The VWF:Ag and VWF:RCo assays performed on ACL TOP also gave low levels of intra- and inter- assay imprecision for normal and pathological control plasmas (CV% range 0.8–4.7). For both normal (observed range: VWF:Ag 44.6–173.9 U/dL; VWF:RCo 43.1–191.5 U/dL) and VWD (observed range: VWF:Ag 0.3–115.1 U/dL; VWF:RCo 0.5–57.2 U/dL) samples there was good correlation between the two VWF:Ag and VWF:RCo Methods: (Pearson correlation coefficient $r = 0.92$ and $r = 0.82$ respectively).

Both new assays systems gave consistent results compared to the previous diagnosis.

AcuStar VWF:RCo and VWF:Ag demonstrated superior lower level of detection compared to HemosIL VWF:RCo and VWF:Ag (0.5 vs. 6 U/dL and 0.3 vs. 12 U/dL respectively).

Conclusions: The VWF:Ag and VWF:RCo assays performed on ACL AcuStar and on ACL Top seem to be reliable and precise. The use of these tests for the VWD diagnosis merits further evaluation in a larger VWD population.

*In development. Not currently saleable.

PB2.44 – Haemophilia: Miscellaneous

PB 2.44-1

Haemophilia and home treatment: optimizing knowledge and practical skills by an e-learning program

Mulders G[1], De Wee E[1], Vahedi Nikbakht M[2], Kruip JHA[1], Elfrink E[1] and Leebeek FWG[1]

[1]Erasmus Univesity Medical Center, Rotterdam; [2]Rotterdam Univesity of Applied Sciences – Expertise Center Innovations in Care, Rotterdam, The Netherlands

Background: Home treatment was first described in 1974, and is currently the standard of care for patients with severe haemophilia. The advantages of home treatment are evident and well-known, and have been recorded in numerous publications. Home treatment increases the responsibility of the patients for their treatment and care. Mistakes may occur by incorrect diagnosis of a bleeding episode, lack of compliance to the proposed treatment regimen, or under dosing in case of life-threatening bleeding events. With home treatment the responsibilities for correct treatment are in part transferred from the physician to the patient or his parents. Adequate education of the patient and/or parent is therefore required. Hence, it is of utmost importance to attain high level of knowledge and practical skills.
Aim: The primary aim of this study was to obtain insight in the knowledge and skills of haemophilia patients who have treated themselves at home for several years. A second aim was to study whether or not the introduction of an educational program by means of an e-learning module, created especially for this purpose, improved the knowledge and skills in the group of patients that were examined. The e-learning program takes maximum of 20 min.
Methods: We performed a randomised intervention study. Participants who were already on home-treatment and had undergone extensive home-treatment training in the past were recruited at theHaemophiliaTreatmentCenter of the Erasmus University Medical Centre. Patients were divided into two groups: the intervention group who had an e-learning training, and the control group, that had no additional training. Subjects had to complete a test at two occasions, which consisted of the intravenous injection of clotting factor concentrate while being observed, and completed a questionnaire with 77 items. After 1 month, all participants completed the same questionnaire (post-test) and were again observed and scored during self infusion. The intervention group received an e-learning program before the second test.
Results: At base-line, the patients (n = 30) showed a relatively low level of knowledge (24 of 48 questions correct) the practical skills of injection are performed correctly by 75% of the patients. At second measurement the e-learning group (n = 16) showed a higher level of knowledge in comparison with the control group (n = 14) who did not receive an e-learning program (36 of 48 questions correct). In the observation of practical skills a difference between the two groups was found as well (using a 20 items checklist, at baseline the patients scored 11 out of 20, at second observation 16 out of 20). Finally, the survey shows a clear association between self-efficacy of the patients and the level of knowledge.
Conclusion: This study shows that patients with haemophilia, who are on home treatment, have a relatively low level of knowledge and skills. This can be improved by an educational intervention, such as an e-learning program. In our centre the e-learning is already implemented for patients with haemophilia in the transition from children to adult care and in the management of home treatment care (as a follow-up training).

PB 2.44-2

Personalised prophylaxis in haemophilia A: how low can you go?

Greig AL, Austin S and Uprichard JN

St Georges Healthcare NHS Trust, London, UK

Background: The United Kingtom Haemophilia Centre Doctors' Organisation (UKHCDO) recognises that the pharmacokinetics of Factor VIII (FVIII) varies considerably amongst adult patients with severe Haemophilia A (between 8 and 23) hours. This is influenced by a number of physiological and pathological variables. In our haemophilia centre we encourage a strict prophylaxis regimen for all severe haemophilia patients, and encourage regimens that are individualised. This is in line with the UKHCDO which recommends that prophylaxis regimens in adults should be personalised using bleeding phenotype and pharmacokinetics.
Aims: We decided to review all prophylaxis regimens in adult patients with severe Haemophilia A, with the aim of reducing the amount of concentrate to the minimum effective level. To date we have collected data from nine patients (from a possible 38) and data collection is ongoing.
Methods: We have found that using prospectively assessed trough levels and bleed diaries in all evaluable patients with severe Haemophilia A, we have been able, in some cases, to significantly reduce the amount of prescribed FVIII administered, with the aim of improving cost effectiveness.
Results: Prior to this review, doses of FVIII for prophylaxis varied between 10 and 40 IU/kg (mean 27 IU/kg). To date, we have found that the number of units per kilogram of FVIII concentrate required for effective prophylaxis ranges from 6 to 40 IU/kg (mean 24.4 IU/kg). In many cases, through patient education, we have been able to reduce trough levels to < 3 IU/dL. This is an ongoing project and we are continuing to reduce the FVIII usage further in patients whose trough is > 3 IU/dL. Dosing regimens are further influenced by patient lifestyle with some requiring infusions every 24, 48 or 72 h. Collecting trough samples can be challenging for a number of reasons, including missed doses, missed appointments and reluctance to return to the clinic for repeated sampling.
Summary: In conclusion, it is clear that in order to be cost-effective and clinically effective, prophylaxis regimens in severe Haemophilia A need to be individualised. The amount of FVIII required may be significantly lower then previously thought. Bleeding phenotype, as well as half-life are important. We have also found that weight reduction initiatives have also reduced consumption of FVIII in some of these patients. Future work includes correlation of FVIII mutation with minimum prophylaxis dose required, and addressing other factors that may be predictors in detmining the miniumum effective dose of FVIII concentrate. There are further challenges; addressing patients mis-conceptions about their prophylaxis regimens and ensuring they are fully informed and involved in all treatment decisions.

PB 2.44-3

Buprenorphine does not influence the inflammatory response in haemophilia A mice with experimentally induced haemarthrosis

Groth MP[1], Kristensen AT[2], Øvlisen KA[1] and Tranholm M[1]

[1]Novo Nordisk A/S, Måløv; [2]University of Copenhagen, Frederiksberg, Denmark

Background: Haemarthrosis is the most common clinical manifestation of haemophilia and is responsible for major morbidity in haemophilia patients. After an intraarticular bleeding episode blood is removed by absorption to the synovial tissue and with recurrent bleeding episodes degradation products of red blood cells accumulate in the tissue triggering an inflammatory response. The murine experimentally induced knee bleeding model is an important model in hae-

mophilia research and as the inflammatory response is a crucial part of the pathogenesis of haemophilic arthropathy any administration of analgesics should ideally not alter this response. Currently it is unknown if the use of analgesia in this model might impact the inflammatory response.
For animal welfare and ethical reasons however, the full analgesic protocol in this model should be continued and the response of buprenorphine on the inflammatory response evaluated.
Aim: The aim of the present study was to investigate the inflammatory response after a needle induced knee bleed in haemophilia A mice treated with buprenorphine or saline.
Materials and Methods: One hundred and sixty mice were randomized in two groups to blindly receive buprenorphine or saline. All mice were anaesthetized and knee injury was induced by inserting a 30G needle into the right knee joint. At t = 6, 24, 48 and 72 h twenty mice from each group were terminated and the following parameters were assessed: Change in bodyweight, change in joint diameter, Visual Bleeding Score (VBS), white blood counts, haematocrit, platelet concentrations, haemoglobin, plasma haptoglobin and plasma and synovial fluid levels of 23 different cytokines (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-9, IL-10, IL-12(p40), IL-12(p70), IL-13, IL-17, eotaxin, G-CSF, GM-CSF, IFN-γ, KC, MCP-1, MIP-1α, MIP-1β, RANTES and TNF-α). Twenty mice were terminated at t = 0 receiving no injury or treatment to provide baseline measures.
Results: No significant alterations were observed in joint diameter, VBS, white blood counts, haematocrit, platelet concentrations and haemoglobin. Furthermore, 21 cytokines in plasma and 22 cytokines in synovial fluid, were unaffected by the administration of buprenorphine. Slight alterations in bodyweight ($P < 0.01$), of plasma G-CSF ($P < 0.05$) and haptoglobin at t = 48 h ($P < 0.05$), plasma and synovial eotaxin ($P < 0.05$ for both) were found in buprenorphine treated mice.
Conclusion: We have demonstrated that buprenorphine does not overall impact the inflammatory response and the use of buprenorphine in the knee bleeding model in haemophilic mice should be continued.
Perspectives: These data should call for further investigation in other inflammatory *in vivo* models and be included in the ethical and 3R considerations applied when working with these models.

PB 2.44-4

Identification and characterization of an L1 insertion in intron 16 of F8 in a patient with hemophilia A

Inaba H, Shinozawa K, Otaki M, Hagiwara T, Amano K and Fukutake K

Tokyo Medical University, Tokyo, Japan

Background: A wide variety of genetic abnormalities in the coagulation factor VIII gene (*F8*) have been found to cause hemophilia A. Among these abnormalities, insertion mutations are relatively rare.
Aim: We aimed to investigate a case of hemophilia A in whom the PCR amplification products from a part of *F8* could not be obtained.
Patient and Methods: The patient was a Japanese male with severe hemophilia A. He had a target joint, which had repeated bleeding episodes, and occasionally had serious bleeding such as iliopsoas muscle bleeding or pharyngeal bleeding. No other cases of hemophilia were found in his family. Genomic DNA was extracted from blood cells using the EZ1 DNA Blood 350 μL Kit (Qiagen) on a BioRobot EZ1 workstation (Qiagen). All 26 exons and their flanking intronic regions of *F8* were amplified independently by PCR and the nucleotide sequence was determined. Each amplicon was purified and directly sequenced by the dideoxy method using a BigDye Terminator Kit (Applied Biosystems). Sequencing was performed on a 48-capillary 3730 DNA Analyzer (Applied Biosystems). The nucleotide sequences were compared with reference sequences.
Results: We could not obtain PCR products from exon 16 or 17 amplification. We therefore considered that intron 16, which was common to both amplifications, might include some genetic abnormality. The PCR product amplified from exons 16–18 of the patient's *F8* was apparently 3 kb larger than that of normal control. This result indicated the possibility that the patient had a large insertion in intron 16. The sequencing of the patient's abnormally large PCR product revealed an insertion size of 2134–2137 bp and indicated that the nucleotide sequence was a part of L1 [LINE (long interspersed elements)-1, non-LTR retrotransposons]. L1 was inserted 98 bp 3' from the end of exon 16 and was flanked by a 10–13 bp target site duplication. The insertion contained 3' portions, which comprised most of the latter half of the L1 sequence, including the poly(A) tract. The insertion was divided into two blocks of sequence, each connected by a head-to-head arrangement. We also identified an intron 22 inversion from the patient's *F8*.
Summary/Conclusion: We identified a quite rare L1 insertion from the *F8* of a patient with hemophilia A. Thus far, such insertions have been reported in only three cases. Two of these three insertions, detected in an exon, were thought to be an etiology of hemophilia A. However, it is reported that the remaining insertion detected in an intron was not an etiology. In this patient, the direct etiology of hemophilia A is intron 22 inversion. If the L1 insertion causes hemophilia, abnormal splicing can be presumed because the possibility that the inserted sequence included a potential splice site was confirmed by *in silico* analysis. However, there is no direct evidence that this insertion causes hemophilia A. Further study is required to determine whether this insertion causes hemophilia A.

PB 2.44-5

Haemophilia A with and without historical inhibitors evaluation of T regulatory and memory B lymphocytes populations

Sevivas T[1], Coucelo M[2], Domingues S[2], Pedreiro S[3], Benedito M[2], Salvado R[2], Martins N[2], Ribeiro LML[2] and Roda ASB[1]

[1]Hematologia CHC- CHUC; [2]Serviço Hematologia CHC- CHUC; [3]Centro de Histocompatibilidade do Centro, Coimbra, Portugal

Background: FVIII inhibitor (IN) development is the most feared complication of substitutive therapy in patients with Haemophilia A (HA). Its major clinical impact justifies thorough investigation of factors that may elucidate the underlying pathophysiology and their modulating factors.
CD4+ CD25+ T regulatory cells (Treg) are involved in the induction of tolerance and prevention of the T helper (Th) response which is responsible for IN development. In the immune response to antigen T-dependent, such as FVIII, the immunological memory is generated via CD19+ CD27+ memory B cells.
Tolerance to FVIII in patients with IN can thus be theoretically obtained by two pathways: increased Treg response and/or CD19+ CD27+ B cell anergy.
Could the characteristics of these two lymphocyte populations be predictive of IN development?
Aims: To evaluate circulating Treg and CD19+ CD27+ cells in HA patients with (HAI) and without (HAnI) history of IN and in a group of healthy volunteer controls (Ctl)
Methods: flow citometry analysis of peripheral blood samples from six HAI, mean age 23y (14–42), 10 HAsI, mean age 18y (2–36) and 14 Ctl, mean age 22y (3–40).
Three HAI were low responders, and three high responders, only one had IN > 5UB at the time the study was performed.
Lymphocytes were gated based on size (FSC) and complexity (SSC). Treg were characterised as CD4+ CD25+ CD127low lymphocytes, and memory B cells as CD19+ CD27+ lymphocytes.
Results: Percentage of CD4+ CD25+ CD127low cells: HAI 8.6 ± 1.1, HAnI 8 ± 1.6 and Ctl 7.6 ± 1.7. CD19+ CD27+ cells: HAI 32.6 ± 19.2, HAnI 26.6 ± 14.3 and Ctl 30.1 ± 10.9. We did not document any statistically significant difference between the three groups studied. The proportion of lymphocytes T and B was similar between the groups.

Conclusion: Given its relevance in the suppression of the antibody-mediated response to substitutive therapy, we would expect a decrease of Treg in the HAI group, which was not observed in this sample.
Treg and CD19+ CD27+ frequency were similar between HAI, HAnI and Ctl groups. We hypothesise the results might be different if all HAI patients had high IN titres at the time of analysis, in keeping with what has been described by other research groups who documented a decrease of circulating CD19+ CD27+ in these patients. In our series, the only patient with IN > 5UB was not significantly different from the HAsi or Ctl. Although the number of patients enrolled is still reduced, our results hint to a lack of predictive value of circulating Treg and CD19+ CD27+ percentage in the development of IN in HA patients

PB 2.44-6

Stop codon readthrough with PTC-124 and gentamycin in hemophilia B caused by nonsense mutations

Chen J[1], Yang L[1], Zhang Y[1], Zhang R[1] and Chai B[2]
[1]*The Second Hospital of Shanxi Medical University;* [2]*Shanxi University, Taiyuan, China*

Background: One of the most important molecular mechanisms in severe hemophilia B, which is caused by the mutations in the factor IX gene, is nonsense mutation, carrying premature termination codon (PTC), which lead to the production of nonfunctional truncated protein. Aminoglycoside antibiotics, such as Gentamycin, could induce readthrough of PTC and increase the production of the protein with nonsense mutation. However, using of high dosage of aminoglycosides for the readthrough therapy, has significant adverse effects including the nephrotoxicity and ototoxicity. PTC-124, a novel and non-toxic chemical compound, could be able to accomplish this task.
Aims: At present, due to lacking of the eradicative therapy, the hemophilia B patients should infusion the expensive blood coagulation factor in their lifetime. So searching for the new drugs has significantly social effects. Through our study, we want to compare the readthrough ability of different concentrations of PTC-124 and Gentamycin in hemophilia B caused by different PTC and provide the basis for the further researches of readthrough therapy.
Methods: The international hemophilia B mutation database was analyzed for finding the hot spots of nonsense mutation sites in FIX gene. The nonsense mutants were constructed by site-directed mutagenesis. Detecting the HEK-293 cells viability after treated with different concentrations of PTC-124 and Gentamycin for 48 h, using CCK-8 (Cell Counting Kit-8). Then, HEK-293 cells were transfected with either the wild-type or mutated constructs by liposome-mediated gene transfer method, then treated with different concentrations of PTC-124 and Gentamycin for 48 h. The mRNA expression levels of FIX gene were detected by real-time PCR. The procoagulant activity (FIX : C) and antigen (FIX : Ag) of FIX in the cell lysate were detected using one stage method and ELISA, respectively.
Results: The hot spots of nonsense mutation sites and our objects in FIX gene were R29X,R116X,W194X,R333X. Except the designed sites, there was no other nucleotide mutations in the sequences of four mutants. The IC50 of PTC124 and Gentamycin in HEK-293 cells were 111.585 ± 9.597 and 4.23 ± 0.32 mM respectively, then select different concentrations of PTC124 and Gentamycin for the readthrough study. Compared with the untreated controls, the mRNA expression levels of FIX gene and the FIX : C and FIX : Ag of FIX in the cell lysate treated with different concentration of PTC124 and Gentamycin were significantly elevated ($P < 0.05$) in those four mutants.
Conclusion: From our data, the PTC124 and gentamycin possessed the similar efficiency of read-through, while with less concentration and toxicity. In hemohilia B, even a small increase in FIX expression level can dramatically ameliorate the clinical phenotype, so the readtrhough approach can be a good therapeutic strategy. Although the aminoglycoside antibiotics, such as Gentamycin, could increase the functional protein prodution, however, these drugs have serious side effects at therapeutically relevant concentrations. PTC124, which is not structurally related to aminoglycosides, could be able to provide a better treatment for hemophilia B caused by nonsense mutation.

PB2.45 – Acquired Coagulation Disorders – III

PB 2.45-1

Hemostasis disorders are indicators of early infectious complications in severe burned

Presniakova M, Kyznetsova V, Borisevich A and Puchenkina E
Nizhny Novgorod Reserch Institute of Traumatology and Orthopedics, Nyzhny Novgorod, Russian Federation

Introduction: Early infectious complications – sepsis and pneumonia developing in acute burn disease are of serious risk for patients with severe heat injury. These complications are characterized by a fulminant, severe course, complex diagnostics, and high case fatality rate. However, the role of hemostasiological disorders in the development of both generalized, and local infections in severe burned is taken into account insufficiently.
Aim: The aim of the investigation was to study the characteristics of hemostasis disorders in the development of purulent-septic complications in acute burn disease.
Methods and Materials: We studied hemostasis state and biochemical measurements of blood in 167 patients with burn area over 20% of body surface, within the period from the 1st to 12th days after burn. In 33 patients acute burn diseases was complicated by sepsis development, in 67 patients – by pneumonia, and 67 patients had no complications in the form of sepsis and pneumonia. The groups under study were balanced in age, damage area and severity. Sepsis and pneumonia were revealed in clinical picture in the period from the 4th to 12th days after burn. DIC syndrome diagnosis was made according to standard criteria: the presence of an etiological factor, hemostasis system imbalance, and dysfunction of shock-organs.
Results: The comparative analysis of findings showed the development of infectious complications in early burn diseases to be preceded by the increase of hemostasis system disregulation. The suppression of endogenous anticoagulants, fibrinolysis depression, and thrombocytopenia were accompanied by the enhancement of procoagulant link of hemostasis system and the decreased functional activity of detoxication organs – the kidneys and the liver. Throughout the study period the hemostasiological indices reflecting the DIC syndrome severity correlated with biochemical blood metabolites indicating hepatorenal failure progression ($r = 0.55–0.85$; $P < 0.05$).
The patients with advanced sepsis and pneumonia had reduced antithrombin III that characterized the functional activity of anticoagulant element, and exhibited prognostic characteristics in terms of poor outcome of burn disease and the development of both generalized ($\chi^2 = 10.6$; df = 2; $P = 0.004$), and local ($\chi^2 = 14.3$; df = 2; $P = 0.0008$) infectious processes. We found the following causes of antithrombin III reduced activity in acute burn disease: elastase inhibition of polymorphonuclear leukocytes on day 1–2 after burn ($r = -0.49$; $P = 0.02$), the use of protein synthesis function of the liver due to blood coagulation activation on day 1–3 ($r = 0.44–0.60$; $P < 0.05$) and the decrease of this function on day 3–12 ($r = 0.34–0.85$; $P < 0.05$).
Retrospective chat analysis of severe burned with verified sepsis and pneumonia showed the changes of hemostasiological indices corresponding to acute DIC syndrome to appear 1–8 days earlier than sepsis and pneumonia manifestations.
Conclusion: 'Early' infectious complications of burn disease develop against the background of profound disorders of hemostasis system corresponding to acute DIC syndrome. Disregulation of hemostasis system is a favourable condition for sepsis and pneumonia, and can be the predictor of their development.

PB 2.45-2

Haemostatic markers predict survival in African patients with burn injuries

Abegunde SO, Abikoye FO and Chira MK
National Orthopaedic Hospital, Lagos, Nigeria

Background: Burn injuries remain a major problem in the developing countries of Africa. They rank among the leading cause of trauma deaths seen in Nigeria due to inadequate health care facilities. Hemorrhage and thrombosis constitute two of the most serious complications of thermal injuries. Significant haemostatic abnormalities can be detected in majority of patients with thermal injuries and these abnormalities underlie the characteristic thrombotic and hemorrhagic diathesis seen in these patients.
Aims: We therefore hypothesized that some molecular markers of coagulation and haemostatic activation may be of clinical predictive relevance in burn patients.
Methods: We studied a total of thirty five patients (mean age 33.7 ± 15. 1; 22 males, 13 females) admitted to the Burns intensive care unit within 24 h of injury and followed up during the period of the first week of burns along with twenty healthy control individuals. Blood was withdrawn on days 1, 2, 3, 5 and 7 or until discharge if < 7 days, and analyzed for hemoglobin (Hb), erythrocyte sedimentation rate (ESR), prothrombin time (PT), activated partial thromboplastin time (APTT), plasma fibrinogen (PFC), and D-dimer (DD) using standard techniques. Clinical variables evaluated include percentage total body surface area burns, percentage full thickness burns, presence or absence of inhalational injury. Results were statistically analyzed using student's t-test and Pearson correlation coefficient. Probability values less or equal to 0.05 were significant.
Results: Showed that there is no significant difference in PT, APTT, PFC and DD in patients with < 5% total body surface area burns compared to controls ($P > 0.05$). However PT, APTT and DD were significantly increased in patients with Burns > 5%, compared to controls ($P < 0.05$), and therefore suggestive of significant hyper coagulation in early phase of burns. There were significant negative correlations between PFC and the percentage of the total body surface area burnt and the percentage of the full thickness burns size. ($r = -0.63$; $r = -0.59$ respectively $P < 0.05$). Severe burns > 45% was associated with a significantly higher frequency of consumptive coagulopathy compared to those with lesser percentage of burns ($P < 0.05$).
Conclusion: PFC may be useful as a marker for predicting survival in burns patients and therefore represent a suitable tool for risk stratification.

PB 2.45-3

Traditional and whole blood coagulative profiles in patients with left ventricle assist devices

Spiezia L[1], Tarzia V[2], Campello E[1], De Franceschi M[1], Bejco J[1], Bortolussi G[1], Vasques F[1], Bottio T[1], Gerosa G[1] and Simioni P[1]
[1]University of Padova, Padova; [2]University of Padua, Padua, Italy

Background: Left ventricle assist devices (LVAD) are increasingly adopted when treating refractory heart failure patients with the indication of either bridge-to-transplant or destination therapy, which is an alternative to cardiac transplantation. According to the flow they produce, LVADs are divided in pulsatile- and continuous-flow devices; the latter – nowadays the most frequently used – are further divided into axial and centrifugal pumps. Antithrombotic prophylaxis is an invaluable mainstay of postoperative LVAD patients' management because of the intrinsic device thrombogenicity and the consequent thromboembolic risk of those patients.
Aims: To compare the impact of two different continuous-flow devices on the traditional and whole blood coagulative profiles: Jarvik 2000, axial flow pump vs. HeartWare HVAD, centrifugal device based on magnetic levitation.
Methods: Data of traditional and whole blood coagulative profiles, and namely thromboelasometric (performed by ROTEM) and aggregometric (performed by Multyplate) evaluations, were reviewed and a comparison between 13 patients with Jarvik 2000 and eight patients supported with HeartWare HVAD was performed.
Results: Platelets count were significantly higher in the HeartWare group than in the Jarvik group (D7 $P = 0.01$; D14 $P < 0.0001$; D21 $P = 0.0002$, D28 $P = 0.003$, D60 $P = 0.002$). Maximum clot firmness (MCF) was significantly higher in the HeartWare group than in the Jarvik group (INTEM: D5 $P = 0.007$, D13 $P = 0.0104$, D21 $P = 0.0004$, D28 $P < 0.0001$; EXTEM: D5 $P = 0.04$, D13 $P = 0.02$, D21 $P < 0.0001$, D28 $P = 0.0001$; FIBTEM: D5 $P = 0.03$, D13 $P = 0.02$, D21 $P = 0.09$). The Area Under the Curve (AUC) was higher in the HeartWare group than in the Jarvik group (TRAPtest: D5 $P = 0.005$, D21 0.04, D28 $P = 0.01$, D13 $P = 0.05$; COLtest D5 $P = 0.004$, D21 $P = 0.01$, D28 $P = 0.02$).
Comparison of the two groups showed significantly higher levels of platelets count, Intem-Extem-Fibtem MCF, TRAP e COL tests in the HeartWare than in the Jarvik group.
Conclusions: Comparison between Jarvik 2000 and HeartWare HVAD proved that the two pumps have almost different effects on coagulative system. Because of the direct implication of ventricular assist devices in the development of acquired von Willebrand syndrome we speculate on the possible different role of each of the two pumps in order to modulate von Willebrand factor plasma levels causing different impairment of the coagulative profile. Larger studies are needed to confirm our findings and to evaluate the possible causative role of von Willebrand factor in the imbalance of coagulation cascade.

PB 2.45-4

Comparison between defects of hemostasis and ROTEM parameters in children with dengue infection

Sosothikul D, Paisan P and Seksarn P
Chulalonkorn University, Bangkok, Thailand

Background: Dengue virus causes a febrile illness, dengue fever (DF), and less frequently a life-threatening illness, dengue hemorrhagic fever (DHF). Bleeding in dengue patients is caused by vasculopathy, thrombocytopenia, platelet dysfunction and coagulopathy.
Aims: To evaluate whether ROTEM, a new global hemostsis analyser, correlate with standard coagulation tests to detect severity of bleeding diathesis in these patients.
Methods: A prospective observational study. Blood was obtained from 70 children: 41children with dengue infection on day 4–6 of the illness (22 with DF,19 with DHF) and 30 age-matched healthy children as controls. Standard coagulation tests and ROTEM parameters were analyzed and compared.
Results: DHF patients had significant higher in PT, aPTT than DF patients but there is no significant difference in fibrinogen level between two groups. DHF patients had a significant longer time in clotting time (CT), clot formation time (CFT) in EXTEM and INTEM than DF patients. In addition, DHF patients had significant lesser maximum clot firmness (MCF) and lower amplitude (A10,A20) than DF patients. We observed a good correlation between platelet count and both INTEM-MCF ($r = 0.82$, $P < 0.001$) and EXTEM-MCF ($r = 0.83$, $P < 0.001$), a moderate correlation between PT and EXTEM-MCF ($r = -0.51$, $P < 0.001$), aPTT and INTEM-MCF ($r = -0.58$, $P < 0.001$) and a weak correlation between fibrinogen and FIBTEM-MCF ($r = 0.34$, $P < 0.001$).
Conclusions: The abnormalities of hemastasis in dengue infection were significant different between disease severity (DF and DHF) as determined by both standard coagulation tests and ROTEM analysis. We also found a strong correlation between platelet count and both INTEM-MCF and EXTEM-MCF.

PB 2.45-5

The ratios of pro to anticoagulant factors: index of hemostatic imbalance in cirrhotic patients

Labidi A, Baccouche H, Mahjoub S, Bssila S, Fekih M, Filai A and Ben Romdhane N

La Rabta University Hospital, Tunis, Tunisia

Background: Patients with liver cirrhosis are characterized by decreased levels of most pro- and anti-coagulant factors. This state result in an unstable balance. Therefore, patients are prone to hemorrhagic and thromboembolic events particularly in advanced stages.
Aim: The aim of this study was to evaluate the ratios of procoagulant to inhibitor coagulation factors in cirrhotic patients according to disease severity.
Methods: A case control study including 51 cirrhotic patients and 51 healthy subjects matched by age and sex was conducted. Patients were stratified according to Child Pugh classification. Procoagulant factor activity (factor VII, II, V, VIII, XII) and inhibitor factor activity: Protein C (STACLOT PC), protein S (STACLOT PS, antithrombin (STACHROM AT) were determined. All tests were performed on STA COMPACT STAGO. Mean value of procoagulant to inhibitor coagulation factor ratios were compared to those in controls and investigated in patients according to Child Pugh classification. Statistical analysis was performed with SPSS software version 19.0.
Results: Mean age was 56.8 years old [range16–86]. Sex ratio was 0.9. Patients were classified in Child Pugh A in 13 patients (25.5%), B in 23 patients (45.1%), C in 15 patients (29.4%). Among ratios, II/PC, V/PC, VII/PC, XII/PC were significantly higher in cirrhotic patients than in controls (respectively, $P = 0.001$, $P = 0.002$, $P = 0.001$, $P = 0.001$) but not between Child Pugh classes. Likewise, VIII/PC, VIII/PS and VIII/AT were significantly higher in cirrhotic patients than in controls ($P < 0.001$) and increased significantly from class A to C ($P < 0.001$), reaching a value of 5. On the other hand, II/PS is lower in cirrhotic patients than in controls showing marginal significance ($P = 0.04$). However, II/PS,V/PS, VII/PS decreased significantly from class A to C.
Conclusion: The ratios of pro- to anti-coagulant factors can be considered as indexes of the coagulation imbalance. This hypothesis was supported by some authors hypothesizing that hypercoagulability was due to high factor VIII combined with low PC. Moreover it should be evaluated in larger studies in cirrhotic patients particularly with thromboembolism events.

PB 2.45-6

Shortened blood coagulation times in two distinct visceral obesity models, WBN/Kob-Lepr(fa) rats and diet-induced obese mice

Asai F, Nagakubo D, Kaji N, Takahashi S, Shirai M and Ito K

Aazabu University, Kanagawa, Japan

Background: Visceral obesity is associated with a high incidence of ischemic heart disease, and many cases are complicated by impaired glucose tolerance, hyperlipidemia, and high blood pressure. The blood coagulation system plays a major role in thrombus formation. However, little is known about the relationship between visceral obesity and blood coagulation.
Aims: The aim of this study was to investigate blood coagulation times in genetically obese rats and diet-induced obese (DIO) mice in order to clarify the relationship between visceral obesity and blood coagulation.
Methods: In this study, we used two distinct obese animal models, genetically obese rats and diet-induced obese mice. In both animal models after body weight had plateaued, blood coagulation times were compared with those of respective control animals. In blood coagulation assays, activated partial prothrombin time (aPTT), prothrombin time (PT), and thrombin time (TT) were measured in citrated plasma. The homeostasis model assessment of insulin resistance (HOMA-IR) was used as an indicator of insulin resistance.
Results: The WBN/Kob-Lepr*fa* (*fa*/*fa*) rat is a new congenic rat created by introducing the Lepr*fa* gene (a mutant gene derived from the Zucker fatty rat) into the WBN/Kob rat. The *fa*/*fa* rats at 10 weeks of age exhibited a significantly ($P < 0.01$) shorter aPTT and PT than age-matched Wistar rats. C57BL/6J mice fed a high-fat diet (60%) for 10 weeks, a DIO model, exhibited significantly ($P < 0.01$) shorter aPTT, PT, and thrombin time than lean mice fed a standard diet. Significantly higher body weight, visceral fat weight, and insulin resistance were also shared by *fa*/*fa* rats and DIO mice.
Summary/Conclusions: These results suggest that visceral obesity is related to accelerated blood coagulation in addition to disrupted metabolism of glucose and lipids. This study showed the existence of accelerated blood coagulation in two distinct visceral obese animal models. To the best of our knowledge, this is the first report on shortened blood coagulation times in *fa*/*fa* rats and DIO mice. In addition to visceral obesity, both models exhibited hyperlipidemia and increased insulin resistance. The *fa*/*fa* rat and DIO mouse can be considered useful obesity models for research on the biomarkers of cardiovascular disease.

PB2.46 – Anticoagulant Agents – VIII

PB 2.46-1

Inhibition of coagulation by the low molecular mass metalloprotease from Indian cobra (Naja naja) venom

Kempaiah K[1], Kumar MS[1] and Girish KS[2]

[1]University of Mysore, Mysore, Mysore; [2]Tumkur University, Tumkur, India

Background: Snake venom metalloproteases (SVMPs) are an interesting class of enzymes known to play key role in snake venom induced pharmacological effects especially, vascular damage and platelet functions. In contrast to P-III class SVMPs which are known for vascular damage causing massive hemorrhage, P-I and P-II class SVMPs are less destructive. SVMPs with fibri(noge)nolytic and platelet aggregation inhibitory properties may serve as therapeutic lead molecules in the management of cardiovascular diseases. In this study, a non-toxic P-I class SVMP which is basic in property that inhibit plasma coagulation and collagen induced platelet aggregation has been isolated and studied from Indian cobra (*Naja naja*) venom.
Aims: To understand the molecular mechanisms of anticoagulant, and antiplatelet properties of the isolated P-I class of SVMP.
Methods: CM-Sephadex C-25 column chromatography, SDS-PAGE, MALDI-TOF mass spectrometry, caseinolytic, plasma re-calcification time, APTT, PT, TCT, fibrinogenolytic, fibrinolytic, fibronectinolytic and collagenolytic activities have been assayed. Preparation of platelet rich and poor plasma, and washed platelets from human and agonists induced platelet aggregation studies have been performed.
Results: In this study a relatively simple and an efficient protocol has been adopted to isolate a low molecular mass metalloprotease which is basic in property from cobra venom. A tandem two step chromatography on a CM-Sephadex C-25 column results in a pure metalloprotease sample that revealed single sharp peak with the molecular mass of 13.87 kD in MALDI-TOF mass spectrometry. Both EDTA and 1,10-phenanthrolene abolished casein, fibrinogen, fibrin, and fibronectin degrading properties and as well as collagen induced aggregation of human washed platelets by the enzyme. The enzyme is devoid of lethality, edema, hemorrhage, dermo- and myonecrosis. Collagens type-I and IV are resistant to proteolytic digestion. But, the enzyme strongly inhibited coagulation of citrated human plasma with a prolonged APTT, PT and TCT responses. It is an α-fibrinogenase with a selective specificity on the Aα-chain of fibrinogen, in addition it hydrolyzed the α-polymer and α-chains of fibrin clot. Of the several agonists

tested, the enzyme specifically inhibited the collagen induced aggregation of human washed platelets with an IC_{50} of 147 ± 10 nM.
Summary/Conclusion: A non-toxic low molecular mass metalloprotease that inhibits plasma coagulation and collagen induced platelet aggregation has been isolated and characterized. Further, studies on the possible mechanisms of inhibition are in progress.

PB 2.46-2

Long-term oral anticoagulant management associated with routine medical care (RMC) in patients with non-valvular atrial fibrillation (NVAF) in Canada

Selby R[1], Mittmann N[2], Isogai P[2], Kaus L[1], Koo M[2] and Sealey F[1]
[1]Sunnybrook Health Sciences Centre; [2]Health Outcomes and PharmacoEconomic (HOPE) Research Centre, Toronto, ON, Canada

Background: There are no prospective, long-term studies describing the process and quality of care (including time in therapeutic range), resource utilization (RU), and quality of life (QoL) associated with being on warfarin for non-valvular atrial fibrillation (NVAF) patients managed through routine medical care (RMC) in Canada.
Methods: Resource utilization associated with Oral Anticoagulant Management (ROAM) is a prospective cohort study conducted across nine Canadian provinces whose objective is to describe the process and quality of care, RU, clinical events and utility scores associated with long-term oral anticoagulant (warfarin) therapy in patients with NVAF. Eligible, consenting patients are followed for 48 weeks and complete a weekly diary providing data on international normalized ratio (INR) test dates and values, RU associated with warfarin monitoring, and all physician visits, procedures and hospitalizations. INR values, test dates and source documentation related to patient-reported clinical events are also collected from the participating physicians. Utility scores, representing the patient's health state, measured using the EuroQol-5D (EQ-5D) standardized QoL instrument are collected every 4 weeks.
Results: Five hundred and fifty-one patients were recruited from April 2008 to July 2012, 92% from RMC (primary care physicians and specialists) and 8% from anticoagulant clinics. Median age [range] was 74 [66, 80] years with 218 females (39.5%). Four hundred eighty-two patients who completed the study and had physician provided INR results are included in this preliminary analysis. Comorbid conditions included hypertension (67%), diabetes (26%) and ischemic heart disease (30%). Physicians reported a total of 6705 INR tests over the study duration (mean ± SD: 15.3 ± 8.3 tests per patient) while patients recorded 7260 tests being completed in their diaries over the same time period (16.8 ± 9.5 tests per patient). Of the patient reported tests 5781 INR results (80%) were communicated to patients, most often by telephone (55%) or in person (21%) within a mean of 1.4 ± 2 days. Average time in therapeutic range (TTR) using the Rosendaal method was 70% using physician reported values and 69% based on patient reported values. Mean INR testing frequency was 28.4 days following an INR in the therapeutic range, 22.9 days following an INR < 2, and 19.3 days, following an INR > 3. The mean baseline [95% CI] utility score was 0.85 [0.84, 0.87]. Mean [95% CI] change in utility scores per 6 months was −0.007 [−0.013, −0.001].
Conclusions: This is the first prospective cohort study of NVAF patients on long-term warfarin therapy being monitored primarily through RMC in Canada. The majority of patients are monitored by telephone with 80% receiving INR results and discrepancies between patient and physician recorded INR test dates. TTR is higher than previously reported for RMC, which may suggest a self-selection bias for better quality physician-patient combinations. Although frequency of testing was appropriate for in-range INRs, the times to testing after out-of-range results appear delayed. Analysis of utility scores showed generally high scores for this community dwelling population, stable over the duration of the study.

PB 2.46-3

Edoxaban, an oral direct factor Xa inhibitor, inhibits tissue-factor induced human platelet aggregation and clot-bound factor Xa *in vitro*

Morishima Y, Honda Y and Kamisato C
Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: Tissue factor-induced platelet aggregation and factor Xa (FXa) bound to clot contribute to the formation and growth of thrombus. Edoxaban is an oral, direct, once-daily and selective FXa inhibitor in late-stage clinical development. Fondaparinux is a parenteral indirect (antithrombin-dependent) FXa inhibitor.
Aims: To determine the effects of edoxaban on human platelet aggregation induced by tissue factor and clot-bound FXa *in vitro* and to compare the effects of edoxaban, a direct FXa inhibitor, with an indirect FXa inhibitor (fondaparinux).
Methods: Citrated human platelet-rich plasma (PRP) from healthy subjects was treated with 3 mM H-Gly-Pro-Arg-Pro-OH AcOH to prevent fibrin polymerization, and spiked with edoxaban or fondaparinux. Human tissue factor (Innovin or RecombiPlasTin) plus 7.5 mM $CaCl_2$ were added to PRP and platelet aggregation was measured with an optical aggregometry. The area under the curve of 5 min-aggregation response was measured. Whole blood clot was formed by incubating human blood with 25 mM $CaCl_2$ for 60 min at 37 °C and washed with ice-cold buffer for four times. The clot was incubated with 0.9 μM prothrombin in the absence or presence of FXa inhibitors for 10 min at 37 °C. For fondaparinux, 2 μM antithrombin was added. The amount of prothrombin fragment F1 + 2 (F1 + 2) was measured with an ELISA. Activity of free FXa was measured using human FXa and its chromogenic substrate S-2222.
Results: Both types of tissue factor (Innovin and RecombiPlasTin) activated human platelets and evoked aggregation. Edoxaban inhibited tissue factor-induced platelet aggregation in a concentration-dependent manner. The IC_{50} values for Innovin and RecombiPlasTin-induced aggregation were 150 and 110 nM, respectively. At 300 nM, edoxaban completely inhibited the aggregation response. Fondaparinux inhibited RecombiPlasTin-induced aggregation with IC_{50} of 9.3 μM, but did not show complete inhibition up to 30 μM. Fondaparinux had no effect on Innovin-induced platelet aggregation. Incubation of clot with prothrombin generated F1 + 2, indicating the activity of FXa in clot. Edoxaban concentration dependently inhibited both free and clot-bound FXa. The IC_{50} values were 2.3 and 8.2 nM, respectively. Fondaparinux inhibited free FXa with IC_{50} of 5.4 nM, but concentrations 40-times higher were required to inhibit clot-bound FXa (IC_{50} = 217 nM).
Conclusions: In this study, edoxaban, a direct FXa inhibitor, was determined to be a more potent inhibitor of tissue factor-induced platelet aggregation and clot-bound FXa than fondaparinux, an indirect FXa inhibitor. We previously reported that edoxaban is superior to fondaparinux in preventing arterial thrombosis (1). The present findings may explain the difference in the effects on arterial thrombosis between these FXa inhibitors and suggest the benefits of direct inhibition of FXa.

1. Fukuda T. et al. Comparison of antithrombotic efficacy between edoxaban, a direct factor Xa inhibitor, and fondaparinux, an indirect factor Xa inhibitor under low and high shear rates. Thromb Haemost. 2011;106:1062–8.

PB 2.46-4

Antithrombotic effect of direct oral anticoagulants as compared to warfarin evaluated experimentally in treated patients

Mendolicchio GL[1], Marchese P[2], Colombo A[1], Lodigiani C[1], Scardino M[1], Ferrari MC[1], Grappiolo G[1], Rota L[1] and Ruggeri ZM[2]
[1]IRCCS Istituto Clinico Humanitas, Rozzano, Milano, Italy; [2]The Scripps Research Institute, La Jolla, CA, USA

Background: Patients undergoing total knee replacement develop deep vein thrombosis if not given thromboprophylaxis; 0.1–1.7% will suffer fatal pulmonary embolism (PE). Oral anti-vitamin K anticoagulants (such as warfarin) are effective for preventing venous thrombosis, but require laboratory monitoring to maintain a therapeutic range as defined with the International Normalized Ratio (INR). New oral anticoagulants directly inhibiting coagulation factor (F) Xa have proven similarly effective and are currently administered in a fixed 'one fits all' dose without laboratory monitoring.
Aims: Our goal was to compare the antithrombotic effect of a FXa inhibitor (rivaroxaban) and warfarin, each administered according to guidelines, measuring platelet aggregation and fibrin deposition in blood perfused over fibrillar collagen type I at two different shear rates.
Methods: Blood containing 0.011 M trisodium citrate was recalcified with 5 mM calcium chloride and perfused over a surface coated with fibrillar collagen type I at the wall shear rate of 300 or 1500/s. Platelets and fibrin were detected in situ through distinct fluorochromes. We tested 10 normal controls, 12 patients treated with warfarin (INR between 1.94 and 2.90) and 10 patients treated with rivaroxaban between 8 and 16 days from the initiation of therapy. The volume of platelet aggregates and fibrin deposited onto collagen was measured from stacks of confocal optical sections separated by 1.5 μm in height. Results are reported here as mean ± standard error of the mean; statistical analysis was performed by one-way analysis of variance.
Results: There was no significant difference in the volume of platelet aggregates formed in blood of normal controls and patients treated with either warfarin or rivaroxaban perfused over collagen at 300 or 1500/s. In contrast, the volume of fibrin formed around and between platelet aggregates was significantly reduced in the warfarin-treated patients both in blood perfused at 300/s (controls: 286749 ± 53104 μm^3; patients: 62105 ± 44282 μm^3; $P < 0.001$) and 1500/s (controls: 231,999 ± 142,998 μm^3; patients: 6724 ± 4131 μm^3; $P < 0.001$). The results in rivaroxaban treated patients were different because the volume of deposited fibrin (215,472 ± 115,956 μm^3) was not significantly different from control in blood perfused at 300/s but was significantly decreased (54,626 ± 66,988 μm^3; $P < 0.001$) in blood perfused at 1500/s. Of note, in warfarin treated patients all individual fibrin volumes were below the lower limit of the normal range; of the rivaroxaban treated patients, 7/10 had normal fibrin volume in blood perfused at the lower shear rate, and 2/10 remained normal even at the higher shear rate.
Summary/Conclusions: Treatment with the direct FXa inhibitor, rivaroxaban, at the dose prescribed according to current guidelines results in a lesser *in vitro* anticoagulant effect than caused by warfarin administration controlled by individual INR testing. The significance of these findings using ex vivo blood perfusion relative to the results of present and future clinical trials remains to be established.

PB 2.46-5

The relationship between anti-Xa activity and complications in orthopaedic patients receiving prophylactic fondaparinux

Matsumoto T[1], Wada H[2], Masahiro H[2], Wakebayashi H[2], Yoshida K[2], Miyamoto N[2], Ohishi K[1], Shimokariya Y[1], Yamada N[2] and Sudo A[2]
[1]Mie University Hospital; [2]Mie University Graduate School of Medicine, Tsu, Japan

Introduction: Preventing the development of deep vein thrombosis (DVT) is clinically important, because pulmonary embolisms (PEs) caused by DVTs are often fatal. Orthopaedic surgery is associated with a very high rate of postoperative venous thromboembolism (VTE). The thromboprophylaxis by fondaparinux is useful in patients after orthopaedic surgery. This study evaluated anti-Xa activity and hemostatic markers in patients who underwent major orthopaedic surgery, and were treated for the prophylaxis of deep vein thrombosis (DVT) with fondaparinux to examine the relationship between anti-Xa activity and DVT or decrease of haemoglobin (Hb).
Methods: The relationship between anti-Xa activity and complications was examined in 176 patients with major orthopaedic surgery treated with 1.5 mg of fondaparinux once a day for 14 days. One hundred forty-two patients were treated with Fondaparinux for 14 days (complete administration; CA group) but 34 patients discontinued prophylaxis due to low Hb level by physician in charge (withdrawal group). All patients also were intermittent pneumatic compression stockings from the day of surgery until postoperative day 2, and they also wore graduated compression stockings continuously. Anti-Xa activity, fibrin and fibrinogen degradation products (FDP), D-dimer, soluble fibrin (SF) and AT activity were measured in 176 patients after THA or TKA before, and on day 1, day 4, day 8, and day 15 of the administration of fondaparinux. The decrease of Hb was calculated from the value obtained on day 1 to the lowest value obtained during 14 days.
Results: The frequency of deep vein thrombosis DVT and Hb decrease were significantly higher in the withdrawal group. The frequency of DVT tended to be higher in the group treated with < 0.2 mg/L of anti-Xa activity and the frequency of > 2 g/dL of Hb decrease was significantly higher in the group with > 0.4 mg/L of anti-Xa activity on day 1. The weight, body mass index and body surface index were the highest in the group with 0–0.2 mg/L of anti-Xa activity, and the Hb decreasing was the highest in the group with > 0.4 mg/L of anti-Xa activity.
Conclusion: The continuous administration of fondaparinux is recommended after major orthopaedic surgery, and anti-Xa activity should be controlled < 0.4 mg/L on day 1.

PB 2.46-6

Association of warfarin therapy after prosthetic heart valve replacement with risk of thromboembolic complications, bleeding and mortality

Murasaki KM, Shimatani Y, Murasaki KM, Uetsuka Y and Nobuhisa H
Tokyo Women's Medical University, Tokyo, Japan

Background: Bioprosthetic valves are more commonly used because many of these patients are elderly and/or have comorbid conditions that render them at increased risk of bleeding with the prolonged anticoagulation therapy that would be required with implantation of a mechanical valve.
Especially in patients with hemodialysis, long-term anticoagulant therapy thought to be controversial for the patients with atrial fibrillation (AF) alone. If these patients have bioprosthetic valve, this may be more complex and difficult problem because with the limited evidence to date based on limited data, the trade-off between reduced thromboembolic events with warfarin and increased bleeding remains uncertain.

Aims: To clarify the association of warfarin treatment with the risk of thromboembolic events (TEs), bleeding events (BEs), and cardiovascular deaths after heart valve replacement surgery in patients with hemodialysis.
Methods: Between January 1, 2004, and May 31, 2011, total number of patients having heart valve replacement in this institute was 501 patients. Of these patients, hemodialysis patients were identified 33 patients. Target PT-INR was set 1.5–2.5 according to Japanese guidelines for high risk of bleeding.
Primary events studied included strokes, thromboembolic events, cardiovascular deaths, bleeding events and all cause of death. Valve types, valve position, ejection fraction, atrial fibrillation, other comorbid disease and risk factors for thromboembolism and bleeding were also evaluated.
Results: Two people were excluded because of perioperative death. Patients were followed up for a mean of 2.2 years. A total of 14 patients were continuing on warfarin (group A) treatment after surgery. TTR of this group was 80.9% throughout study periods.
Seventeen patients discontinued warfarin treatment (group B) at the first 3 month after surgery. Baseline characteristics were not different from two groups. There were nine TEs, nine BEs and seven deaths (cardiovascular death 3)
There was no thromboembolic event in group A. On the other hand, group B have nine TEs (Ischemic stroke 4, Myocardial Infarction 4). However, there was no significant increase of BEs (Group A 4cases, Group B five cases, $P = 0.959$) between both groups. All cause of death and cardiovascular death were also no significant difference between two groups
Conclusion: In this well-controlled and low anticoagulant intensity, valve replacement patients with hemodialysis have similar risk for BEs despite warfarin therapy, but have significantly increased risk of TEs without warfarin therapy. Close and careful anticoagulant control is useful for those hemodialysis patients with heart valve replacement.

PB 2.47-1

Biochemical and pharmacological differentiation of dabigatran, apixaban and rivaroxaban

Fareed J, Syed D, Kahn D, Jeske W, Escalante V, Iqbal O, Hoppensteadt D, Cunanan J and Walenga JM
Loyola University Medical Center, Maywood, IL, USA

Introduction: New oral anticoagulants represent synthetic low molecular weight (< 500 daltons) peptidomimetic inhibitors of thrombin and factor-Xa. To date, limited data to compare the active form of dabigatran with apixaban and rivaroxaban in biochemical and pharmacological studies is available. The purpose of this study is to compare the three drugs in various biochemical and pharmacological studies to establish differences, which may predict their safety and efficacy profile in different indications.
Materials and Methods: The active form of dabigatran was purchased from Selleckcham (Houston, TX). Apixaban and rivaroxaban were obtained commercially and were of synthetic origin. The whole blood anticoagulant activities of these agents were measured using celite ACT by supplementing in native human whole blood (n = 10–12) at a concentration of 1 μg/mL. The TEG profile was also determined at concentrations < 250 ng/mL. The anticoagulant studies were carried out at a range 0–2.5 μg/mL utilizing various aPTT, PT, Heptest and PICT test. Thromboplastin induced thrombin generation was measured using a fluorimetric method (Technoclone Austria) in a concentration range of 0-1 μg/mL in PPP and PCCs. Proteomic analysis of thromboplastin activated PCCs and its inhibition by the three agents was also studied, followed by western blotting analysis to characterize cleavage products. Platelet aggregation studies were carried out in human PRP (n = 15–20) using ADP, epinephrine, collagen, arachidonic acid and 2.5U thrombin reagent. The bleeding profile of each agent was measured in a modified rat-tail bleeding time.
Results: In the ACT studies at 1 μg/mL, dabigatran produced significantly higher anticoagulant effects (306 ± 16) vs. saline (124 ± 6), in contrast to apixaban (142 ± 5) and rivaroxaban (149 ± 6.8). In the TEG analysis, dabigatran produced marked alterations of such TEG parameters as r-time, k-time, ma and angle in contrast to both rivaroxaban and apixaban, which exhibited weaker effects. In the PT, aPTT, and Heptest, dabigatran produced relatively stronger anticoagulant effects in comparison to rivaroxaban and apixaban. In the PICT test, dabigatran produced relatively stronger anticoagulant effects, whereas, rivaroxaban exhibited somewhat weaker effects and apixaban showed the weakest effects. In PPP, dabigatran produced stronger thrombin generation inhibition (IC-50 = 0.19–0.23 μg/mL) in comparison to apixaban (IC-50 = 0.22–0.39 μg/mL) and rivaroxaban (IC-50 = 0.43–0.90 μg/mL); however, in the PCCs (Octaplex and Beriplex), dabigatran (IC-50 = 0.41–1.12 μg/mL), apixaban (IC-50 = 0.05–0.06 μg/mL) and Rivaroxaban (IC-50 = 0.05–0.06 μg/mL). In the proteomic analysis in PCCs, while both apixaban and rivaroxaban inhibited the generation of thrombin as evident by the absence of 36 kDa peak, dabigatran did not inhibit the generation of the 36 kDa peak. All agents did not have any effect on agonist induced platelet aggregation, except dabigatran, which inhibited thrombin induced platelet aggregation. In the rat-tail bleeding studies, at 100 μg/mL, dabigatran produced the strongest effects (32 ± 6 min) followed by rivaroxaban (21 ± 4 min) followed by apixaban (7 ± 2 min).
Conclusions: These studies demonstrate that the oral anti-Xa and IIa inhibitors not only inhibit their target enzymes but produce their anticoagulant, anti-protease and thrombin generation inhibition effects by multiple mechanisms. The inhibitory profile of each agent exhibited a different spectrum and is matrix dependent. Dabigatran appears to produce stronger anticoagulant effects in comparison to rivaroxaban and apixaban. Differences in thrombin generation inhibitory profiles among these agents were also noted.

PB 2.47-2

Bone density in patients with VTE treated with VKA. Follow-up of 25 patients over 10 years

Hajduk B, Wawrzynska L, Kuca PJ and Tomkowski WZ
The National Tuberculosis and Lung Diseases Research Institute, Warsaw, Poland

Background: There are still areas of uncertainty as regards the correlation between reduction in bone density and long-term anticoagulant prophylaxis with vitamin K antagonists (VKA).
Aims: To estimate the reduction in bone mineral density (BMD) in venous thromboembolism (VTE) patients anticoagulated long-term with VKA and receiving or not osteoporosis prophylaxis (OP).
Methods: In the period from 1998 to 2011 25 VTE patients were permanently treated with VKA. (INR target = 2.5). Among them nine patients received additionally OP (OP included Alfacalcidol 0.25 μg and Calcium Carbonate 1500 mg daily). During follow-up in every patient there was assessed three times BMD – at the beginning of the study and after 5 and 10 years of observation. Two different bones (femoral neck and lumbar spine 2–4) were studied.
Results: In 15 patients without OP after 5 and 10 years the mean reduction in femoral neck BMD was 0.087 g/cm^2 (min. −0.008 g/cm^2, max. 0.212 g/cm^2, median 0.093, SD 0.066) and 0.217 g/cm^2 (min. 0.048 g/cm^2, max. 0.437 g/cm^2, median 0.207, SD 0.106) respectively. The reduction in lumbar spine BMD after 5 and 10 years was 0.060 g/cm^2 (min. −0.205 g/cm^2, max. 0.391 g/cm^2, median 0.047, SD 0.141) and 0.205 g/cm^2 (min. 0.003 g/cm^2, max. 0.539 g/cm^2, median 0.190, SD 0.125) respectively. In nine patients with OP after 5 and 10 years the mean reduction in femoral neck BMD was 0.060 g/cm^2 (min. −0.091 g/cm^2, max. 0.232 g/cm^2, median 0.503, SD 0.102) and 0.122 g/cm^2 (min. −0.133 g/cm^2, max. 0.402 g/cm^2, median 0.148, SD 0.167) respectively. The reduction in lumbar spine BMD after 5 and

10 years was 0.056 g/cm^2 (min. −0.190 g/cm^2, max. 0.381 g/cm^2, median 0.075, SD 0.154) and 0.092 g/cm^2 (min. −0.181 g/cm^2, max. 0.239 g/cm^2, median 0.144, SD 0.136) respectively.
Conclusions: In VTE patients treated with VKA without OP the reduction in BMD was noted earlier and was more profound (especially between 5 and 10 years of observation) in comparison with those with OP.

PB 2.47-3
Effect of Dabigatran and Rivaroxiban on thrombomodulin mediated activation of protein C and thrombin activated fibrinolysis inhibitor (TAFI)

Hoppensteadt D, Cunanan J, Lewis B and Fareed J
Loyola University Medical Center, Maywood, IL, USA

Introduction: The new oral anticoagulant agents Dabigatran and Rivaroxiban target thrombin and factor Xa to mediate their anticoagulant effects perspectively. This study was designed to investigate the effects of active form Dabigatran and Rivaroxiban on the activation process of protein C and TAFI by thrombin-thrombomodulin complex.
Materials and Methods: The active form of Dabigatran was synthesized. While Rivaroxiban was extracted from commercially available tablets. Both agents were dissolved in appropriate solution matrices at a stock concentration of 100 μg/mL. Thrombin-thrombomodulin mediated activation of protein C and TAFI were measured using specific chromogenic substrate based methods at a concentration of 0–10 μg/mL in different matrices. The activation of Protein C and TAFI was laso measured using mass spectrometric and immunoblotting methods.
Results: Dabigatran produced a strong inhibition of the generation of both the activated protein C and TAFI (IC_{50} < 1.0 μg/mL) whereas Rivaroxiban did not produce any inhibition of the activation of either of these proteases. Dabigatran also inhibited the amidolytic actions of thrombin-thrombomodulin complex whereas Rivaroxiban did not produce any effect. Neither Dabigatran nor Rivaroxiban produced a direct inhibition of activated protein C or TAFI at concentrations of up to 10 μg/mL. Mass spectrometric and immunoblotting methods showed that Dabigatran blocked the activation of both TAFI and Activation C by thrombin-thrombomodulin complex.
Conclusions: The persistant inhibition of thrombin and its regulatory effects by Dabigatran may differentiate its pharmacologic profile from Rivaroxiban. Since thrombin plays several regulatory functions, its persistent inhibition may compromise hemostatic regulation. The observed adverse events such as the reported myocardial infarction signal may be related to the indiscriminate inhibition of thrombin.

PB 2.47-4
Are global hemostasis assays superior to prothrombin time (INR) for the assessment of hemostatic correction after warfarin withdrawal before invasive procedures?

Mavri A, Vene N, Ostasevski-Fernandez N, Vucnik M and Segnar M
University Medical Centre, Ljubljana, Slovenia

Background: In patients on chronic warfarin therapy who require invasive procedures (e.g. endoscopy, biopsy, major surgery etc.), warfarin is temporarily withdrawn. For monitoring of hemostatic correction after warfarin withdrawal prothrombin time (INR) is currently the test of choice, although there is only a weak association between INR and bleeding after these procedures.
Aim: To establish whether global hemostasis assays are superior to INR for establishing the risk of bleeding after invasive procedures.
Methods: Forty-two patients (68 ± 12 years, 12 women) were included after informed consent was obtained and followed for 30 days after the invasive procedure. The study was approved by the Slovene Ethics Committee. INR, thrombin generation (Technothrombin®), overall hemostasis potential (OHP), overall coagulation potential (OCP) and overall fibrinolytic potential (OFP) were determined in venous blood obtained during warfarin treatment and after warfarin withdrawal on the day of invasive procedure.
Results: During warfarin treatment median INR value of 2.5 (2.1–2.8) decreased to 1.3 (1.2–1.4, both values inter-quartile range) on the day of the procedure. Comparing values during warfarin treatment with values after warfarin withdrawal enhanced thrombin generation was observed (lag time: 19.2 vs. 14.0 min, $P < 0.001$; peak thrombin: 73.0 vs. 182.0 nM, $P < 0.001$; time to peak: 23.7 vs. 18.5 min, $P < 0.001$; endogenous thrombin potential: 955.5 nM × min vs. 2163.4, nM x min, $P < 0.001$, respectively) and global hemostasis was increased (OHP: 17.4 Abs-sum vs. 21.9 Abs-sum, $P = 0.002$; OCP: 23.2 Abs-sum vs. 26.2 Abs-sum, $P = 0.002$; OFP 22.7% vs. 17.9%, $P < 0.001$, respectively, all values medians).
During warfarin treatment INR values negatively correlated with endogenous thrombin potential ($R = -0.38$, $P < 0.5$), but no association was observed between INR and OHP, OCP or OFP. On the other hand significant associations were observed between thrombin generation variables (lag time: $R = 0.55$, $P < 0.001$; peak thrombin: $R = 0.44$, $P < 0.01$; time to peak: $R = 0.58$, $P < 0.001$; endogenous thrombin potential: $R = 0.35$, $P < 0.05$), OHP ($R = 0.27$, $P = 0.09$), OCP ($R = 0.62$, $P < 0.001$), and OFP ($R = 0.47$, $P < 0.01$) determined during warfarin treatment with those determined after warfarin withdrawal.
Eight out of 42 patients (19%) suffered one major (after prostatectomy) and seven minor bleedings (after colon dilatation, colonoscopy, revision after prostatectomy, prostate biopsy, coronary bypass surgery) in the follow-up. Patients who bled did not differ significantly from patients with no bleeding in any of the measured variables.
Conclusions: Global hemostasis assays were not superior to prothrombin time (INR) for the assessment of hemostatic correction after warfarin withdrawal, since with these assays we were not able to differentiate between patients who bled after invasive procedure from those who did not. The most important predictors of haemostatic profile in an individual patient after warfarin withdrawal were her/his parameters during warfarin treatment.
The study was supported by the Slovenian Research Agency, Grant no. J3-2128.

PB 2.47-5
Off-label use of recombinant factor VIIa: results from a 10-year university hospital study

Khleif A[1], Chong K[2] and Escobar MA[1]
[1]Gulf States Hemophilia and Thrombophilia Center; [2]Memorial Hermann Hospital, Texas Medical Center, Houston, TX, USA

Background: Recombinant factor VIIa (rFVIIa; NovoSeven, Novo Nordisk, Denmark) was first approved for use by the Food and Drug Administration roughly 15 years ago to treat patients with congenital or acquired hemophilia and inhibitors. Despite concerns regarding the effectiveness and safety of its off-license indications, rFVIIa has increasingly been used to prevent and treat excessive bleeding due to trauma and/or surgery in clinical settings.
Aims: The primary objectives of this study were to examine off-label rFVIIa use in non-hemophilic patients by ordering service, dose, and patient survival. Survival was determined by the patient's discharge status either to their home, or transfer to an outside facility including a nursing home, long-term care facility or hospice.
Methods: We performed a retrospective evaluation among patients who received rFVIIa and were admitted to Memorial Hermann Hospital – Texas Medical Center (MHH-TMC) between August 2002 and December 2012. The Medication Use Evaluation (MUE) was utilized to track rFVIIa use, and all data for this study were obtained from clinical pharmacy records. Administration of rFVIIa was based on a stringent protocol and required approval by the attending hematolo-

gist as well as clinical pharmacist. Recombinant FVIIa was only utilized as an adjunct therapy to standard of care procedures and conventional methods of hemostasis were used prior to rFVIIa consideration, which included the use of blood products, surgical therapy, topical hemostatic agents, and/or interventional radiology. Patients were eligible to receive the drug based on the following criteria: (i) the patient had received at least 10 units of packed red blood cells and fresh frozen plasma, (ii) the patient had a fibrinogen level > 200 mg/dL, and (iii) the patient had a platelet count > 50,000/mm^3.

Results: During the 10-year study period, a total of 889 patients received off-label rFVIIa at MHH-TMC. Between 2002 and 2007, there was greater than a five-fold increase in the number of patients receiving rFVIIa for off-label indications, after which utilization was consistently steady. Cardiovascular surgery (n = 212) was the most frequent context for use of rFVIIa followed by trauma (n = 169), pediatric services (n = 117) and neurosurgery (n = 117), and neurology (n = 102). Doses ranged from 20 to 90 μg/kg of body weight (each patient received an average of 4000 μg per dose) with an average of 1.2 doses given per patient, which is well below the allowable two doses allotted by the protocol. Roughly 56% of patients receiving off-label rFVIIa were discharged from the hospital during the reporting period. In addition, the ratio of off-label to label use of rFVIIa at MHH-TMC was 87% and 13%, compared with the national ratio of 97% and 3%.

Conclusions: Recombinant FVIIa continues to be used for off-license indications in hospital settings with varying patient outcomes. Further research regarding the efficacy and safety associated with the drug's off-label use is necessary.

PB 2.47-6

Measurement of dabigatran and rivaroxaban in primary prevention of venous thromboembolism in 106 patients, who have undergone major orthopedic surgery. An observational study

Samama MM[1], Guinet C[1], Le Flem L[1] and Debue J-M[2]

[1]Biomnis Laboratory, Ivry-sur-Seine; [2]Clinique des Maussins, Paris, France

Background: No routine coagulation laboratory test is recommended during rivaroxaban or dabigatran treatment. However measuring drug concentration and/or anticoagulant activity can be helpful in some special clinical settings, such as bleeding, thrombosis recurrence, reversal monitoring or emergency surgery.

Aims: The effects of dabigatran etexilate and rivaroxaban on various coagulation assays have been previously studied in normal plasma spiked with increasing concentrations of the drug. In contrast, few data are available in routinely treated patients. In order to perform and to interpretate the results of these tests, it is necessary to determine the usual responses of patient's plasma.

Methods: We have used several coagulation tests in a prospective study including 106 patients receiving thromboprophylactic treatment with dabigatran 150 or 220 mg od and rivaroxaban 10 mg od for major orthopaedic surgery. The most common tests – prothrombin time (PT) and activated partial thromboplastin time (aPTT) – give results, which vary according to the reagent used. To overcome this limitation, we advocate the use of plasma calibrators, which suppresses the inter-laboratory heterogeneity of results. Anti-Xa measurement and Hemo-Clot, a thrombin diluted clotting assay, are specific assays which have been proposed for rivaroxaban and dabigatran respectively. These tests, conventional PT, aPTT and thrombin generation (TG) have been performed.

Results: We demonstrated that measurements of both drugs can determine reliably the drug concentration in patients' plasmas. PT is more prolonged with rivaroxaban than with dabigatran. Interestingly, the pattern of TG was clearly different in relation to the difference in the mechanism of action of the two new anticoagulants.

Conclusion: A significant inter-individual variability of response is demonstrated. The mean Cmax of rivaroxaban is 140 ng/mL (extremes 0–412). This result is in good correlation with the previous French similar study (Freyburger G. et al. 2011) showing the feasibility of this measurement. Rivaroxaban induces a greater increase of PT than dabigatran. aPTT is sensitive to dabigatran. Rivaroxaban concentrations were in good agreement with two other studies while unexplained lower concentrations than expected were found in dabigatran patients receiving 220 mg once a day [mean Cmax 60 ng/mL (extremes 0–320)]. An interference by pantoprazole, which was given to each patient and which reduces dabigatran absorption, could explain the observed lower than expected results. A complementary study is in progress to confirm this hypothesis.

PB2.48 – Anticoagulant Agents – X

PB 2.48-1

Ambulatory treatment of venous thrombosis in patients older than 85 years

Štalc M, Vizintin-Cuderman T and Kovac A

University Medical Centre, Ljubljana, Ljubljana, Slovenia

Background: Incidence of venous thrombosis (VT) increases markedly with age. Treatment of VT in very old patients presents unique problems related to aging such as renal insufficiency, low body weight and numerous co-morbid conditions. Age is also an independent risk factor for major bleeding during anticoagulant therapy. Since elderly patients are often excluded from clinical trials, treatment regimens based on results from clinical trials might not be suitable for very old patients with VT. Furthermore, data on outpatient management and outcome in very old patients treated for VT is scarce.

Aim: The aim of our study was to analyse clinical characteristics and outcomes of patients with VT who were older than 85 years and were treated in outpatient ambulatory setting.

Methods: In the retrospective study, data of consecutive patients treated for VT at our centre from January 2010 to December 2012 were analysed. Only patients aged ≥ 85 years were included in further analysis. Clinical characteristics and outcome (bleeding, VT recurrence and death) within 30 days of therapy were identified by manually reviewing the patients' records. Also, the patients and/or their caregivers were contacted by telephone. Categorical data were compared using c^2 test.

Results: Among 1100 patients with objectively confirmed VT of lower legs, 102 (9.3%) patients were older than 85 years. Ninety-five (93.1%) were eligible for ambulatory treatment (mean age 88.7 (85.1–97.9) years, 71.6% women, 96.8% proximal VT, 82.1% first event). 40.0% of ambulatory treated patients were residents of nursing homes and 44.2% had chronic kidney disease or heart failure. On average, the number of concomitant drugs in these patients was 5.3. VT was provoked in 58% of patients, the most common risk factor being poor mobility (32%) followed by cancer (15.8%). The latter was newly diagnosed in 14/15 patients. All cancer patients were treated with low molecular weight heparin (LMWH). Non-cancer patients were initially treated with once daily LWMH followed by warfarin (INR 2–3). Average time to therapeutic INR was 8.8 days. Self-injection of LMWH was performed in 42% of patients. At 30 days, major non-fatal bleeding events were registered in three (3.2%) patients (two gastrointestinal, one haematoma in abdominal wall). There were two (2.1%) recurrences of VT, both in patients on warfarin at INR values in therapeutic range. Two (2.1%) patients died; one from cancer, for the other the cause of death could not be established. Among several variables we examined for possible association with adverse outcomes (self-injection of LMWH vs. injection by professional, kidney disease or heart failure, warfarin vs. LMWH, nursing home vs. home treatment), none proved statistically significant.

Summary: The incidence of major bleeding in our patients exceeds the incidence of VTE recurrence, but neither incidence is higher than those

already reported in a cohort of patients older than 65 years. Therefore, even in very old patients with several concomitant diseases treatment of VT on outpatient basis seems safe and reasonable.

PB 2.48-2

Self-reported adherence with warfarin and new oral anticoagulants in patients on chronic oral anticoagulant therapy

Carrier M[1], Van der Salm K[2], Wells PS[1], Rodriguez RA[1], Duchesnes L[3] and Erkens PGM[2]

[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Maastricht University, Maastricht, The Netherlands; [3]Ottawa Heart Institute, Ottawa, ON, Canada

Background: Non-adherence to prescribed medications is a common clinical problem among patients with chronic conditions. The efficacy and safety of anticoagulation therapy might be significantly decreased in patients with poor adherence. Recently approved new oral anticoagulants (NOAC) have a shorter half-life compared to vitamin-K antagonists (VKA) and therefore there are theoretical concerns that patients with non-adherence on NOACs might be at higher risk of adverse events (recurrent venous thromboembolism or stroke/systemic embolism). Furthermore, poor dose timing (i.e. delay between the time taking during the day) might also be a concern among patients taking NOACs, especially if taken once daily. Self-reported adherence of patients on anticoagulant therapy (warfarin and NOACs) is seldom in the literature.

Aims: To assess the self-reported adherence of patients on oral anticoagulant therapy and compare adherence between patients on VKA and NOAC (rivaroxaban and dabigatran).

Methods: A cross-sectional study, of consecutive patients followed at our oral anticoagulants clinic was performed. All patients completed an anonymous survey (22 questions) including the 4-item Morisky score to assess self-reported adherence. The Morisky score has been previously validated to assess non-adherence and its reliability is high (Chronbach alpha 0.61). Non-adherence was defined as patients with one or more positive answers to one of the four questions from the Morisky score. Timing adherence and a preference towards reminders were also investigated.

Results: A total of 273 patients on anticoagulant therapy that completed the survey. The median age was 72 (range 19–92). Fifty one (18.7%) patients were using NOAC (13.6% rivaroxaban and 5.1% dabigatran). Non-adherence was reported by 40.5% (95% CI: 34.0–47.3%) of patients in the VKA group and 43.1% (95% CI: 29.3–57.8%) of patients in the NOAC group (38.4% and 53.8% for rivaroxaban and dabigatran respectively). Dose timing adherences were 90% for both groups (90.2% for NOAC and 93.2% for VKA group). Finally, 25.8% of the total patients agreed that a regular reminder would be beneficial. The preference for frequency was either weekly or daily and e-mail was the most popular reminder tool.

Summary/Conclusions: Rates of non-adherence to anticoagulants are high among patients requiring long-term anticoagulotherapy. There are no major differences in self-reported rates of adherence between VKA and NOAC. Given the short half-life of NOACs, future trials evaluating the risk of arterial or venous events in patients without adequate adherence are needed.

PB 2.48-3

Non-clinical safety and efficacy of prothrombin complex concentrates (PCC) for the reversal of dabigatran mediated anticoagulation

Herzog E[1], Kaspereit F[1], Krege W[1], Van Joanne R[2], Dickneite G[1] and Pragst I[1]

[1]CSL Behring GmbH, Marburg; [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Background: Prothrombin complex concentrates (PCC) have been successfully used for the acute treatment and perioperative prophylaxis of bleeding in acquired deficiency of the prothrombin complex coagulation factors in case of vitamin K antagonist overdose. Recently, PCC mediated reversal of bleeding could also been shown following treatment of rabbits with high doses of the direct thrombin inhibitor dabigatran [Pragst et al., 2012].

Aims: It was the aim of the present study to evaluate the potential procoagulant risk associated with the use of PCC for anticoagulation reversal.

Methods: Rabbits were anesthetized and an arterial-venous shunt (AV-shunt) was created by connecting the right jugular vein and left carotid artery via a catheter both jointed by a glass body. An ear artery catheter served to monitor hemodynamic, coagulation and hematological parameters. Following baseline measurements, animals received an intravenous (IV) loading dose (t = 0 min) followed by a continuous IV infusion of dabigatran (BIBR-953), the active metabolite of dabigatran etexilate (Boehringer Ingelheim, Germany) via the ear vein (t = 1–90 min) to maintain stable plasma levels exceeding clinically relevant doses. At 5 min prior to opening of the AV-shunt, PCC (Beriplex P/N, CSL Behring) was administered (t = 15 min). The AV-shunt was temporarily opened, and blood flow, thrombotic occlusion time and thrombus wet weight determined over 30 min (t = 20–50 min). Afterwards, anticoagulation-induced bleeding and reversal was assessed following a standardized kidney injury. Total blood loss and time to hemostasis were monitored over a 30 min observation period (t = 60–90 min). Furthermore, blood samples were collected to determine thrombin inhibition levels (HTI assay), thrombin generation (TGA), prothrombin time (PT), D-Dimers, thrombin-antithrombin (TAT) complexes and F1 + F2 fragments. Finally, kidney, heart, lung and brain tissue were prepared for histopathological evaluation with special focus on possible procoagulant changes.

Results: Dabigatran anticoagulation was observed following loading doses of ≥ 75 μg/kg as indicated by reduced incidence of thrombotic occlusion, increased thrombotic occlusion time and reduced thrombus wet weight after opening of the AV-shunt. At doses ≥ 200 μg/kg, even the addition of PCC at high doses of 300 U/kg could not fully reverse dabigatran induced anticoagulation within the AV-shunt model. At the same dabigatran doses (≥ 200 μg/kg), marked bleeding signals were obtained following kidney incision compared to control, which were reversed dose-dependently by IV infusion of PCC. Treatment with 300 U/kg of PCC resulted in the formation of lung thrombi (grade 1 = minimal). However, the incidence of lung thrombi was reduced dose-dependently with increasing plasma levels of dabigatran measured.

Summary/Conclusion: Overall, the study confirmed the effective reversal of dabigatran induced bleeding by PCC while maintaining dabigatran's expected anticoagulant effects. Furthermore, the potential procoagulant effects of high dose PCC could be markedly reduced or even completely inhibited in the presence of dabigatran.

PB 2.48-4

Rivaroxaban for the treatment of symptomatic deep vein thrombosis and/or pulmonary embolism in Chinese patients: a subgroup analysis of the EINSTEIN DVT and PE studies

Wang Y[1], Wang C[2], Chen Z[3], Zhang J[4], Liu Z[5], Jin B[6], Ying K[7], Shao Y[8] and Meng IL[9]

[1]Zhongshan Hospital, Shanghai; [2]Beijing Institute of Respiratory Medicine Beijing Chaoyang Hospital, Beijing; [3]Beijing Chaoyang Hospital, Beijing; [4]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai; [5]Cardiovascular Insititute & Fuwai Hospital, Fuwai; [6]Huazhong University of Science and Technology, Huazhong; [7]Sir Run Run Shaw Hospital Affiliated with School of Medicine, Zhejiang, China; [8]The 2nd Affiliated Hospital of Harbin Medical University, The Netherlands; [9]Bayer HealthCare, Berlin, Germany

Background: The worldwide EINSTEIN DVT and EINSTEIN PE phase III programme included 8282 patients with acute symptomatic deep vein thrombosis (DVT) and/or pulmonary embolism (PE) and showed that a single-drug approach with fixed-dose rivaroxaban, an oral Factor Xa inhibitor, was as effective as dual-drug combination therapy with enoxaparin, overlapping with and followed by international normalized ratio-guided vitamin K antagonist (VKA) therapy, in reducing the risk of symptomatic recurrent venous thromboembolism (VTE). In a pooled analysis of these studies, rivaroxaban was also associated with a significant reduction in the occurrence of major bleeding ($P = 0.002$). The EINSTEIN programme is the first time that Chinese hospitals have participated in a worldwide programme for the treatment of DVT and PE.

Aim: To assess the efficacy and safety profile of rivaroxaban for the treatment of VTE in a subgroup of patients from China.

Methods: A total of 439 Chinese patients who had acute symptomatic DVT ($n = 211$), or PE with or without DVT ($n = 228$), were randomized to receive rivaroxaban (15 mg twice daily for 3 weeks, followed by 20 mg once daily) or standard therapy with enoxaparin (1 mg/kg twice daily) overlapping with and followed by an adjusted-dose VKA for 3, 6 or 12 months. The primary efficacy outcome was symptomatic recurrent VTE. The principal safety outcome was major or non-major clinically relevant bleeding. Major bleeding was a prespecified secondary outcome.

Results: The primary efficacy outcome occurred in 7 (3.2%) of 220 patients in the rivaroxaban group and in 7 (3.2%) of 219 patients in the enoxaparin/VKA group (hazard ratio, 1.04; 95% confidence interval, 0.36–3.0; $P = 0.94$). The principal safety outcome occurred in 13 (5.9%) of 219 patients in the rivaroxaban group and in 20 (9.2%) of 218 patients in the enoxaparin/VKA group (hazard ratio, 0.63; 95% confidence interval, 0.31–1.26; $P = 0.19$). No major bleeding was seen in patients receiving rivaroxaban, while major bleeding was observed in 5 (2.3%) patients receiving enoxaparin/VKA therapy. In frail patients (defined as age > 75 years and/or creatinine clearance < 50 mL/min and/or body weight ≤ 50 kg), major or non-major clinically relevant bleeding occurred in 4 (8.9%) of 45 patients receiving rivaroxaban compared with 7 (15.2%) of 46 patients receiving enoxaparin/VKA therapy.

Summary/Conclusions: In Chinese patients with acute symptomatic DVT and/or PE, rivaroxaban appeared to be as efficacious as standard enoxaparin/VKA therapy. Consistent with the results in the overall analysis, Chinese patients who received rivaroxaban were observed to have fewer major bleeding events than Chinese patients who received enoxaparin/VKA. The results obtained with rivaroxaban in Chinese patients are consistent with those seen in the larger worldwide programme.

PB 2.48-5

Comparison of use of prothrombin complex concentrates vs. recombinant factor VIIa (rVIIa) in warfarin related intracranial hemorrhage

DeLoughery TG

Oregon Health & Science University, Portland, OR, USA

Background: Intracranial hemorrhage (ICH) related to warfarin is a devastating occurrence with high rates of morbidity and mortality. It is thought that prompt reversal of the warfarin effect is crucial for improved outcomes. Although there is data that outcomes are improved with the use of prothrombin complex concentrates (PCC), in the United States the four-factor PCC are not available. For years after its introduction rVIIa was used to reverse warfarin and was recommend for this purpose in several guidelines. Recent data has been published showing effectiveness of a 3-factor PCC – low dose rVIIa (PCC-rVIIa) combination in warfarin related ICH.

Aims: This abstract reviews our 4 year sequential experience with first using rVIIa and then PCC-rVIIa for warfarin-ICH.

Methods: Permission was obtained from the IRB to review 67 charts of patients with warfarin -ICH who received either PCC or rVIIa. Patients either had spontaneous ICH or ICH related to a ground level fall (GLF). Patients on warfarin with ICH due to more extensive trauma were not analyzed. The standard warfarin-ICH reversal protocol from 2009 to 2011 was 40 μg/kg of rVIIa. In 2011 this was changed to 4000 units of Profilnine plus 1 mg of rVIIa to provide VII activity. (Sarode R, et al. J Neurosurg. 2012;116(3):491–7.)

Results: Sixty-seven patients were identified during this time period – 23 received rVIIa and 44 received PCC-rVIIa. Age, clinical indications for anticoagulation, and type of ICH were well matched in the two groups.

	PCC-rVIIa	rVIIa
Mean age	72.6 ± 2.0	75.5 ± 2.6
Reason for anticoagulation (%)		
Atrial fibrillation	28 (63)	16 (69)
Cardiac valves	6 (14)	4 (17)
Deep venous thrombosis	8 (18)	3 (13)
Spontaneous	22 (50)	10 (43.5)
GLF	22 (50)	13 (56.5)
Intracerebral hemorrhage	25 (57)	13 (56.5)
Subdural hematoma	15 (34)	10 (43.5)
INR before treatment	3.6 ± 0.4	2.9 ± 0.3
INR after treatment	0.8 ± 0.02	0.93 ± 0.17
Change in INR	2.8 ± 0.4	2.0 ± 0.3
FFP units	0.8 ± 0.2	2.1 ± 0.4*
Died	13 (29)	8 (34)
Discharged to home	18 (40)	3 (13)*

Conclusion: Effectiveness of warfarin reversal as measured by INR was the same in both groups. Despite similar death rates more patients who receive PCC-rVIIa were able to be discharge to home rather than to a care facility. In conclusion while it appears that PCC-VIIa may be associated with better functional outcomes, ICH in warfarin patients has a considerable mortality rate no matter what agent is used for reversal.

PB 2.48-6

Is clot structure impaired in patients on warfarin?

Adamidou D[1], Riddell A[2], Aghishi S[2], Mohadam L[2], Priest P[2] and Chowdary P[2]

[1]Ippokratio Hospital, Thessaloniki, Greece; [2]Katharine Dormandy Haemophilia Centre and Thrombosis Unit, Royal Free Hospital, London, UK

Background: Global assays for monitoring patients on warfarin have been proposed in cases where conventional INR fail to correlate the clinical phenotype.

Aim: We investigated the anticoagulant effect of warfarin on clot strength by means of whole blood coagulation assays.
Methods: We enrolled in the study 56 patients (27 male/29 female) with a median age of 66 (18–89) years. They were on long term anticoagulation for a median period of 3 (0.5–16) years. Twenty nine were on warfarin for primary prophylaxis (22 atrial fibrilation-7 valve replacement) and 27 for secondary prevention (thrombotic events). All patients were in steady state at the time of sampling with INR of 2.5 (1.5–4.1) and on no other medication affecting haemostasis. Platelet counts were within normal. Changes in clot structure were assessed by HAS (Hemodyne Hemostasis Analysis System) measuring clot elastic modulus (CEM), TEG (Tromboelastography) measuring maximum amplitude (MA) and ROTEM (Thromboelastometry) expressed by maximum clot firmness (MCF). Citrated whole blood containing corn trypsin inhibitor (20 μg/mL) was clotted in the presence of $CaCl_2$ and low tissue factor (0.35 pM) and was evaluated using TEG and ROTEM whereas for HAS we used native recalcified whole blood. Reference ranges were based on measurements of 20 normal individuals under the same experimental conditions and internal quality control was run in parallel. Plasma levels of clotting factors (F) FII, FVII, FX, FIX and Clauss fibrinogen were also measured.
Results: We found significant reduction in CEM on patients receiving warfarin compared to normals (mean 12.5 ± 1.1 vs. 28.3 ± 2.8) Kdynes/cm^2 but no changes for MCF (mean 56.2 ± 2.2 vs. 55.2 ± 0.8) mm and MA (mean 58.5 ± 1.4 vs. 60 ± 0.9) mm respectively. Fibrinogen levels 3.3 (2.2–8.1) g/L correlated strongly with all clot strength parameters: CEM (r 0.7), MA (r 0.6), MCF (r 0.5) ($P < 0.001$). There was no correlation between INR and any of the markers used to assess clot stiffness. MCF and MA were strongly correlated with each other (r 0.8) with no difference in absolute values ($P < 0.001$).
Conclusions: The dose effect of warfarin expressed by INR was not found on any of the clot strength markers. Fibrinogen as expected was the only factor of those examined related to clot stiffness. Nevertheless we noticed a discrepancy among the tests applied in this setting. The big reduction found with HAS was not detectable with neither ROTEM or TEG. One explanation for our findings could be the different principle of function between the machines used leading to different sensitivity towards factors affecting clot strength. The possible impairment of clot elastic properties as reflected in HAS may be through platelet interactions and could offer an explanation for the diversity in clinical phenotype often found in patients anticoagulated with warfarin sharing the same INR.

Quality of anticoagulation and bleeding and thrombotic risk in relation to CHADS2 score: analysis AF cohort of Epica study

Daniela P[1], Antonucci E[2], Cenci C[2], Paoletti O[3], Ageno W[4], Palareti G[5] and Testa S[3]

[1]AOU Careggi; [2]University of Florence, Florence; [3]AO Istituti Ospitalieri di Cremona, Cremona; [4]University of Insubria, Varese; [5]AOU Sant'Orsola-Malpighi, Bologna, Bologna, Italy

Background: The quality of anticoagulation expressed as time in therapeutic range (TTR) is associated to both bleeding and thrombotic events during vitamin K antagonists treatment. It is unknown if TTR in patients with Atrial Fibrillation (AF) is related to their baseline stroke risk.
Aim: Aim of this study is to evaluate TTR in relation to $CHADS_2$ score in the AF cohort of EPICA Study (1).
Methods: We defined patients with TTR ≥ 60% as adequately anticoagulated. We calculated the distribution of patients with TTR < 60% and the rate of bleeding and thrombotic events in relation to $CHADS_2$ score.
Results: We studied 3015 AF patients (males 45%; median age 83 years, range 80–102; 7620 patient-years). The total quality of anticoagulation measured as time spent within, above and below the TTR was 63%, 14% and 23%, respectively (IQR for TTR = 50–75). During follow-up 132 major bleeding and 112 thrombotic events were recorded. The distribution of patients with TTR < 60% and bleeding and thrombotic events in relation to $CHADS_2$ score is reported in table.
Conclusion: As expected, the rate of major bleedings and of thrombotic events increase with $CHADS_2$ score. Instead, no difference in the quality of anticoagulation is found in relation to $CHADS_2$ score.

Fixed vs. variable dosing protocols for prothrombin complex concentrate (PCC) for the emergency reversal of warfarin anticoagulation at two university teaching hospitals

Appleby N[1], Keane N[2], O'Rourke A[3], Enright H[3], Leahy M[2], O'Leary H[2], McHugh J[3] and O'Keeffe D[2]

[1]Meath and National Children's Hospital, Adelaide; [2]University Hospital Limerick, Limerick; [3]Adelaide, Meath and National Children's Hospital, Dublin, Ireland

Background: Four factor PCC is recommended for the emergency reversal of warfarin anticoagulation but the optimal dosing strategy remains unclear.
University Hospital Limerick (UHL) employs a fixed dosing protocol of 25 iu/kg of PCC. The Adelaide, Meath and National Childrens Hospital (AMNCH) protocol advises 25 – 50 iu/kg of PCC depending on INR at baseline.
Our study compares the performance of two dosing protocols for the emergency reversal of anticoagulation in a real world clinical setting.
Methods: Consecutive patients treated with PCC for reversal of warfarin anticoagulation at two university teaching hospitals over a 3 year period were identified from hospital transfusion records. Indication for anticoagulation, indication for and dose of PCC, survival and incidence of thrombosis for 30 days following PCC were recorded. INR at 1 and 4 h following PCC infusion were recorded.
The primary outcome was the proportion of patients achieving an INR ≤ 1.5 at 1 and 4 h post infusion of PCC. Secondary outcomes were survival and incidence of thrombosis.
Results: One hundred and fifty-three patients (84 at UHL and 69 at AMNCH) received PCC for the reversal of warfarin anticoagulation from 1st January 2010 to 31st December 2012. The median age, indication for anticoagulation, reason for emergency reversal and baseline INR were similar between the two groups.
All patients at UHL received PCC at 25 iu/kg.
At AMNCH, 44.9% of patients received PCC at 25 iu/kg, 18.1% at 35 iu/kg and 25.4% at 50 iu/kg.
The median INR was similar between the fixed dose and the variable dose group at 1 h (INR 1.5 vs. INR 1.3) and at 4 h (INR 1.5 vs. INR 1.2) post infusion of PCC.
The proportion of patients achieving an INR ≤ 1.5 at 1 h was not significantly different between the fixed dose and the variable dose (53.3% vs. 70%, $P = 0.37$). There was no significant difference in the percentage of patients achieving INR ≤ 1.5 between the two groups at 4 h post infusion (73.3% vs. 81.4%, $P = 0.069$).
In the subgroup of patients with INR ≥ 5.0 at baseline, the median INR between the fixed and variable dosage groups was similar at 1 h (INR 1.8 vs. INR 1.5) and at 4 h (INR 1.6 vs. INR 1.4). At 1 h,

46.2% of patients in the fixed dose group and 50% of patients in the variable dose group achieved an INR ≤ 1.5.
There were 18 deaths within 24 h of PCC infusion. This subgroup had a higher median INR at baseline (median INR 5.0) but responded to PCC, achieving a median INR 1.2 at 4 h post infusion. The most frequent cause of death was intracranial bleeding.
One pulmonary embolism occurred 28 days post PCC infusion.
Conclusion: Prothrombin complex concentrate prescribed with fixed dosing protocol performs as well as a variable dosing protocol for emergency reversal of warfarin anticoagulation in a real world clinical setting.

PB 2.49-3
Chronic anticoagulation: how the population is changing

Testa S, Paoletti O, Bassi L, Cancellieri E, Damiolini E, Zambelli S and Zimmermann A
Haemostasis and Thrombosis Center-A.O. Istituti Ospitalieri, Cremona, Italy

Background: In the last 20 years we observed a huge increase of patient on life-saving anticoagulant therapies for both treatment of venous thromboembolism and cardioembolic stroke prevention related to atrial fibrillation and heart valve replacements.
At present inItaly, Anticoagulation Clinics (ACs) manage patients chiefly on antivitamin K antagonists (AVKs). Even before the introduction of the direct oral anticoagulants (DOA), in the last 10 years patient population has already changed because of an increase of chronic treatments with other anticoagulant drugs, such as low molecular weight heparin (LMWH) or pentasaccharides, which require different management systems.
Aims: The aim of the present study was to analyse patient characteristics, clinical and laboratory controls, considering patient management in an AC in 2002 compared to 2012.
Besides, suitability of our net-telemedicine system to support patient management was evaluated.
Methods: We analyzed laboratory and clinical data stored in our centralized net supported program -TAOnet® Roche – based on a telemedicine system activated from 2001, bi-directional connected with peripheral health care units (Nursing Homes, Groups of General Practitioners and other hospitals of the area).
Each patient has an informatic record, updated in real time, including information on: general clinical conditions, complications, diet intake and drug co-medication, general compliance and drug adherence, significant clinical events such as hospitalizations, surgery and invasive procedures, laboratory test like PT INR (venous or capillary) for AVK patients and aXa activity for LMWH and fondaparinux patients, blood cell count, renal function.
Results: The 10 years activity comparison (2002–2012) showed a significant rise of the patient population from 2122 to 4352 pts, with a mean age that increased from 74 years (range 21–94 year) to 78 (range 14–103 year). Atrial fibrillation was the most frequent clinical condition that increased from 43% of the total population in 2002 to 52% in 2012; venous thromboembolism passed from 17% to 15.4%, while cardiac prosthesis from 20.7 to 12%. Within anticoagulant drugs warfarin is the most frequent used (89% of the total patient population in 2012), while acenocumarol showed a significant decrease (−22%) compared with 2002. We observed a more frequent use of LMWH on long term treatments, from 0.4% in 2002 to 3.6% in 2012. Also clinical and laboratory management has changed in relation to type of drug used, as confirmed by frequency of visits, increase of anti-Xa activity and blood cell count testing and creatinine determination. Our telemedicine system gave the opportunity to re-modulate management in relation to different molecules, assuring a good standardization of clinical control for each patient.
Conclusion: This evaluation gave us some important indications:

1 The population of anticoagulated patients has changed in the last 10 years also for type of drug used and management, even before the introduction of the direct oral anticoagulants in our country
2 Patient management has been adapted for each type of anticoagulant
3 Our clinical-lab program, through a telemedicine system, has given the possibility to modulate management in relation to patient-drug characteristics

PB 2.49-4
Pilot-scale production and purification of snake venom-derived antiplatelet agents

Jugder BE, Dashnyam P, Buyanbadrakh B, Byambasuren S and Buyanbat A
Mongols Sciences Institutes, Ulaanbaatar, Mongolia

Background: Snake venom toxins have been reportedly used as a rich source of a number of proteins of biotechnological interest due to their wide range of effects on haemostasis. These effects vary greatly: coagulant, anticoagulant, platelet-activating, anti-platelet, fibrinolytic and hemorrhagic, in either enzymatic or non-enzymatic pathways. *Gloydius* venom contains a variety of proteins that possess antiplatelet activities.
Methods: This study presents recent development in our laboratory to produce and purify antiplatelet proteins/peptides derived from *G. blomhoffii brevicaudus* snake venom. Different matrices of HPLC (size exclusion, ion exchange, affinity and reverse phase chromatography) were employed for purifying the enzymes and their biological and biochemical properties were characterized by using thrombin time assay, SDS-PAGE, 2-D electrophoresis, enzyme electrophoresis, platelet aggregation assay, coagulation assay and MALDI-TOF mass spectrometry.
Results: A purified phospholipase A2 (PLA2) was an acidic protein with Mr of 13 kDa, pI 4.17 and pH optimum 8.5. The PLA2 exhibits 90% ADP-induced platelet aggregation inhibition with a specific activity of 240 U/mg. The fibrino(geno)lytic enzyme (Mr 20 kDa, pH optimum 6.0, pI 7.0) inhibits platelet aggregation 85% and delays thrombin time test by more than 6 min. The protein C activator (Mr 30 kDa, pH optimum 8.0, pI 5.0) also shows an antithrombotic effect (60–70%) in rabbits. Moreover, the isolated plasminogen activator (Mr 27 kDa, pI 6.0) did not activate nor degrade phrothrombin and factor X, serine protease.
Conclusion: Bioprocesses to produce and purify active antiplatelet agents from *G. blomhoffii brevicaudus* venom have been developed, using modern liquid chromatography matrices and, as a result, the patents of novel purification processes were obtained. The satisfactory activities comparable to similar commercially available enzymes have been demonstrated. Ongoing work to optimize large-scale production process is being undertaken.

PB 2.49-5
Telemedicine via CareOnline-system in patients with vitamin-K-antagonist-therapy

Zeiter B, Hecking C, Hendelmeier M, Krämer I, Wild P, Walter U and Schinzel H
Universitätsmedizin Mainz, Mainz, Germany

Background: The thrombosis service at the University Hospital Mainz (TDM) was established in 2008 along the lines of the model in the Netherlands to optimized the VKA-therapy. Good INR adherence is essential for the safety and efficacy of vitamin K antagonist (VKA) therapy. In order to care patients living far away from the center the CareOnline-system was established.
Aims: The main objective was to evaluate the impact of specific medico-telemedicine care on the effectiveness of VKA-therapy in patients who could not reach the center.

Methods: Twenty-four patients were attended in the therapeutic drug monitoring (TDM) via the CareOnline-system. The patients or members of the family or local nurses received an extensive consultation on the anticoagulation therapy, the CareOnline-system and were educated in INR-self-testing. The INR-values, the health-data e.g. medical changes, acute illness, bleeding complications, thromboembolism, changes in comedication were documented in a standardized schedule. The data were transfered via scanner and telephone-adapter to the computer of the center. The INR-management (dosage recommendation, INR-monitoring) was performed by special educated staff via telefone and in addition via a letter on the same day. The duration of the pilot study was 12 month. The endpoint was time in therapeutic range (TTR – Rosendaal-method) after stable INR-adjustment (three consecutive INR values within the therapeutic range and VKA intake for a minimal period of 4 weeks). The ideal INR-range was 2–3, the extended INR-range was 1.8–3.2. The INR was routinely measured every 7 days.
Results: A total of 1086 INR-value were measured during the the observation time. The median of the TTR in ideal INR-range (2.0–3.0) was 80.6%. In the extended INR-range (1.8–3.2) the TTR was reached by 88.3%. Neither severely bleeding complications nor thromboembolic events were observed.
Conclusion: Patients with VKA-therapy living far away from coagulation-centers could be treated with a specialized medico-telemedicine care-system. The first results of the pilot study are encouraging. Medical care out of towns/centers will become more difficult in the near future (lack of doctors countryside). Therefore new structure are necessary to quarantee treating patients with high qualty.

PB 2.49-6

First experience of structured introduction of new oral anticoagulants in a Swedish health care district: dabigatran as an alternative to warfarin in atrial fibrillation

Arbring K, Chaireti R, Janzon M, Uppugunduri S, Jansson K and Lindahl T

Faculty of Health Sciences, Linköping, Sweden

Background: The number of patients on oral anticoagulants (OAC) in Sweden is approaching 200,000 and the treatment is still almost exclusively warfarin. Roughly half of these patients are treated with OAC for stroke prevention in atrial fibrillation.
Dabigatran was the first new oral anticoagulant (NOAC) for stroke prevention in non-valvular atrial fibrillation on the Swedish market.
Even though Swedish warfarin treatment is of very high quality with an excellent time in therapeutic range even in routine care, and warfarin still is the drug of choice for many patients, the NOACs have the potential of increasing the number of atrial fibrillation patients on OAC. On the other hand, the cost of dabigatran treatment is expected to be higher than warfarin treatment.
Choosing the patients that will benefit the most from dabigatran treatment (as an alternative to warfarin) will be the best possible use of economical resources. The Anticoagulation clinics (ACCs) provide an organization possible to use for a follow-up program to gain experience of the drug under Swedish 'real life' conditions.
Aims: To optimize medical benefit and resource utilization by a structured introduction of new oral anticoagulants in our catchment area.
Methods: In the Östergötland County Council area (approx. 430,000 inhabitants) a multi professional group developed an introduction and follow-up program for NOAC treatment. Dabigatran was the first NOAC drug to be introduced.
The program consists of: A physician check list with inclusion and exclusion criteria for dabigatran treatment as in the RELY study as well a local additional criterion (warfarin treatment not suitable, e g difficulties in achieving a stable INR)
A referral procedure to the ACC. If deemed eligible for dabigatran treatment by the ACC physician, the patient is started on dabigatran, otherwise warfarin treatment is initiated or continued if possible.
A follow-up program for at least 12 months.
A reimbursement model where the referring unit has no cost for dabigatran treatment when prescribed within the introduction program, but is charged the full cost for prescriptions outside the program.
Results: Until now approximately 100 patients have been referred to the introduction program, and approximately half of these patients were started on dabigatran treatment in the central health care district of Östergötland. Medical contraindications as well as referring physician and patient misconceptions were reasons not to start dabigatran. Almost no patients were started on dabigatran treatment outside the introduction program.
Summary/Conclusion: We propose that a structured introduction, as described here, may assist the referring physician and the patient in choosing the optimal OAC for the individual patient, while at the same time achieving optimal use of economical resources. In Östergötland introduction programs will be designed for upcoming NOACs, next rivaroxaban and apixaban, as well.

PB2.50 – Blood Coagulation System – II

PB 2.50-1

Identification of hypercoagulability in the rat model of microvascular thrombosis using spatial clot growth dynamics

Surov S[1], Vuimo TA[2], Semenova EA[3], Kaplanskaia IB[3], Ataullakhanov F[1] and Panteleev MA[1]

[1]Center for Theoretical Problems of Physicochemical Pharmacology; [2]HemaCore LLC; [3]National Research Center for Hematology, Moscow, Russian Federation

Background: Thrombotic complications of vascular diseases are the leading cause of mortality worldwide. Conventional diagnostic assays are often poorly sensitive to thrombotic complications and hypercoagulability (i.e. a tendency to the occurrence of thrombosis or abnormally high blood clotting). Evolving techniques that allow imaging of clot growth during thrombus formation and evaluation of sensitivity of such techniques are of great interest.
Aims: The aim of the study was to investigate the ability of the spatial clot growth assay (thrombodynamics) to detect hypercoagulability and thrombotic complications in the rat model of systemic collagen/epinephrine-induced thrombosis.
Methods: Microvascular thrombosis was provoked in Wistar male rats by administration of epinephrine/collagen solution (60 and 0.5 mg/kg, respectively) via the femoral artery. Blood samples for analysis of coagulation were withdrawn at the baseline and 5, 15, 30, 60, 120 min after administration. The performed thrombodynamics assay is based on videomicroscopic observation of fibrin clot propagation in a non-stirred layer of platelet-free plasma activated by the immobilized tissue factor. The following parameters of clot growth were determined on the basis of the image series: lag time (t_{lag}), initial (V_{in}) and stationary (V_{st}) clot growth velocity, presence of activator-independent clotting (characteristic for hyper-coagulation). The aPTT was measured using the standard laboratory assay following the manufacturer's protocol. Biopsy samples (heart, lung, kidney, liver) were retrieved and processed for hystopathological examination using Martius Scarlet Blue fibrin staining to identify microvascular thrombi.
Results: Rats undergoing microvascular thrombosis showed evidence of hypercoagulability indicated by the thrombodynamics assay, that is: presence of spontaneous clots of different intensity at 5 min and later after administration of collagen/epinephrine which indicated the severity of thrombosis and did not allow to detect V_{in} and V_{st}; increase of both V_{in} and V_{st} (if these parameters are detectable after induced

thrombosis) with the maximum at 15 min after administration – V_{in} and V_{st} increased from 49 ± 7 and 25 ± 3 μm/min at the baseline to 74 ± 7 and 34 ± 3 μm/min, respectively. Although severity and duration of thrombotic complications measured with thrombodynamics are various and have individual differences, hypercoagulability is clearly visible by this method as opposed to the aPTT test which does not indicate the hypercoagulable state. aPTT was only shortened once (from 19.7 ± 0.1 to 15.1 ± 0.1 s) in case of severe thrombosis which led to death. A slight hypercoagulability was detected in the control group with the maximum at 30 min (spontaneous clots did not appear here), this can be explained by surgical intervention and trauma while inserting the femoral artery catheter. Microvascular thrombi of different intensity were found in all organs in the experimental group, at the same time single thrombi of minimal intensity were found in the control group.

Summary/Conclusions: Spatial clot growth assay (thrombodynamics) is sensitive to a hypercoagulable state in the rat model of microvascular thrombosis indicating its diagnostic utility for the evaluation of hypercoagulability and thrombotic risk.

PB 2.50-2

Effects of shear flow on the microstructure and elasticity of incipient clots in whole blood and fibrin-thrombin gels

Badiei N, Curtis DJ, Campbell AI, Hawkins KM, Lawrence MJ, Sowedan A, Evans PA and Williams PR

Swansea University, Swansea, UK

Background and Aims: The effect of flow on the rate of blood coagulation has been extensively studied, both *in vitro* and *in vivo*, but little is known about the effects of shear flow on the underlying clot microstructure. The aim of the work presented herein was to investigate the influence of an imposed shear stress on the incipient microstructure of clots formed in both whole blood and fibrin gel systems. The incipient clot is defined herein as the clot that exists when the sample undergoes a transition from viscoelastic liquid to viscoelastic solid like behaviour and hence marks the point at which the rudimentary clot forms.

Methods: Incipient clot microstructure has been characterised by studying the response of the forming clot to small amplitude oscillatory shear stress waves, a technique known as small amplitude oscillatory shear (SAOS). In order to investigate the effect of an imposed shear field a steady stress has been superimposed onto the small amplitude oscillatory waveform. Hence it has been possible to probe changes in incipient clot microstructure induced by the presence of the steady shear field. Visualisation of mature fibrin clot microstructure has also been carried out using laser scanning confocal microscopy (LSCM) and SEM.

Results: In both fibrin gels and whole blood, fractal dimension, D_f (which characterises the complexity of the incipient clot microstructure in the range $1 < D_f < 3$) increased significantly, from a range of 1.99 ± 0.01 (fibrin clots) and 1.74 ± 0.12 (whole blood) at conditions of zero superimposed shear, to a maximum of 2.34 ± 0.04 (fibrin clots) and 2.2 ± 0.09 (whole blood) at the maximum level of superimposed steady shear stress studied herein, suggesting that the clots become more dense and compact under shear. These results are in good agreement with both LSCM and SEM images, which show dramatic changes in fibrin clot morphology with increasing steady shear stress. Increasing applied steady stress resulted in compact stretched bundles of fibrin fibers with few empty spaces.

Summary and conclusions: Significant compaction of incipient blood clots and fibrin gels has been observed as a consequence of applied steady shear stress during coagulation/gelation. The clinical significance of this work can be explained in terms of the potential consequences for fibrinolysis; the nature of clot microstructure under *in-vivo* conditions; and to aid development of thrombolytic or 'clot busting' treatments.

PB 2.50-3

The alterations of hemostasis and thromboelastometry in children after hematopoietic stem cell transplantation

Sirachainan N[1], Iamsirirak P[1], Pakakasama S[1], Hongeng S[1], Kadegasem P[1], Sirireung S[2] and Chuansumrit A[1]

[1]Department of Pediatrics, Faculty of Medicine; [2]Department of Nursing, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand

Background: Hematopoietic stem cell transplantation (HSCT) is currently a curative therapy for malignant and non-malignant hematologic disorders. The disturbance of hemostasis, demonstrated by increased coagulation markers and decreased coagulation and anticoagulation proteins, was reported during the early period post-HSCT. Thromboelastometry, a point-of-care measurement, can assess global hemostasis involving the interaction between coagulation and anticoagulation proteins, fibrinolysis and platelets. Therefore, it may be an alternative method for predicting of an abnormal hemostasis and deciding on the appropriate treatment.

Aims: To demonstrate the changes of hemostasis and thromboelastometry in children post-HSCT and to demonstrate hemostasis complications in children post-HSCT.

Methods: A prospective cohort study was conducted on children who had undergone HSCT. Following informed consent, blood was collected for thromboelastrometry, coagulation markers[thrombin antithrombin complex (TAT), D-dimer, prothrombin fragment (F1 + 2) and anticoagulation proteins (protein C, protein S and antithrombin activities) at pre-HSCT, day 0 (day of stem cell infusion), 14, 30, 60, 90 and 180 post-HSCT.

Results: Twenty patients (six autologous and 14 allogeneic HSCT) and 40 controls were enrolled. Mean + SD for the age of patients (9.0 + 4.8) and the controls (8.3 + 4.6) were similar. There were 10 patients with severe Thalassemia, eight with malignancy and two with other diseases.

At pre-HSCT, protein C and AT activities were significantly lower in patients compared to the levels in the controls. Thromboelastrometry parameters included clotting time (CT) in extem, was significantly longer in patients compared to the level in the controls. Maximum clot firmness (MCF) in extem and fibtem, and lysis index at 60 min (intem) were lower in patients compared to the levels in the control group.

During SCT period, platelet counts were significantly lower on during day 0 until day 180 post-HSCT when compared to the level at pre-HSCT. F1 + 2 levels were significantly higher on day 14, 30 and 90 post-HSCT when compared to the levels at pre-HSCT. On day 90, post-HSCT Protein C and AT activities returned to control levels. The thromboelastometry parameters included CT (intem), lysis index at 60 min (intem) significantly increased on day 14, and day 0 and 14, respectively while MCF (extem) significantly decreased on day 0, 14, 30 and 60 post-HSCT.

Nine patients developed 11 bleeding episodes. Fifty-five percent of the total bleeding episodes occurred on day 0 and 14. Veno-occlusive disease (VOD) was found in four patients between days 8 and 22 post-HSCT. Three significant differences, the platelet count at day 60, AT activity at day 30, MCF (extem) at day 14 and 30, were found in VOD group when compared to the levels of the patients without complication. MCF (extem) on day 14 was significant difference in VOD group compared to the level in bleeding group.

Conclusions: To our knowledge, this study was the longest prospective study and the first to demonstrate the changes of thromboelastometry in HSCT. The abnormal hemostasis was demonstrated at pre-HSCT and post-HSCT, and returned to normal values on day 180 post-HSCT. The abnormalities of thromboelastrometry may result from the decreased clotting factors, low platelet counts and hypofibrinolysis. In the future, thromboelastometry may be used to predict VOD and bleeding complications and to guide the treatment of these complications.

PB 2.50-4

Self-assessed Villalta score in DVT patients and in matched venous thrombosis-free controls

Utne KK, Wik H, Sandset PM and Ghanima W
Østfold Hospital, Fredrikstad, Norway

Background: A substantial number of patients with deep vein thrombosis (DVT) subsequently develops post-thrombotic syndrome (PTS). The Villalta score has been recommended by the International Society of Thrombosis and Haemostasis for diagnosing PTS. The score consists of five symptoms and six signs, none of which are disease specific.
Aims: (i) to assess the rate of PTS after DVT using a modified and self-assessed Villalta score; (ii) to estimate Villalta score in a non-DVT population.
Methods: This cross-sectional study included consecutive patients treated for DVT at Oestfold Hospital, Norway, 3–9 years prior to the inclusion. Villalta score was assessed in the ipsi- and contralateral extremities and in controls using adapted scheme for self-assessment of the Villalta score previously developed and used by our group (correlation coefficient = 0.84 when compared to conventional Villalta score). The study subjects were requested to find two sex and age-matched, venous thrombosis free controls, so called buddy controls. PTS was classified into four categories: severe (> 14), moderate (10–14), mild (5–9) and absent (< 5). The study was approved by the Regional Ethics Committee and written informed consent was obtained from all patients.
Results: Median duration of observation following DVT in 114 patients [median age 61 years; males 76 (66%)] was 5.5 years (range 3.5–8.7). Twenty-one patients had greater than one DVT in the ipsilateral extremity, but none had DVT in the contralateral extremity.
Mean (SD) of Villalta scores in ipsilateral extremities was 7.3 (7.2), in contralateral 3.7 (4.7), and in right and left of controls (n = 83) 2.7 (3.7)/2.4 (3.7), respectively. There was a mediocre correlation between Villalta in ipsi- and contralateral extremities (r = 0.5; P = 0.001). In Ipsilateral extremity 48 patients (42%) had no PTS, 40 (45%) mild, 11 (10%) moderate, and 15 (23%) had severe PTS. Corresponding distribution of Villalta scores [n (%)] in contralateral extremity were 83 (73%), 16 (14%), 8 (7%) and 7 (6%), and in controls, right and left extremities, were 63 and 70 (76–85%), 17 and 10 (21–12%), 2 (2%) and 1 (1%), respectively
Summary/Conclusions: The rate of PTS measured by self-assessed Villalta score in the ipsilateral extremity (59%) was comparable to other studies in which Villalta was assessed by qualified personnel. Villata score of > 4 points was found in 27% of the contralateral extremities and in up to 24% of the controls. Villalta score > 9, indicating moderate-severe PTS was mainly found in ipsilateral (23%) extremity; equivalent scores were substantially less in the contralateral (13%) extremities and in controls (3%). Mean score and distribution of Villalta grades were comparable in contralateral and in controls. To our knowledge, this is the first study to determine Villalta score in a control population with no previous DVT. Self-assessment of the Villalta score may represent a limitation of this study.
In conclusion, our results indicate the low specificity of Villalta score particularly at scores < 10. Increasing the threshold of the Villalta scores for diagnosing PTS may thus be required to improve the accuracy of Villalta score.

PB 2.50-5

Oxidized phosphatidylcholine and ethanolamine from 12- and 15-lipoxygenase significantly enhance tissue factor dependent thrombin generation *in vitro*

Slatter DA[1], Garcia-Diaz Y[2], Porter N[2], Aldrovandi M[1], Jenkins V[3], O'Donnell VB[1] and Collins PW[1]
[1]Cardiff University, Cardiff, UK; [2]Vanderbuilt University, Nashville, TN, USA; [3]St James's Hospital, Dublin, Ireland

Background: On activation, platelets generate a family of six oxidized phospholipids (PL) via 12-lipoxygenase activity. These comprise 12-hydroxyeicosatetraenoic acids (HETE) attached to either phosphatidylethanolamine (PE) or phosphatidylcholine (PC). Macrophage and neutrophils can generate 15- and 5-HETE PLs respectively.
Aim: To characterise the effects of HETE-PE and HETE-PC on coagulation reactions.
Methods: Liposomes (5% unoxidised PS, 55–65% unoxidised-PC, 20–30% unoxidised-PE and 0–10% either HETE-PE or HETE-PC) were generated incorporating recombinant tissue factor (rTF, 10pM). The rTF/liposomes (final PL concentration 4 μmol) were used to trigger coagulation (TG) in normal plasma, or FVIII deficient plasma and thrombin generation (TG) measured by use of a Thrombinoscope. Separately, the liposomes (without rTF) were tested for their ability to support the tenase, prothrombinase and TF/FVIIa complexes in purified protein reactions.
Results: TG in the presence of liposomes made from unoxidised (control) PLs and rTF resulted in a peak thrombin (PT) of 3 nM. When liposomes were composed of 10% HETE-PL, PT rose to 88 nM with 12-HETE-PE, 72 nM with 15-HETE-PE, and 11 nM with 5-HETE-PE added. Of note, oxidised PC also enhanced TG. PT rose to 133 nM with 15-HETE-PC, 87 nM with 12-HETE-PC and 29 nM with 5-HETE-PC added. The HETEs retained their effects in FVIII deficient plasma. PT in FVIII deficient controls was zero, but in 10% HETE-PL, this rose to 21 nM with 12-HETE-PE or 15-HETE-PE, 5 nM with 5-HETE-PE, 38 nM with 15-HETE-PC, 32 nM with 12-HETE-PC, or 16 nM with 5-HETE-PC added. Increased PT correlated with a reduced lag time. Differences between HETE isomers were statistically significant (P < 0.01) except that between 12- and 15-HETE-PE in normal plasma, and values were taken from a representative experiment of two. A concentration dependent relationship was demonstrated for 12- and 15-HETE-PE, with incremental increases from 0% to 10% of the total phospholipid content causing equally incremental effects on PT (n = 2 experiments). The lowest quantities of oxidised lipid that showed a statistically significant effect (P < 0.01) was 1% 12-HETE PE with a PT of 17 nM, and 3% 15-HETE-PE which had a PT of 18 nM. Concentration dependency is being investigated for the HETE-PCs.
15-HETE-PE did not affect the tenase, prothrombinase, TF/FVIIa, or soluble sTF/FVIIa reactions (n = 5–8 experiments).
Conclusion: HETE-PEs and HETE-PCs significantly elevate thrombin generation even in factor VIII deficient plasma. The mechanism(s) involved are under investigation.

PB 2.50-6

A case with reduced coagulation factor VII level caused by novel compound heterozygous mutations

Seki R, Yoko S, Takata Y, Osaki K, Nagafuji K and Okamura T
Division of Hematology and Oncology, Kurume University School of Medicine, Kurume, Japan

Background/Aims: Coagulation factor VII is a plasma serine protease precursor with a critical role in initiation of the blood coagulation process. VII deficiency is a rare coagulation disease. We investigated the molecular mechanisms of a FVII deficiency in a patient with compound heterozygous mutations.

Clinical history: A 50-year-old Japanese male was referred to our hospital because of resection of thyroid tumor. He had no bleeding history. However, by preoperative screening test, prothrombin time (PT) was prolonged 31sec). The activated partial thromboplastin time (APTT) was in normal range. The VII activity and antigen were greatly reduced (activity, 5.0%; antigen, 6.5%). Other hemostatic data were normal. VII deficiency was diagnosed. The parents were not consanguineous, although family examination could not be done.
Methods: Genomic DNA was extracted from peripheral blood leukocytes by a standard method. All exons, exon-intron boundaries and the 5' promoter regions were amplified by PCR. Cyclic sequencing was performed by using an Applied Biosystems DNA sequencing analyzer 310.
The electrophoretic mobility shift assay (EMSA) was analyzed by incubation of PCR products with wild-typed and mutated promotor sequences and nuclear extracts of HepG2 cells.
Results: Sequence analysis revealed that the patient was identified to be a compound heterozygote. One allele showed a point mutation (L26->P) in the central hydrophobic core of the signal peptide, which was previously reported inJapan. Another allele had a novel point mutation of a −58G to C substitution before the translation start site in the hepatocyte nuclear factor 4 (HNF-4) binding site. A moderate reduction in binding affinity of a specific nuclear protein to the −58C-containing oligonucleotide was found by EMSA assays.
Discussion: Several promoter mutations cause VII deficiency due to disruption of specific binding of nuclear protein to promoter elements. It is known that −61T->G and −55C->T show severe bleeding phenotype, in the other hand, asymptomatic or mild bleeding in −60T->C and −59 T->G. In this study, a mutation with −58 G->C was found to retain the mild binding ability with HNF-4. Kavlie et al. reported that the results from EMSA competition comparison are also in agreement with the severity of the clinical symptoms found in the affected patients. A L26->P mutation have been reported inJapanas a VII Morioka that caused an impaired secretion through translocation to and retention in ER with extensive intracellular degradation.
Summary/Conclusion: We reported an asymptomatic compound heterozygous VII deficiency that was identified to be a L26->P and a novel mutation of −58 G->C.

PB2.51 – Blood Coagulation Tests – VII

PB 2.51-1

Investigation of methodological sources of bias in the measurement of vitamin K1 (phylloquinone) in human serum at endogenous concentrations

Card DJ[1], Shearer MJ[2], Schurgers LS[3], Ruwona P[2] and Harrington DJ[2]
[1]Nutristasis Unit; [2]St. Thomas' Hospital, London, UK; [3]University of Maastricht, Maastricht, The Netherlands

Background: Vitamin K is an essential micronutrient involved in the posttranslational modification of various Gla proteins including coagulation factors II, VII, IX and X, proteins C and S, osteocalcin and matrix Gla protein. Serum or plasma vitamin K_1 (phylloquinone) concentrations correlate with dietary intake and functional markers of vitamin K status (e.g. undercarboxylated factor II (PIVKA II)) and provide a useful guide to tissue stores. The Vitamin K External Quality Assurance Scheme (KEQAS) is dedicated to the harmonisation of vitamin K measurement, enabling more reliable cross-comparison of studies of vitamin K status. Previous data has shown that assay bias contributes to about 30% variance seen in comparison of inter-laboratory vitamin K_1 analysis.
Aims: The aim of this study was to quantify the assay bias for each KEQAS participant and to attempt to link the data to specific methodological variations.
Methods: Sources of bias were investigated by distributing a questionnaire to all KEQAS participants (n = 25, response rate = 100%) specifically relating to key methodological information. Bias was calculated for vitamin K_1 results returned between February 2009 and October 2012 generated from serum (n = 22) and ethanolic (n = 10) samples. During this period the majority of KEQAS participants employed HPLC with in-line chemical reduction and fluorescence detection, however two laboratories employed HPLC with mass spectrometry (HPLC-MS).
Results: Mean individual laboratory bias ranged from −28 to 30%. Laboratory bias ranking altered very little when results from ethanolic samples were removed indicating bias did not originate from chromatographic interferences in the serum. The two HPLC- methods returned the two most negatively biased values of −22 and −28% respectively. A major finding was that seven groups (28%) using a commercially available calibrator, returned results with positive bias (range = 13–23%, mean = 19%).
Conclusion: The KEQAS Steering Committee is currently in talks with the manufacturer of the calibrator in order to investigate the reasons for the disparity between KEQAS participants using this commercial calibrator and participants using calibrators prepared in-house. Currently it is not possible to determine the significance of the negative bias seen in results from the two HPLC-MS methods. This may reflect their status as an improved method, free from interferences or may be a result of other confounding methodological factors. Measurement of vitamin K_1 by HPLC-MS represents a potential reference method although further evidence is required to establish this.

PB 2.51-2

The effect of dabigatran on the PTT, thrombin time and clauss fibrinogen assays

Szkotak A, Nahirniak S and Stang L
University of Alberta, Edmonton, AB, Canada

Background: Dabigatran is the only oral Direct Thrombin Inhibitor (DTI) in clinical use. While it does not require routine coagulation monitoring, testing may be necessary in patients with complications such as bleeding. The sensitivity of the PT and PTT assays is limited, and the Thrombin Time (TT) has been suggested as a simple and widely available alternative. However, the TT may be also be affected by changes in fibrinogen level. Further, the most common method of measuring the fibrinogen level, the Clauss assay, is essentially a calibrated dilute TT and may therefore show interference by Dabigatran.
Aims: To compare the sensitivity of the PTT and TT to Dabigatran in patients with acute bleeding or thrombosis. To assess the potential for using TT combined with the Clauss fibrinogen assay as a method of Dabigatran evaluation.
Methods: Data and blood samples were collected between September 1, 2011 and November 1, 2012 on patients taking Dabigatran and presenting to the Emergency Department with an acute complication. PT, PTT, TT, and the Clauss fibrinogen test were performed and compared to the results of the Hemoclot Direct Thrombin Inhibitors (Hyphen Biomed/Aniara) assay calibrated for Dabigatran level measurement. In addition, plasma samples with various fibrinogen levels were spiked *in vitro* with Dabigatran ranging from low trough (10 ng/mL) to the highest supratherapeutic concentrations reported *in vivo* in overdosed patients (5000 ng/mL). Interference in the Clauss fibrinogen assay was assessed using the following commercial reagents: STA-Fibrinogen 5 (Diagnostica Stago), HemosIL Fibrinogen-C (Instrumentation Laboratory Company), HemosIL QFA Thrombin (Instrumentation Laboratory Company) and Dade Thrombin (Siemens Healthcare Diagnostics Products GmbH).
Results: Seventeen patients were captured, 14 of which presented with bleeding, one of which had an ischemic stroke and two in which the presenting complaint was not identified. These patients demonstrated a significant negative bias in PTT results for Dabigatran level compared to normal plasma. TT remained highly sensitive (at least 10 ng/

mL) to the presence of Dabigatran under all clinical circumstances investigated. There was wide variation in the sensitivity of commercial fibrinogen assays to Dabigatran. One assay (HemosIL Fibrinogen-C) showed interference at supratherapeutic as well as therapeutic levels resulting in falsely low fibrinogen levels. Interference could however be mitigated by re-testing at a higher plasma dilution factor. Conclusions The utility of the PTT is compromised in patients with acute complications while on Dabigatran therapy and is not recommended for measurement of drug clearance. The TT assay is a simple and reliable alternative, particularly when used in combination with the fibrinogen level. However, there is wide variation in commercial fibrinogen assay sensitivity to Dabigatran and we would recommend against the use of assays that demonstrate interference in the therapeutic range.

PB 2.51-3

Prediction of unfavourable outcome with rotational thromboelastometry in patients with acute liver injury/failure

Habib M[1], Roberts L[2], Patel R[2], Bernal W[3] and Arya R[2]

[1]King's College Hospital; [2]King's Thrombosis Centre; [3]Liver Institute at King's, London, UK

Background: Patients with liver disease often show profound haemostatic abnormalities which may be better characterised by global coagulation assays such as Rotational Thromboelastometry (ROTEM).

Aim: We used ROTEM, which measures several parameters of clotting whole blood, to define the haemostatic profile in patients with acute liver injury/failure (ALI/F), defined as acute liver dysfunction with coagulopathy ± hepatic encephalopathy (HE), in comparison with healthy controls.

Methods: We recruited 35 patients with ALI/F and 40 matched controls between July 2011 and September 2012. Standard coagulation assays (PT, APTT) and detailed haemostatic profiling including platelet count, fibrinogen, D-dimer, coagulation factors (FII, FV, FVII, FVIII) in addition to ROTEM were performed. Parameters assessed by ROTEM were Clotting time (CT, seconds), Clot firmness time (CFT, seconds) Alpha-angle (degrees) and Maximum clot firmness (MCF, mm) using EXTEM, INTEM and FIBTEM to initiate clot formation.

Results: Mean patient age was 34 years, with 63% male. Aetiology was acetaminophen hepatotoxicity in 60%. Fifty-four percent of patients had ALF, 40% with HE grade ≥ 3; median bilirubin, AST and creatinine were 88 μM, 3131 IU/L and 159 μM respectively. Five (14%) patients had unfavourable outcome; 4 (11%) underwent liver transplantation and 1 (3%) died, while 30 (86%) had transplant-free survival (TFS). Five patients had minor bleeding.

All patients had abnormal coagulation profiles with median INR 3.22 (IQR 2.46–6.93), APTR 1.56 (1.28–1.95), platelet count 110 × 10^9/L (66–167), D-dimer 8000 ng/mL (5950–8000) and decreased coagulation factors compared to controls ($P < 0.001$ for all comparisons), except for FVIII which was increased 247 u/dL (214–356) compared to 123 u/dL (97–139; $P < 0.001$).

For both Extem and Intem Median CT, CFT were significantly longer in patients than controls while median MCF and α-angle were significantly lower ($P < 0.001$; for all comparisons). Patients also had longer Fibtem CT with lower MCF than controls ($P < 0.001$).

CT correlated directly to lactate, AST, INR and APTR and inversely to Fibrinogen, FII, FV and FVII while CFT correlated inversely to platelet count, fibrinogen and FVIII. In contrast MCF correlated directly to platelet count, fibrinogen and FVIII as did α-angle to platelet count and FVIII.

Patients with unfavourable outcome had a significantly more hypocoagulable ROTEM profile with a significantly longer Extem_CT 110 (89–243), Intem_CT 244 (212–352), Fibtem CT 94 (71–571), Extem_CFT 301 (160–598) and Intem_CFT 385 (149–717) and lower Extem_MCF 38 (33–54), Intem_MCF 38 (28–53), Extem_α-angle 47 (33–67) and Intem_α-angle 45 (31–67) when compared to those with TFS Extem_CT 68 (557–81; $P = 0.003$), Intem_CT 207 (177–224; $P = 0.025$), Fibtem CT 60 (53–81; $P = 0.022$), Extem_CFT 146 (126–184; $P = 0.034$) and Intem_CFT 121 (105–159; $P = 0.034$) Extem_MCF 51 (47–54; $P = 0.04$), Intem_MCF 51 (47–55; $P = 0.038$), Extem_ α-angle 63 (59–68; $P = 0.034$) and Intem_α-angle 70 (65–72; $P = 0.033$). In identification of 'non-survivors' ROC analysis reveals Extem-CT (0.92) to be a better predictor of poor outcome than other clotting parameters though numbers are small. There was no significant difference in standard coagulation assays.

Conclusion: All patients with ALI/F showed hypocoagulable ROTEM profiles without major bleeding. Patients with unfavourable outcome had abnormal ROTEM profiles, with Extem-CT potentially of use in identifying patients at risk for unfavourable outcome.

PB 2.51-4

Impact of dabigatran on routine and specific coagulation assays in patients treated by dabigatran.

Gemen E, Kariman A, Van Dijk J, Van Eck M and Pequeriaux N

Jeroen Bosch Hospital, 's-Hertogenbosch, The Netherlands

Background: Dabigatran, as a new oral anti coagulant (NOAC), is a direct thrombin inhibitor which is used in patients with non-valvular atrial fibrillation, to reduce the risk of stroke. With a half-life-time of 14–17 h and a renal clearance of 80%, no need of follow up of dabigatran plasma concentrations is necessary in normal situations. In case of bleeding, overdose and before (urgent) surgery, it is recommended to investigate plasma levels of dabigatran and activated partial thromboplastin time (aPTT). For other purpose coagulation tests are required and the clinician and the laboratory specialist must be aware of the impact of the NOAC's on the coagulation assays to avoid misinterpreting test results.

Aim: The aim of our study was to investigate the effect of dabigatran on the thrombin enzyme or -substrate depended routine and specific coagulation assays in patients treated by dabigatran. Until now, most of the studies are *in vitro* studies with dabigatran spiked plasma.

Methods: Nineteen patients with non-valvular atrial fibrillation treated by dabigatran (> 5 years) were included. The daily oral dose of dabigatran was twice 110 or 150 mg. We measured in citrated platelet poor plasma the following coagulation assays/reagens: international normalized ratio (INR)/STA Hepato Quick®, prothrombin time (PT)/STA Neoplastin plus®, activated partial thromboplastin time (aPTT)/STA APTT kaolin®, fibrinogen/STA fibrinogen®, antithrombin III (ATIII)/STA antithrombin III®, lupus anticoagulant (LAC)/STA CLOT DRVV® screen and confirm and PTT-LA®, and the extrinsic and intrinsic pathways factors II-V-VII-X-VIII-XI-XI-XII/STA factors® on a STA-R Evolution® coagulation analyser (Diagnostica Stago, France). Although we measured activated protein C resistance (APC)/Pefakit APC-R factor V Leiden® (Pentapharm, Basel, Swiss) and dabigatran concentration with Hemoclot thrombin inhibitors® (Hyphen Biomed, Neuville-sur-Oise, France) on the STA-R Evolution®.

Our patients have no coagulation disorders before entering the study. Ethical approval was obtained for conducting the study at the Jeroen Bosch Hospital.

Results: In 18 patients with dabigatran levels ranged from 16 to 240 ng/mL, we found the following results. aPTT rises to abnormal values (range 30.6–67.3 s) as dabigatran concentration increases. As expected, factors of the intrinsic pathway (VIII-IX-XI-XII) were strongly underestimated as dabigatran concentration increases. PT was less affected. Extrinsic factors II-V-VII-X were less underestimated. LAC diagnostic tests were strongly prolonged. APC-R was extremely influenced and was not measurable in our patients. All affected assays seemed to respond in a dose-dependent manner. INR, fibrinogen (Clauss method) and ATIII (based on inhibition of thrombin) were not affected.

One patient showed a dabigatran level of 639 ng/mL. In this patient all assays were strongly affected, except INR and fibrinogen.
Summary/Conclusion: Our results are in accordance with previous results reported in studies with dabigatran spiked plasma. We showed the effect of dabigatran on routine and specific coagulation assays. Most of the assays are influenced, sometimes strongly, which makes the daily interpretation of routine and specific coagulation results a challenge.

PB 2.51-5

The prothrombin time is a poor indicator of plasma rivaroxaban levels in *ex-vivo* samples from patients taking rivaroxaban

Zebeljan D[1], Kershaw G[2], Motum P[1], Mui B[3], Hsu D[1] and Steve L[1]
[1]*Liverpool Hospital, Liverpool;* [2]*Royal Prince Alfred Hospital;* [3]*Concord Hospital, Sydney, NSW, Australia*

Background: Plasma rivaroxaban levels can be measured by prothrombin time (PT)-based or anti-Xa-based assays calibrated with sets of plasma samples spiked with rivaroxaban. Studies have shown linear dose-responses of PT to rivaroxaban levels when normal pooled plasma is spiked with rivaroxaban over a wide range of concentrations, and that the slope of the dose-response line varies with the type of thromboplastin reagent used. There is limited data on the effect of rivaroxaban on the PT of plasma in patients taking rivaroxaban.
Aims: To assess the degree of variability between PT and plasma rivaroxaban concentration in samples from patients receiving rivaroxaban.
Methods: Double-spun citrated plasma samples (n = 46) from outpatients and in-patients (n = 33) taking prophylactic doses of rivaroxaban were stored deep-frozen until tested. The plasma rivaroxaban levels were determined by anti-Xa based commercial chromogenic assay (Diagnostica Stago). PTs were determined with three recombinant thromboplastins (Innovin, Recombiplastin, Neoplastine R), one rabbit brain thromboplastin (Neoplastine CI Plus) and one human placenta thromboplastin (Thromborel S). All PTs were run on two analysers employing different clot detection principles: optical (Behring coagulation system) and mechanical (STA-R Evolution).
Results: Rivaroxaban levels ranged from 8 to 508 ng/mL, with a median of 119 ng/mL. For all 10 thromboplastin-analyser combinations there was a dose-dependent increase in PT with increasing rivaroxaban level ($P < 0.0001$ for all). The increase in PT with rivaroxaban levels was more consistent with use of recombinant thromboplastins compared to tissue-derived reagents. Values for r^2 for the five thromboplastins were, for BCS and STA-R analysers, respectively: Neoplastine R 0.839 and 0.856; Recombiplastin 0.776 and 0.738; Innovin 0.638 and 0.628; Neoplastine CI Plus 0.491 and 0.572; Thromborel S 0.409 and 0.508. These r^2 values were only marginally different, and not always improved, when PT values were converted to INR. Inspection of individual scatterplots shows a wide range of rivaroxaban concentrations between patients with the same PT. These differences in rivaroxaban levels were 2-fold to 4-fold in many instances. For the reagent with the highest r^2 values, Neoplastine R, a PT of > 30 s on the STA-R and > 35 s on the BCS was indicative of rivaroxaban levels > 400 ng/mL.
Summary/Conclusions: There is wide variation between different thromboplastins in their sensitivity to plasma rivaroxaban concentration as measured by the PT. In none of the 10 reagent-analyser combinations were these relationships close enough to allow the PT to reliably predict the plasma rivaroxaban level. Therefore assessment of plasma rivaroxaban requires a specific assay.

Impact of sample preparation procedure in the spatial clot growth assay

Dashkevich NM[1], Vuimo TA[2], Ovsepyan RA[2], Soshitova NP[2], Surov S[2], Panteleev MA[1], Ataullakhanov F[1] and Negrier C[3]
[1]*Center for Theoretical Problems of Physico-Chemical Pharmacology;* [2]*HemaCore LLC, Moscow, Russian Federation;* [3]*Hopital Edouard Herriot, Lyon, France*

Thrombodynamics is a new global coagulation assay based on spatial separation of coagulation activation and propagation phases. Coagulation is activated by immobilized tissue factor and propagates in thin layer of non-stirred plasma. Clot growth is monitored by light-scattering videomicroscopy system and the rate of clot growth is measured.
To be used as a diagnostic tool Thrombodynamics assay requires standardization and validation. In this study we examined the key stages of the sample preparation procedure to minimize variability due to pre-analytical conditions.
Blood was collected into sodium citrate tubes at a 9:1 volume ratio. It was processed by centrifugation at 1600 g during 15 min to obtain platelet-poor plasma (PPP). To obtain platelet free plasma (PFP), the supernatant was centrifuged 5 min at 10,000 g. To avoid contact activation 200 μg/mL of Corn Trypsin Inhibitor was used.
Eight types of citrate blood collection tubes of four manufactures were tested: Sarstedt Monovette, BD Vacutainer (glass and plastic tubes), Greiner Bio-One Vacuette (3.2%, 3.8% of sodium citrate and CTAD), Terumo Venosafe (3.2% and 3.8% of sodium citrate). All the tubes were tested for ≥ 10 apparently healthy volunteers. Rate of clot growth in PFP was not significantly different (P = 0.05) for seven types of the tubes (all of them were plastic). Values obtained with glass Vacutainer tubes were significantly higher (P = 0.05). Mean values of clot growth rate for all the plastic tubes ranged from 25.5 ± 1.9 to 27.6 ± 2.1 μm/min. The mean value for Vacutainer glass tubes was 30.8 ± 3.8 μm/min. There was no significant correlation for clot growth rate for different types of the tubes showing random error introduced by the tubes choice.
APTT values were not significantly different for all the tubes tested (P = 0.05).
For 44 healthy individuals we compared the results with plasma obtained by single blood centrifugation for 15 min at 1600 g (PPP) and plasma that was additionally centrifuged 5 min at 10,000 g (PFP). The significant increase in clot growth rate (P = 0.05) was observed in PPP (28.5 ± 4.2 μm/min) compared to PFP (24.3 ± 2.9 μm/min). There was a significant correlation for the clot growth rate (r = 0.77, P = 0.05) that shows a systematic shift of values obtained with a single centrifugation.
Different centrifugation protocols were studied: the second centrifugation was performed at 10,000 g for 5 min and at 1600 g for 20 min. No significant difference was observed for these methods (n = 7, P = 0.05). If the second centrifugation was performed there was no difference between 1600 and 2100 g for the first 15 min centrifugation (n = 8, P = 0.05).
Twelve samples of fresh and frozen-thawed PFP were compared. Clot growth rates significantly increased for frozen plasma (27.4 ± 2.8 μm/min) compared to non-frozen samples (25.3 ± 1.9 μm/min) (P = 0.05). There was a significant correlation for the clot growth rate (r = 0.65, P = 0.05)
In summary, we showed that glass blood collection tubes cannot be used for the Thrombodynamics assay probably due to increased contact activation, but most of the plastic tubes are suitable. Plasma obtained with one centrifugation and frozen plasma can be used but it requires the corresponding reference values.

PB 2.52-1

Validation of methods for determination of procoagulant activities in immunoglobulins using the NIBSC reference reagent for FXIa

Jose M, Pons B, López L, Faro M, López M and Jorquera JI
Instituto Grifols, Parets del Valles, Spain

Background: An increased rate of thromboembolic adverse event reports associated with the use of an intravenous immunoglobulins (IVIG) from a specific manufacturer has been ascribed to increased residual activated coagulation factor XI (FXIa) and possibly other impurities. Since no reference material was available, the National Institute for Biological Standards and Control (NIBSC) developed a FXIa reference reagent prior to the development of a International Standard to promote standardization of analytical methods.
Aims: To validate the methods for testing procoagulant activities in IVIG using the NIBSC Reference Reagent for Activated Blood Coagulation Factor XI (FXIa) code 11/236.
Methods: The following activation markers were validated: Non-activated partial thromboplastin time (NaPTT) and thrombin generation (TGT) test (both using normal platelet poor plasma -PPP- and FXI deficient plasma), FXI antigen -Ag- using an enzyme immunoassay and FXIa by chromogenic assay. The NaPTT was tested at 1/5 and 1/10 dilutions. In all cases, a standard curve with the NIBSC reference reagent that contains 10 arbitrary units (U) per mL was used. Using this reagent all methods were validated in terms of linearity of FXIa and limit of detection (LOD) and limit of quantitation (LOQ) of FXIa. The validation parameters of specificity, accuracy and robustness were also established.
Results: The NaPTT-PPP showed a LOD of 0.018 U/mL and the LOQ for its technique was 0.055 U/mL. The NaPTT-FXI has a LOD of 0.003 U/mL and the LOQ was established at 0.008 U/mL. For both TGT (TGT-PPP and TGT-FXI), the LOD and LOQ were 0.001 and 0.002 U/mL, respectively. In case of FXI assays, the LOD and LOQ for FXI:Ag were 0.35 and 1.06 U/mL, respectively. With the chromogenic FXIa assay, the LOD was 0.0005 U/mL and the LOQ was 0.0015 U/mL. The linearity FXIa range was established in all cases.
Summary: In order to standardize homogenize the procoagulant test applied to discard the thromboembolic risk of IGIV, NaPTT and TGT tests, FXI:Ag and chromogenic FXIa assay have been validated using the NIBSC Reference Reagent for Activated Blood Coagulation Factor XI (FXIa) code 11/236 with satisfactory results. The validated methods were specific, accurate, precise and robust as well as applicable to final product and production intermediate materials.

PB 2.52-2

Human thrombin liquid reagent for fibrinogen determination in samples containing dabigatran

Camacho E, Bono M and Martorell D
Diagnostic Grifols, Parets del Vallés, Spain

Background: New oral anticoagulant drugs have recently emerged in the pharmaceutical market. Dabigatran is an oral direct thrombin inhibitor that reaches peak plasma concentrations in the range between 100 and 400 ng/mL, and trough concentrations in the range between 20 and 150 ng/mL. DG-FIB L Human is a liquid reagent from Grifols for the quantitative determination of fibrinogen using the Clauss method, characterized by a broad measurement range, which avoids the need of retesting samples with abnormally high or low levels of fibrinogen. It has been reported that dabigatran can interfere with fibrinogen Clauss tests, leading to erroneous results. A slight modification of the current procedure set for DG-FIB L human in Q Hemostasis Analyzer (Grifols) has been tested in order to avoid the dabigatran interference in fibrinogen determination.
Aims: To study the performance of the reagent DG-FIB L Human in Q Hemostasis Analyzer for the quantitative determination of fibrinogen in human plasma that contains dabigatran.
Methods: All tests were performed in the optical coagulometer Q Hemostasis Analyzer (Grifols). The modified procedure involves a modification of the ratio between plasma and thrombin concentration in the reaction. Linearity and limits of detection and quantification were determined using DG-Ref (Grifols) as calibrator plasma. Precision and accuracy were studied at different levels of fibrinogen with or without spiked dabigatran. The performance of the current and the new procedures was compared in 28 normal and 48 abnormal fibrinogen samples from patients not treated with dabigatran. The effect of dabigatran on the new procedure was studied determining the fibrinogen Clauss of high, normal and low fibrinogen samples (n = 31) at three concentrations of dabigatran (0, 200 and 400 ng/mL).
Results: Both procedures, the current and the new, showed similar performance in terms of precision, accuracy and linearity in samples without dabigatran. With the new procedure the measurement range was 85–1300 mg/dL of fibrinogen, which is an improvement compared to the current method (70–950 mg/dL). The new procedure showed comparable precision results between the samples with or without dabigatran at 200 ng/mL, with coefficients of variation of 4.25% and 4.19% for the normal and 7.14% and 7.12% for the abnormally low fibrinogen level, respectively. The addition of 400 ng/mL of dabigatran to the samples did not affect the accuracy (maximum bias of 9.0%). In the method comparison study using samples without dabigatran, a good correlation of results using the current and the new procedure was observed and no significant differences were detected in a Passing Bablok fit and a difference plot (allowable bias of 15%). The addition of dabigatran to fresh frozen samples at concentrations of 200 and 400 ng/mL produced no significant difference (allowable bias of 15%) in fibrinogen results obtained with the new procedure.
Conclusions: DG-FIB L Human reagent is suitable for routine determination of fibrinogen Clauss. A new procedure is available for quantification of fibrinogen in human plasma samples, including those from dabigatran treated patients containing a dabigatran concentration up to 400 ng/mL.

PB 2.52-3

The rate of reduction in D-dimer level for patients with venous thromboembolism responding to antithrombotic therapy

Chan HW[1], Li N[2], Lau K[1] and Chan AK[1]
[1]McMaster University, Hamilton, ON; [2]Western Ontario University, London, ON, Canada

Background: D-dimer is a degradation product from the breakdown of cross-linked fibrin. The absence of D-dimer was used to rule out the diagnosis of venous thromboembolism (VTE). Newer D-dimer assay allows quantitative measurement of D-dimer levels. It has been shown that elevated D-dimer level may be associated with higher risk of recurrence when antithrombotic therapy is discontinued. Yet, when patients with venous thrombosis responding to anticoagulant treatment, the dynamic profile of D-dimer is still obscure.
Aim: This study was to evaluate the rate of reduction in D-dimer levels when venous thrombosis was resolving after anticoagulant treatments in patients without other confounding conditions causing high D-dimer levels.
Methods: A retrospective chart review was performed for consecutive patients with newly diagnosed VTE and was treated in a regular fashion with low-molecular-weight heparin (LMWH), bridged to warfarin with a target international normalized ratio (INR) of 2.0–3.0. Patients were excluded if falsely elevated D-dimer level might occur in the following conditions: concurrent bleeding, after resuscitation or trauma, post-thrombolysis, recurrence or progression of venous thromboembolism within 3 months from the first day of diagnosis, disseminated intravascular coagulation, hemolysis, hepatic or renal failure. Quantitative immunoturbidimetric assay was used to determine D-dimer level

every 1–2 weeks. Patients were followed regularly in the clinic for at least 3 months. In this study, patients were defined as responders if no recurrence was detected, either clinically or with radiological imaging, within 3 months. Correlation of coefficient (R^2-value) was used to evaluate the measurable D-dimer level (500–4000 mg/L FEU) against time interval. Student's *t*-test was used to compare the rate of changes in D-dimer levels among between patient groups. A *P*-value of < 0.05 was considered statistically significant.

Results: D-dimer level were evaluated in 13 patients, nine with DVT only and four were complicated by PE. There was a linear decrease in the D-dimer levels when patients with venous thromboembolism were treated with anti-thrombotic drugs. The R^2-value was 0.949, suggesting D-dimer level decreased at the average rate of 119.4 mg/L FEU/day with the median rate at 96.9 mg/L FEU/day and the 25th and 75th percentile were 85.4 and 130 mg/L FEU/day respectively. There was no statistical difference when comparing patients with deep vein thrombosis (DVT) only and those complicated by pulmonary embolism (PE). The rate of reduction in D-dimer level was not associated with the duration to achieve target INR when warfarin therapy was first initiated.

Summary/Conclusion: For patients with newly diagnosed VTE responding to antithrombotic therapy, D-dimer level decreased at a constant rate when it is in the measurable range. Consequently, in the absence of other comorbid conditions causing falsely elevated D-dimer levels, managing physicians may use serial quantitative measurements of D-dimer to monitor the response of therapy, thus allowing early intervention in case of treatment failure. In the absence of other confounding factors, reduction in D-dimer levels appears to be a good surrogate marker for the resolution of thrombus. This is potentially an informative tool for comparing the efficacy of various antithrombotic therapies.

PB 2.52-4

Specific and global coagulation assays in the diagnosis of mild haemophilia A

Bowyer AE[1], Van Veen J[1], Goodeve AC[2], Kitchen S[1] and Makris M[1]

[1]Sheffield Teaching Hospitals; [2]University of Sheffield, Sheffield, UK

Background: FVIII activity (FVIII:C) can be measured by three methods; one (FVIII:C1) or two-stage clotting (FVIII:C2) and chromogenic (FVIII:CR). The FVIII:C of most individuals with mild haemophilia A (MHA) is the same regardless of the method employed. Approximately 30% of MHA patients demonstrate marked discrepancy in FVIII:C activity measured with the different methods. There are two types of assay discrepancy; the lower two-stage form (reduced FVIII:C2 or FVIII:CR with higher FVIII:C1) which is linked to a bleeding diathesis and the lower one-stage form (reduced FVIII:C1 and higher FVIII:C2 or FVIII:CR) where the bleeding risk is minimal or unclear. The current ISTH definition does not define the type of assay to be used in diagnosis and misclassification of some patients with MHA and normals can occur.

Objective: To investigate the incidence of assay discrepancy, assess the impact of alternative reagents on FVIII:C activity assays and determine the usefulness of global assays of haemostasis in MHA.

Methods: The APTT, FVIII:C1, FVIII:C2 and FVIII:CR were measured in 84 individuals with MHA using different reagents. Assay discrepancy was defined as two-fold or greater differences between FVIII:C1 and FVIII:C2. Rotational thromboelastometry (ROTEM) and calibrated automated thrombography (CAT) were performed in discrepant and non-discrepant patients.

Results: Two-fold or greater assay discrepancy was observed in 31% of individuals; 12% with the lower FVIII:C2 form and 19% with the lower FVIII:C1 form. An individual's genotype did not always predict their phenotype. A normal APTT was demonstrated in 11% patients. No statistically significant difference was noted between FVIII:C2 and three FVIII:CR kits ($P < 0.05$). The ROTEM did not discriminate well between MHA and normal subjects. The CAT parameters, ETP and peak thrombin, correlated well with FVIII:C1 and FVIII:CR levels ($r > 0.75$) in our cohort. We showed the meanETPto be 66% of normal in the lower two-stage group and 69% of normal in the non-discrepant group. Mean peak thrombin was 33% and 43% of normal respectively. Patients and carriers of p.Tyr365Cys which is linked to lower one-stage discrepancy and, in our cases no bleeding, had normal ETP and normal or only mildly reduced peak thrombin.

Conclusions: Thirty-one percent of MHA patients exhibited significant (two-fold or greater) assay discrepancy. In our study, 4% of MHA patients would not be diagnosed by laboratories employing only FVIII:C1 assays. Laboratories should utilise both one stage and two-stage (or chromogenic) assays in the diagnosis of patients with possible mild haemophilia A. The APTT cannot be relied on as a screening test where FVIII:C is > 30 IU/dL and in some patients with the lower two-stage form of assay discrepancy where the APTT is within normal limits. Chromogenic assays are a suitable alternative to FVIII:C2. The clinical utility of global assays of coagulation still remains to be defined although some CAT parameters did correlate with phenotype in this small study of assay discrepant patients.

PB 2.52-5

An ECT based assay for thrombelastometry using solid lyophilized pellet reagents

Erber M and Lee G

Friedrich – Alexander University Erlangen – Nuremberg, Erlangen, Germany

Background: Along with the development of new anticoagulant drugs the Ecarin clotting time (ECT) became an important method to measure their activity in plasma. The ECT is insensitive for both heparin and classical oral anticoagulants but sensitive for direct thrombin inhibitors (DTI). Unlike aPTT the ECT increases linearly with plasma DTI concentration and therefore provides a method to monitor DTI plasma levels.

Aims: In solution ecarin is stable for 24 h at room temperature. The aim of this work is to develop a stable point – of – care system for thrombelastometry using lyophilized ecarin pellets. These pellets were designed to dissolve immediately in order to add them directly to the whole blood sample right before measurement.

Methods: Droplets were generated using a micro annular gear pump (HNP Mikrosysteme) connected to a Sterican® needle (Braun) and were frozen in liquid nitrogen. The lyophilization process was conducted using a Vertis Freeze dryer (SP Scientific). Whole blood (WB) coagulation profiles were determined using a thrombelastometry device (ROTEM®; Tem International GmbH). Citrated WB was received from the university medical center's blood donation service. Ecarin activity after freeze drying was determined by measuring the ECT and using the respective volume of the initial solution (stored at −80 °C) as a reference. The pellet system was also compared to the standard ROTEM® ECATEM procedure using 20 µL of an ecarin solution (c = 21.5U/mL). The references were recalcified using 20 µL of a 0.2 M $CaCl_2$ solution. The pellet system was recalcified using $CaCl_2$ pellets which were also produced by lyophilization and contained the respective amount of Ca^{2+}.

Results: The liquid pellet formulation contained trehalose as a bulking agent and 125 U/mL ecarin. The lyophilized ecarin pellets (diameter: 1.67 ± 0.03 mm) had a mean mass of 0.72 ± 0.02 mg corresponding to an initial droplet volume of 3.45 ± 0.04 µL. The activity of ecarin after FD was 102.18 ± 7.52%. The results for ECT obtained with the pellet system did not differ from the results obtained using the standard liquid system (CT_{pellet} = 73.0 ± 4.7s, CT_{liquid} = 73.8 ± 1.0s; $n = 10$; $P < 0.05$). Melagatran served as a DTI and was added to the whole blood sample covering concentrations from 0 up to 1.6 mg/mL. The ECT for the liquid system as well as for the pellet system increased linearly with increasing Melagatran concentration. Since stability is

another key aspect ecarin pellets were placed under controlled conditions (40 °C; 50% ambient humidity) in a climate chamber. The activity of ecarin did not significantly ($P < 0.05$) decrease during a 4 week storage period.

Conclusion: In summary it is possible to avoid the stability issue of ecarin solutions and preserve activity by using lyophilized pellets instead of liquid reagents. Therefore the pellet system might become a ready – to – use tool to determine DTI levels in clinical practice by measuring ECT. In addition other coagulation assays could be manufactured as lyophilized pellets as well to avoid additional dilution of the sample.

PB 2.52-6

The effect of platelet poor plasma storage time on thrombin generation inter-assay variability using calibrated automated thrombography

Bennett AS, Roberts L, Patel R and Arya R

King's Thrombosis Centre, London, UK

Background: There is increasing use of calibrated automated thrombography (CAT) in the investigation of haemostatic disorders. To be a clinically relevant assay methods must be standardised and results reproducible. Sample storage time may influence results, particularly if collection takes place over a prolonged period. The acceptable storage time of PPP for thrombin generation testing is currently undefined.

Aims: To assess the effect of PPP storage time on the inter- assay variability obtained in a single centre on the most commonly reported parameters; lag time (LT), time to peak (ttP), peak thrombin (peak) and estimated thrombin potential (ETP).

Methods: Venous blood was collected from five healthy male volunteers with minimal stasis using 21-gauge butterfly needles. The first 5 mL was discarded and the second draw divided into BD vacutainers containing 0.109M trisodium citrate; corn trypsin inhibitor (CTI) at a final concentration of 18.3 μg/mL was added to half the samples. PPP prepared following double centrifugation at 4750 *g* for 10 min was pooled prior to freezing at −40 °C. Hemker's thrombin generation method was carried out by a single user with the Thrombinoscope™ assay, utilising reagents obtained from the manufacturer (Thrombinoscope BV, Maastrichts, Netherlands). Pooled male plasma was tested at 4, 5, 6, 7, 8, 9, 13, 14, 18, 20, 21 and 52 weeks using three thrombin generation assays. The first involved 5pM tissue factor (TF) and 4 μM phospholipids (PL). The second incorporated thrombomodulin (TM), a protein C pathway sensitising agent, at a final concentration of 6 nM TM, found in pre-testing to correspond to suppression of ETP by approximately 50%. The third (1pM TF and 4 μM PL) tested PPP in the presence of CTI. All samples were run in triplicate with calibration wells. Intra-assay variability was tested on PPP derived from one healthy female volunteer, collected and prepared as above. Four weeks after freezing, all three assays were performed, each consisting of 16 samples run in triplicate with a calibrator.

Results: Inter-assay variability for the standard 5pM TF assay was excellent, with coefficients of variation (CV) < 6% for all parameters over 52 weeks. In the presence of TM, CV was < 10% for all parameters up to 13 weeks but increased over time; peak thrombin and ETP were predominantly affected reaching 11.8% and 13.6% at 52 weeks respectively. The 1pM TF assay produced CV that were still acceptable at < 8.5% across 21 weeks for all parameters. Intra-assay CV was excellent throughout (LT 4.8%, 4.2%, 3.1%; ttP 3.3%, 2.5%, 2.4%; Peak thrombin 2.8%, 3.1%, 3.7% and ETP 2.5%, 5.4% and 3%) for the three assays; 5pM TF without TM, 5pM TF with TM, 1pM TF in the presence of CTI respectively.

Summary: Reproducibility of the method is demonstrated, with excellent intra-assay variability. Inter-assay CV's were acceptable (< 10%) for all assays using PPP stored for up to 3 months. These results demonstrate that study samples should be analysed at a consistent time point following their collection, and that batch testing at the end of studies may lead to less reliable data.

PB2.53 – Blood Coagulation Tests – IX

PB 2.53-1

Effect of clot detection method on total error calculated by CLSI protocol EP-10

Duboscq C[1], Ceresetto J[1], Trobo S[2], Stemmelin G[1], Shanley C[1], Rabinovich O[1] and Bullorsky EO[1]

[1]Hospital Britanico; [2]Hospital Pirovano, Buenos Aires, Argentina

Nowdays, the most accepted approach for analytical performance goals is based on the biological variation (BV). In haemostasis laboratory, there are no reliable data on BV of all the investigated analytes. On the other hand, required optimal analytical quality set by biological variation is difficult to achieve.

The aim of this study is to compare the total error (TE) calculated by CLSI protocol EP-10 (preliminary evaluation of quantitative clinical laboratory measurement procedures) with three different detection method in automatic coagulometers: optic, nephelometric and viscosity. The performed tests were PT, FVII and FVIII in% (one stage clotting assay with two dilutions) and fibrinogen (FBG) in mg% by Clauss method. The used thromboplastin ISI was instrument specific: ISI = 1.15 for optic, ISI = 1.11 for nephelometric detection and an ISI = 1.34 for viscosity detection.

The TE values were compared with allowed TE (TEa) fixed by BV and CLIA requirements. Normal and low commercial controls (NC and LC) with target value were used; the control medium levels (MC) was prepared mixing 3.5 vol of NC and 1.5 vol of LC for PT and equal vol of each control for factors and fibrinogen.

Results: The TE determined for PT were: nephelometric 8.9%, optic: 5.8% and viscosity 6.2%. For fibrinogen, TE was: nephelometric 10.5%, optic 10.4% and viscosity 10.8%. For FVII TE were: nephelometric 10.6%, optic 9.5% and viscosity. 10.2% and for FVIII the TE were: nephelometric 12%, optic 10 .5% and viscosity 11.3%.

None of the TE determined in our laboratory achieved the optimum TEa fixed by BV, but the obtained FBG, FVII and FVIII Total Error were within desirable limits fixed by BV by all detection methods. The PT -TE determined with optic and viscosity method were within TE desirable limits fixed by BV but the nephelometric method only achieved the minimum level of quality requirement established by VB. Quality requirement fixed by CLIA for TP and Fibrinogen were reach by the three detection methods.

Conclusions:

1 There were no differences in TE calculated by EP-10 between different methods of clot detection
2 Although our laboratory is participating successfully in an external quality program and also use internal quality control, it is very difficult for clot detection methods to reach the optimum quality requirements fixed by BV. It is particularly true for PT, a global test, whose result depends on the interaction of several factors. The question is: which is the desirable quality for a reliable application of these tests as screening tests for patients with blood coagulation abnormalities or for monitoring anticoagulated patients with warfarin.

PB 2.53-2

INR portable monitors: efficacy of a quality control system

Paoletti O, Bassi L, Cancellieri E, Dellanoce C, Zimmermann A, Delpero N and Testa S

Haemostasis and Thrombosis Center, A.O. Istituti Ospitalieri, Cremona, Italy

Background: Since 2001 our Haemostasis andThrombosisCenter decentralized anticoagulation patient management through using portable monitors (PM) in a telemedicine system, bi-directional connected with peripheral health care units (PHU) such as Nursing Homes, Groups of General Practitioners and other hospitals of the area.
One of the main problem in decentralization management is the assurance of the quality provided by systems used.
Aims: The aims of the project were: (i) define a quality control (QC) analytical system for coagulation portable monitors used in the web organization; (ii) measure precision and accuracy in each single peripheral site to ensure good global analytical quality
Methods: Central laboratory coagulometer (STA-R; Roche) was considered as reference system. In PHU were used Coaguchek XS (Roche). Based on current guidelines for laboratory QC, the following criteria were defined:

1 PM suitabily: (i) precision calculated on normal plasmas pool, repeated 10 times, acceptable if CV < 5%; (ii) accuracy, evaluated on 10 pathological specimens with INR < 4.0, accettable if INR differences < ± 0.5.
2 Intra-assay precision: each PHU elaborates monthly the Lewej-Jennings cards. Internal QC, provided by the company, was performed at the beginning of each session and every 20 samples. A CV between ± 20% was considered acceptable.
3 Quaterly accuracy to assess the agreement between analytical instruments: three samples at different therapeutic range were analyzed in duplicate. Differences £ 0.5 INR was considered acceptable.
4 External quality assessment (NEQAS): it considers both laboratory data and clinical treatment, to assess the accuracy of the global therapeutic management.

Results: In the nine PHU, 18 portable monitors were used to perform 18,210 test/year. Analytical precision was very good with a CV always < 5%. Control system showed only two controls out of range (on 360 total controls = 0.55%), giving practical indication for immediate instrument replacement. The external QC NEQAS was optimal.
Conclusions: The adopted QC protocol give an accurate and precise control of PM in use, ensuring the quality of analytical data and, by consequence, optimal patient therapeutic management. QC is a mean to ensure good results and we think that national authorities should garantee the application of correct protocols to allow PM use.

PB 2.53-3

Conventional and new global haemostasis laboratory test reveal hypercoagulation in primary multiple myeloma patients

Gracheva M[1], Urnova ES[2], Mendeleeva LP[2], Sinauridze E[2], Balandina A[3], Tarandovskiy ID[2], Vasiliev SA[2], Parovichnikova EN[2], Savchenko VG[2] and Ataullakhanov F[3]

[1]Federal Research Center for Pediatric Hematology, Oncology and Immunology; [2]National Research Center for Hematology; [3]Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow, Russian Federation

Background: During diagnosis and induction polychemotherapy patients with Multiple Myeloma (MM) have an increased thrombotic risk so anticoagulant treatment is prescribed. In some cases standard preventive anticoagulant therapy is insufficient and thrombosis occurs.
Aims: The aim of this study is to reveal laboratory tests that can detect increased thrombotic risk.
Methods: The study included 18 primary MM patients. The following assays were performed: activated partial thromboplastin time (aPTT), thrombin time (TT), International normalized ratio (INR), XIIa dependent fibrinolysis, D-dimers, thrombin generation test (TGT), thromboelastography (TEG), Thrombodynamics (a new method based on a spatial fibrin clot growth registration). Thrombodynamics is characterized by initially clot growth rate (V_i) and spontaneous clotting (indicator of prothrombotic risk).
Results: TGT indicated hypercoagulation in 15 patients (83%): A max was increased in 14 whereas ETP was increased in four patients. Among this group hypercoagulation was confirmed by Thrombodynamics in nine patients (increased Vi and/or spontaneous clotting), aPTT in five patients, D-dimers in seven patients, TEG in four patients. There were three cases with hypercoagulation by TGT where all other performed tests detected normal or hypocoagulation state.
In a group with normal TGT (three patients) Vi was in norm, there were no spontaneous clotting; aPTT was extended in two cases and normal in one case, D-dimers were increased in one patient and in norm in two cases, TEG was in norm.
TT was extended in seven patients, others in normal region. INR was increased in four patients, others in normal region. Correlation between D-dimers and XIIa dependent fibrinolysis time was detected ($R = 0.94$, $P < 0.05$).
One patient had iliofemoral thrombosis in 16 days after the survey. The following results during the primary assay had been registered: increased peak $A_{max} = 225$ nM (normal range 50–170 nM), $V_i = 62$ μm/min (normal range 36–56 μm/min), no spontaneous clotting, shortened aPTT = 30 s (normal range 32–37 s), extended D-dimers level 8.1 mg/L (normal range 0–0.5 mg/L) and all TEG parameters in normal range.
Conclusion: In primary MM patients hypercoagulation state was revealed in nine cases (50%) at least by two tests: TGT and Thrombodynamics. In patient with occurred thrombosis aPTT, D-dimers, TGT and Thrombodynamics revealed increased thrombotic risk.

PB 2.53-4

Thrombin generation test: a new and simplified expression of results

Dellanoce C, Paoletti O, Bassi L and Testa S

Haemostasis and Thrombosis Center, AO Istituti Ospitalieri, Cremona, Italy

Background: Thrombin generation (TG) is a global test which describes the haemostatic patient assessment. Because of poor standardization and automation, and difficulties in assigning an individual clinical value TG is not currently available in routine clinical practice. Another actual limitation of TG use is represented by difficulties in finding methodologies able to express synthetic results useful to practical and comprehensive interpretation.
Aims: Aims of the present study were: (i) evaluate haemostatic assessment using TG in four populations: normal patients, congenital/acquired haemophilia, congenital thrombophilia, patients with prolonged aPTT, afferring to emergency department; (ii) evaluate a methodology to simplify the expression of TG results
Methods: A total of 100 patients were studied: 40 healthy donors (I); 20 congenital/acquired haemophilias (II), 20 congenital thrombophilia patients (III) and 20 with prolonged aPTT (IV). TG was performed on Calibrated Automated Thrombogram (CAT-Stago, France) a semi-automatic instrument using fluorogenic substrate. The activation of coagulation was obtained by adding small amounts of tissue factor and phospholipids using PPP reagent (CAT- Stago, France). Blood samples for TG study were collected, immediate centrifuged and poor platelet plasma stored at −80 °C. The results calculated were: lag time (min), peak (nM), time to peak (min), velocity index (nM/min), endogenous thrombin potential-ETP (nM*min).
To evaluate the possibility to describe a thrombin potential as expression of the activation phase related to the total amount of thrombin

generated in relation to the peak, we used the following formula: Peak related to Thrombin Generation – PTG (nM) = area under the curve from t0 to time to peak (activation phase ETP) (nM*min)/total ETP (nM*min) × peak (nM).

Results: The four populations showed the following results expressed as mean ± 1DS:

1 Normal subjects: ETP (nM*min) = 1494.4 ± 307.2; PTG (nM) = 91.6 ± 16.0
2 Haemophilia: ETP (nM*min) = 507.1 ± 256.3; PTG (nM) = 11.2 ± 8.3
3 Thrombophilia: ETP (nM*min) = 1692.8 ± 269.2; PTG (nM) = 104.7 ± 15.5
4 Prolonged aPTT: ETP (nM*min) = 1207 ± 515.3; PTG (nM) = 64.9 ± 41.3

Results obtained in the fourth group, selected on the base of a prolonged aPTT in patients afferring to the emergency department, are expression of the differences in haemostatic profiles, both hyper- and hypo-coagulable, as shown by standard deviation

Conclusion: Thrombin generation, as expression of the balance between hyper- and hypo-coagulability, has well defined the four population studied, both through ETP results than PTG. In our opinion PTG has the advantage to better describe the haemostatic assessment, including the three main parameters of TG test. Further studies are required to validate its value as screening test in daily clinical practice.

PB 2.53-5

Procoagulant changes in blood plasma as a result of plasmapheresis

Surov S[1], Ovsepyan RA[1], Vysochin I[2], Serebriyskiy I[3], Kobzeva N[2], Khvatov VB[2], Ataullakhanov F[1] and Vuimo TA[3]

[1]Center for Theoretical Problems of Physicochemical Pharmacology; [2]N.V. Sklifosovsky Institute of Urgent Care; [3]HemaCore LLC, Moscow, Russian Federation

Background: Although plasmapheresis donation is a relatively safe technique commonly used today, there are reported cases of severe, sometimes lethal complications if it is applied in donors with thrombophilia or other thrombotic risk factors. Presently, insufficient attention is paid to either donor coagulation state before plasmapheresis and coagulation parameters of collected plasma.

Aims: The aim of the study was to evaluate the donors' coagulation status prior to plasmapheresis and to compare it with that of collected plasma using spatial clot growth assay (thrombodynamics) previously reported to be sensitive to procoagulant changes in plasma.

Methods: The study involved 50 male subjects aged 20–45 with plasma donation experience of not less than five times. Analysis of coagulation was carried out at different points: (i) 1 min prior to plasmapheresis; (ii) in the collected plasma product; (iii) in the thawed collected plasma product (fresh frozen plasma). At every point, different types of plasma were examined. They were: (i) platelet-free plasma (Sample PFP) and frozen platelet-poor plasma (Sample fPPP); (ii) product platelet-free plasma (Sample pPFP); (iii) product fresh frozen platelet-poor plasma (Sample fPPP*). The method used, thrombodynamics, is based on a videomicroscopic observation of fibrin clot propagation in a non-stirred layer of plasma activated by the immobilized tissue factor. The following parameters of clot growth were determined on the basis of the image series: lag time (t_{lag}), initial (V_{in}) and stationary (V_{st}) clot growth velocity, presence of activator-independent clotting.

Results: Compared with PFP, sample pPFP had evidence of hypercoagulability as indicated by a significantly higher median [range] of V_{in} and V_{st} (58 μm/min [44–72 μm/min] vs. 46 μm/min [36–55 μm/min] and 30 μm/min [21–41 μm/min] vs. 25 μm/min [20–29 μm/min], respectively. $P < 0.05$). Compared with fPPP, sample fPPP* had also evidence of hypercoagulability as indicated by a significantly ($P < 0.05$) higher median [range] of V_{in} and V_{st} (64 μm/min [56–74 μm/min] vs. 60 μm/min [50–69 μm/min] and 37 μm/min [29–48 μm/min] vs. 35 μm/min [27–43 μm/min], respectively. $P < 0.05$). Moreover, there were four cases when plasmapheresis led to activator-independent spontaneous clotting in product plasma, which indicates the high rate of hypercoagulability. Two of them showed slight hypocoagulability prior to plasmapheresis as well.

Summary/Conclusions: Plasmapheresis procedure shifts coagulation parameters from normo- to hypercoagulable state, as shown by thrombodynamics assay. Thrombodynamics can have a potential utility for the evaluation of both donors' coagulation status prior to plasmapheresis and product plasma collected using plasmapheresis.

PB 2.53-6

Thrombin Dynamics Test: a new global coagulation assay for the evaluation of the propagation phase of thrombin generation

Gerotziafas T, Ketatni H, Elalamy I and Galea V

Tenon University Hospital, Paris, France

Introduction: Prothrombin Time and aPTT are routinely used for the evaluation of coagulation but they ignore thrombin generation (TG) process. The rate of the propagation phase of TG, which is governed by the formation of the enzymatic complexes prothrombinase and intrinsic tenase, is related to the presence of hypercoagulability and is decreased by the anticoagulant treatment. Thrombin Dynamics Test (TDT) is a new assay that measures the rate of the propagation phase of thrombin generation. In the present study we evaluated the performance of the assay.

Materials and methods: TDT was performed as follows: 60 μL of platelet poor plasma (PPP) are mixed with 40 μL of NaCl (0.9%) and 20 μL In-TDT activator. After 3 min incubation at 37 °C 60 μL of In-TDT Reagent were added. Thrombin generation, triggered by aPTT/elagic acid based reagent, is detected by fast thrombin-based conversion of a chromogenic substrate and release of p-nitro-aniline which is continuously recorded at 405 nm (ThermoScientificMultiskan FC). Fibrin formation in the sample is inhibited by the addition of fibrin polymerization inhibitor (Pefabloc). All reagents were kindly offered by Pentapharm (Basel Switzerland). The Peak value of the 1st derivative of thrombin formation representing the maximum velocity of the propagation phase of thrombin generation was analysed. To establish normal range and to control the performance of the assay TDT was done on PPP from 50 healthy individuals. TDT was also performed on samples from patients treated with VKA ($n = 50$) and patients with endogenous thrombin potential (ETP) higher than 2500 nM × min, tested with Calibrated Automated Thrombogram ($n = 50$). Values of the tested samples are expressed as percentage versus a normal control sample (Calibrator) supplied from Pentapharm.

Results: The intra- and inter-assay variability was 2% et 6% respectively. The inter-individual variability was 15%. The thrombin dynamics in healthy individuals was 106.7 ± 16.5% and the Lower and Upper Normal Limit were 74% and 140%. TDT was not influenced by the sex and the age of healthy individuals. In VKA treated patients TDT was correlated with the INR ($r = 0.5$, $P = 0.006$). No corrélation was found between TDT and the values of Endogenous Thrombin Protential.

Conclusion: The TDT, using aPTT-like reagents is a user friendly global coagulation assay not requiring any particular pre-analytical conditions. TDT showed a very satisfactory performance and low inter/intra- assay variability and is not influenced by the age and the sex of the studied individuals. The inter-individual variability was 15% being similar to that of other global coagulation assays and is sensitive to detect hypocoagulablity induced by VKA treatment. TDT measures a different parameter of thrombin generation than the ETP of thrombogram.

PB2.54 – Coagulation Factor XI – I

PB 2.54-1

Ongoing risk of thrombosis with factor XI concentrate: 5 years experience in two centres

Batty P[1], Honke A[2], Uprichard J[3], Bowles L[1], Hart DP[2], Pasi J[2] and Austin S[3]

[1]Royal London Hospital; [2]Barts and the London School of Medicine and Dentistry, QMUL; [3]St George's Hospital, London, UK

Background: Factor XI (FXI) deficiency is an autosomally inherited bleeding disorder of variable clinical phenotype. Treatment options in the peri-operative period include expectant management, anti-fibrinolytics and plasma derived (pd) FXI concentrates. Two pd FXI concentrates are currently available in the United Kingdom. Initial use of both concentrates was complicated by reports of thrombosis. These episodes typically occurred in elderly patients, especially those with vascular risk factors. Since these episodes, changes have been made to the manufacturing process of both concentrates, but the relevance to thrombotic risk is unknown.
Aims: To retrospectively review the indications for FXI concentrate usage, efficacy and thrombotic events over a five-year period at two haemophilia treatment centres.
Methods: The clinical and laboratory data for all factor XI concentrates issued between November 2006 – November 2011 at both centres were reviewed, using paper and electronic records.
Results: Twenty-nine (17 male/12 female) patients with FXI deficiency were treated over the study period. The median age was 59 years (14–92). Twenty-one patients had severe FXI deficiency (FXI:C ≤ 15 IU/dL) and eight mild FXI deficiency (FXI:C > 15 IU/dL). The median baseline FXI:C was 9 IU/dL (< 1–51). A total of 93 doses of FXI concentrates were issued (31 Hemoleven (LFB) and 62 FXI (BPL)) over 64 treatment episodes. The indications for FXI infusions were to cover surgery in 87.5% (56/64), trauma/bleeding in 7.8% (5/64), non-surgical delivery in 3.1% (2/66) and as a test dose prior to surgery in 1.6% (1/64). The median number of infusions per treatment episode was 1 (1–10). The median dose of FXI concentrate used was 17 U/kg (6–42). The median peak FXI:C obtained was 61 IU/dL (26–172). Pharmacological thromboprophylaxis was used during 17.2% (11/64) of treatment episodes. There were six episodes of clinically significant bleeding with four requiring infusion of a FXI concentrate, two additional medical review, one a blood transfusion and one oral iron replacement therapy. The lowest recorded peak FXI:C in this group was 44 IU/dL. Three of these patients (3/6) were receiving pharmacological thromboprophylaxis. Two thrombotic episodes (2/64) were documented in the study period. Both occurred in patients using Hemoleven to cover surgery. The first (multiple pulmonary emboli) occurred in a patient with traditional vascular risk factors following complex orthopaedic surgery (peak FXI:C 50 IU/dL) not covered by pharmacological thromboprophylaxis. The second (transient ischaemic attack) occurred in a patient with no known cardiovascular risk factors following major urological surgery (peak FXI:C 70 IU/dL). No immune or infective complications were reported.
Conclusions: Our retrospective review demonstrates the efficacy and safety issues of using FXI concentrates across a wide range of indications. There were six episodes of clinically significant bleeding all of which were controlled with a single additional dose of FXI concentrate or standard intervention. Two thrombotic episodes occurred following major surgery, despite cautious FXI use. We suggest thorough assessment of vascular risk factors in patients requiring FXI concentrate to cover surgical procedures. Consideration of pharmacological thromboprophylaxis remains essential.

PB 2.54-2

Identification of two novel mutations in sequential nucleotides of the factor XI gene in a Dutch Caucasian family with inherited factor XI deficiency

Mulder R, Wiewel-Verschueren S, Meijer K and Mulder A

UMCG, Groningen, The Netherlands

Background: Factor XI deficiency is an autosomal recessive disorder and is predominantly present in Ashkenazi Jews. To achieve sufficient haemostasis the haemostatic level of factor XI needs to be between 15% and 20%. However, the correlation between factor XI level and bleeding tendency is weak and inconsistent. Factor XI gene contains 15 exons and 14 introns located on the long arm of chromosome 4 (4q35) and more than 240 mutations have been reported.
Aim: We performed an analysis in order to determine the molecular background of factor XI deficiency in a Dutch Caucasian family.
Methods: Factor XI activity levels were determined by an one-stage clotting assay (Siemens, Marburg, Germany), which was standardised using a home-made normal plasma pool. The reference interval, based on a locally performed reference range, was 65–150 U/dL. The assay was performed using a Sysmex CA-7000 (Siemens, Marburg, Germany). Direct sequencing analysis of all 15 exons and flanking introns of factor XI gene was performed to detect mutations.
Results: Sequencing analysis showed in all three subjects with factor XI deficiency the presence of two novel heterozygous mutations in sequential nucleotides in exon 3 of the factor XI gene: a silent mutation (NM_000128.3(FXI):c.177C>T) that preserves amino acid Phenylalanine at position 59 and a potential missense mutation (NM_000128.3(FXI):c.178A>C). These mutations were not found in another sister and two daughters with normal levels of factor XI. NM_000128.3(FXI):c.178A>C may lead to a conversion of hydrophilic and median sized Threonine at position 60 to hydrophilic large Proline. Multiple alignment analysis of the human factor XI gene sequence with sequences of other vertebrates was performed using OMA browser. The alignment showed that Threonine is highly conserved among other species. To evaluate the possible effect of Threonine to Proline substitution on the molecular structure of factor XI, we used a computer-based model (2f83) in Swiss PDB Viewer.
Threonine 60 interacts with Phenylalanine 30, Serine 96, and Valine 77 through strong hydrogen bonds. After substitution, only an interaction remains with Valine 77. Furthermore, due to its biochemical properties, Proline might result in steric hindrance with Phenylalanine 59. To prove that the novel mutations are not polymorphisms, we also performed sequence analysis in 100 unrelated healthy volunteers. No healthy volunteer carried these mutations. Additionally, these mutations may inactivate exon splicing enhancers (ESEs), leading to failure of splicing and exon skipping or inclusion of intron segments in mRNA. To test the possibility that these mutations cause a splicing defect, we used the motif-scoring matrices in a web-based program called ESEfinder. The two novel mutations did not result in an additional or abolishment of ESE.
Conclusions: It is likely that the presence of these two novel heterozygous mutations may modify the factor XI function and are associated with factor XI deficiency in a Dutch Caucasian family.

PB 2.54-3

Comparison of thromboelastographic parameters before and after fresh frozen plasma treatment in patients with factor XI deficiency and with ex-vivo samples spiked with FXI concentrate

Pike GN[1], Thachil J[1], Cumming A[1], Burthem J[1] and Bolton-Maggs P[2]

[1]Manchester Royal Infirmary; [2]National Blood Service, Manchester, UK

Background: The options for perioperative management of patients with factor XI deficiency include Solvent Detergent Fresh Frozen Plasma (SD-FFP) or factor XI concentrates. Although FXI:C levels are often monitored peri-operatively, it has been previously shown that there is poor correlation between FXI:C levels and bleeding tendency in these patients. For this reason, we used the technique of thromboelastography as an investigative tool to assess treatment response in patients with factor XI deficiency. Previous studies have demonstrated prolonged Clot Formation Times (CFT) and alpha angles on thromboelastography in these patients.

Aims: To determine the various thromboelastographic parameters before and after SD-FFP treatment in patients with factor XI deficiency undergoing surgery and after ex-vivo samples were spiked with factor XI concentrate.

Methods: Five patients with partial FXI deficiency (baseline FXI:C levels 34–47 IU/dL) and one patient with severe FXI deficiency (FXI:C level < 1 IU/dL) were treated with SD-FFP prior to surgery (dose range 13.3–24.3 mL/kg). FXI:C levels and ROTEM® thromboelastography parameters (triggered with a tissue factor concentration of 0.12 pm) were analysed prior to and after treatment with SD-FFP. In addition, in one patient with partial FXI deficiency, baseline whole blood samples were spiked ex-vivo with different amounts of FXI concentrate (equivalent to 10, 20, 30 and 40 units/kg) and similar measurements were performed.

Results: Following administration of SD-FFP to the six patients, the FXI:C levels increased by a median of 20 IU/dL (range 14–27 IU/dL). Following the ex-vivo spiking of the whole blood with factor XI concentrate, the FXI:C levels increased to 76 IU/dL (with 10 units/kg), 102 IU/dL (with 20 units/kg), 118 IU/dL (with 30 units/kg) and 143 IU/dL (with 40 units/kg).

The CFT values shortened by a median of 164s (range 45–179 s) and the alpha angle increased by a median of 21° (range 7–27°) with SD-FFP. Interestingly, although CFT values decreased to 131s and 102s and the alpha angle increased to 65° and 70° respectively with 10 and 20 units/kg of the concentrate, no further improvement were noticeable with the higher doses beyond that achieved with 20 units/kg although there was an increase in factor XI levels. This indicates a possible ceiling effect of FXI concentrate dosage on these parameters. Importantly, for clinical purposes, it was noticeable that a lower CFT (92s vs. 102s) and higher alpha angle (72° vs. 70°) were achieved with the SD-FFP *in-vivo* compared to the FXI concentrate.

Summary: Improvement in Clot Formation Time and alpha angle parameters on thromboelastography are seen following the treatment of FXI deficient patients with SD-FFP and in one patient with partial FXI deficiency following ex-vivo spiking experiments with FXI concentrate up to a dose of 20 units/kg. SD-FFP is at least as effective as factor XI concentrate in correcting thromboelastographic abnormalities in factor XI patients undergoing surgery.

PB 2.54-4

Factor XI in the relation to fetal loss: the frequency of the risk alleles

Sokol J[1], Kamil B[2], Juraj C[3], Maria S[4], Anna A[5], Jan S[3], Lenka L[3], Jan D[2] and Peter K[3]

[1]Jessenius Faculty of Medicine in Martin, Comenius University, Martin; [2]Department of Gynecology and Obstetrics, Jessenius Faculty of Medicine; [3]Department of Hematology and trasfusiology, Jessenius Faculty of Medicine; [4]Department of Biochemistry, Jessenius Faculty of Medicin Jessenius Faculty of Medicine, Slovakia; [5]Department of Oncology, Hematology Service, Institute Gustave Roussy, Paris, France

Background: Pregnancy is a prothrombotic state and a pathological exaggeration of this hypercoagulability has been increasingly linked to pregnancy loss and placenta-mediated complications. Pregnancy loss is a very significant public health issue, associated with maternal morbidity and mortality and psychological trauma. Thrombophilia (sometimes hypercoagulability or a prothrombotic state) is an abnormality of blood coagulation that increases the risk of thrombosis. The correlation between a high level of F XI and the risk of the occurrence of venous thrombosis influenced also by genetic factors was confirmed by Leiden Thrombophilia Study and MEGA study. High levels of factor XI are associated with thrombotic diseases, and severe factor XI deficiency shows protective effects against deep vein thrombosis (DVT) and ischemic stroke

Aims: In our study we focused on coagulation factor XI, which plays the main role in the coagulation cascade. We compared the level of coagulation factor XI between patients with fetal loss vs. control subjects with no history of fetal loss and thrombosis. Subsequently evaluate the frequency of the risk alleles in the relation to fetal loss.

Methods: The study was approved by the Ethical committee, Jessenius Faculty of Medicine, Comenius University – No. EK950/2011. Informed consent was obtained from each participant.

Factor XI was determining using a coagulometer (Sysmex, CA 1500, Japan). Two single-nucleotide polymorphisms (SNPs) of factor 11 gene and one SNP of CYP4V2 gene were evaluated. DNA was extracted from peripheral blood leukocytes. Isolation of genomic DNA from the whole blood was performed with SiMaxTM Genomic DNA Extraction kit (SBS Genetech Co., Ltd., China) according to the manufacturer′s instructions. The gene polymorphisms were identified with the use of restriction fragment length polymorphism and high resolution melt analysis (in the check on process of one of tag SNP), with in-house design of individual polymerase chain reaction.

Results: We examined 55 patients with fetal loss (the average age of 31.9 ± 4.1 years) and 31 healthy controls (the average age of 32.74 ± 8.94 years). A total number of patients with one to four spontaneous abortions were: 22 (40%), 24 (44%), 6 (11%) and 3 (5%), respectively.

We found significantly higher level of factor XI ($P < 0.04$) in patients with fetal loss vs. control subjects. The occurrence of two SNPs (rs2289252, rs2036914) of the factor 11 gene and one SNP (rs13146272) of CYP4V2 gene were not significantly different between patients with fetal loss and control subjects.

Summary/Conclusion: Increased levels of factor XI may be a potential risk factor for fetal loss. High levels of factor XI diagnosed at the women with fetal loss are not probably dedicated to the presence of risk alleles (rs2289252, rs2036914, rs13146272).

PB 2.54-5

A newly diagnosed with congenital factor XI deficiency in a mild hemophilia A patient by gene analysis

Otaki M, Shinozawa K, Inaba H, Chikasawa Y, Seita I, Amano K and Fukutake K

Tokyo Medical University, Tokyo, Japan

Introduction: Congenital factor XI deficiency is a rare autosomal recessive bleeding disorder that is highly prevalent in Ashkenazi Jews but rare in other ethnic groups. In Japan, only 28 cases were registered in the national survey for blood coagulation disorders carried out in 2011. Patients with factor XI deficiency show a widely varied bleeding tendency after trauma and surgery. Hemophilia A is a congenital X-linked bleeding disorder caused by various mutations in the factor VIII gene. Patients with severe hemophilia experience joint and muscle bleeding, whereas bleeding symptoms in patients with mild hemophilia are usually caused only as a result of surgery or major injury. In the present study, we investigated the genes responsible for both factor VIII and XI deficiency and newly diagnosed factor XI deficiency in a patient with mild hemophilia A.

Methods: The study was approved by the Ethics Committee of Tokyo Medical University, and the patient gave his written informed consent. Genomic DNA was extracted from leukocytes. The coding regions and exon/intron boundaries in both the factor VIII and XI genes were amplified by polymerase chain reaction (PCR). The PCR products were purified and direct sequenced with an Applied Biosystems 3730 DNA Analyzer.

Patient and Results: The patient, a Japanese man in his early 70s, presented to a local hospital with nasal and gingival bleeding after tooth extractions; he was previously diagnosed as having mild hemophilia A in his 40s. He received on-demand treatment with factor VIII concentrate at that hospital. He was then admitted to our hospital for cataract surgery. His activated partial thromboplastin time was very prolonged at 125.9 s as compared with usual mild hemophiliacs. His prothrombin time was normal. Factor VIII and XI levels were 20% and 1.5%, respectively. Levels of other coagulation factors acting in the intrinsic pathway, factors IX, XII, and von Willebrand factor, were within normal range. Factor VIII and IX inhibitor, lupus anticoagulant, and anti-CLbeta2GPI and anticardiolipin antibodies were not detected. We diagnosed combined factor VIII and XI deficiency after considering these results. In the genetic analysis, we identified a novel missense mutation, Ile2032Thr, in exon 20 of the factor VIII gene. A homozygous missense mutation, Phe221Ser, in exon 7 was also identified in the factor XI gene by direct sequencing. Interestingly, this factor XI mutation was not detected in Ashkenazi Jews; however, it was reported previously in two unrelated Japanese cases.

Discussion: A recombinant Phe221Ser mutant protein expression study reported that the mutant in the factor XI gene would cause a secretion defect (*Jpn J Thromb Hemost. 2005;16:304–311*). Although difficult to diagnose only from the patient's mild bleeding symptoms, his diagnosis was confirmed by gene analysis

Conclusion: We identified both a novel lle2032Thr mutation located in the A3 domain of the factor VIII protein and a previously reported homozygous Phe221Ser mutation located in the apple 3 domain of the factor XI protein as a mutation causing hemophilia A and factor XI deficiency.

PB 2.54-6

Pharmacodynamic tests for factor XI participation in haemostasis

Kluft C, Van Leuven K and Laterveer R

Good Biomarker Sciences, Leiden, The Netherlands

Background: Patients with factor XI deficiency show an increased risk of bleeding up till 50% factor XI antigen level. Below 50% factor XI antigen bleeding risk is increased but does not correlate to antigen levels.

Correction of clotting time in the APTT is already practically achieved at low concentrations of 10% factor XI (IC50 = 5%)

This shows a clear discrepancy between APTT testing and clinical effects. A functional method to evaluate individual risks and responses to treatment below 50% factor XI is lacking

Aims: To help to solve a diagnostic need.

To develop a functional method that shows a clear dose response between 0% and 50% antigen levels of factor XI mimicking the patient information as a potential pharmacodynamic method to include individual aspects and monitor factor XI supplementation.

Methods: We prepared mixtures of normal and factor XI depleted plasma and evaluated the response on read outs of various global methods, compared to the APTT. The methods evaluated were: thrombin generation (TGA-RCH ® of Technoclone, with 5 pM tissue factor); a newly devised chromogenic test for Xa generation, started with micronized silica, made independent of thrombin by addition of an excess of hirudin; thromboelastography (Rotem ® with tissue factor or contact activation) with and without induced lysis by adding t-PA.

Results: For all methods we studied the dose response between 0% and 100% factor XI.

We identified two methods with a higher dose response range.

These methods were the newly devised factor Xa generation test and thromboelastography with low tissue factor (1:250 diluted Extem ®) and with added t-PA.

The first method revealed that the peak of factor Xa generation was clearly dose-dependently decreased and delayed in the range of antigen concentrations of factor XI below 50%. The IC 50 was found to be 10% for peak height.

The thromboelastography method showed that the lysis rate of thrombi was dose-dependently increased over the whole range from 100% to 0% factor XI. This effect may add to occurrence of less persistent haemostatic plugs.

Conclusion: We have identified two methods showing sensitivity to low factor XI in a physiological relevant range of 0–50%, thus correlating with clinical data. They represent phenotypes other than clotting times (as in APTT), notably factor Xa generation and clot lysability. These global functional methods are candidates for pharmacodynamic methods which may express effects of individual factors and might help to explain bleeding risks in patients and be useful for monitoring need/effect of supplementation in deficient patients.

PB2.55 – Coagulation Factor VIII – IV

PB 2.55-1

Factor VIII level correlates with hemolysis and may contribute to the hypercoagulability of children with sickle cell disease

Noubouossie D[1], Lê PQ[2], Rozen L[2], Willems D[1], Ngalula Mujinga M[2], Ferster A[2] and Demulder A[1]

[1]CHU Brugmann; [2]Hôpital Universitaire des Enfants Reine Fabiola, Brussels, Belgium

Background: Factor VIII (FVIII:C) level is often increased in sickle cell disease (SCD) which is considered as a hypercoagulable state. This state is evidenced by increased markers of coagulation activation and increased thrombin generation (TG). It is influenced by the rate of hemolysis. However, the contribution of factor VIII level to this hypercoagulability is still unclear.

Aims: (i) to assess the relationship between FVIII level, von Willebrand factor antigen level (vWF Ag), markers of hemolysis and markers of inflammation (ii) to assess the contribution of elevated FVIII levels in TG and DDimers level in SCD children at steady-state.

Methods: FVIII level, vWF Ag, TG and DDimers were measured in 50 SCD children at steady-state aged between 2 and 18 years (median: 9). TG was triggered in platelets-poor plasma using 1 pM tissue factor and 4 μM phospholipids with and without thrombomodulin. The amount of thrombomodulin added was that expected to produce a 50% reduction of total thrombin generated. Only the endogenous thrombin potential (ETP), the peak height and the percentage reduction of ETP with addition of thrombomodulin (RETP) were analyzed for TG. FVIII level (%) was measured using a one stage clotting assay. DDimers and vWF Ag levels were measured using immunoturbidimetric assays. FVIII, vWF Ag and DDimers assays were performed using the STA-evo coagulation automate (Stago, Asnières-sur-Seine, France). Total hemoglobin (THb), reticulocyte count (Retic) and lactate deshydrogenase (LDH) level were also measured as markers of hemolysis. Highly sensitive C-reactive protein (hsCRP) was measured as marker of inflammation. Correlations between variables were assessed using the Spearman's test. $P < 0.05$ was considered significant.

Results: Median (IQR) values of FVIII, vWF Ag and hsCRP levels were respectively: 258.5% (194.8–307.8), 170% (127–198) and 3.14 mg/L (1.34–6.98).

FVIII level strongly correlated with vWF Ag ($r = 0.77$; $P < 0.001$), LDH ($r = 0.50$; $P = 0.001$) and reticulocytes count expressed as percentage ($r = 0.62$; $P < 0.001$). More modest but significant correlation was also observed with THb ($r = -0.32$; $P = 0.023$), absolute reticulocytes count ($r = 0.38$; $P = 0.009$), DDimers level ($r = 0.34$; $P = 0.030$), ETP ($r = 0.37$; $P = 0.009$), peak height ($r = 0.35$; $P = 0.015$) and RETP ($r = -0.39$; $P = 0.006$) of TG. No significant correlation was found between FVIII level and hsCRP ($r = 0.20$; $P = 0.214$).

Conclusion: As expected, elevation of FVIII level in SCD is associated to parallel increase of vWF level. However, the results of this study suggest that elevation of FVIII level seems to be related to hemolysis rather than chronic inflammation. Significant correlations with DDimers level and TG indicate a probable contribution of elevated FVIII level to the hypercoagulability observed in SCD children. The negative correlation observed with RETP in TG suggests that elevated FVIII level may also contribute to increased resistance to activated protein C after addition of thrombomodulin.

PB 2.55-2

Molecular changes in LRP1 and FVIII genes in patients with venous thromboembolism and high FVIII levels

Bittar LF, Siqueira LH, De Paula EV and Annichino-Bizzacchi JM

University of Campinas, Campinas, Brazil

Background: Venous thromboembolism (VTE) is a multifactorial disease, and increased levels of factor VIII (FVIII) has been demonstrated as risk factor for VTE. The low-density lipoprotein receptor-related protein 1 (LRP1) is a multifunctional receptor which plays an important role in endocytosis and catabolism of its ligands, including the FVIII.

Aims: The aim of the study was investigate if after a long-term follow-up, patients with high levels of FVIII after anticoagulant treatment. Moreover, we investigated in these patients, the presence of molecular changes in specific exons of LRP1 and FVIII genes which encode regions of interaction between these two proteins.

Design and Methods: Our initial cohort consisted of 300 adult patients with a first episode of acute VTE occurring between January 1990 and September 2004. In 2004, in a first assessment, FVIII levels were evaluated in all these patients and in 300 matched controls. In 2011, all patients from this initial cohort who originally presented FVIII levels above the 90th percentile ($n = 100$) were recruited for a second assessment of FVIII activity (FVIII:C). In total, 68 patients agreed to participate. Control subjects were again selected according to age, gender, ABO blood group. FVIII levels were measured by a one-stage clotting assay. The regions of LRP1 and FVIII genes of VTE patients were analyzed by automated capillary sequencing.

Results: Median age of the 68 patients (19 male and 49 female) was 47 years, and median of the first DVT episode was 10 years. In the first measure of FVIII, in our initial cohort, the median of the first DVT episode was 3 years. The control group consisted of 74 subjects (28 male and 46 female) with a median age of 45 years.

FVIII levels was significantly higher in patients when compared to controls [158.0 IU/dL, (82.0–216.0) vs. 126.1 IU/dL, (83.4–187.1); $P < 0.001$]. Those patients also showed higher plasma FVIII when compared to controls [235.8 IU/dL, (200.3–510.0) vs. 127.2 IU/dL, (80.1–211.0); $P < 0.001$] when previously analyzed. FVIII levels were significantly lower at the moment when compared to the initial assessment ($P < 0.001$).

We evaluated the exons 14–20 and junctional intronic regions of LRP gene, and the exons 10, 11, 16, 26 and junctional intronic regions of FVIII gene. We identified five molecular changes in the LRP gene, including two silent alterations not previously described, C2767T and G3376A (Ser970Ser), two intronic alterations in the intron 16: G3137 + 81A (previously described), C3137 + 54T and one in the intron 18 (T3380 + 114C) both not previously described. None molecular change was found in the regions of FVIII gene.

Conclusions: We demonstrated a persistent increase of FVIII levels in a subset of patients after 10 years of the first DVT, but in a much lower magnitude than that observed in the first 3 years of the disease. Despite we have found five molecular changes in the LRP gene oh VTE patients, further evaluations in a healthy group with normal FVIII levels are necessary to determine the role of these molecular changes on the modulation of FVIII levels and/or VTE risk.

PB 2.55-3

Effect of unstructured polypeptide insertions on the recombinant expression of human factor VIII

Kumar SR[1], Liu T[1], Kulman J[1], Chang P-YB[2], Ding S[2], Bardan S[1], Moore N[1], Patarroyo-White S[1], Pierce GF[1], Schellenberger V[2], Jiang H[1], Mei B[1] and Peters RT[1]

[1]Biogen Idec, Waltham, MA; [2]Amunix, Inc, Mountain View, CA, USA

Background: Fusion of unstructured polypeptides of defined amino acid composition and low immunogenic potential, known as XTEN technology, has proven to be an effective means of extending *in vivo* half-life of biotherapeutics. We are employing the XTEN technology to improve the half-life of human coagulation factor VIII (hFVIII). One or more XTENs at varying lengths were inserted to inter-domain sites, intra-domain sites, and/or C terminus of hFVIII. The insertion sites were identified based on FVIII structure analyses excluding genetic mutations reported in hemophilia A patients.

Aim: The aim of this study was to determine the effect of XTEN insertion(s) on the expression of recombinant hFVIII.

Methods: An expression vector encoding human B-domain-deleted FVIII (BDD-FVIII) was constructed using pcDNA4.1, and the XTEN modifications were generated following optimized molecular cloning procedures. The XTENs used in this study were of three different lengths (composed of 42, 144 or 288 amino acids) and of two types with slightly different amino acid compositions – AE XTEN (containing A, E, G, P, S and T) and AG XTEN (containing A, G, P, S and T). The FVIII-XTEN fusion constructs were transiently expressed in HEK293F cells using polyethyleneimine as a transfection agent. Five days post transfection the conditioned cell culture media were analyzed for FVIII activity using a chromogenic assay (Coatest); for FVIII variants with single XTEN insertion, the conditioned media were also analyzed for FVIII antigen level by ELISA.

Results: The impact of XTEN insertion on FVIII expression was found to be insertion site dependent. FVIII-XTEN remained active after single XTEN insertions at many sites, predominantly in the A domains, while insertions at some sites abolished expression. We iden-

tified three insertion sites, B domain (N745), a3 domain (Q1656) and C terminus, where a single XTEN resulted in consistently higher levels of antigen and activity than non-modified BDD-FVIII, though this could be due to either higher expression or greater stability of the protein in the cell culture media due to the XTEN insertion. Increasing the number of insertions (up to six) decreased the observed activity in a progressive fashion. In the case of multiple insertions, an XTEN at a3 domain (Q1656) partially rescued the suppression of expression resulting from XTEN insertion at another site such as those in A1, A2 and A3 domains. In general AG XTENs resulted in slightly higher observed activity than AE XTENs.

Conclusions: Human FVIII retained activity following the insertion(s) of one or more XTENs when insertion points are appropriately selected, even when one or more insertions were at intra-domain sites of FVIII. Single XTEN insertions at three specific sites enhanced the FVIII activity level. These results indicate that active FVIII-XTEN fusion proteins can be generated, providing multiple candidates for assessment of half-life extension in *in vivo* studies.

PB 2.55-4

Pharmacokinetic results from a Phase I/III study of a novel recombinant single-chain factor VIII (rVIII-SingleChain) compared to octocog alfa in severe haemophilia A patients

Pabinger I[1], Klamroth R[2], Valentino LA[3], Gill JC[4], Levy H[5], Samuels R[5], Parasrampuria R[5] and For the CSL 627-1001 Strudy group[5]

[1]Medizinische Universitaet Wien, Vienna, Austria; [2]Vivantes Hospital, Berlin, Germany; [3]Rush University Medical Center, Chicago, IL; [4]Medical College of Wisconsin, Milwaukee, WI; [5]CSL Behring, King of Prussia, PA, USA

Background: rVIII-SingleChain (CSL627, CSL Behring, Marburg) is a homogeneous, more stable recombinant FVIII containing a covalent bond linking the light and heavy chains. It has increased affinity to von Willebrand factor (VWF) resulting in faster and more efficient binding compared to other rFVIII molecules. VWF, the natural carrier protein of FVIII, increases the half-life of all FVIII. After activation, the resultant FVIIIa is identical to that derived from activation of a two-chain FVIII.

Aims: This multinational (Austria, Germany, Italy, USA) clinical trial is designed to assess the pharmacokinetics (PK), efficacy, tolerability and safety of rVIII-SingleChain. We report on the PK of rVIII-SingleChain compared with octocog alfa (Baxter, Westlake Village, CA)

Methods: Up to 30 PTPs ≥ 18 year-old with severe hemophilia A (FVIII:C < 1%) with > 150 exposure days to factor VIII were eligible for enrollment. Following an infusion of 50 IU/kg octocog alfa, PK was measured over 72 h, and after a 4 day washout, PK was repeated after an infusion of rVIII-SingleChain. Subjects were then assigned to treatment with rVIII-SingleChain either as prophylaxis or on-demand treatment for a minimum of 6 months and 50 EDs. Prophylaxis subjects were treated with rVIII-SingleChain at 20–40 IU/kg every second day or 20–50 IU/kg two to three times per week at the investigator's discretion. Patients were assessed monthly: reviewing bleeding events, response to rVIII-SingleChain, adverse drug reactions including the incidence of inhibitors, laboratory safety and virus safety parameters.

The pharmacokinetics of rVIII-SingleChain and octocog alfa were assessed on the basis of FVIII activity measured using both the one-stage and chromogenic substrate assay. The following PK parameters were calculated for baseline-corrected FVIII activity using a non-compartmental model analysis with WinNonlin Phoenix (Version 6.3): The area under the plasma activity-time curve from time zero to the last quantifiable concentration (AUC_{last}); the area under the plasma activity-time curve from time zero to infinity (AUC_{inf}); the observed maximum plasma activity after drug administration (C_{max}); incremental recovery (IU/mL/IU/kg) defined as FVIII activity (IU/mL) obtained 30 min following infusion; clearance (CL), and terminal elimination half-life ($t_{½}$).

Results: Currently 25 patients (median age 32 years, range: 19–60 years) have completed PK studies with octocog alfa and rVIII-SingleChain and the study continues to recruit subjects for PK and treatment. Individual plasma and median activity-time profiles for rVIII-SingleChain and octocog alfa were compared and show favorable kinetics for incremental recovery, AUC_{last} and half-life. Differences between FVIII levels measured with one-stage and chromogenic substrate assay were noted.

We will present detailed PK for rVIII-SingleChain and comparator, safety and efficacy data.

Summary/Conclusions: rVIII-SingleChain has excellent PK, and satisfactory safety and efficacy to advance to late-stage development. PK parameters indicate advantages over two-chain rFVIII.

PB 2.55-5

Influence of age on recombinant factor VIII pharmacokinetics: results from clinical pharmacology studies of turoctocog alfa

Recht M[1], Cerqueira M[2], Karim A[3] and Møss J[4]

[1]Oregon Health & Science University, OR, USA; [2]HEMORIO, Rio de Janeiro, Brazil; [3]National Blood Centre, Kuala Lumpur, Malaysia; [4]Novo Nordisk A/S, Søborg, Denmark

Background: Five open-label, multi-centre clinical studies (three phase 1 and two phase 3 trials) conducted in 18 countries worldwide (Brazil, Croatia, Germany, Israel, Italy, Japan, Lithuania, Macedonia, Malaysia, Poland, Russia, Serbia, Spain, Switzerland, Taiwan, Turkey, the UK and the US) have explored the pharmacokinetics (PK), safety and efficacy of turoctocog alfa, a human recombinant coagulation factor VIII (rFVIII) developed for the prevention and treatment of bleeding in patients with haemophilia A.

Aims: To investigate the influence of age on the PK characteristics of turoctocog alfa.

Methods: PK characteristics of turoctocog alfa were assessed in previously-treated paediatric (< 12 years of age) and adolescent or adult (≥ 12 years of age) patients with severe haemophilia A (FVIII activity level ≤ 1%) in a non-bleeding state and with no history of FVIII inhibitors. PK parameters were assessed following a wash-out period (≥ 3 days in paediatric patients; ≥ 4 days for adolescent/adult patients) and a subsequent single intravenous 50 IU/kg dose of turoctocog alfa. All patients were previously treated with ≥ 50 exposure days (paediatric patients) and ≥ 150 exposure days (adolescent/adult patients) to any FVIII product. Blood was sampled at regular intervals throughout a 48-hour period post-dose. PK parameters (incremental recovery of FVIII, AUC, and terminal half-life [$t_{½}$]) were based on FVIII activity, measured using a one-stage clot assay and a two-stage chromogenic substrate assay. Plots of mean PK endpoints by age or bodyweight across trials were used for a descriptive evaluation of dependency.

Results: Data from a total of 61 patients (aged 1' '54 years, including 28 patients < 12 years of age) were included, totalling 83 assessments. PK parameterswere comparable between young children (aged 0' '< 6 years) and older children (aged 6' ' ≤ 12 years). Overall, AUC and $t_{½}$ tended to increase with increasing age, with lower AUC and shorter $t_{½}$ seen in children (aged 6' '≤ 12 years) compared with adults (aged ≥ 18 years), whereas there was no clear relationship between age and incremental recovery of FVIII. Similar apparent relations between age and pharmacokinetic parameters (AUC and $t_{½}$) were also observed within the adult population alone (> 18 years). However, it cannot be excluded that factors other than age also may have influenced the differences observed.

Summary/Conclusions: Our results suggest that there may be differences in the PK characteristics of turoctocog alfa according to age. The observed apparent positive relation between age and PK parame-

ters for turoctocog alfa is in line with previous findings for commercially available FVIII products.

PB 2.55-6

N-Glycosylation of rVIII-SingleChain, a novel recombinant single-chain factor VIII

Schmidbauer S, Witzel R, Robbel L, Metzner H, Weimer T and Schulte S

CSL Behring GmbH, Marburg, Germany

rVIII-SingleChain represents a novel type of factor VIII (FVIII) product, a homogeneous recombinant single-chain FVIII, that is currently under clinical development. Commercially available FVIII products so far are two-chain molecules consisting of light and heavy chains. The pharmacokinetic properties as well as activity and immunogenicity of a protein may be affected by its post-translational modifications. Especially N-glycosylation of a protein has an impact on size, hydrophobicity and charge. It is known that the N-glycosylation pattern of recombinant proteins strongly depends on the cell type used for expression. Production cells should therefore also be selected thoroughly in view of the resulting N-glycosylation. In the present study the N-glycosylation pattern of rVIII-SingleChain was investigated and was also compared to different commercially available rFVIII products.

rVIII-SingleChain was expressed in CHO cells and purified by chromatographic methods. BDD rFVIII and full-length rFVIII were obtained from commercial sources. The investigation of the respective carbohydrate structures was performed after release of N-glycans by PNGase F and subsequent fluorescence labeling. The labeled N-glycans were analyzed by anion exchange chromatography at high pH (HPAEC) and ESI-MS.

rVIII-SingleChain manufactured in CHO cells is characterized mainly by complex type, core fucosylated N-glycan structures that are highly sialylated. As expected also high mannose type N-glycan structures were detectable. A similar pattern was observed for commercially available recombinant rFVIII products, a BDD rFVIII and a full-length rFVIII product, both expressed in CHO cells. The N-glycan structures of human plasma-derived FVIII expressed in the liver were also considered for comparison purposes. Plasma-derived FVIII contains sialylated bi-antennary complex type N-glycans as main structure besides some high mannose type oligosaccharides (T. Hironaka et al., JBC (1992), 267(12): 8012–8020). Based on the experimental and clinical experience with the commercially available rFVIII molecules it can be assumed that the known CHO cell-type specific N-glycosylation patterns of rFVIII are suitable models when choosing a cell line for expression of a new biocompatible and safe rFVIII product.

PB 2.56-1

Gas6 plasma levels in elderly patients with acute venous thromboembolism (VTE) predict major bleeding under anticoagulation and mortality but not recurrent VTE

Angelillo-Scherrer A[1], Calzavarini S[2], Méan M[3], LImacher A[4], Rodondi N[3] and Aujesky D[3]

[1]University Hospital of Lausanne (CHUV); [2]Lausanne University Hospital, Lausanne; [3]Bern University Hospital and University of Bern, Bern; [4]University of Bern, Bern, Switzerland

Background: Growth arrest-specific gene 6 (Gas6) product is a vitamin K-dependent protein which plays a role in thrombus stabilization as *Gas6* deficient mice are protected against venous and arterial thrombosis. Patients with venous thromboembolism (VTE) display elevated Gas6 plasma levels as compared to healthy volunteers.

Aims: We aimed to assess whether elevated Gas6 levels are associated with VTE recurrence, major bleeding, and all-cause mortality.

Methods: In a multicenter Swiss cohort, we prospectively enrolled consecutive patients aged ≥ 65 years with acute, symptomatic VTE between September 2009 and March 2012. Follow-up was until october 2012. Gas6 level was measured in plasma at baseline by ELISA. We defined elevated Gas6 levels as results above the median, low Gas6 levels being those below the median. Baseline characteristics of patients were compared with Gas6 levels below and above the median. We estimated the cumulative incidence of a first VTE recurrence, major bleeding under anticoagulation, or death event using the Kaplan-Meier technique and compared incidence rates among patients with elevated and low Gas6 levels by logrank tests. Associations between Gas6 levels and the time to the first event were assessed by Cox-regression. Adjustment was done for age, gender, and known risk factors for VTE recurrence, bleeding, and mortality.

Results: Of the 853 patients studied, 435 (51%) patients had elevated Gas6 levels. The median follow-up time was 18 months (interquartile range 9.5–24.2). Patients with elevated Gas6 were older (76 vs. 74 years) and were more likely to have immobilization, active cancer, post-thrombotic syndrome, history of major bleeding, chronic liver disease, anemia, high risk of fall, and a lower arterial oxygen saturation than patients with low Gas6.

The cumulative incidence of recurrent VTE did not differ between patients with elevated and low Gas6 levels (5.3 vs. 4.8 events per 100 patient-years; $P = 0.71$). However, patients with elevated Gas6 had a significantly higher cumulative incidence of major bleeding (10.5 vs. 5.9 events per 100 patient-years; $P = 0.03$) and overall mortality (18.6 vs. 5.7 events per 100 patient-years; $P \leq 0.001$) than patients with low Gas6. After adjustment, Gas6 levels were significantly associated with major bleeding (hazard ratio [HR] 2.13, 95% confidence interval [CI] 1.07–4.26) and overall mortality (HR 6.55, 95% CI 4.01–10.70) but not with recurrent VTE (HR 1.50, 95% CI 0.62–3.60).

Conclusions: Our study demonstrates that patients with elevated Gas6 levels are older and sicker than those with low Gas6 levels. Elevated Gas6 levels at baseline are significantly associated with future major bleeding under anticoagulation and overall mortality but not with VTE recurrence.

PB 2.56-2

Influence of the 3K3A-activated protein C variant on the *in vitro* fibrinolytic activity of tPA

Fernandez JA[1], Mosnier LO[1], Davis TP[2], Zlokovic BV[3] and Griffin JH[1]

[1]The Scripps Research Institute, La Jolla, CA; [2]Blood Brain Barrier Research Laboratory, College of Medicine, University of Ariz, Tucson, AZ; [3]Zilkha Neurogenetic Institute, University of Southern California, Keck School of, Los Angeles, CA, USA

Background: Tissue plasminogen activator (tPA) is used to treat ischemic stroke, but its use is limited by a narrow safety window and by increased bleeding risk. Activated protein C (APC) is neuroprotective in preclinical ischemic stroke models. Remarkably, APC, in spite of having intrinsic anticoagulant activity, reduces tPA-induced bleeding and neurotoxicities primarily due to its ability to initiate cell signaling that provides anti-inflammatory and anti-apoptotic activities and stabilizes vascular endothelial barriers, thereby reducing leakage.

Aims: The APC variant 3K3A-APC in which the three lysines 191–193 are replaced by three alanines is neuroprotective in stroke models and the subject of current efforts for translation to a novel biologic for ischemic stroke therapy when combined with tPA. Because APTT and fibrinolytic *in vitro* assay data have implications for bleeding risks and for achieving reperfusion, we used these assays to study 3K3A-APC and tPA combinations.

Methods: APTT assays were performed in the presence of recombinant tPA and human plasma-derived APC or recombinant 3K3A-APC. Fibrinolytic turbidometric assays employed plasma clots containing tPA, APC and/or 3K3A-APC. Clot lysis time was defined as the time for 50% clot lysis.
Results: The anticoagulant potency of APC and of the 3K3A-APC variant in the presence or absence of 3.0, 1.0, and 0.5 μg/mL of tPA was determined from the prolongation of the APTT. Data showed that in the absence of tPA, the mutations in the 3K3A-APC variant caused loss of approximately 90% of anticoagulant activity compared to APC. There was no significant effect of tPA on the anticoagulant activity of 3K3A-APC, although at the highest concentration of tPA (3.0 μg/mL) in presence of 90 and 140 nM, several additional seconds of APTT prolongation was seen. When human normal pooled plasma that contained 20 nM APC or 3K3A-APC and tPA at varying concentrations was clotted by addition of thrombin and then clot lysis was monitored over several hours, the clot lysis time was dose-dependently shortened by increasing tPA. The presence of 20 nM of either normal or variant APC had no statistically significant effect on the ability of tPA to induce clot lysis compared to buffer controls. When the fibrinolytic activity of 0.25 μg/mL tPA was assayed in the presence of varying concentrations of each APC species, there was no statistically significant effect for either APC species when the APC level was ≤ 50 nM. However, plasma-derived APC exhibited profibrinolytic effects when present at ≥ 70 nM. But the 3K3A-APC mutant with its greatly reduced anticoagulant activity did not influence the fibrinolytic activity of tPA even when present at levels up to 140 nM.
Conclusions: Based on these results, when 3K3A-APC is present at very high levels in plasma, there appears to be no deleterious effects of tPA on the APTT or of 3K3A-APC on the fibrinolytic activity of tPA. Thus, if one considers tPA and 3K3A-APC combinations for ischemic stroke, this study failed to generate concerns about any undesirable effects of one agent on the other agent's activities that are reflected in APTT and fibrinolytic assays.

PB 2.56-3
Differences in isoforms of antithrombin in infants and adults

Karlaftis V[1], Attard C[1], Monagle P[2] and Ignjatovic V[1]
[1]Murdoch Childrens Research Institute; [2]The University of Melbourne, Melbourne, Vic., Australia

Background: Antithrombin (AT), a key anticoagulation protein, has been shown to exist in various isoforms in adult plasma: native AT (NAT), cleaved AT, pre-latent AT (pre-LAT) and latent AT (LAT). The NAT isoform is present in two glycoforms, α-AT and β-AT, where a single glycosylation site difference leads to a significant difference in the affinity of these isoforms for heparin. The AT isoforms present in infants and children are yet to be characterized and are likely to play an important role in the interaction of AT with heparin. Knowing that 15% of patients at tertiary paediatric hospitals are administered some form of heparin therapy, research focusing on age-specific differences AT isoforms may have vast clinical implications.
Aims: To investigate the differences in AT isoforms in healthy infants compared to adults.
Methods: Citrated, platelet-poor plasma samples from infants (28 days–1 year old) and adults were collected and stored at −80°. All participants were healthy individuals, without previous thromboembolic events, family history of bleeding or thrombosis, and not subjected to any form of anticoagulant therapy. This protocol was approved by the Royal Children's Hospital, Melbourne, Ethics Committee (# 20031).
AT was purified from plasma using an AKTA FPLC system and a 1 mL HiTrap NHS-activated column (GE Healthcare) which was coupled with 6 mg of polyclonal sheep anti-human AT-specific antibody (Affinity Biologicals). The elution profiles were compared between the pooled sample from infants and adults.
Results: The AT elution peak obtained for the adult samples was made up of two peaks with a retention time of 27.65 and 28.07 min in comparison to the single AT elution peak for infants with a retention time of 28.07 min.
Summary/Conclusions: These results indicate that there are differences in the AT isoforms between infants and adults. The profiles indicate that the AT isoforms present in infants may be more similar to the first peak observed in the adult samples which elute at the same times. This needs to be confirmed in a larger number of samples. The specific differences in AT between the samples will be further characterised using mass spectrometry to retrieve sequence information, and to establish the precise molecular weight of the different AT isoforms. Furthermore, the specific heparin binding of the different AT isoforms has never been determined.
The final results regarding age-specific differences in the ratio of these isoforms in age-specific plasma samples is important when considering the clinical implications that these variations may have on heparin therapy.

PB 2.56-4
Effect of functional alpha2macroglobulin and antithrombin concentration on thrombin generation and decay in liver cirrhosis patients

Kremers RMW[1], Ninivaggi M[1], Bloemen S[1], Chayouâ W[1], Kleinegris MC[1], Koek GH[2], Ten Cate-Hoek AJ[2], Wagenvoord R[1] and Hemker CH[1]
[1]CARIM, Maastricht University; [2]Maastricht University Medical Center, Maastricht, The Netherlands

Background: α2Macroglobulin (α2M) has been reported to increase two- to four-fold in liver cirrhosis patients, whereas the level of antithrombin and other serpins (AT) as well as of procoagulant factors decreases proportionally to the severity of the disease. α2M and AT are responsible for the decay of thrombin. The increase of one inhibitor and the decrease of others may result in a net change in the inhibitory capacity of the plasma. A net decrease of the over-all inhibitory capacity might counterbalance the decrease of procoagulant factors.
Aims: To relate the over-all decay constant of thrombin as well as the isolated α2M dependent decay constant to the plasma levels of α2M and AT, both in a set of normal controls as well as in a series of patients with liver cirrhosis.
Methods: AT concentrations were determined by titration with purified α-thrombin. α2M was determined by saturation with excess α-thrombin and removal of excess free thrombin with AT-heparin. Thrombin generation was measured with the whole blood (WB) CAT technique. The pseudo first order decay constant of thrombin was obtained from the descending slope of the TG curves; the pseudo-first order constant of α2M-dependent decay from the formation velocity of the α2M-thrombin complex. Inhibitor concentrations were correlated to decay parameters by Pearson's correlation analysis. Differences in decay parameters and inhibitor concentrations between the patient and control group were analysed with the Mann-Whitney test.
Results: The α2M and AT assays performed well, with intra-assay CVs of 5.1% and 3.1% and inter-assay CV's of 11.9% and 7.8%. Mean α2M and AT concentrations in the group of healthy subjects were 3.6 ± 0.9 and 2.1 ± 0.3 μM, respectively, which is comparable to values reported in the literature. α2M levels in liver cirrhosis plasma samples were significantly increased (5.0 ± 1.0 μM; $P = 0.002$) compared to the control group, and AT levels were found to be significantly decreased (1.6 ± 0.7 μM; $P = 0.037$). The over-all thrombin decay constant in healthy controls was 0.375 ± 0.030/min (CV 8%) and the α2M dependent one 0.028 ± 0.013/min (CV 46%). In the cirrhosis group these figures were 0.285 ± 0.083 and 0.036 ± 0.013/min.
In the ensemble of the samples total thrombin decay and thrombin decay by serpins is significantly correlated with the AT level ($P = 0.005$ and $P = 0.001$, respectively). The α2M level is significantly

associated with the α2M dependent decay parameter only ($P = 0.002$). The overall parameter of thrombin decay in a TG curve was on the mean 24% lower in cirrhosis patients than in controls ($P = 0.006$), showing that an increase in α2M cannot completely compensate for the loss of AT in liver cirrhosis patients.

Conclusion: Inter-individual variation in thrombin inhibitor concentrations causes variation in thrombin decay (CV 8%) and thereby contributes to variation in net thrombin generation (CV 16%). In liver cirrhosis AT decreases and α2M increase but the latter increase cannot compensate for the former decrease. This makes that over-all TG is less affected than could be expected from the decrease of procoagulant factors.

PB 2.56-5

Antithrombin assays can vary in sensitivity to homozygous antithrombin Budapest III, a defect that causes heparin resistance

Cooper PC[1], Hickey KP[2], Beauchamp NJ[3], Horn L[4], Hughes C[5], Bellamy M[6], Maclean RM[2], Kitchen S[2] and Makris M[7]

[1]Sheffield Teaching Hospitals (NHS Foundation Trust), Sheffield; [2]Royal Hallamshire Hospital, Sheffield Teaching Hospitals NHS Foundation Trust; [3]Sheffield Diagnostic Genetics Service, Sheffield Children's NHS Foundation Trust; [4]Department of Haematology, St James's University Hospital; [5]Department of Specialist Laboratory Medicine, St James's University Hospital; [6]Department of Anaesthetics, St James's University Hospital, Leeds; [7]Department of Cardiovascular Science, University of Sheffield, UK

Background: Antithrombin (AT) is an important inhibitor of thrombin and FXa, and deficiency results in increased tendency to venous thrombosis. AT deficiency may be due to lack of production (type I) or to production of functionally defective AT (type II), the defect may affect the reactive site (type RS), heparin binding site (type HBS) or have more than one effect (type PE). Subjects with homozygous HBS defects may have an inadequate laboratory response to heparin therapy. Low molecular weight heparin (LMWH) may be measured using anti-FXa reagents that may or may not include added AT. Antithrombin level is routinely assayed by measuring AT inhibition of thrombin or FXa in the presence of heparin, by means of chromogenic substrates.

Aims: We present data on two patients homozygous for the type II AT deficiency, AT Budapest III. Both patients showed poor laboratory response to LMWH when tested with a chromogenic anti-Xa assay that does not include added AT (AFXaA). We report discrepancies between commercial AT assays.

Methods: Blood from two subjects (A and B) was taken into 0.109M sodium citrate approximately 4–6 h post injection of LMWH, and plasma anti-FXa activity was measured by Coamatic AFXaA on Sysmex analyser. Antithrombin activity was measured on ACL TOP analyser (Instrumentation Laboratory, IL) by four chromogenic assays: Berichrom (Siemens) bovine thrombin-based assay modified by using 30s inhibition time; Innovance human FXa-based assay (Siemens); Liquid Antithrombin assay using bovine FXa (IL); and Coamatic assay utilising bovine FXa (Quadratech). Antithrombin antigen was measured by Liatest ATIII assay (Stago) modified for ACL TOP analyser. Two dimensional electrophoresis (2d CIE) of AT was performed in the presence and absence of heparin using antibodies from Dako, and genetic analysis was carried out by direct sequencing of *SERPINC1*.

Results: Both patients had anti-FXa levels of < 5 IU/dL 4–6 h post injection of maximal therapeutic dose LMWH, and this level did not increase when mixing patient plasma with an equal volume of normal plasma. AT activity (Berichrom) and AT antigen levels were reduced in both patients, (activity/antigen IU/dL) levels were 38/50 in patient A and 45/60 in patient B. In both subjects 2d CIE of AT indicated defective heparin binding, and both were found to be homozygous for AT Budapest III. Chromogenic AT level also varied by FXa-based assay, patient A had Liquid Antithrombin level of 41 IU/dL and Innovance AT level of 17 IU/dL, whereas patient B had Liquid Antithrombin level of 52 IU/dL and Innovance AT level of 14 IU/dL. In one sample from patient A, Berichrom AT was 31 IU/dL, and Coamatic AT was 30 IU/dL.

Summary/Conclusions: The inadequate anti-FXa response 4–6 h after injection of therapeutic dose LMWH was not corrected by addition of AT (pooled normal plasma), which may indicate increased clearance of plasma LMWH. AT activity levels varied by assay type, and the assay utilising human FXa showed significantly lower AT activity than the other assays, the lower level might better explain the poor anti-FXa response to LMWH in these two patients with AT Budapest III.

PB 2.56-6

Anticoagulant effect of two new estrogens (R- and S-Fenetame)

Flores M[1], Fernández JMG[2], Marin RO[3], Uribe-Lezama EC[4], Herrero-Díaz F[4], Fourtoul van der TG[5], Pinzon E[6], Torres I[6], Salgado V[6] and De la Pena-Díaz A[6]

[1]Instituto Nacional de Cardiología Ignacio Chávez; [2]UNAM, Instituto de Química; [3]UNAM, Facultad de Química; [4]UNAM; [5]UNAM, Facultad de Medicina, Departamento de Biología celular y Tisular; [6]UNAM, Facultad de Medicina, México, D.F., Mexico

Introduction: Estrogenic therapies increase the risk of thrombosis. Continuing with our program of design and synthesis of new estrogen compounds with antithrombotic activity, we had designed and synthesized N-[(3-Hydroxy-1,3,5(10)-estratriene-17β-il)]-(R)-(+)-β-methylphenethyl-amine (R-fenetame) and N-[(3-Hydroxy-1,3,5(10)-estratriene-17β-il)]-(S)-(+)-β-methylphenethyl-amine (S-fenetame).

Aim: Characterize by X-ray spectroscopy R- and S-fenetame and determine the whole blood clotting time.

Material and Methods: The estrogens derivatives were designed and synthesized at the Institute of Chemistry, UNAM. The compounds were dissolved in DMSO and administered subcutaneously to male mice, 29–33 g of weight, strain CD1 which remained at controlled temperatures 21–24 °C, food and water *ad libitum*, light-dark cycles of 12–12 h. After 24 h of the administration, we measured the whole blood clotting time with 25 μL of a whole blood sample, obtained of the dorsal vein of the mice. The blood was made alternately flow by gravity between two marks in a capillary tube (angles ± 60° with respect to the horizontal plane). We record the time until the blood is clot and stop to flow in the capillary tube. The protocol was approved by the institutional scientific and ethic committees.

Results: We obtained the the X-ray molecular structure of (i) R-fenetame and (ii) S-fenetame, in a solid state. The blood clotting time was measured by (sec, mean and SE). Results show the difference respect to the control group (in percent). Both estrogen enantiomers treated mice have to increase de blood clotting time. S-fenetame and R-fenetame, to dose of 1, 2 year 4 mg/kg: increased 16, 43 and 20% and 61, 184* and 27%, respectively. *$P \leq 0.05$ vs. vehicle. ANOVA, with Dunnett. Prism 5.0

Conclusions: The results show that both enantiomers increased the blood clotting time in a dose dependent manner. R-fenetame showed a two times stronger increase the blood clotting time compared with S-fenetame.

PB2.57 – Fibrinogen/Fibrin – III

PB 2.57-1

Genotype and phenotype of a large series of patients with congenital dysfibrinogenemia

Casini A[1], Boehlen F[1], Neerman-Arbez M[2] and De Moerloose Ph[1]
[1]University Hospitals of Geneva; [2]University of Geneva Faculty of Medicine, Geneva, Switzerland

Background: Congenital dysfibrinogenemias (CD) are characterized by biosynthesis of a structurally abnormal fibrinogen molecule that exhibits reduced functional properties compared to level of fibrinogen antigen. To date a large number of mutations have been identified in patients with CD, although few are predictive of the clinical phenotype. In order to better understand the clinical complications in relation to the genotypes, we report a survey of 65 CD diagnosed in our laboratory.
Methods: Biological and clinical characteristics were recorded at reception of samples using a standardized case report. After isolation of genomic DNA, exons and intron-exon junctions of the fibrinogen genes were amplified by polymerase chain reaction (PCR) and sequenced.
Results: Between 2005 and 2012 we diagnosed 65 CD. Samples were sent to our laboratory principally to perform a familial screening (n = 23, 36%), before surgery (n = 14, 21%), following thrombosis (n = 8, 12%) and for investigation of bleeding (n = 7, 11%). The median age at time of DNA analysis was 36 years (range 1–76 years). The median fibrinogen activity (Clauss method) was 0.66 g/L (range 0.1–2.3) and the median antigen fibrinogen was 3.5 g/L (range 1.4–5.3). Mutations were identified in the coding sequences of fibrinogen genes in all 54/54 (100%) probands. Heterozygous missense mutations in residues Arg35(Arg19) of FGA in exon 2, Arg301(Arg275) of FGG exon 8 and surrounding residues accounted for almost 75% of CD. Twenty-three patients (43%) had mild bleeding episodes, easy bruising, epistaxis and menorrhagia being the most frequent. Thirteen (20%) and 3 (5%) patients experienced at least one venous or arterial thrombosis, respectively. A total of 30 pregnancies were reported, including 6 (20%) miscarriages. Deliveries were not associated with bleeding complications.
Conclusions: Mutations in exon 2 of FGA and in exon 8 of FGG are the most frequent causes of CD. At the time of diagnosis half of patients experienced mild bleeding or thrombotic events. CD is associated with miscarriage. An ongoing trial is evaluating the long term follow-up of these patients in order to better define the true incidence of bleeding complications and/or thrombotic events during the course of disease.

PB 2.57-2

Proteases in human pancreatic juice degrade both liquid and carrier-bound fibrin sealants *in vitro*

Adelmeijer J, Porte RJ and Lisman T
University Medical Center Groningen, Groningen, The Netherlands

Background: Fibrin sealants are used in a variety of surgical procedures mainly to control bleeding and to reinforce suture lines. Furthermore, these products are frequently applied to enhance tissue sealing for purposes other than induction of hemostasis in procedures including liver, lung, and pancreatic surgery. We have previously shown that fibrin sealants are unstable in the presence of human bile, and this observation may explain the lack of efficacy of fibrin sealants to avoid bile leak-related complications following liver surgery. Fibrin sealants have been used in pancreatic surgery for almost 35 years with the main aim of preventing fistula formation as a consequence of leakage of pancreatic juice. However, the clinical efficacy of this approach is still unclear.
Aims: Here we investigated the stability of commercially available liquid and carrier-bound fibrin sealants in the presence of pancreatic fluid using *in vitro* experimentation.
Methods: Fibrin clots were generated *in vitro* from two commercially available liquid fibrin sealants and exposed to saline or human pancreatic fluid. Degradation of clots was assessed by weighing clots or by examination of release of fibrin degradation products. Also, pancreatic fluid was exposed to the carrier-bound fibrin sealant Tachosil, and stability of the sealant was assessed qualitatively and quantitatively by measuring fibrin- and collagen degradation products.
Results: Clots generated from liquid fibrin sealants degrade rapidly in pancreatic fluid, but not in normal saline, as evidenced by a rapid reduction in clot weight and release of fibrin degradation products. Exposure of Tachosil to pancreatic fluid results in rapid degradation of both the fibrin and collagen part of the sealant, as evidenced by release of fibrin- and collagen degradation products and a visual inspection of sealant integrity. Protease inhibitor cocktails or individual serine protease inhibitors reduce breakdown of both liquid sealants and Tachosil, and a collagenase inhibitor reduces breakdown of Tachosil.
Conclusions: Proteases present in pancreatic juice effectively degrade both liquid and carrier-bound fibrin sealants *in vitro*. These results may imply that the use of these products in pancreatic surgery with the aim to prevent fistula formation as a result of leakage of pancreatic fluid may serve limited purpose.

PB 2.57-3

The same mutations in patients with congenital dysfibrinogenemia leading to different clinical manifestations

Zhou J[1], Jiang L[2], Ding Q[3], Xi X[2], Wang X[3] and Wang H[2]
[1]Shanghai Institute of Hematology, Ruijin Hospital; [2]Shanghai Institute of Hematology; [3]Ruijin Hospital, Shanghai, China

Background: Congenital dysfibrinogenemia is known as a disorder with various manifestations. Fifty percent of affected people are asymptomatic, while 25% of affected ones suffer bleeding and the other 25% have thrombotic risk.
Aims: This study is to investigate the different clinical manifestations appeared in two unrelated dysfibrinogenemia families with the same mutations. Proband A has haemorrhagic manifestations, while proband B undergoes thrombosis performance.
Methods: PCR amplification and direct sequencing technology were used to identify the mutations in these patients. The antigen level (Fg:Ag) and activity level (Fg:C) of fibrinogen patients were detected by immunoturbidimetric assay and clauss assays, respectively. Routine thromboelastogram (TEG) test was performed to evaluate the comprehensive coagulation status of patients and functional fibrinogen TEG test was carried out to evaluation the level of functional fibrinogen in patients. Fibrinogen clottability, fibrin polymerization and fibrinolysis measurement were applied to evaluate the functional fibrinogen in patients. Aα, Bβ and γ chains of fibrinogen were detected by Western blot.
Results: The value of Fg:C in these two probands was 0.35 and 0.6 g/L, and the ratio of Fg:C and Fg:Ag was lower than 0.5 in both of them, which can diagnose them as dysfibrinogenemia. We identified the same compound heterozygous: AαArg289Gln, which is a novel mutation, and γArg275Cys in these two patients, as well as their family members. The molecular weight of Aα, Bβ and γ chains of fibrinogen in these two probands were the same as that in normal pooled plasma shown by western blot results. The CI value in TEG test was −8.1 in proband A, showing hypocoagulated status in her body, while that in proband B was within the normal reference range, which may due to antithrombotic drugs she had taken. The MA value in functional fibrinogen TEG test totally depends on the levle of functional fibrinogen. It was 2.8 in proband A and 3.2 in proband B, which was lower than the low limit of normal reference range (10~25), suggesting

the reduced level of functional fibrinogen in both patients, which was also consistent with their diagnosis as dysfibrinogenemia. The fibrinogen clottability rate was 18.15% and 47.26%, respectively, in proband A and proband B, compared to that in normal control. The fibrinogen polymerization curve of proband A was almost on the baseline, suggesting bleeding manifestation in this patient. The takeoff time in the curve of proband two was earlier than that in normal control, indicating its thrombosis risk, although its peak value was relatively lower. The fibrinolysis rate of proband B was slower than that of proband A, and the dissolving rate was 38% in proband A and 20% in proband B, further indicating thrombosis risk in proband B.

Conclusion: Our results were consistent with clinical manifestations of the patients, which can further explain the different manifestations in these patients. We have excluded all the other polymorphisms related to thrombosis. So, we propose a hypothesis that it may be the different assembly of proteins that leads to the different clinical manifestations in these two patients.

PB 2.57-4

Novel fibrinogen gamma-chain mutation p.Asp342Asn (fibrinogen Pisa) associated with hepatic fibrinogen storage disease and hypofibrinogenaemia

Robusto M[1], Braidotti P[1], Nastasio S[2], Maggiore G[2], Peyvandi F[3], Asselta R[1] and Duga S[1]

[1]University of Milan, Milano; [2]Università di Pisa, Pisa; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy

Background: Type I fibrinogen deficiencies (hypofibrinogenemia and afibrinogenemia) are rare congenital disorders characterized by low or unmeasurable plasma fibrinogen antigen levels. Their genetic bases are represented by mutations within the three fibrinogen genes, FGA, FGB, and FGG, coding for Aalpha, Bbeta, and gamma fibrinogen chains. So far, about 130 genetic defects have been reported to cause a- or hypofibrinogenemia, but only four mutations, all located in the fibrinogen gamma-chain gene, were shown to cause hepatic endoplasmic reticulum storage disease (ERSD).

Aims: To find the genetic basis of hypofibrinogenemia and to investigate the possibility of hepatic fibrinogen storage disease in a 4-year-old female with elevated serum aminotransferases.

Methods: Plasma functional and antigen fibrinogen levels were measured by an assay based on fibrin polymerisation time and by an enzyme-linked immunosorbent assay, respectively. Mutational screening was performed by direct sequencing of PCR products covering the coding sequence of FGA, FGB, and FGG genes. Liver histology was evaluated by light microscopy and immunocytochemistry.

Results: The proband had concordantly reduced functional and immunologic fibrinogen levels (136 and 117 mg/dL, respectively), distinctive of hypofibrinogenemia. Molecular screening revealed the presence of a novel heterozygous transition (c.1024G>A) in exon 8 of FGG, leading to the p.Asp342Asn missense mutation (p.Asp316Asn, according to the mature protein numbering). This non-conservative amino acid substitution involves a highly conserved residue located in the C-terminal globular D-domain of the gamma chain. The same mutation was found also in the proband's mother and grandfather, who also had similarly reduced plasma fibrinogen levels but no sign of liver disease. Histological analysis of hematoxylin-eosin stained sections of proband liver biopsy samples revealed hepatocyte cytoplasmic microvescicular steatosis and the presence of small globular and needle-like inclusions. These inclusions were negative with PAS-D and iron histochemical reactions, not refracting with polarized light and not auto fluorescent. All cytoplasmic inclusions of hepatocytes were strongly immunoreactive with anti-fibrinogen antibody.

Conclusions: This work reports the identification of the fifth mutation in the FGG gene leading to hypofibrinogenemia and liver ERSD. As described in other families, our data confirm that the link between the FGG mutation and ERSD is not as strong as that with hypofibrinogenemia.

PB 2.57-5

Molecular characterization of the fibrinogen molecule in seven unrelated patients from Cordoba, Argentina

Guglielmone H[1], Minoldo S[2], Jarchum G[2], Rodriguez G[1] and Bastos L[2]

[1]Universidad Nacional de Córdoba, Córdoba; [2]Sanatorio Allende, Cordoba, Argentina

Background: Inherited disorders of fibrinogen (Fg) are classified according to a complete lack of Fg in plasma (afibrinogenaemia), a partial deficiency (hypofibrinogenaemia) or evidence of an abnormal circulating molecule (dysfibrinogenaemia). In addition, a mix of both qualitative and quantitative conditions (hypodysfibrinogenaemia) has been reported.

Aim: In the present report we describe the molecular characterization of the Fg molecule from unrelated patients which show abnormal laboratory results consistent with the presence of alterations in the Fg.

Materials and Methods: Blood samples from seven patients without hemorrhagic or thrombotic history were analyzed by PCR using genomic DNA under standard conditions. Primers were designed from the sequence for each fribrinogen genes (GenBank accession numbers M64982, M64983 and M10014). Activated partial thromboplastin time (APTT), prothrombin time (PT), thrombin time (TT) and reptilase time (RT) were assayed on a semi-automatic coagulometer. Plasma functional Fg (Fg:C) was performed by Clauss method and Fg antigen (Fg:Ag) by Mancini test using specific polyclonal antibodies.

Results: All the samples analyzed showed a prolonged TT and RT compared to normal values (42 ± 15 vs. 12 ± 2 s and 39 ± 23 vs. 18 ± 3 s respectively). According to the ratio Fg: C/Fg: Ag four patients were included in the group of dysfibrinogenaemias (0.39 ± 0.22) and three in the hypofibrinogenaemias (0.83 ± 0.13) compared with normal values (> 0.75). In three patients with low levels of Fg:C we found the same mutation in the gamma chain (Phe281Leu). In the remaining patients the gamma chain showed a described mutation (Arg275Hys) and in other cases new mutations were found. Alpha and beta chain mutation were absent in all the patients analyzed.

Discussion: New and known mutations in the gamma chain of Fg were found in our cohort of patients from Cordoba, Argentina and the most important finding was associated with the presence of Phe281Leu mutation associated with low levels of Fg.

PB 2.57-6

Stream with high shear rate decreases tensile strength of plasma clots

Savushkin AV

Chita State Medical Academy, Chita, Russian Federation

Coagulation problems are very important for many diseases and their treatment. In natural conditions clotting mostly takes place into moving blood, but there is very little information in publications about influence of a stream on properties of the clot and thrombus.

The aim of our work was to study if the stream conditions can influence on tensile strength of plasma clots.

The samples of blood were obtained from 30 volunteers. Centrifugation was used to get plasma. Clotting took place into the cell of the special stretching measure equipment, where plasma had been flowing before stop as the result of coagulation. After that cylindrical plasma clot (diameter 6 mm) was slowly stretched before rupture and critical force was registered. The clots formed in unmoving plasma were used

as 'the control'. Two regimes of plasma stream were examined: (i) average shear rate was 45.4 + 15.8 (1/s); (ii) average shear rate was 55.1 + 23.0 (1/s). These speeds are natural for venous blood stream. In control group the rupture force equaled 177 + 53 mN. In group A it was less on 13 + 10 mN (authenticity coefficient 1.3), and in group B it was less on 22 + 9 mN (authenticity coefficient 2.44).
Thus the clots formed in flowing plasma were shown to have less tensile strength than ones formed in unmoving substrate.

PB2.58 – Other Coagulation Factors – II

PB 2.58-1

Two novel mutations in the gamma carboxylase gene causing VKCFD1

Watzka M, Blaurock N, Horneff S and Oldenburg J
Institute for Experimental Haematology and Transfusion Medicine, Bonn, Germany

Background: Post-translational conversion of glutamic acid (Glu) in gamma-glutamyl carboxyglutamic acid (Gla) is an essential step in biosynthesis of biologically active vitamin K-dependent coagulation factors including factor II, VII, IX, X, Protein C, and Protein S, as well as active calcium binding proteins matrix Gla protein (MGP) and osteocalcin (bone Gla protein, BGP). This conversion is catalyzed by the microsomal enzyme gamma-glutamyl carboxylase (GGCX) which requires vitamin K hydroquinone as a cofactor. The process generates equimolar amounts of vitamin K 2,3-epoxide, which in turn is reduced by vitamin K 2,3-epoxide reductase complex subunit 1 (VKORC1) to vitamin K quinone and further to vitamin K hydroquinone in the vitamin K cycle. Combined deficiency of these factors (VKCFD) is caused by defects in either GGCX or VKORC1 and represents a very rare autosomal recessive disorder.
Methods: Direct sequencing of VKORC1 and GGCX genes was applied for mutation detection in a 13 year old girl originating from Germany. Vitamin K dependant coagulation factor activity was significantly diminished. Furthermore, the girl was presented with atrial septal defect, supra valvular pulmonary stenosis, cochlear hearing loss, hypertelorism, short-neck, flat nasal bridge, and underdeveloped ear helix. Treatment with 20 μg vitamin K/day results in mostly normal VKD coagulation factor activity. This study was approved by the local ethics committee and informed consent was obtained prior to genetic analysis.
Results: In our patient, two compound heterozygous mutations in GGCX gene were detected (p.Ser284Pro; p.Trp315*). Thus, VKCFD1 can be diagnosed as cause of combined vitamin K dependant coagulation factor deficiency.
Conclusions: Due to its type, the nonsense mutation p.Trp315* must be considered causative for the observed phenotype. The missense mutation Ser284Pro to date has also not been reported, the sequence around Ser284 is highly conserved and therefore functional relevance is likely. Indeed, this region forms part of the interface of the fourth transmembrane helix and the second ER-lumenal loop. As the resulting proline due to its structure is known as a 'helix-breaker', the observed mutation might result in a disturbed topology of this enzyme. The reported defects in heart, bone, and cartilage development most probably are result of missing gamma-carboxalation of MGP, BGP, and periostin. Treatment with high doses of vitamin K normalises function of vitamin K dependent coagulation factors.

PB 2.58-2

Real-life use of high and standard initial doses of activated recombinant Factor VII (rFVIIa) in patients with haemophilia A and B with inhibitors – data from the UKHCDO/NHD registry

Hay CRM[1], Bjerre J[2] and Dolan G[3]
[1]*Manchester Royal Infirmary, Manchester, UK;* [2]*Novo Nordisk, Bagsværd, Denmark;* [3]*Queens Medical Centre, Nottingham, UK*

Background: Activated recombinant FactorVII (rFVIIa) is an established treatment for bleeding episodes in haemophilia patients with inhibitors. In the United Kingdom, rFVIIa is recommended at standard (3 × 90 μg/kg) or high (1 × 270 μg/kg) doses, the latter providing more rapid but equally effective control of bleeding. When licensing the higher dose,EMA requested post-marketing surveillance for thrombosis in patients receiving high-dose regimens.
Aims: A post-marketing surveillance study was conducted by the UK National Haemophilia Database to assess the use and safety of low and high initial rFVIIa doses.
Methods: The UK National Haemophilia Database (NHD) collected treatment and safety data prospectively on patients treated with rFVIIa from UK centres and submitted this quarterly to Novo Nordisk for transmission to EMA between 1/1/08 and 30/6/11. Safety data included adverse drug reactions. Dosage was decided by the managing clinician. The initial rFVIIa dose was categorised as low (≤ 90 μg/kg), intermediate (90–180 μg/kg) or high (180–270 or ≥ 270 μg/kg). A single-dose regimen was defined as one dose per >26 h. The study was conducted in accordance with the Declaration of Helsinki and was terminated when the EMA were satisfied.
Results: In total, 139 patients received rFVIIa for 1356 treatment episodes. Sixty-seven patients with haemophilia A or B were treated for 1057 (78%) episodes (median 7.0 episodes/patient, range 1–124). Ninety-nine percent (1048) of episodes occurred in inhibitor patients. Most (1009 episodes) were treatments, on demand, for non-surgical bleeding. A high initial rFVIIa dose (≥ 180 μg/kg) was used for 406/1057 (38%) of episodes, while 51% of episodes were treated with lower rFVIIa doses (≤ 90 μg/kg, 16%; 90–180 μg/kg, 35%; incomplete data, 11%). Higher initial doses tended to be used in haemophilia patients compared with other bleeding disorders (median 146.3 vs. 39.1 μg/kg; mean 178.4 vs. 60.0 μg/kg). Forty-seven (70%) patients and 539 (51%) episodes were treated with a single dose of rFVIIa, representing the most frequently-used regimen. In patients with any bleeding disorder, a single rFVIIa dose was ≥ 180 μg/kg suggesting a reduced need for repeat dosing when higher-dose regimens are used. The duration of treatment (median 2.5 h, range 2.5–1616.5) and number of required doses (median 1; range 1–88) were also lower when initial doses ≥ 180 μg/kg, were used compared with lower doses (90–180 μg/kg: median duration of treatment 5.1 h [range 2.5–2498.7], median number of required doses 2 [range 1–131]). No adverse drug reactions, including thromboembolic events, disseminated intravascular coagulation or anti-rFVIIa antibody formation, were reported in any patient.
Conclusions: Real-life data for the use of rFVIIa in patients with haemophilia with inhibitors shows that a single dose is the most frequently used regimen, especially with higher initial doses, and that the use of higher initial dosing is associated with reduced treatment duration. No thromboses or adverse drug reactions were reported for any rFVIIa treatment or dosage. These data suggest that a high rFVIIa dose is effective for treating bleeding episodes, decreases the number of doses and duration of treatment without compromising safety.

PB 2.58-4

Recovery of factor XIII and thromboelastometry during pregnancy in a case of severe factor XIII deficiency

Poulsen LH, Larsen OH and Funding E

University Hospital of Aarhus, Aarhus, Denmark

Background: Severe factor XIII (FXIII) deficiency is a rare congenital disorder associated with bleeding and spontaneous abortion, unless replacement therapy is initiated early in pregnancy. Based on case reports the recommendation is to maintain a FXIII level above 10% from 5 weeks of gestation, but the ideal dose to secure pregnancy remains to be elucidated. *In vitro* studies using global coagulation assays such as thromboelastometry show significant alteration of coagulation kinetics in FXIII-spiked whole blood. Thromboelastometry may provide additional useful information on clot formation and stability in FXIII-deficiency, however, published data are sparse.

Aims: In a case of severe FXIII deficiency, we report the usefulness of thromboelastometry in addtion to FXIII recovery measurements in the successful management of pregnancy and delivery.

Methods and Results: A 31-year old woman weighing 95 kg with a typical history of recurrent miscarriages was referred to our department for coagulation analyses. She was diagnosed with severe FXIII subunit A deficiency with a FXIII antigen level of < 1% (HemosIL™). At the time of diagnosis she was pregnant gestation week 8 with discrete vaginal bleeding and replacement therapy with plasma derived FXIII (Fibrogammin®) was started immediately. Bleeding ceased, and there were no further complications. Initially, the patient visited the outpatient clinic every week with repeated evaluation of recovery by measurement of FXIII antigen level. The suggested starting dose of 250 ie FXIII weekly had to be increased to 500 ie before an acceptable trough level close to 10% was achieved. Subsequently recovery was performed every second week. From gestation week 27 the dose was further increased to 750 i.e. weekly. Due to the increasing FXIII demands and a continuous propensity for epistaxis, whole blood thromboelastometry (ROTEM®) was performed before and after *in vivo* FXIII replacement in parallel with FXIII recovery in week 33. Standard assays in addition to a low tissue factor assay was applied and normal whole blood clot formation and stability was observed following *in vivo* replacement in concordance with the FXIII recovery. Hence, the dosing was considered safe and maintained unchanged. Before delivery by sectio gestation week 40 the patient received 1500 i.e. of FXIII, and there were no excess bleeding.

Conclusion: The required dose of FXIII replacement to maintain FXIII levels above 10% was higher than reported in most cases, probably due to the patients increased bodyweight. As expected dose requirements increased during the pregnancy. These observations underscore the necessity of individualized coagulation monitoring during the entire pregnancy. Furthermore, evaluation by thromboelastometry aided dose adjustment and is a useful supplement to FXIII antigen measurements.

PB 2.58-5

Health-related quality of life in hemophilia patients with inhibitors receiving prophylaxis with anti-inhibitor coagulant complex (AICC): results from AICC prophylaxis study

Stasyshyn O[1], Antunes S[2], Mamanov V[3], Ye X[4], Xiong Y[4] and Tangada S[4]

[1]Institute of Blood Pathology and Transfusion Medicine, Liviv, Ukraine; [2]UNIFESP, Sao Paulo, Brazil; [3]Hematology Research Center of the Russian Academy of Medical Sciences, Moscow, Russian Federation; [4]Baxter Healthcare, Deerfield, IL, USA

Background: Hemophilia patients with inhibitors face significant challenges in controlling bleeds and are at high risk for arthropathy which may impact health-related quality of life (HRQoL).

Aims: This analysis aimed to determine whether prophylactic treatment with FEIBA (AICC) for hemophilia patients with inhibitors improved HRQoL compared to on-demand treatment as well as the impact of annual bleed rates (ABRs) on HRQoL.

Methods: A one-year prospective, randomized, open-label and parallel clinical study was conducted to compare the efficacy, safety, and HRQoL of prophylactic vs. on-demand treatment in hemophilia A or B patients with high-titer inhibitors and ≥ 12 bleeds a year. All patients gave informed consent and the study was conducted according to the Declaration of Helsinki and its amendments. Patients were randomized into two study arms: prophylaxis 85 ± 15 U/kg every other day vs. on-demand over a course of 12 months. HRQoL was assessed using the EQ-5D (age ≥ 14 years), hemophilia-specific QoL instruments: Haem-A-QoL for adults (age ≥ 16 years) and Haemo-QoL for pediatrics (age < 16 years), and Visual Analogue Scale (VAS) for Pain (age ≥ 12 years). HRQoL was collected at baseline, 6-month and termination for each arm. HRQoL changes from baseline to termination were compared between the two arms using the Student t-test and were interpreted as being clinically meaningful if they exceeded their respective minimally important difference (MID) threshold. Regression for repeated measure using data at baseline, 6-month and termination was conducted to assess the impact of ABRs on physical HRQoL.

Results: Thirty-six subjects (mean age = 27.4 years) met the study criteria, of these, 17 received prophylaxis and 19 received on-demand treatment. After 12 months of follow up, patients on prophylaxis reported a mean improvement of 0.075 on EQ-5D index score and 15.7 on EQ-5D VAS, both larger than the established MIDs for these measures (0.07 and 7, respectively). Little change in EQ-5D scores was seen in the on-demand arm. The EQ-5D health profile showed that a larger percentage of patients reported improved function compared to the on-demand patients, particularly in mobility (16.7% vs. 6.3%), self-care (25.0% vs. 6.3%), and usual activities (25.0% vs. 12.5%). With regard to Haem-A-QoL, prophylaxis, not on-demand, patients reported improvement in physical HRQoL (21.9) and overall HRQoL (9.5) larger than estimated MID thresholds (11.4 and 7.7, respectively). For Haemo-QoL, analysis was limited due to the small number of pediatric patients who completed the questionnaire. In addition, prophylaxis patients showed a larger reduction in general pain as compared to on-demand patients (23.2 vs. 5). While no statistically significant differences in HRQoL were found between the treatment arms, this study was not statistically powered to detect the difference in these parameters. When controlling for age and time, ABR was found to have significant negative impact on hemophilia-related physical HRQoL ($P < 0.05$). Patients experienced higher ABRs had significantly worse physical HRQoL than those with lower ABRs.

Conclusions: Patients on prophylaxis showed greater improvement in HRQoL than those who received on-demand treatment. In addition, reduced ABRs led to better physical HRQoL among hemophilia patients with inhibitors.

PB 2.58-6

Plasma levels of factor VIIa-antithrombin complex in normal pregnancy and in patients with pre-eclampsia

Spiezia L, Visentin S, Radu C, Bon M, Woodhams B, Cosmi E and Simioni P

University of Padova, Padova, Italy

Background: Increasing tissue factor (TF)-dependent activity has been reported to occur both during normal pregnancy and in patients who develop pregnancy complications (e.g. pre-eclampsia (PE)). During normal pregnancy there is a progressive increase in TF dependent activity as the pregnancy advances making it difficult to differentiate the advance of normal pregnancy from the development of pregnancy complications like PE. Simple diagnostic tests are needed that may give early warning of developing complications so that earlier treatment can be initiated. At present no sensitive routine tests for TF activity is available, probably as a consequence of the low concentrations of TF in the circulation. In normal subjects, TF activity is considered to be < 10 pM, much lower than the sensitivity of any present available routine assay. One approach that could be used is to use an assay that can indirectly reflect increasing TF activity. One candidate for this may to measure the plasma levels of factor VII-antithrombin complex (FVIIa-AT). FVIIa-AT has been shown to reflect the degree of intravascular exposure and production of TF and may thus have some utility in monitoring pregnancy.
Aim: A case-control study to evaluate plasma levels of FVIIa-AT and FVIIa during normal pregnancy and in patients with PE.
Methods: One hundred and five pregnant women referred to the Section of Maternal Foetal Medicine of University Hospital of Padua, were entered into the study. These included $n = 30$ women in the first (T1), $n = 30$ in the second (T2), $n = 30$ in the third (T3) trimester of pregnancy and 15 women with PE. As controls samples were collected from 30 normal non-pregnant women. Samples were only collected after obtaining informed consents from the patients.
FVIIa-AT complex levels were determined in plasma using a specific ELISA and FVIIa measured using a clot based assay based on activation by truncated TF (both from Diagnostica Stago, Asnieres, France).
Results: Plasma FVIIa-AT complex levels (mean ± standard deviation, SD) were significantly higher in pregnant (119 ± 24pM) than in healthy (103 ± 18pM, $P = 0.001$) women. FVIIa-AT increased with advancing pregnancy but the increase did not reach statistical significance. No significant difference in FVIIa-AT levels between women during T3 and with PE was observed. FVIIa levels were stable through out pregnancy but were found to be lower in PE (this decrease did not reach statistical significance). Women with PE had significantly higher FVIIa-AT/FVIIa ratio than women during T3 and this change was statistically significant (2.01 ± 0.44 vs. 1.50 ± 0.29, $P = 0.001$).
Conclusion: Increased levels of FVIIa-AT were found in normal pregnancy reflecting the expected increase in TF activity. Using either the FVIIa-AT or FVIIa assay alone, could not be used to discriminate patients with PE from advancing normal pregnancy. This study did show that the FVIIa-AT/FVIIa ratio may have clinical utility for detection of PE. Further studies are needed to confirm our results and to see if the increase in FVIIa-AT/FVIIa ratio has clinical utility in predicting the occurrence of PE. Studies are also needed to see if this method can detect developing PE at an earlier stage than present methods.

PB2.59 – Regulation of Coagulation and Fibrinolysis – II

PB 2.59-1

Acute atherothrombotic stroke is not associated with systematic enhancement of thrombin generation

Gerotziafas T[1], Psychogios K[2], Vemmos K[2], Vandreden P[3] and Elalamy I[1]

[1]Tenon University Hospital, Paris, France; [2]Acute Stroke Unit, Alexandra Hospital, University of Athens, Athens, Greece; [3]Research and Development, Diagnostica Stago, Gennevilliers, Paris, France

Background: Thrombosis and atherosclerosis are major contributors to the development of ischemic atherothrombotic stroke. However thrombosis is more than a local reaction leading to the obstruction of the atherosclerotic vessel or the embolization of the vessels above the atherosclerotic lesion. We hypothesised that arterial thrombosis triggered by plaque rupture is related to a generalized hypercoagulable state. In the present study we explored the evolution of thrombin generation in acute ischemic stroke patients.
Methods: We enrolled 21 patients with ischemic stroke. Eligibility criteria were: age > 18 years, first-ever in life stroke of atherosclerotic origin, symptom onset < 3 h before admission. *Exclusion criteria*: non atherothrombotic stroke (i.e. lacunar, cardioembolic,cryptogenic), liver or renal insufficiency, active cancer and recent chemotherapy, rheumatoid disease, VKA, UFH or LMWH treatment during the last 15 days, contraindications to antiplatelet treatment. Platelet Poor Plasma (PPP) samples were tested with Calibrated Automated Thrombogram using PPP-5pM TF reagent. Samples were obtained at the following time-points: T1: on admission (after the confirmation of the diagnosis of acute stroke); T2: 12 h and T3: 24 h after initiation of aspirin; T4: at discharge from the stroke unit at 10 days after treatment initiation. Patients received prophylaxis LMWH after T3. The control group consited of 21 age and sex-matched healthy individuals. The endogenous thrombin potential (ETP), the Peak and the mean rate index (MRI) of TG were analysed.
Results: At inclusion (T1), thrombin generation was not significantly different between acute stroke patients and the control group. At time points T2, T3 and T4 thrombin generation was not significantly different as compared either to T1 or to the control group. s well as was similar between controls and patients at time-points 1, 2 and 3. At time point 4 a significant increase of ETP was observed, compared to the control group and to the previous time points. A significant increase was observed for the Peak of thrombine at time point 1 and 4. TtPeak was slightly shorter at time-point 1. The mean rate index (MRI) of the propagation phase of thrombin generation was significantly lower in patients (at each studied time point) compared to the control group.
Conclusion: The present study demonstrates that patients with atherothrombotic stroke do not present biological signs of activation of blood coagulation either at the acute phase or during the hospitalization period. These data support the concept of the preponderance of platelet activation in the pathogenesis of acute atherothrombotic stroke.

PB 2.59-2

A novel methodology for modulation of fibrin clot lysis: the role of fibrinogen-targeted artificial binding proteins

King R, Tiede C, McPherson M, Manfield I, Fishwick C, Tomlinson D and Ajjan R
Leeds University, Leeds, UK

Background: Cardiovascular disease (CVD) remains the main cause of morbidity and mortality in the developed world. Fibrin clot structure and fibrinolysis can determine predisposition to CVD and manipulating the prothrombotic environment can reduce the risk of vascular events. However, current treatment strategies are only partially effective at reducing the thrombotic milieu, and frequently associated with adverse events secondary to bleeding. Therefore, identification of new therapeutic targets is necessary to reduce thrombosis potential in high risk subjects.

Aims: The aim of the research was to utilise an artificial binding protein (adhiron) phage display library to screen fibrinogen for binding peptides that could interfere with clot lysis, in particular interaction with plasminogen inhibitor (PI).

Methods: A phage display library consisting of two loops of nine amino acids, constrained in a protein scaffold was used to screen against fibrinogen (library size: 10^{10} adhirons). After multiple rounds of panning, high affinity binding adhirons were released by the addition of excess PI. To determine if the adhirons were acting at functionally relevant sites, fibrinogen-binding adhirons were tested in turbidimetric assays using plasma and purified systems. Time from full clot formation to 50% lysis was taken as clot lysis time. In a plasma system, adhiron/fibrinogen molar ratio was kept at 5:1, whereas this ratio was reduced to 2:1 in the purified system.

Results: Numerous adhirons were seen to bind fibrinogen and therefore only those with the highest binding affinities were tested, including a total of eight adhirons. In a plasma system, time to 50% clot lysis was 840 s, with four adhirons increasing this by a mean of 894 s (range 144–1872). One adhiron abolished clot lysis, another adhiron reduced clot lysis by 48 s whereas two had no effect. We then tested adhirons that prolonged, reduced and had no effect on plasma clot lysis in a purified system, both in the presence and absence of PI.

In a purified system and in the absence of PI, adhiron A2 prolonged clot lysis from (mean ± SD) 648 ± 34 to 996 ± 85 s ($P < 0.05$), whereas adhirons G2 and G4 had no significant effect at 708 ± 51 and 672 ± 34 s, respectively. Clot lysis time in the presence of PI was 1332 ± 85 s, which was further increased to 2016 ± 68in the presence of adhiron A2, whereas G4 had the opposite effect with clot lysis time reduced to 1152 ± 68 s ($P < 0.05$). G2 had no significant effect on PI-mediated prolongation of clot lysis (1356 ± 51 s).

Summary: The use of a phage display system allows rapid screening of proteins with numerous random peptides for the investigation of coagulation protein interactions. In this instance the interactions between fibrinogen and PI were analysed. We discovered two adhirons that bind to fibrinogen at functionally active sites and were capable of enhancing and reducing the effects of PI respectively. These adhirons could be the focus of novel therapeutic agents for thrombotic disorders and may even be beneficial in those with bleeding tendencies.

PB 2.59-3

Bradykinin enhances sympathetic nerve-induced cardiac tPA release possibly by transactivation of the β2-adrenergic receptor

Aspelin T, Eriksen M, Carlson CR, Ilebekk A and Lyberg T
Department of Medical Biochemistry, Oslo University Hospital, Ullevål, Oslo, Norway

Background: Both infusion of the endogenous vasodilator bradykinin (BK) and stimulation of cardiac sympathetic nerves (SS), induce cardiac tPA release. Electrophysiological studies on transfected frog oocytes have shown that BK-receptor 2 (BK_2R) and β2-adrenergic receptors (β_2-AR) form heterodimers which may allow cross-talk between the receptors, and transactivation of β_2-AR by BK (KK Haack et al, 2010). However, clinical consequences of this receptor interaction have so far not been shown.

Aims: In the present study in pigs, we investigated *in vivo* the interplay between BK and SS stimulation on cardiac tPA release, and furthermore if ß-blocker had an effect on this potential interaction. Finally, we examined interaction between BK_2R and β_2-AR in left ventricular myocardium (LV).

Methods: Six pigs were subjected to 4 min of electrical SS_1. Thirty min later, 9 min of coronary BK_1 infusion was given, and the last 4 min with simultaneous SS_2 (BK_1/SS_2). Subsequently, β-blocker (propranolol) was given and the stimulations were repeated (BK_2 and BK_2/SS_3). Blood was collected frequently and simultaneously from a shunt in the adjacent coronary vein and from the femoral artery, and cardiac tPA release was determined. Mean of three samples in each stimulation period was used to estimate total tPA release. Co-immunoprecipitation studies in lysates from isolated LV biopsies were performed using antibodies against β_2-AR and BK_2R.

Results: SS_1 induced a 6.3 ± 2.2-fold increase in tPA release compared to baseline, whereas BK_1 induced a 13.2 ± 4.8-fold transient increase in tPA release with return to baseline (at 3 min) despite continuing BK infusion, probably due to desensitization. At this point of BK-desensitization, SS_2 combined with continued BK infusion induced 13.5 ± 4.7-fold increase in cardiac tPA release, an increase of 2.3 ± 0.3-fold as compared to SS_1. Following β-blockade, BK_2 and BK_2/SS_3-induced tPA release was not significantly different from baseline release. BK_2R co-precipitated with β_2-AR demonstrating interaction between BK_2R and $ß_2$-AR in LV.

Summary/Conclusions: The present study demonstrates physical interaction between BK_2R and $ß_2$-AR in pig LV myocardium. Despite desensitized BK_2R *in vivo*, BK still enhanced SS-induced cardiac tPA release indicating BK-transactivation of β_2-AR. β-blocker seemed to inhibit both BK and combined BK/SS-induced tPA releases. Importantly, this is the first *in vivo* study showing interplay between SS and BK stimulation through BK-transactivation of $ß_2$-AR, i.e. heterodimerized with BK_2R, thus leading to enhanced SS-induced cardiac tPA release.

PB 2.59-4

Processed vs. pooled plasma enhances thrombin generation and reduces tissue factor pathway inhibitor

Jouppila A[1], Sandset PM[2] and Lassila R[3]
[1]HUCH Research Institute, Helsinki, Finland; [2]Oslo University Hospital, Oslo, Norway; [3]Helsinki University Central Hospital, Helsinki, Finland

Background: Standardized solvent/detergent treated pooled human plasma (Octaplas®, Octapharma) is indicated for the management of bleeding patients requiring replacement of multiple plasma coagulation factors, for patients with coagulation deficiencies due to hepatic disease, for patients undergoing cardiac surgery or liver transplantation, and for the treatment of thrombotic thrombocytopenic purpura (plasma infusion or plasma exchange). Severe protein S deficiency is a contraindication for administration of plasma, the reason being historical coincidence of thromboembolic complications. However, the mechanism behind this contraindication remains uncertain, as the levels of natural anticoagulants in Octaplas® are reported to represent normal references.

Aim: Our aim was to study thrombin generation capacity and the content of tissue factor pathway inhibitor (TFPI) in various plasma samples.

Methods: As plasma samples Octaplas®, standard human plasma (SHP, Siemens) for clinical chemistry grade and pooled unprocessed

plasma (PP) (both fresh and freezed) were used. Thrombin generation was measured with calibrated automated thrombogram (CAT, Thermo Labsystems) in the absence of corn trypsin inhibitor and free and total TFPI antigen with specific ELISA (Asserachrom® Free TFPI, and Total TFPI, Stago). The lipid content regarding total cholesterol, triglycerides (TG), low (LDL) and high density lipoproteins (HDL) and protein S free antigen and protein C activity were measured with routine techniques and APTT with coagulometer (Amelung KC4, Sigma) using Actin FSL reagent (Siemens).

Results: APTT baseline results were similar, 35, 30 and 30 s in Octaplas®, SHP and PP, respectively. In CAT, however, all variables indicated enhanced thrombin generation in Octaplas®; time to peak (ttpeak) was 4 s and peak 280 nM, in SHP ttpeak was 7 s and peak 225 nM, while in PP ttpeak was 8 s and peak only 155 nM (65% of that with Octaplas®). Total TFPI concentration was compatible with the CAT data. In PP total TFPI was highest, 53.7 ng/mL and free TFPI was 12.5% of the total. In Octaplas® (two batches, blood group O and A) total TFPI was 60% less, being 33.4 and 36.7 ng/mL, respectively, but free TFPI was 25% of the total. In SHP total TFPI was 45.7 ng/mL free TFPI representing 25%. The lipid content was the lowest in Octaplas® (TG 0.65; LDL < 0.1; HDL 0.49 mM) in comparison to SHP (TG 1.02; LDL 2.0; HDL 0.97 mM) and PP (TG 0.86; LDL 2.5; HDL 1.55 mM). Protein S free antigen and protein C activity were 81% and 103% in Octaplas®, 90% and 98% in SHP and 95% and 125% in PP, respectively.

Conclusions: Octaplas® demonstrated most thrombin generation and least TFPI antigen concentration in comparison with SHP and pooled plasma. This finding may bear implications in patients with deficiencies of natural anticoagulants, and suggest that Octaplas® units are effective already at smaller quantities.

PB 2.59-5

Resveratrol and its dimers down-regulate protein S mRNA expression in HepG2 cells

Tsuda H[1], Nakazono E[1], Sata S[1], Kishi A[2], Matsukawa T[2] and Ohnuki K[3]

[1]Nakamura Gakuen University, Fukuoka; [2]Mikakuto Co., Ltd., Osaka; [3]Kyushu Nutrition Welfare University, Kitakyushu, Japan

Background: Protein S is an anticoagulant factor that acts as a cofactor of activated protein C and its plasma level is decreased in high-estrogen conditions such as pregnancy and oral contraceptive use. Protein S deficiency is known to be genetic as well as environmental risk factor for venous thromboembolism. Resveratrol (3,5,4′-trihydroxy-*trans*-stilbene), a phytoestrogen in red wine and various plants, has been reported to possess many health benefit effects including anti-atherosclerotic, anti-cancer and anti-aging effects. We previously demonstrated that resveratrol down-regulates protein S expression in HepG2 cells independently of estrogen receptor (Hiroto Y. et al. Thromb Res 2011;127:e1-e7).

Aims: This study aimed to determine whether the newly synthesized resveratrol dimers, having no affinity with estrogen receptor, affect protein S expression in HepG2 cells.

Methods: The resveratrol dimers, UHA4002 and UHA4003, were prepared by heat-treatment of resveratrol in alkaline solution, followed by purification with reverse-phase HPLC and a LH-20 gel-column. The structure of the dimers was determined by the physical data of nuclear magnetic resonance and mass spectrometry. HepG2 cells were incubated with resveratrol and resveratrol dimers, and then the mRNA expressions of protein S, protein C and b chain of C4b-binding protein (C4BP-b) were analyzed by reverse transcription-polymerase chain reaction using a Thermal Cycler Dice Real Time System (Takara).

Results: One hundred mM resveratrol down-regulated protein S mRNA expression in HepG2 cells to about 30% of control (0.1% DMSO); however, protein C and C4BP-b mRNA expressions were not affected, as previously reported. At a concentration of 10 mM, both UHA4002 and UHA4003 down-regulated protein S mRNA expression to 40–50% of control; while resveratrol showed no effect. Although C4BP-b mRNA expression was not affected by resveratrol dimers, protein C mRNA expression was inhibited by 10 mM UHA4003.

Conclusion: Both resveratrol dimers down-regulated protein S mRNA expression in HepG2 cells at a concentration of less than one-tenth of resveratrol, furthermore, UHA4003 suppressed protein C mRNA expression. These two dimers conserve the two hydroxyls at carbon-3 and -5 of resveratrol, which may be prerequisite for the protein S mRNA suppression by resveratrol and its dimers.

PB 2.59-6

Twelve weeks of daily exercise reduces thrombin generation in young, overweight males

Gram AS[1], Skov J[2], Bladbjerg E-M[2], Ploug T[1], Sjödin A[1] and Stallknecht BM[1]

[1]University of Copenhagen, Copenhagen; [2]University of Southern Denmark, Esbjerg, Denmark

Background: Physical activity has several acute effects on blood coagulation. Notably, enhancement of coagulation can be detected immediately after exercise. Much less is known about the effects of long-term exercise programs on coagulation variables, some of which are risk markers for cardiovascular disease (CVD). Obesity is an important risk factor for CVD, and treatment of obesity is challenging and the results often disappointing. Therefore, individuals who are overweight but not yet obese constitute a subpopulation that undoubtedly has a potential of benefit regarding primary CVD prevention.

Aims: We hypothesized that 12 weeks of strictly controlled exercise with-out diet modification would induce changes in thrombin generation in plasma from moderately overweight subjects. The present study aimed to quantify these changes and investigate whether the effects of exercise on thrombin generation were dose-dependent.

Methods: A total of 61 overweight (BMI: 25–30, percentage body fat: ≥ 25%) and sedentary (VO_2 max < 45 mL/min/kg) male subjects between 20 and 40 years were randomized to one of three groups. One group was instructed to perform aerobic exercise corresponding to 600 kcal/day (~60 min/day, HIGH), another to perform aerobic exercise corresponding to 300 kcal/day (~30 min/day, MOD) and the last to maintain their habitual lifestyle (CON). Three times per week, the subjects in the HIGH and MOD groups exercised at an intensity above 70% of VO_2 max. The subjects were monitored throughout the program and instructed not to change their dietary habits. Fasting venous blood samples were collected before and after the intervention. Thrombin generation was assessed by the automated calibrated thrombogram method.

Results: The 12-week intervention was completed by 53 individuals, who showed excellent training compliance (MOD: 98.9%; HIGH: 96.1%). There were no significant differences in the measured variables between the three groups at baseline. The exercise-induced reduction in body weight (MOD: −3.6 kg, $P < 0.01$; HIGH: −2.7 kg, $P < 0.01$) and increases in aerobic capacity were significant in the HIGH and MOD, but not the CON group. The endogenous thrombin potential (ETP) was significantly reduced in the HIGH (2164 nM*min vs. 2001 nM*min, $P = 0.038$, $n = 18$) and MOD (2224 nM*min vs. 2044 nM*min, $P < 0.01$, $n = 18$), but not in the CON (2144 nM*min vs. 2179 nM*min, $P = 0.24$, $n = 17$) group. The changes in ETP were not significantly different between the HIGH and MOD group (−163 vs. −180 nM*min; $P = 0.85$). However, when the CON group was compared with the HIGH and MOD group combined, the change in ETP differed significantly (33 vs. −174 nM*min, $P = 0.02$).

Conclusions: We found that young, overweight men following an intensive exercise program for 12 weeks had a significant reduction of around 8% in ETP. The reduced coagulability is of clinical interest,

since it could reflect a reduced risk for CVD. Notably, this effect was not dependent on dose of exercise, since the reductions in ETP in the HIGH and MOD group were similar, but different from the CON group. Further studies are needed to elucidate whether the observed effects can be ascribed to exercise alone or the induced weight loss.

PB2.60 – Cancer and Thrombosis – V

PB 2.60-1

High resolution transcriptomic analysis of trousseau syndrome

Dalkilic S[1], Ozkeserli Z[1], Ilk O[2], Oguzulgen IK[3], Akar N[4] and Ozdag H[1]

[1]Ankara University Biotechnology Institute; [2]Middle East Technical University; [3]Gazi University; [4]TOBB ETU Hospital, Ankara, Turkey

Background: As first described by Armand Trousseau in 1865, there is a strong association between cancer and venous thromboembolic disease. This association has been validated in several studies demonstrating high incidence of malignancy in individuals who present unprovoked venous thromboembolism. Although this association has been validated by recent studies, its underlying molecular mechanisms remain elusive.

Aims: In this study we have examined the association between cancer and venous thromboembolism with the objective to determine whether idiopathic thromboembolism, cancer, cancer plus thromboembolism cases and healthy controls have a specific molecular signature characterizing each of these groups.

Methods: One hundred and twenty blood samples (30 idiopathic venous thromboembolism, 30 epithelial cancer, 30 epithelial cancer plus venous thromboembolism and 30 healthy controls) were recruited in this study. Peripheral blood samples were collected in PAXgene tubes. Total RNA was isolated by PAXgene Blood RNA Kit according to manufacturer's instructions. RNA quantity was assessed spectrophotometrically (NanoDrop). RNA integrity was checked on Agilent Bioanalyzer using RNA 6000 Nano Kit. cRNA samples were prepared using Affymetrix GeneChip 3′ IVT Kit. RNA samples were hybridized to Affymetrix GeneChip HGU-133 Plus 2.0 arrays. CEL files were analysed by dCHIP software. Differentially expressed gene lists were obtained for each comparison after the quality control, preprocessing, variance filtering steps. Functional annotation cluster and pathway analyses were conducted on DAVID bioinformatics resources.

Results: We have determined differentially expressed gene sets for each pairwise comparison using rigorous bioinformatic analyses. The number of genes in these sets was 278 for Cancer vs. Control, 98 for Cancer vs. Idiopathic Venous Thrombosis, 217 for Cancer plus Thrombosis vs. Control, 122 for Idiopathic Venous Thrombosis vs. Cancer plus Thrombosis, 331 for Idiopathic Venous Thrombosis vs. Control, 147 genes for Cancer vs. Cancer plus Thrombosis groups. Hierarchical cluster analysis showed that these gene sets were able to distinguish four sample groups from each other. Pathway and gene ontology analyses demonstrated that the genes in differentially expressed gene sets mostly belong to cancer, spliceosome, Jak-Stat signaling pathway and Leukocyte migration pathways.

Conclusions: In this exploratory study, we have identified specific gene expression profiles that are able to distinguish the four sample groups from each other. The ongoing confirmatory experiments along with gene ontology and pathway analyses of these gene expression profiles will shed light on the pathology of Trousseau syndrome.

PB 2.60-2

Estrogens downregulate TFPI expression in breast cancer cells

Ali HO[1], Stavik B[1], Dørum E[1], Iversen N[2], Sandset PM[1] and Skretting G[1]

[1]Research Institute of Internal Medicine, Rikshospitalet; [2]Oslo University Hospital, Ullevaal, Oslo, Norway

Background: Estrogens influence the pathology and development of hormone-sensitive cancers such as breast, ovarian and endometrial cancers. Tissue factor pathway inhibitor (TFPI) is a Kunitz-type serine protease inhibitor of the extrinsic coagulation pathway and has recently been associated with breast cancer cell development. Moreover, low levels of TFPI have been detected in the plasma of healthy post-menopausal women receiving hormone replacement therapy (HRT), indicating a possible link between estrogen and TFPI.

Aims: To investigate how estrogen and estrogen analogues may regulate TFPI expression.

Methods: Estrogen receptor alpha (ERα) expressing cells (MCF-7) and ERα negative cells (MDA-MB-231) were treated with estrogen and different estrogen analogues and the relative expression of TFPI mRNA and protein was measured using qRT-PCR and ELISA, respectively. Transient ERα overexpression in MDA-MB-231 and downregulation in MCF-7 cells was induced by cDNA and siRNA transfections, respectively, and was followed by stimulation with estrogens. Luciferase reporter gene constructs were used to evaluate whether the effects of estrogens were mediated through the TFPI promoter.

Results: The relative expression of TFPI mRNA and protein was significantly downregulated by more than 50% after 6 h incubation following treatment with 17β- estradiol (E2) and another potent estrogen agonist, 17α-ethynylestradiol (EE2), in ERα expressing MCF-7 cells, but not in the ER negative MDA-MB-231 cells. Moreover, TFPI mRNA was unaffected by raloxifene, a selective estrogen receptor modulator (SERM). The E2 mediated downregulation of TFPI mRNA was abolished by fulvestrant, an estrogen receptor antagonist. Furthermore, the downregulation of TFPI was not dependent on newly synthesised proteins suggesting that the estrogen mediated downregulation of TFPI may be through the ERα receptor. Overexpression of ERα in MDA-MB-231 cells induced E2 mediated downregulation of TFPI mRNA. Results from on-going ERα knockdown studies in MCF-7 cells and TFPI promoter activity assays will also be presented.

Conclusions: Estrogens significantly downregulate TFPI in ERα expressing breast cancer cells and our results indicate that their effect on TFPI promoter may be primary. These findings may help explain the aggressiveness of hormone-sensitive breast cancers.

PB 2.60-3

Internalized Protein C inhibitor (PCI) reverses impaired histone modification in Jurkat T-cell lymphoma cells

Furtmüller M[1], Sarg B[2], Lindner H[2] and Geiger M[1]

[1]Medical University of Vienna, Vienna; [2]Medical University Innsbruck, Innsbruck, Austria

Background: Acetylation and methylation of Lys-residues in the tails of histones has a crucial role in regulation of chromatin structure and gene expression. In cancer epigenetic modification of histones is altered. A significant loss of monoacetylation of Lys16 and trimethylation of Lys20 of histone H4 has been shown in lymphoma cells (Fraga et al., 2005). So far little is known about mechanisms leading to impaired histone modification in cancer cells. A nuclear isoform of cathepsin L removes the N-terminal tail of histone H3 during differentiation of mouse embryonic stem cells (Duncan et al., 2008). This H3 cleavage by cathepsin L removes binding sites for histone modifying

enzymes: for methylation of H4Lys20, the methyltransferase Suv4-20 h has to bind to H3Lys9 (Gonzalo, 2005).
PCI is a secreted serine protease inhibitor. Low PCI expression is associated with malignant phenotype (Naggara et al., 2008). PCI inhibits cathepsin L and decreases tumor cell migration (Fortenberry et al., 2010). PCI is internalized by leukocytes and translocates to the nucleus (Baumgärtner et al., 2007).
Aims: We wanted to determine if internalized PCI inhibits the processing of histone H3 by cathepsin L in cancer cells, and thereby increases the level of trimethylated Lys20 of histone H4.
Methods: Subcellular fractionation, Western blotting, acid extraction of isolated nuclei, separation of histones by HPLC, separation of non-acetylated H4 from monoacetylated H4 by capillary electrophoresis, and estimation of the degree of methylation of these two H4 forms by mass spectrometry.
Results: PCI prevented the cleavage of H3 by cathepsin L *in vitro*, as judged from Western blots. Analysis of subcellular fractions of blood leukocytes in Western blots revealed localization of PCI antigen in the nuclei of normal lymphocytes. To assess whether PCI prevents H3 cleavage *in vivo*, Jurkat lymphoma cells, which contain very little endogenous PCI, were incubated for 2 h with 300 nM recombinant mouse PCI (mPCI) and subcellular fractions were prepared. Fractions were analyzed by Western blotting with anti-mouse PCI, allowing differentiating between endogenous PCI and internalized mPCI. mPCI was found in different nuclear fractions. Cathepsin L colocalized with mPCI in the nuclease- digested fraction and in the nuclease-resistant fraction. In these fractions an additional high-molecular weight form of cathepsin L, probably corresponding to a covalent complex of PCI with cathepsin L, was seen. In cells incubated with mPCI no cathepsin L cleavage product of H3 was detected, and histone H4Lys20 trimethylation was increased to 18.8% (nonacetylated form) compared to 7.3% in control cells. Monoacetylated H4Lsy20 showed 5.7% trimethylation in mPCI-treated cells and 2.1% in control cells.
Summary: We hypothesize that internalized PCI inhibits cathepsin L thus preventing cleavage of histone H3 and rescuing trimethylation of histone H4 at Lys20 in Jurkat lymphoma cells.

PB 2.60-4
The factor XII-driven intrinsic coagulation cascade contributes to prostate cancer-associated pulmonary embolism

Nickel KF and Renné T
Karolinska Institutet, Stockholm, Sweden

Background and Aim: Deep venous thrombosis and subsequent pulmonary embolisms are frequent and life-threatening complication in prostate cancer (PC) patients. Mechanisms of PC-driven thrombosis are poorly understood and safe strategies to interfere with cancer-driven procoagulant activity remain a major medical challenge. We report a pathway by that PC-cell released particles (prostasomes) induce thrombosis *in vivo*.
Methods and Results: Clotting analyses revealed that PC-cell derived prostasomes are highly procoagulant in human and murine plasma. Prostasome-driven procoagulant activity was defective in plasma lacking the intrinsic pathway protease factor XII or its substrate factor XI. Factor XII inhibitors interfered with prostasome-driven procoagulant activity. To analyze the *in vivo* relevance of prostasomes for venous thrombosis, we challenged genetically modified mice in a model of pulmonary embolisms. Intravenous infusion of cell and PC patient purified prostasomes triggered lethal pulmonary embolism in wild-type animals. In contrast, ablation of factors XII or XI, or combined deficiency in factors XII and XI largely protected mice from prostasome-induced lethal pulmonary embolism.
Conclusion: The data identify the factor XII-driven intrinsic coagulation pathway triggered by prostasomes as a new player in PC-associated pulmonary embolisms. Inhibition of this pathway offers a novel and safe therapeutic strategy to interfere with thrombosis in PC patients.

PB 2.60-5
Analysis of the expression of RNase in blood cells involved in homeostasis in the vascular system

Murata A[1], Fujimoto K[1], Nishio M[2] and Koyama T[1]
[1]Tokyo Medical and Dental University, Tokyo; [2]Research Institute, National Center for Global Health and Medicine, Tokyo, Japan

Background: Extracellular RNA may be released from cells in cases of injury, vascular disease, or malignancy in the vasculature. It has been recognized as a novel procoagulatory and permeability-increasing factor *in vivo* and *in vitro* and it is counteracted by pancreatic-type ribonuclease (RNase 1) in endothelial cells (PNAS 2007;104:6388–93, Thromb Haemost 2011;105:345–55). Based on the identification of RNase 1 in plasma and serum, it is proposed that the enzyme is expressed by vascular cells to regulate extracellular RNA. Conversely, RNase inhibitor (RI) may be expressed in a variety of cells to protect RNA against degradation by certain RNases.
Aims: Although a gene expression profile analysis of vascular vs. lymphatic endothelium revealed strong expression of RNase 1 in the vascular endothelium, no detailed characterization of the expression and functions of RNase in the vasculature has been carried out so far. We aimed to investigate the expression and function of RNases in cells which come in contact with blood, such as blood cells and malignant cells.
Methods: We investigated the expression and activity of RNase 1 and RI using RT-PCR, western blot analysis, immunocytochemical staining and RNase activity tests in various leukemia cell lines, a multiple myeloma cell line, peripheral blood mononuclear cells, platelets, and red blood cells. We compared them with the human umbilical vein endothelial cell line EAhy926.
Results: Analyzing cell lysates and supernatants, the expression of RNase 1 and RI was determined variously at the mRNA and protein levels in all blood cells. RI was ubiquitously expressed in the blood cells. RNase activity in supernatants derived from EAhy926 cells was higher than in supernatants derived from the other cells. When incubated for different times in serum-depleted culture medium, RNase activity in supernatants derived from EAhy926 cells increased progressively, but it decreased gradually in supernatants from the other cells.
Summary/Conclusions: The RNA/RNase 1 in blood cells and malignant cells may be a novel contributor to the regulation and maintenance of vascular homeostasis.

PB 2.60-6
Inhibition of TFPI increases the sensitivity of thrombin generation assay to procoagulant microvesicles

Gheldof D[1], Mullier F[2], Chatelain B[2], Dogné J-M[3] and Chatelain C[2]
[1]Department of Pharmacy Namur Thrombosis and Hemostasis Center (NTHC)-Narilis; [2]NTHC-NARILIS, CHU UCL Mont-Godinne-Dinant, Mont-Godinne; [3]NTHC-NARILIS, University of Namur, Namur, Belgium

Introduction: Patients with cancer have a 7- to 10-fold increased risk of developing venous thromboembolism (VTE). Circulating microvesicles (MVs) could be a predictive biomarker for VTE in cancer. Thrombin generation assay (TGA) is a useful technique to detect procoagulant activity of MVs. However, TGA suffers from a lack of sensitivity due to the presence of Tissue Factor Pathway Inhibitor (TFPI) in plasma.
Aims: To improve the sensitivity of TGA to tissue factor (TF) by limiting the interference of TFPI.

Methods: Serial dilutions of MDA-MB231 cells were incubated for 45 min at 37 °C to generate MVs. Samples were then centrifuged and supernatants which contain MVs were used for TGA. Normal pooled plasma was incubated with inhibitor of TFPI or was diluted twice to decrease plasma level of TFPI. Lagtime was used as a surrogate marker of TGA to detect procoagulant activity of MVs.
Results: (i) Inhibition of TFPI decreased twice the cell concentration needed for a significant reduction of lagtime and decreased 2.4-fold the intra-assay variability. (ii) Plasma dilution had no impact on the TGA sensitivity when TGA was triggered by MVs derived from MDA-MB-231.
Conclusions: Thrombin generation is a very sensitive method to study the procoagulant activity of TF-MVs. The sensitivity can be increased by inhibition of TFPI with specific monoclonal antibody against its Kunitz Domain I. A two times plasma dilution is an interesting cheaper alternative to study the procoagulant activity of MV by TGA with a good sensitivity, especially when low plasma quantities are available.

PB2.61 – Cancer and Thrombosis – VI

PB 2.61-1

Poor predictive value of the pulmonary embolism severity index in hospitalized cancer patients with acute pulmonary embolism

Squizzato A, Riva N, Grazioli S, Turato S, Ageno W and Dentali F
University of Insubria, Varese, Italy

Background: Active cancer increases the risk of pulmonary embolism (PE) and the development of a thromboembolic event is associated with a worse prognosis. Specific risk stratification tools are needed to optimize the management of oncological patients with PE. The PE Severity Index (PESI) and the Simplified PESI (sPESI) accurately classified the general PE population in low or high risk of mortality; however the prevalence of cancer patients did not exceed 25%.
Aims: The aim of this analysis was to evaluate the performance of PESI and sPESI in oncological patients with PE.
Methods: Consecutive patients admitted to the tertiary hospital of Varese (Italy) with an objectively diagnosed PE between January 2005 and December 2009 were included. Information on clinical presentation, diagnostic work-up, risk factors, treatment and mortality rate at 1- and 3-month follow-up was collected. This sub-analysis examines the 150 oncological patients extracted from the entire population.
Results: Mean age was 69.6 (± SD 11.6) years and 84 (56%) patients were male. Most common primary sites of cancer were lung (25.2%), colon-rectal (13.3%) and bladder (8.4%). Active cancer was present in 121 patients, of whom 47 had a metastatic disease.
Overall mortality rate was 20.7% (95%CI, 15.0–27.8%) at 1-month and 38.7% (95%CI, 31.2–46.7%) at 3-month. The high risk category was overestimated, since the PESI classified 96.7% of patients and the sPESI 100% of patients at high risk of mortality. As a result, the PESI showed a high sensitivity but a very low specificity among cancer patients (100% and 4.2% respectively at 1-month follow-up, 98.2% and 4.3% respectively at 3-month follow-up). The accuracy of these two prognostic rules was lower than in the general PE population (AUC for PESI 0.66, 95%CI 0.57–0.75, and AUC for sPESI 0.69, 95%CI 0.59–0.79, at 1-month, P for comparison = 0.401). These results were confirmed at the 3-month follow-up.
Conclusions: The results of this analysis suggest that PESI and sPESI lose their discriminatory ability when applied to a pure oncological population. The creation of a new clinical prediction rule is advisable in order to redefine the risk of death in cancer PE patients.

PB 2.61-2

A retrospective review of myeloma patients over a 6 year period to investigate the prevalence of venous thromboembolism (VTE) and the risk factors associated with it

Crowley MP, Gilligan O and O'Shea S
Cork University Hospital, Cork, Ireland

Background: Multiple myeloma is a malignant disorder characterized by clonal proliferation of plasma cells. VTE is one of the leading causes of death in cancer patients. Patients with haematological malignancies have the highest risk, adjusted for age and sex. Myeloma therapies such as thalidomide and lenalidomide (IMiDs) further increase the risk. There are few dedicated studies in the literature looking at the prevalence of VTE in myeloma patients. Almost all published data is extrapolated from treatment studies where they look at the incidence of thrombotic side effects in highly selected populations. Myeloma is a disease of the elderly and in this population, co-morbidities are inherent. Therefore, looking at the rate of VTE in randomised controlled trials designed to evaluate treatment efficacy may not be generalisable. Many assessment scores have been suggested to estimate the risk of VTE in the cancer setting such as the Khorana score (*Khorana et al Blood 2008*) but these have mainly been validated in solid organ tumours.
Aims: To estimate the prevalence of VTE in a 'real world' myeloma population, to assess the risk factors associated with VTE and to investigate the validity of the Khorana score to assess the risk of VTE in myeloma patients.
Methods: The medical charts of patients with a diagnosis of myeloma attending a tertiary referral centre in Ireland between Jan 1st 2007 and Dec 31st 2012 were reviewed. The pre-treatment Khorana score was then calculated.
Results: Two hundred and seventeen patients were identified with an average age at diagnosis of 65 ± 12.26 years (Range 30–89).The male to female ratio was 5:3. Myeloma subtypes included IgG 53%, IgA 24%, Light Chain 17%, Non secretory 4%, IgD 2% and IgM < 1%. The ISS stage was known for 77–28% (49/168) were stage I, 49% (82/168) were stage II and 23% (39/168) were stage III. Sixty-six percent (143) received 1–2 lines of therapy, 32% (69) received 3–4 and 2% (5) received > 4. Sixty-nine percent (149) received IMiDs and 98%(146) of these were administered with either high dose steroids or chemotherapy. Seven percent had a second malignancy. Khorana scores were follows: 1–59%, 2–36%, 3–4% and 4–1%. Overall, there were 9675 months of follow-up with an average of 44.58 ± 37 months (Range 1–231 months) per patient. Twelve percent (27) had an episode of VTE (7% PE, 5% DVT). Non-parametric tests were performed to see if there was an association between use of IMiDs, co-existing malignancy, no. of treatment courses or Khorana score and the occurrence of VTE in this population but none were significant.
Conclusions: The prevalence of VTE in this population was similar to previously published reports. Myeloma patients have many risk factors for VTE but in this population, no one was predictive. The Khorana score was not helpful in assessing risk in this population. This is likely due to myeloma patients being under represented in cancer-associated thrombosis studies. As myeloma therapies and outcomes are rapidly changing, a dedicated prospective study is *r*.

PB 2.61-3

Survival in renal cell carcinoma patients with venous tumor thrombus: a retrospective case–control study

Ihaddadene R[1], Yokom D[2], Le Gal G[1], Moretto P[3], Reaume N[4], Canil C[5] and Carrier M[1]

[1]Ottawa Hospital Research Institute and University of Ottawa, Ottawa, ON; [2]University of Ottawa, Ottawa, ON; [3]The Ottawa Hospital Cancer Centre, Ottawa, ON; [4]Ottawa Regional Cancer Center, Ottawa, ON; [5]The Ottawa Hospital Cancer Centre and University of Ottawa, Ottawa, ON, Canada

Background: Renal cell carcinoma (RCC) with tumor thrombus (TT) remains a challenging topic in urological oncology. Approximately 4–10% of RCC patients have tumor invasion of the venous system, with extension into the renal vein (RV) and the inferior vena cava (IVC) in 65% and 35%, respectively. Despite advances in immunotherapy and targeted therapy, the standard of care for RCC with tumor thrombus is surgical resection, including radical nephrectomy and tumor thrombectomy. While it has been well established that tumor thrombus is associated with a worse prognosis, controversy remains as to the clinical importance of the localization of tumor thrombus. Some studies have shown survival differences based on the level of tumor thrombus (e.g. RV vs. IVC involvement) whereas others did not.
Aims: Our objective was to evaluate the impact of tumor thrombus and tumor thrombus level on survival in RCC patients treated with radical nephrectomy and tumor thrombectomy.
Methods: A case-control study of patients with RCC treated at our hospital from January 1st, 2005 to July 1st, 2012 was undertaken. Imaging studies and pathology reports of all included patients were reviewed to identify TT and its location. TT was defined as the presence of vascular invasion on the pathology report or an intra-luminal filling defect in the renal, hepatic veins, or IVC (infra and supradiaphragmatic) directly extending from a renal mass detected on computed tomography or magnetic resonance imaging. The primary endpoint was overall survival during the follow-up period. Hazard ratios (HR) for death and corresponding 95% confidence intervals (CI) were obtained.
Results: From a cohort of 927 RCC patients, a total of 193 stage 3–4 patients that underwent surgery were included: 66.8% were males, median age was 62.0 years (range 22–88) and 48.2% were stage 4. Tumor thrombus was present in 108 cases (12%). TT was limited to the RV in 70.4% (76/108), infradiaphragmatic IVC in 13.0% (14/108), within the hepatic vein in 1.9% (2/108), and supradiaphragmatic IVC in 13.0% (14/108). The median survival time was 47.0 months (95% CI: 31.7–52.3) in the tumor thrombus group and 65.0 months (95% CI: 42.2–87.8) in the control group. Compared with controls, all patients with tumor thrombus had worsened overall survival [HR = 1.8; 95% CI: 1.1–2.9; $P = 0.02$]. Patients with RV involvement only did not have worsened overall survival compared to those with infradiaphragmatic IVC [HR = 2.0; 95% CI: 0.9–4.3; $P = 0.07$] and supradiaphgramatic IVC [HR = 1.6; 95% CI: 0.8–3.3; $P = 0.2$]. Further, no significant difference in survival was noted between patients with infra and supradiaphragmatic IVC involvement [HR = 1.3; 95% CI: 0.5–3.4; $P = 0.5$].
Conclusions: Patients with RCC are at high risk of tumor thrombus (12%). Patients with RCC and tumor thrombus undergoing radical nephrectomy and tumor thrombectomy have a reduced survival compared to surgical RCC patients without tumor thrombus. Localization of tumor thrombus level was not associated with worse overall survival. New therapies are needed to complement surgical intervention to improve survival among RCC patients with tumor thrombus.

PB 2.61-4

The association of folate-related gene polymorphisms with colorectal cancer risk in Koreans

Kim NK[1], Kim JO[1], Jang MJ[2], Kim JW[2], Young Joo J[1] and Oh D[1]

[1]CHa University; [2]School of Medicine, CHA university, Seongnam, South-Korea

Background: Folate is important for cell division and homeostasis because it has the essential role in the synthesis of S-adenosyl-methionine, which is the methyl donor required for all methylation reactions in cells. In addition to the physiologic function of cell homeostasis, it has been investigated that folate may has important role in the carcinogenesis, especially in colorectal cancer (CRC) development.
Aims: We performed this study to investigate relationship between folate-related gene polymorphisms and CRC prevalence.
Methods: In the present study, we analyzed seven polymorphisms of *MTHFR* (677C>T and 1298A>C), *TS* (*TSER* 2R/3R and 1494 0/6 bp), and *RFC-1* (−43T>C, 80G>A, and 696C>T), in 514 healthy controls and 477 patients with CRC. The genotyping of was performed using polymerase chain reaction or polymerase chain reaction-restriction fragment length polymorphism assays.
Results: *MTHFR* 1298CC was associated with CRC in age > 62 years, female, rectal cancer, and ≥ 5 cm cancer groups. *TSER* 2R2R was connected to CRC prevalence of normotensive and non-lymph node invasion groups. *RFC-1* −43CC increased CRC risk in nondiabetic, ≥ 5 cm cancer, and lymph node invasion groups. In gene-environmental interaction analysis, *MTHFR* 1298CC with hypertension and *MTHFR* 1298CC with diabetes mellitus showed synergistic risk effects.
Summary/Conclusion: Our study suggests that the pivotal roles of folate-related gene polymorphisms on CRC development.

PB 2.61-5

Chemotherapy as a risk factor of DIC and thrombophilia in ovarian cancer patients

Vorobev A, Vorobev A and Makatsaria A

The First Moscow State Medical Sechenov University, Moscow, Russian Federation

Background: Patients with gynecologic cancer represent group of the highest risk of thrombotic and hemorrhage complications, especially during chemotherapy. The chemotherapy are significant contributed the risk of VTE and hemorrhage complications in cancer patients, especial with widespread malignant process. Chemotherapy stipulates for endothelium damage, direct platelet activation and reduction of fibrinolytic activity.
Purpose: To determine necessary range of laboratory tests for a high-grade estimation of haemostasis state in ovarian cancer patients undergoing chemotherapy.
Materials and Methods: One hundred and sixteen patients with ovarian cancer undergoing chemotherapy were divides at random on two groups: I group 56 has received biosimilar LMWH Hemapaxan 0.4 mL (4000 IU) before each chemotherapy curse and II group 60 has not received any anticoagulant prophylaxis during chemotherapy.
Laboratory tests: Platelet aggregation tests with different stimulators: Adrenaline, Ristocetin and ADP in various concentrations, platelet factor 4 (PF4). DIC and thrombophilia marker tests: D-dimer, TAT complexes, F1 + 2 prothrombin fragments. Fibrinolytic activity tests: determine PAI level, Protein C and S levels.
Results: Before operation thrombofilia and DIC was detected in 65% cancer patients, subcompensated forms was in 35%.
In postoperative period in 96% cancer patient were detected thrombofilia and DIC, and about third of patients has thrombocytopatia and coagulopatia. The rate of the subcompensated forms of DIC was 57%, decompensated 21%.

We have detected the sign of thrombofilia and DIC in more than 90% patient during chemotherapy. The rate of the subcompensated forms of DIC was 30%, decompensated 23%. It was observed damage of fibrinolytic activity due to iatrogenic effects of chemotherapy: reduction in proteins C and S levels, increase PAI concentration, platelets hyperaggregation in ristotetin presence.
In I group normalization of lab test results was detected during 2–3 days after chemotherapy course in comparison with II group normalisation was in 5–7 days in 22% and in 7–12 day in 58%, in 20% was not registered spontaneous normalisation.
Conclusion: Due to endothelium protection activity LMWH in ovarian cancer patients during chemotherapy significantly reduce intensity of thrombofilia and DIC. 85–90% patients with cancer of female genitals required permanent preventive anticoagulant prophylaxis.

PB 2.61-6
Prophylaxis for venous thromboembolism in patients treated for acute lymphoblastic leukemia – a systematic review

Lauw MN[1], Hubers LM[1], Barco S[1], Van Ommen CH[2], Hutten BA[1], Biemond BJ[1] and Middeldorp S[1]
[1]Academic Medical Center; [2]Emma Children's Hospital, Academic Medical Center, Amsterdam, The Netherlands

Background: Venous thromboembolism (VTE) occurs frequently in patients with acute lymphoblastic leukemia (ALL). Reported incidences vary between 2% and 36%. Occurrence is often associated with treatment components, particularly asparaginase. The efficacy and optimal approach of VTE prevention during ALL treatment are unclear.
Aims: To investigate the efficacy and safety of systemic thromboprophylaxis, using either blood-derived products, i.e. fresh frozen plasma, cryoprecipitate or antithrombin concentrate, or anticoagulant agents, i.e. (low-molecular-weight) heparin, fondaparinux or oral anticoagulants (vitamin K antagonists), on VTE incidence in pediatric and adult patients treated for primary ALL with asparaginase therapy. Also, the impact of thromboprophylaxis on overall survival and treatment outcomes of ALL were investigated.
Methods: We systematically searched The Cochrane Central Register of Controlled Trials (CENTRAL, *The Cochrane Library*, Issue 7 2012), MEDLINE (January 1966 to August 2012; accessed via Pubmed) and EMBASE (January 1980 to August 2012; accessed via OVID). We handsearched conference proceedings and checked references of included studies. Randomized controlled trials (RCTs) that assessed the efficacy and safety of systemic thromboprophylaxis in patients treated for primary ALL with asparaginase therapy were eligible. Interventions included any dose of fresh frozen plasma, cryoprecipitate, antithrombin concentrate, (low-molecular-weight) heparin, fondaparinux or oral anticoagulants, in comparison with no intervention or placebo, or a comparison of two different interventions. Three authors independently assessed eligible articles for inclusion in the review and systematically extracted the data from selected articles. If necessary, study authors were contacted for more information. Discrepancies were resolved by discussion or with the opinion of a fourth author. Risk of bias, quality of evidence, potential heterogeneity and reporting biases were explored, a sensitivity analysis applied if applicable.
Results: Of 304 identified citations, 44 articles were selected for full-text evaluation. Cross-referencing of articles yielded another 20 articles. Finally, one RCT enrolling 109 patients fulfilled our inclusion criteria and was analyzed for our review. This study assessed a randomization between antithrombin concentrate infusions (once weekly for 4 weeks) and no intervention in children treated for primary ALL. Outcomes were symptomatic and asymptomatic thrombosis (by radiographic screening following completion of the induction phase), and bleeding events. seven of 25 analyzed children with antithrombin had thrombosis (28.0%) vs. 22 of 60 patients without antithrombin (36.7%; OR 0.67; 95% CI 0.3–2.3, $P = 0.43$). One major bleeding event (1.7%) occurred in the non-antithrombin arm vs. no major but two minor bleeds in the antithrombin arm. Impact of thromboprophylaxis on survival or ALL treatment outcomes was not assessed.
Conclusions: Only one RCT in children with ALL was identified. In this study, no statistically significant effect of antithrombin infusions was seen on the outcomes of interest, but the sample size was small with a skewed randomization ratio, and may have missed a clinically important effect. No RCTs were found addressing other blood-derived products or anticoagulants. Therefore, the efficacy and safety of thromboprophylaxis to prevent VTE during ALL treatment remain unclear. The use of thromboprophylaxis during ALL treatment, in particular during asparaginase therapy, needs to be assessed in randomized controlled trials.

PB2.62 – Antiphospholipid – III

PB 2.62-1
Myocardial ischaemia and coronary atherosclerosis in patients with antiphospholipid syndrome

Padjas A, Plazak W, Celinska-Löwenhoff M, Iwaniec T, Swadzba J, Luberda T, Podolec P and Musial J
Jagiellonian University Medical College, Krakow, Poland

Background: In recent years it became apparent that mortality in patients with generalized autoimmune diseases like antiphospholipid syndrome (APS) and/or systemic lupus erythematosus (SLE) is mainly due to severe cardiovascular complications. Conventional risk factors for coronary artery disease do not explain this increased risk. Suggested non-coventional factors include, among others, the presence of antiphospholipid antibodies (aPL). Their elevated levels have been associated with arterial and microvascular thrombosis.
Aims: To evaluate possible influence of aPL on myocardial ischaemia assessed by single-photon emission computerized tomography (SPECT) and coronary atherosclerosis assessed by multidetector computerized tomography (MDCT) in APS patients.
Methods: SPECT (Tc 99 m sestamibi) and MDCT–based coronary calcium scoring were performed in consecutive APS patients (12 females, four males, aged 28–62, mean 47.3) without clinical signs of heart disease. Anticardiolipin (aCL) and anti-beta2 glycoprotein I ($a\beta_2$-GPI) antibodies (IgG and IgM class) were measured by ELISA and lupus anticoagulant (LA) according to ISTH guidelines.
Results: SPECT revealed myocardial perfusion defects in 12 (75%) patients: in 3 (19%) exercise-induced, and in 9 (56%) persistent. MDCT revealed coronary calcifications in 5 (31%) patients. The number of plaques ranged from 1 to 11 (median 2), volume 3 – 201.7 mm^3 (median 7), calcium scores 1.3–202.6 (median 5.7). In patients with perfusion defects or coronary calcifications ($n = 12$), as compared to patients without these pathologies ($n = 4$) the levels of IgG aCL and/or IgG $a\beta_2$-GPI antibodies were significantly higher and LA present more often (IgG aCL: 63.25 ± 23.1 vs. 19.22 ± 8.8, $P = 0.05$; IgG $a\beta_2$-GPI: 44.05 ± 21.3 vs. 11.25 ± 5.3, $P = 0.05$; LA: 10/12 (83%) vs. 2/4 (50%), respectively). No such association was seen for IgM-class antibodies.
Conclusions: In many symptom-free, relatively young APS patients SPECT shows myocardial perfusion defects and, in one third of them, coronary calcifications. These well-known cardiovascular risk markers, were associated with the presence of LA and higher levels of aCL and $a\beta_2$-GPI antibodies. In such patients advanced search for cardiovascular risk factors and proper preventive measures are warranted.

PB 2.62-2

Confirmation of the initial antiphospholipid antibody positivity depends on antiphospholipid antibody profile

Denas G[1], Ruffatti A[2], Del Ross T[2], Tonello M[2], Cuffaro S[2], Hoxha A[2], Banzato A[2], Elisa B[1], Alessia B[1] and Pengo V[1]

[1]Clinica Cardiologica Padova; [2]Rheumatology Unit, Padova, Italy

Background: The revised classification criteria for the antiphospholipid syndrome (APS) state that antiphospholipid (aPL) antibodies [Lupus Anticoagulant (LAC) and/or anticardiolipin (aCL) and/or anti β2-glycoprotein I (aβ2GPI) antibodies] should be detected on two or more occasions at least 12 weeks apart. Consequently, classification of patients' risk and adequacy of treatment may be deferred by 3 months.
Aims: In order to early classify patients risk, we evaluated whether initial aPL positive profiles were predictive of aPL persistence in patients testing positive for aPL.
Methods: Consecutive patients, referred to our Center, initially testing positive to one or more of the tests exploring the presence of aPL were evaluated again after 3 months. Tests were performed according to the latest guidelines. LAC, aCL and aβ2GPI antibodies were considered positive when their value was above the 99th percentile of 40 healthy subjects. Positive aPL subjects were classified as triple positive (LAC+, aCL+, aβ2GPI+, same isotype), double positive (LAC-, aCL+, aβ2GPI+, same isotype) and single positive (LAC or aCL or aβ2GPI antibodies as the sole positive test).
Results: During a 4-year period, of the 1520 initially screened individuals, 225 were found positive to one or more tests for aPL. Of these 161 were available for confirmation after 3 months. Patients were classified as triple positive (n = 54: LAC+, aCL+, aβ2GPI+, same isotype), double positive (n = 50: LAC-, aCL+, aβ2GPI+, same isotype) and single positive (n = 57: LAC or aCL or aβ2GPI antibodies as the sole positive test). Among subjects with triple positivity at initial testing, 98% (53 out of 54) had their aPL profile confirmed after 12 weeks. Double and single positivity groups had data confirmed in 84% (42 of 50) and 40% (23 of 57) of the individuals, respectively.
Conclusions: Our results show that patients initially testing positive for all three aPL tests (high-risk subjects with triple positive aPL profiles) remain positive after 12 weeks. An anticipation of diagnosis may be beneficial for an early decision on the type of antithrombotic treatment.

PB 2.62-3

Establishment of standardized international units for IgG anti-β2glycoprotein antibody measurement

Willis RA[1], Grossi C[2], Borghi MO[2], Meroni P[2], Lakos G[3], Crisostomo M[4], Lopez L[5], Olschowka N[6], Watkins M[4] and Pierangeli S[1]

[1]University of Texas Medical Branch, Galveston, TX, USA; [2]Istituto Auxologico Italiano, Cusano Milanino, Italy; [3]NOVA Diagnostics, Inc., San Diego; [4]Bio-Rad Laboratories Inc, Hercules, CA; [5]Corgenix Inc, Broomfield CO, USA; [6]Thermo Fisher Scientific, Phadia GmbH, Freiburg i. Br., Germany

Background: Current classification criteria for antiphospholipid syndrome (APS) calls for 'standardized' positive lupus anticoagulant, IgG/IgM anticardiolipin (aCL) and/or IgG/IgM anti-β2glycoprotein (aβ2GPI) antibodies in the presence of classic symptoms for identification of the disease. Despite numerous efforts aimed at standardization of antiphospholipid testing there still exists considerable inconsistency.
Aims: We sought to prepare a reference preparation (RP) and to establish international consensus units (IU) for the measurement for IgG aβ2GPI antibodies.
Methods: Whole IgG fractions were affinity-purified (AP) from a blend of sera from two primary APS patients (PAPS) with high IgG aβ2GPI levels using a Protein G Sepharose column followed by an NHS-activated Sepharose column coupled to β2GPI. Purity of β2GPI AP fractions was confirmed using SDS-PAGE; fractions with high activity were pooled, concentrated and sterile-filtered. The protein concentration of the AP material was determined using spectrophotometric measurement at 280 nm and Bradford protein assays and assigned a value based on the definition that 1 IU/mL equates to 1 μg/mL of AP aβ2GPI. A reference preparation (RP) serum blended from the two original PAPS patients was assigned an IU value using original AP material as a calibrator. The RP and 30 samples were sent to six commercial companies for testing in their respective kits (eight total) according to an approved protocol to enable evaluation of linearity, unit equivalency and commutability. Companies (and kits) included INOVA Diagnostics (QUANTA Lite ® β2GPI IgG ELISA, QUANTA Flash ® β2GPI IgG chemiluminescent assay), Bio-Rad Laboratories (BioPlex ® 2200 APLS IgG Kit, Anti-β2Glycoprotein I IgG EIA Test Kit) TheraTest (EL-β2GPI IgG kit), Corgenix (IgG Anti-β2Glycoprotein I Test Kit), Phadia (EliA β2Glycoprotein I IgG) and Instrumentation Laboratory (HemosIL® AcuStar anti-β2Glycoprotein-I IgG).
Results: The pooled AP material had a protein concentration of 103.1 μg/mL (OD280 nm) and 108.8 μg/mL (Bradford) and was assigned a value of 100 IgG aβ2GPI IU/mL. RP had a value of 270 IgG aβ2GPI IU/mL. The linearity (R^2) of the RP curve for the various assays ranged from 0.9600 to 0.9983 excluding the Bio-Rad EIA test kit, which had a value of 0.8994. When a 4-PL curve was used for that assay the correlation was improved. The value of the RP in the various arbitrary kit units ranged from 115 to 9993.1 units. Commutability samples fit very well within 95% prediction intervals and had excellent correlation when comparing assays.
Conclusion: The RP demonstrates excellent linearity in the various aβ2GPI IgG assays and can be considered adequate to be used as a calibrant/reference material. Available assays will be able to use this RP material effectively since there is very good correlation of results of commutability samples among the various assays, including ELISA formats and some new assays with wider analytical measuring ranges that use different arbitrary units of measurement for calibration. New international consensus units as well as an adequate RP are now available to be used for the measurement of IgG aβ2GPI antibodies. These studies contribute significantly to the much-needed standardization of aβ2GPI immunoassays.

PB 2.62-4

An open-label prospective pilot mechanistic study of fluvastatin in persistently antiphospholipid antibody-positive patients

Willis RA[1], Erkan D[2], Murthy V[1], Basra G[1], Vega JA[2], Ruiz-Limon P[1], Carrera-Marin AL[1], Jatwani S[1], Gonzalez E[1] and Pierangeli S[1]

[1]University of Texas Medical Branch, Galveston, TX; [2]Hospital for Special Surgery, New York, NY, USA

Background: Antiphospholipid antibodies (aPL) induce a proinflammatory and pro-thrombotic state by upregulating the production of various cytokines, chemokines, and tissue factor (TF). Fluvastatin reduces TF expression and the thrombogenic effects of aPL as shown *in vitro* and in mice studies.
Aims: The purpose of this prospective pilot study was to examine the effects of fluvastatin on pro-inflammatory and pro-thrombotic biomarkers in persistently aPL-positive subjects.
Methods: Persistently aPL-positive patients (as per APS classification criteria) received fluvastatin 40 mg daily for at least 3 months. At 3 months, patients were instructed to stop fluvastatin and they were followed for another 3 months. Serum samples were collected at base-

line and monthly thereafter for 6 months. Exclusion criteria included pregnancy, statin use, prednisone > 10 mg/day, and immunosuppressive use (except hydroxychloroquine (HCQ). Interferon (IFN)-α, Interleukin(IL)1β, IL6, IL8, inducible protein (IP)10, tumor necrosis factor (TNF)-α, vascular endothelial growth factor (VEGF), and soluble CD40 ligand (sCD40L) levels were determined by a multiplex assay (Millipore, Billerica,MA) in the sera of patients and controls. Plasma samples were used to detect sTF using a chromogenic assay. aCL (IgG, IgM and IgA), aβ_2GPI (IgG, IgM and IgA), soluble intercellular cell adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1, and E-selectin (E-sel) were evaluated by ELISA. We analyzed the monthly change in biomarker levels for the entire cohort (Spearman test) and also for four subgroups (Kruskal–Wallis).

Results: Of 41 patients recruited, 24 completed the study (mean age: 44.6 ± 13.6 year; female: 70%; Primary APS:8, SLE/APS:7, Asymptomatic aPL:5; SLE/aPL:4; HCQ: 61%; and anticoagulation: 43%). The withdrawal reasons were: 15 were lost at follow-up and two experienced muscle crumps with no evidence of elevated CPK or liver enzymes. The treatment with fluvastatin resulted in decreased biomarker levels and the proportion of patients with decreased levels ranged from 25% to 89% of the 24 aPL positive patients that completed the study. The mean maximum biomarker reduction was significant for IL6, IL1β, VEGF, IFNα, IP-10, sCD40L, TNFα and sTF when compared to baseline values. Fluvastatin did not significantly affect levels of IL-8, sICAM-1, sVCAM1 and sE-sel. The mean maximum reduction of biomarkers was achieved between 30 and 54 days of treatment for all biomarkers. aCL and anti-β2GPI titers remained unchanged. After discontinuing treatment with fluvastatin, many patients that had fluvastatin-induced reduction of biomarker levels had subsequent increases in these levels. The proportion of patients that had a rebound elevation in biomarker levels ranged from 14% to 90% for the various biomarkers. The mean maximum biomarker increase after stopping fluvastatin treatment was statistically significant for IL-1β, VEGF, TNFα, IP-10, sCD40L, and sTF.

Conclusion: Our pilot study demonstrating that fluvastatin can reversibly reduce the pro-inflammatory and prothrombotic biomarkers in persistently aPL-positive patients with or without SLE provides the basis for future larger randomized-controlled trials to examine the effects of the statins on the aPL-induced biomarkers as well as on the aPL-related clinical manifestations.

PB 2.62-5

Establishment of standardized international units for IgM anti-β2glycoprotein antibody measurement

Willis RA[1], Grossi C[2], Borghi MO[2], Meroni P[2], Lakos G[3], Olschowka N[4], Lopez L[5], Hardy J[6], Crisostomo M[6] and Pierangeli S[1]

[1]University of Texas Medical Branch, Galveston, TX, USA; [2]Istituto Auxologico Italiano, Cusano Milanino, Italy; [3]NOVA Diagnostics, Inc., San Diego, CA, USA; [4]Thermo Fisher Scientific, Phadia GmbH, Freiburg i. Br., Germany; [5]Corgenix Inc, Broomfield, CO; [6]Bio-Rad Laboratories Inc, Hercules, CA, USA

Background: Current classification criteria for antiphospholipid syndrome (APS) calls for positive 'standardized' antiphospholipid tests including IgG/IgM anti-$\beta_2$glycoprotein (aβ_2GPI) antibodies in the presence of classic symptoms for identification of the disease. Despite numerous efforts aimed at standardization there still exists considerable inconsistency in antiphospholipid testing. We sought to prepare a reference preparation (RP-M) and to establish international consensus units (IU) for the measurement for IgM aβ_2GPI antibodies.

Methods: Whole IgM fractions were affinity-purified (AP) from sera from APS patients with high IgM aβ_2GPI levels using a 2-mercatopyridine-coupled Sepharose column followed by an NHS-activated Sepharose column coupled to β_2GPI. Purity of β_2GPI AP fractions was confirmed using SDS-PAGE; fractions with high activity were pooled, concentrated and sterile-filtered. The protein concentration of the AP material was determined using Bradford protein assays and assigned a value based on the definition that 1 IU/mL equates to 1 μg/mL of AP aβ_2GPI. A reference preparation (RP-M) serum from an APS patient with high titers of IgM aβ_2GPI activity was assigned an IU value using original AP material as a calibrator. The RP-M and 30 samples were sent to several commercial companies for testing in their respective kits according to an approved protocol to enable evaluation of linearity, unit equivalency and commutability. Companies (and kits) included INOVA Diagnostics (QUANTA Lite ® β_2GPI IgM ELISA, QUANTA Flash ® β_2GPI IgM chemiluminescent assay), Bio-Rad Laboratories (Anti-β_2Glycoprotein I IgM EIA Test Kit) Corgenix (IgM Anti-β2 Glycoprotein I Test Kit), and Phadia (EliA ß2-Glycoprotein I IgM).

Results: The pooled AP material had a protein concentration of 15.125 μg/mL and was assigned a value of 15 IgM aβ_2GPI IU/mL. The RP-M had a value of 220.3 IgM aβ_2GPI IU/mL. The linearity (R^2) of the RP curve for the various assays ranged from 0.9649 to 0.9983. The value of the RP-M in the various arbitrary kit units ranged from 72.5 to 1143.4 units. Commutability samples fit very well within 95% prediction intervals and had excellent correlation when comparing assays.

Conclusion: The RP-M demonstrates excellent linearity in the various aβ_2GPI IgM assays and can be considered adequate to be used as a calibrant/reference material. The results of commutability studies suggest that this material can be used on a wide array of assays including ELISA formats and some newer assay formats with wider analytical measuring ranges that use different arbitrary units of measurement for calibration. New international consensus units as well as an adequate RP-M are now available to be used for the measurement of IgM aβ_2GPI antibodies. These studies contribute significantly to the much-needed standardization of aβ_2GPI immunoassays.

PB 2.62-6

Laboratory diagnosis of the antiphospholipid syndrome: evaluation of two new automated chemiluminescent assays for anticardiolipin and anti-β2glycoprotein I detection

Novelli C, Morelli B, Bollini B and Grassi C

Legnano Hospital, Legnano (Milan), Italy

Background: The antiphospholipid syndrome (APS) identifies a condition of vascular occlusion increased risk and/or pregnancy complications. APS diagnosis requires the combination of at least one clinical (vascular occlusion and/or pregnancy complications) and one laboratory criterion; this has to be confirmed 12 weeks apart.

The Anticardiolipin (aCL), anti-$\beta_2$glycoprotein I (aβ_2GPI) and Lupus Anticoagulant (LAC) tests are the laboratory criteria for diagnosis of APS. Standardization of aCL and/or aβ_2GPI assays still remain difficult, automation could be helpful to improve inter- and intra-laboratory variability.

Aim: Aim of our study is the evaluation of two new fully automated chemiluminescent systems (ACL AcuStar and Zenit RA) for the detection of aCL (IgG – IgM) and aβ_2GPI (IgG – IgM).

Methods: Ninety retrospective patient samples (serum or platelets-poor plasma; LAC pos:15/86 and LAC neg: 71/86), referred to our Center for laboratory diagnosis of APS, have been tested for aCL (IgG – IgM) and aβ_2GPI (IgG – IgM) on both analyzers.

Results: Positive samples according to manufacturer's cut-off indications: 16/90 aCL IgG, 11/90 aCL IgM, 15/90 aβ_2GPI IgG and 8/90 aβ_2GPI IgM with ACL AcuStar; 13/90 aCL IgG, 12/90 aCL IgM, 14/90 aβ_2GPI IgG and 13/90 aβ_2GPI IgM with Zenith RA, respectively.

Analytical agreement between the two methods were 92.2% for aCL IgG and 96.7% for aCL IgM; 96.7% for aβ_2GPI IgG and 92.2% for aβ_2GPI IgM.

Eleven samples were positive for all of three tests including LAC with both chemiluminescent systems evaluated.
Conclusion: In comparison to classic ELISA testings, these two fully automated walk-away analyzers with random-access capabilities are easy to use and significantly reduce the hands-on time.
We have observed good analytical agreement for both aCL and aβ_2GPI assays. It is important that each laboratory will establish its own reference intervals.
Despite last Lupus guidelines published in 2009, we have noticed that only few request for diagnosis of APS were correct, including all three panels together (aCL, aβ_2GPI and LAC), and aβ_2GPI was less frequently requested.

PB2.63 – Arterial Vascular Disorders – III

PB 2.63-1

Circulating beta antithrombin glycoform increases during the acute ischemic cerebrovascular event

De La Morena-Barrio ME[1], Martínez-Martínez I[1], Miñano A[1], García A[2], Águila S[1], Navarro-Fernández J[1], Bohdan N[1], Iniesta JA[2], Vicente V[1] and Corral J[1]

[1]Centro Regional de Hemodonación, Hospital Morales Meseguer, UMU, IMIB; [2]Servicio de Nerulogía, Hospital Universitario Reina Sofía, Murcia, Spain

Despite the control of thrombin is crucial in the development of atherothrombosis, antithrombin, the main endogenous inhibitor of thrombin, has been classically considered to play a role only in venous thrombosis. Additionally, available methods to study antithrombin do not discriminate between the two main glycoforms present in plasma. Thus, no study has evaluated the levels of β-antithrombin in thrombotic disorders, despite this glycoform lacking a glycan at N135 residue, has higher heparin affinity and shows predominant vascular localization. These features support that β-antithrombin might function as the major inhibitor of thrombin *in vivo* even being the less abundant form in plasma (10%). Firstly, we have developed a simple, cheap, and fast method able to specifically distinguish β-antithrombin by using only few microliters of plasma. The method quantifies the anticoagulant activity of β-antithrombin by activating the molecule with heparin under a high salt concentration that does not allow a-antithrombin activation. This method was validated with a and β glycoforms of antithrombin purified from plasma of healthy subjects, as well as with recombinant antithrombin glycoforms. We used this novel method and the classical one that determines the whole antithrombin anticoagulant activity (α + β) in plasma of patients with ischemic cerebrovascular disease during the acute event and 1 year later. We recruited 117 consecutive and unrelated patients (mean age 73 years, 52% males). The total levels of antithrombin did not significantly differ from that of a cohort of 97 healthy control subjects (97.6 ± 12.7% vs. 99.9 ± 6.4%, respectively $P = 0.105$) and did not significantly change 1 year after the event on available samples (100 ± 13.1%). However, it is important to point out that five cases had significant deficiency of antithrombin (values < 70%) during the acute event. In two cases, a consumption of antithrombin can be suggested since values increased after 1 year and/or values of other anticoagulants (protein C or S) were also reduced during the acute event. In contrast, in the other three cases, a congenital deficiency of antithrombin could be suspected based on antithrombin levels 1 year after the event and/or in relatives. Interestingly, sequencing of the *SERPINC1* gene revealed a heterozygous missense mutation responsible for the Budapest III variant (L99F) in the patient with the strongest deficiency at the moment of the stroke (32%): a 50 year-old male who suffered a lacunar stroke but had no previous thromboembolic events. In contrast, plasma β-antithrombin of patients during the acute event was significantly higher than in the control cohort (105.0 ± 17.7% vs. 97.1 ± 12.2%, respectively; $P < 0.001$). Moreover, in available samples, we observed a significant decrease of β-antithrombin over 1 year time ($P = 0.04$) and 1 year after the thrombotic event, β-antithrombin levels reached values observed in controls. These results might be explained by the release of β-antithrombin from the vascular compartment to the circulation during the acute event.
Conclusions: These data sustain a role of antithrombin in stroke and shows new knowledge on β-antithrombin, one potentially relevant glycoform that might be studied in different thromboembolic diseases using the method that specifically detect this glycoform.

PB 2.63-2

Toll like receptor (TLR)-4 modulates the effects of hyperglycemia and hyperinsulinemia on tissue factor procoagulant activity in blood

Singh A, Rao AK and Boden G

Temple University School of Medicine, Philadelphia, PA, USA

Background: Tissue factor (TF) is the principal initiator of blood coagulation. We have shown: (i) TF levels are elevated in type 1 and 2 diabetes mellitus (DM) patients; (ii) in healthy subjects and T2DM patients hyperglycemia (HG), hyperinsulinemia (HI) and combined HG + HI (24 h infusion clamps) increased whole blood TF-procoagulant activity (TF-PCA); (iii). However, in T1DM patients, neither HG or HI, nor HG + HI increased TF-PCA. Aims: To understand the mechanisms for these differences, we studied the effects of HG and HI *in-vitro* in whole blood from healthy individuals under unstimulated and lipopolysaccharide (LPS)-stimulated conditions. T2DM patients have enhanced platelet-monocyte activation and elevated plasma LPS, a ligand for TLR-4. We postulated that TLR-4 modulates TF-PCA.
Methods: Glucose (200 mg/dL, HG) and insulin (1, 10 or 100 nM, HI) were added either alone or in combination (HG + HI), in the presence or absence of 1 mg/mL LPS to blood from six healthy subjects and incubated for 4 h at 37 °C. TF-PCA (2 and 4 h) was measured in whole blood lysates by a two-stage clotting assay and TLR-4 (4 h) by ELISA.
Results: Basal plasma glucose and insulin were 75 ± 4 mg/dL and 99 ± 24 pM ($n = 6$, mean±SE), respectively. At 2 h HG increased TF-PCA from 22 ± 5 to 41 ± 7 U/mL ($P = 0.006$). Insulin increased TF-PCA: insulin 10 nM (to 33 ± 8, $P = 0.033$) and 100 nM (to 44 ± 12, $P = 0.04$). HG + HI (insulin 1, 10 or 100 nM) increased TF-PCA to 42 ± 6, 50 ± 9 and 63 ± 12 nM (all $P < 0.05$ over basal), respectively. LPS markedly increased TF-PCA at 2 h (22 ± 5 U/mL to 826 ± 93, $P < 0.001$). HG induced a small increase over LPS. However, insulin inhibited LPS-induced TF-PCA at 10 nM (from 826 ± 93 to 587 ± 119, $P = 0.037$) and 100 nM insulin. In presence of LPS, HG + HI (1 nM) markedly increased TF-PCA over that with LPS alone (from 826 ± 93 to 2369 ± 234 U/mL, $P = 0.003$). TLR-4. HG alone increased TLR-4 (3.6 ± 1–18 ± 6, $P = 0.04$) with an uptrend with HI. HG + HI (100 nM) increased TLR-4 to 15.6 ± 3 ($P = 0.02$). LPS increased TLR-4 levels at 4 h by 11-fold (4.4 ± 0.8–49.3 ± 5 ng/mL). Added HG did not cause further increase; however, HI inhibited LPS-induced TLR-4 (1 nM HI: 14.6 ± 4.8 vs. 41.7 ± 9.7, $P = 0.006$). With HG + HI, TLR-4 levels were comparable to those with LPS alone; thus, HG overrides insulin inhibition. TLR-4 levels strongly correlated with TF-PCA ($r = 0.71$, $P \leq 0.0001$). Whole blood TLR-4 in T2DM subjects (0.7 ± 0.1 ng/mL, $n = 6$) was lower than in T1DM (3.2 ± 0.9 ng/mL, $n = 8$) and healthy subjects (3.6 ± 1.1 ng/mL, $n = 4$).
Conclusions: (i) In non-diabetic subjects HG, HI and HG + HI increased whole blood TF-PCA. Insulin inhibited LPS-induced increase in TF-PCA. Thus, insulin effect is influenced by the cellular activation state and HG overrides the inhibitory effect. (ii) TLR-4 plays a major role in modulating TF-PCA levels. (iii) Differences in cellular activation state and TLR-4 levels may be the basis for the differences in TF-PCA responses in healthy subjects, T1DM and T2DM in our infusion studies.

PB 2.63-3

Hemostatic factors as predictors of recurrent vascular events up to 12 years after ischemic stroke: the Sahlgrenska Academy Study on ischemic stroke outcome

Pedersen A[1], Redfors P[1], Lundberg L[1], Hanson E[1], Blomstrand C[1], Gils A[2], Rosengren A[3], Declerck PJ[2], Jood K[1] and Jern C[1]

[1]Institute of Neuroscience and Physiology, Gothenburg, Sweden; [2]Laboratory for Pharmaceutical Biology, Faculty of Pharmaceutical Sciences, Leuven, Belgium; [3]Institute of Medicine, The Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Background: The hemostatic factors tissue plasminogen activator (t-PA), von Willebrand factor (VWF) and fibrinogen are known from prospective studies to predict arterial thrombotic events. Previously we reported an association between convalescent plasma levels of the Thrombin Activatable Fibrinolysis Inhibitor (TAFI) activation peptide (AP) with the composite outcome recurrent vascular events and/or death within 2 years after stroke in the Sahlgrenska Academy Study on Ischemic Stroke (SAHLSIS). Here, we examined the associations between plasma levels of t-PA antigen, VWF, fibrinogen, and TAFI and the long-term risk of recurrent vascular events in SAHLSIS Outcome.
Methods: SAHLSIS Outcome comprises 600 consecutively recruited ischemic stroke patients aged 18–69 years that have been prospectively followed for up to 12 years. Blood was drawn under strictly standardized conditions both in the acute (day 1–10, median 4) and the convalescent phase, 3 months after index stroke. Plasma levels of fibrinogen were measured by an automated clot-rate assay, and the levels of t-PA antigen, VWF, intact TAFI and TAFI-AP by ELISAs. Vascular deaths, recurrent stroke, and coronary events were registered through national registers and medical records. Hazard ratios (HR) for associations between plasma levels and recurrent vascular events were calculated using Cox Regression models.
Results: The mean follow-up time was 8.5 (SD 1.6) years. No patient was lost to follow-up. Seventy-five vascular deaths, 119 recurrent strokes, and 53 coronary events were registered. In univariate analyses acute and 3-month levels of t-PA antigen, VWF and fibrinogen, but not TAFI or TAFI-AP, showed significant associations with vascular death. Similar results were obtained when analysing all events combined (n = 184). No significant associations were observed with recurrent stroke. In multivariate analyses, adjusting for vascular risk factors and hsCRP, the association for t-PA and vascular death was retained; HR per 1 SD increase in t-PA antigen 1.40 (95% CI 1.05–1.88, P = 0.02).
Conclusion: In young and middle-aged ischemic stroke sufferers, the convalescent plasma level of t-PA was an independent predictor of long-term risk of vascular death. Levels of t-PA, VWF and fibrinogen were associated with an increased risk of the combined outcome of fatal and non-fatal vascular events, but these associations were not independent of vascular risk factors in our study.

PB 2.63-4

Does the immature platelet function (IPF) in chest pain patients presenting to the emergency department aid in the diagnosis of acute coronory syndrome?

Berny-Lang MA[1], Darling CE[2], Frelinger AA AL[1], Barnard M[1], Gerrits AJ[1] and Michelson AD[1]

[1]Dana-Farber Cancer Institute, Harvard Medical School, Boston Children's Hospital, Boston, MA; [2]University of Massachusetts Medical School, Worcester, MA, USA

Background: Patients presenting to the emergency department (ED) with chest pain and suspected acute coronary syndrome (ACS) are assessed by history, physical examination, electrocardiogram and serum markers of myocardial necrosis. However, early and accurate identification of patients with ACS vs. non-cardiac chest pain remains problematic. Previous studies reported that the mean platelet volume (MPV) is elevated in ACS and that elevated MPV may be predictive of recurrent myocardial infarction. Based on the hypothesis that platelet turnover is increased in ACS, resulting in elevated levels of younger, larger and potentially more active platelets, MPV may be an indirect measure of the immature platelet fraction (IPF). Indeed, studies suggest that the IPF is increased in ACS. We therefore hypothesized that the IPF may assist in the diagnosis of ACS in chest pain patients in the ED.
Aims: To determine if the measurement of IPF assists in the diagnosis of ACS in patients presenting to the ED with chest pain.
Methods: In this single-center study, adult patients (≥ 18 years of age) presenting to the ED with chest pain and/or suspected ACS were considered for enrollment. Exclusion criteria included trauma, pregnancy, elevated serum creatinine, anemia, thrombocytopenia and evidence of bleeding. In addition to routine ED admission laboratory tests, an EDTA-anticoagulated blood sample was drawn. Within 24 h of collection, blood samples were analyzed in a Sysmex XE-2100 hematology analyzer for platelet count, MPV and the percentage and concentration of immature platelets (IPF and IP concentration, respectively). IRB-approved written informed consent was obtained for the use of data from patients meeting enrollment criteria. Patients were followed in the hospital to determine their final diagnosis. Results were stratified into ACS or non-ACS (non-cardiac, non-thrombotic) patient groups.
Results: A total of 280 patients were enrolled in the study. Eleven subjects were excluded due to measurement error, consent withdrawal, inconclusive diagnosis or exclusions as per the study protocol. Two patients were diagnosed as non-cardiac, thrombotic (i.e., not classified as either ACS or non-ACS) and were excluded from analyses. Data from 226 ACS-negative (non-cardiac, non-thrombotic) and 41 ACS-positive patients were analyzed. Platelet counts and MPV were not statistically different between ACS-negative and ACS-positive patient groups. The IPF was 6.0 ± 1.3% and 5.1 ± 0.4% and the IP concentration was 10.0 ± 0.3 and 11.7 ± 1.3 × 10^3/μL for non-ACS and ACS, respectively, with no statistically significant differences between ACS-negative and ACS-positive groups for either measurement.
Summary/Conclusions: In patients presenting to the ED with chest pain, no differences in IPF, IP concentration or MPV were observed in non-ACS vs. ACS patients (n = 267). This study suggests that the IPF, the IP concentration and MPV do not assist in the diagnosis of ACS in chest pain patients presenting to the ED.

PB 2.63-5

Fractal dimension (Df): a novel biomarker to assess change in clot structure in cerebrovascular disease following therapeutic intervention

Stanford SN[1], Sabra A[1], Lawrence MJ[1], Morris K[2], Hawkins KM[1], Williams R[1], Storton S[1], Wani M[3] and Evans PA[3]

[1]Swansea University, Swansea; [2]Cardiff Metropolitan University, Cardiff; [3]ABMU Health Board, Swansea, UK

Background: Stroke is the second largest cause of death Worldwide.[1] Abnormal haemostasis plays an important role in the pathophysiology of cerebrovascular disease (CVD) due to the development of an abnormally dense clot structure[2,3]. Standard techniques assessing clot structure have limited clinical use. Fractal Dimension (D*f*) (of the incipient clot) is a promising novel biomarker [4] that can quantify clot structure.
Aims: This study aims to explore the role of D*f* in quantifying changes in clot structure and evaluating the efficacy of therapeutic intervention in stroke and Transient Ischaemic Attack (TIA).
Methods: A prospective observational study of 50 patients with CVD (stroke/TIA) with a control group of 50 healthy volunteers. This study was given a favourable ethical opinion by the South West Wales Research Ethics Committee. Only patients or legal representatives

who gave written informed consent or assent respectively were enrolled onto the study. Rheological testing (D*f* analysis) was performed in addition to standard coagulation tests. Further assessment took place at 24 and 72 h to assess the effects of therapeutic intervention on clot structure.

Results: Our previous analysis has confirmed that D*f* in normal subjects is 1.74 (SD 0.04). On admission in CVD subjects mean D*f* was 1.78 (SD 0.05). After 24 and 72 h the mean D*f* was 1.78 (SD 0.05) and 1.74 (SD 0.05) respectively. Although there was no change in D*f* at 24 h, at 72 h it was significantly lower than the mean at presentation ($P < 0.05$; one way ANOVA). These findings also show that D*f* is significantly higher in patients with CVD than in healthy subjects at presentation but not at 72 h.

Conclusion: In this study D*f* accurately quantified the effects of CVD and therapeutic intervention on clot structure. D*f* was significantly elevated in the acute phase and returned to normal at 72 h.

PB 2.63-6

MMP-10: a new biomarker in peripheral artery disease?

Roncal C[1], Martínez-Aguilar E[2], Gomez-Rodriguez V[3], Fernandez-Alonso L[2], Rodríguez JA[3], Orbe J[3] and Paramo JA[3]

[1]Laboratory of Atherosclerosis and Inflammation; [2]Hospital of Navarra; [3]CIMA-University of Navarra, Pamplona, Spain

Background: Peripheral arterial disease (PAD) is associated with a poor prognosis in terms of cardiovascular morbidity and mortality. Matrix metalloproteases (MMPs) contribute extensively to vascular remodeling by degrading extracellular matrix (ECM) components. Circulating levels of MMP-10 are associated with different inflammatory markers, increased carotid intima media thickness, and the presence of carotid plaques. Moreover, MMP-10 expression is detected in endothelial cells (ECs) and macrophages within human atherosclerotic plaques in association with C-reactive protein (CRP), suggesting a role for MMP-10 in cardiovascular diseases.

Aims and Methods: To analyze the role of this protease in PAD, MMP-10 was measured in 139 patients (71 ± 11 years), and sex and age matched healthy controls ($n = 148$, 64 ± 8 years). Moreover, the role of MMP-10 *in vitro* was determined in endothelial cells from WT and MMP-10 deficient mice (*Mmp10*−/−).

Results: Subjects with PAD were older, and presented higher frequency of diabetes and hypertension ($P < 0.05$). The levels of fibrinogen (493 ± 135 vs. 293 ± 72 mg/dL; $P < 0.01$), hs-CRP (1.7 ± 2.9 vs. 0.5 ± 1.3 mg/L; $P < 0.01$) and MMP-10 (987 ± 520 vs. 729 ± 320 pg/mL; $P < 0.01$) were increased in PAD patients compared to controls while TIMP-1 was reduced (205 ± 88 vs. 410 ± 61 g/mL; $P < 0.01$). We then divided the population in patients presenting intermittent claudication (IC, $n = 76$), and critical leg ischemia (CLI, $n = 63$) based on Rutherford's score. CLI subjects were older, more diabetic and hypertensive compared to IC patients ($P < 0.05$), and presented increased levels of fibrinogen (552 ± 158 vs. 444 ± 89 mg/dL; $P < 0.01$), hs-CRP (3.1 ± 3.8 vs. 0.6 ± 1.0 mg/L; $P < 0.01$) and MMP-10 (1080 ± 467 vs. 905 ± 549 pg/mL; $P < 0.01$). *In vitro Mmp10*−/− endothelial cells presented reduced migration, proliferation and tube formation capacity compared to WT ($P < 0.05$).

Conclusions: Our results suggest that MMP-10 may be a biomarker in PAD and that it could be involved in the pathological changes underlying this disease.

PB2.64 – Diagnosis of VTE – III

PB 2.64-1

Are standardized algorithms used in clinical practice in seven different European countries to aid in the diagnostic work-up for suspected venous thromboembolism?

Kristoffersen AH[1], Ajzner E[2], Roger D[3], Sozmen EY[4], Carraro P[5], Faria AP[6], Watine J[7], Meijer P[8] and Sandberg S[9]

[1]Haukeland University Hospital, Bergen, Norway; [2]Jósa András Teaching Hospital, Nyíregyháza, Hungary; [3]Clinical Hospital Center Zagreb, Zagreb, Croatia; [4]Ege University, Faculty of Medicine, Izmir, Turkey; [5]Hospital Sant'Antonio, Padova, Italy; [6]Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisbon, Portugal; [7]Hôpital de la Chartreuse, Villefranche-de-Rouergue, France; [8]The External quality Control for Assays and Tests (ECAT) Foundation, Leiden, The Netherlands; [9]Norwegian Quality Improvement of Primary Care Laboratories (NOKLUS), Bergen, Norway

On behalf of the working group in post-analytical external quality assessment (WG-PEQAS) of the European Federation of Clinical Chemistry and Laboratory Medicine (EFLM).

Background: It has been shown that the need for radiologic imaging can be reduced by 30–40% if standardized algorithms consisting of clinical decision rules (CDRs) and D-dimer tests are used in the diagnostic work-up for patients with suspected venous thromboembolism (VTE).

Aims: The aim of this study was to explore if algorithms combining CDRs and D-dimer testing are used as recommended in different European countries.

Methods: Physicians working within emergency and internal medicine departments were invited, through the national medical associations, to answer a web based questionnaire. The physicians were presented with two case histories with questions related to diagnosis and exclusion of suspected pulmonary embolism (Patient A, high pretest probability) and deep venous thrombosis (Patient B, low pretest probability). The physicians were asked to estimate the probabilities of VTE before and after D-dimer testing, to answer how they would use and interpret D-dimer and their use of radiologic imaging. They were also asked if they regularly used clinical decision rules and type of rule.

Results: Altogether, 548 physicians from seven different European countries responded, after exclusion of 78 physicians who did not regularly diagnose VTE. For patient A, most physicians (63%) suggested a high pretest probability or likely diagnosis of PE. Still, 11.1% stating high probability would request D-dimer alone and 68.8% both D-dimer and radiologic imaging. Only 19% requested radiologic imaging alone. If the D-dimer result was negative in this patient, 16.6% suggesting a high probability even would regard PE as excluded. For patient B, the majority (82.7%) of the physicians suggested a low pretest probability or unlikely DVT diagnosis. D-dimer alone was requested by 65.6% of physicians, while 13% of clinicians would request *both* D-dimer and radiologic imaging and 10.8% only radiologic imaging. CDRs were always or often used by 31.9% of the physicians. The pretest probability estimates in percent varied substantially for both patients A and B, regardless of the use of CDRs. If CDRs were used often and/or always, the probability that the physician would do the correct action was higher for several questions compared to if CDRs were seldom or never used, but the probability estimates for VTE were not different between these groups.

Conclusions: Exclusion of VTE by negative D-dimer results might underdiagnose VTE in high probability patients and puts the patients into significant risk. Applying radiologic imaging without or in parallel with D-dimer testing in low probability VTE cases imply extra burden on the health care system, and could be avoided if standardized algorithms were followed. Results from this study suggest that standard-

ized algorithms are not systematically followed by a substantial amount of physicians.

PB 2.64-2

Association between treatment regimen and quality of life assed by EQ-5D-3L and pain interference in adults with haemophilia with and without inhibitors in the global HERO study

Tricarico A

Ethos, Newtown, PA, USA

Background: Treatment options for congenital haemophilia A (HA) and B (HB) with or without inhibitors include on-demand and prophylactic factor replacement. Little is known about the relationship between treatment regimen and quality of life (QoL) in people with haemophilia (PWH) with and without inhibitors.

Aims: To examine the association between treatment regimen and QoL in adult PWH with and without inhibitors from the Haemophilia Experiences, Results and Opportunities (HERO) Study.

Methods: A *post-hoc* analysis of data from PWH ≥ 18 years from 10 countries (AR/DZ/CN/CA/DE/FR/IT/ES/GB/US)) participating in the HERO Study. PWH completed a standard EQ-5D-3L[TRADEMARK] assessment. EQ-5D index was calculated based upon the US method (Shaw et al. 2005).

Results: In total, 675 PWH completed qualitative and quantitative questions on QoL and well-being. Most PWH reported HA (498), 86 reported HB and 91 reported HA/HB with inhibitors. Half (n = 45) of those reporting inhibitors were from the US. PWH with inhibitors were younger (median/maximum age 34/69 years) than those without inhibitors (36/86 years). At a global level, treatment was somewhat evenly split between on-demand (289, 43%) and prophylaxis (207, 31%); fewer reported on-demand plus situation prophylaxis (146, 22%). This was similar for PWH with inhibitors (on-demand 43 [47%] including 20 US, prophylaxis 29 [32%] including 22 US, on-demand with situational prophylaxis 7 [8%]). Most adult PWH (598, 89%) and PWH with inhibitors (86, 95%) reported pain had interfered with their daily life in the past 4 weeks; of those, 301 (50%) reported constant pain (38 [44%] with inhibitors). Mean EQ-5D index for PWH with inhibitors was 0.707; it was 0.745 for HA and 0.741 for HB; median EQ-5D index was the same for HA, HB and PWH with inhibitors (0.778). Mean EQ-5D for PWH on prophylaxis was 0.707, 0.712 for PWH on-demand and 0.731 for PWH treated on-demand with situational prophylaxis. Almost half of PWH reported no issues with mobility (HA: 41%, HB: 38%, inhibitors: 44%). Most PWH reported no issues with usual activity (HA: 81%, HB: 79%, inhibitors: 74%). For PWH with inhibitors, the percentage reporting no issues with usual activity was similar across treatment regimens (on-demand: 72%, prophylaxis: 79%, on-demand with situational prophylaxis, 71%). Approximately half of PWH reported no issues with self-care (HA: 56%, HB, 49%, inhibitors: 43%) or anxiety/depression (HA: 54%, HB: 53%, Inhibitors: 54%).. Few PWH denied any pain/discomfort (HA: 26%, HB: 28%, inhibitors: 19%). Self-care is the only index that shows a significant difference between the types of haemophilia. Statistical comparison for mobility and usual activity was not possible due to the small number of PWH who responded to each question.

Conclusions: Globally, adult PWH with inhibitors in HERO had a lower mean EQ-5D index and more frequently reported problems in individual EQ-5D domains than those without inhibitors. While differences in age and treatment regimen across participating countries limit descriptive analysis; multivariate analyses may yield further insights. The underlying reasons for treatment regimens (e.g. pain vs. bleed control, desired activity participation, employment) likely also impact quality of life, and need to be factored into future studies.

Performance of fibrin monomer in the evaluation of patients with suspected pulmonary embolism

Bates SM[1], Parpia S[2], McGrath J[3], Johnston M[4] and Hoogendoorn H[3]

[1]*McMaster University;* [2]*Ontario Clinical Oncology Group;* [3]*Hemostasis Reference Laboratory, Inc., Hamilton, ON, Canada*

Background: During thrombin generation, fibrinopeptide A is released from the fibrinogen molecule, leading to the formation of fibrin monomer and cross-linked fibrin. Simultaneous triggering of the fibrinolytic system results in plasmin clipping of cross-linked fibrin with D-dimer release. Fibrin monomer, therefore, is an early indicator of thrombin generation. Studies evaluating this molecule for the exclusion of venous thromboembolism have had inconsistent results; however, the high specificity of fibrin monomer for venous thrombosis has been suggested as a potential advantage over D-dimer in this setting.

Aim: We sought to evaluate the performance of fibrin monomer (STA LIATEST®FM) in a large cohort of patients with suspected pulmonary embolism (PE).

Methods: Seven hundred and ninety-four available frozen samples from a prospective cohort study of 808 consecutive patients with suspected PE were tested for both fibrin monomer and D-Dimer (STA LIATEST®DDi), according to the manufacturer's instructions. All patients underwent pre-test probability assessment using the Wells model. Patients were characterized as PE positive or negative according to the results of objective testing and 3 month follow-up. Suspected venous thromboembolism was adjudicated centrally. The study protocol was approved by the institutional review board of each participating center and is consistent with the principles of the Declaration of Helsinki.

Results: One hundred and two patients (12.8%) were diagnosed with PE. Five hundred sixty-five had low pre-test probability, while 172 and 57 were classified as having a moderate and high pre-test probability, respectively. Concordance between D-dimer and fibrin monomer results was moderate to low (Pearson r – 0.41). The normal range for fibrin monomer is < 8.0 μg/mL. Using this cutpoint, the assay had an overall sensitivity of only 42.2% (95% CI, 32.6–52.3%) and a specificity of 88.7% (95% CI, 86.1–90.9%), with a corresponding negative predictive value (NPV) of 91.2% (95% CI, 88.8–93.2%) and positive predictive value (PPV) of 35.5% (95% CI, 27.2–44.8%). Decreasing the cutpoint to 5.0 μg/mL resulted in a slight improvement in sensitivity (66.7%; 95% CI, 57.2–75.6%) with resultant loss in specificity (66.6%; 95% CI, 63.0–70.1%). The NPV remained too low for this test to be used to confidently exclude PE (93.1%; 95% CI, 90.4–95.1%), even in patients with a low pre-test probability (95.9%; 95% CI, 93.3–97.6%). In comparison, using a cutpoint of 0.5 μg FEU/mL, the D-dimer assay had an overall sensitivity, specificity, and NPV of 98.0%, 42.5%, and 99.3%, respectively. Although increasing the fibrin monomer cutpoint to 50 and 100 μg/mL resulted in specificities of over 90%, even in patients with a high pre-test probability, the prevalence of disease was not sufficiently high (35.1%) to result in a PPV sufficient to confidently rule-in PE (62.5% [95% CI, 25.9–89.8%] and 66.7% [95% CI, 24.1–94.0%], respectively). In order for a positive result to generate a PPV of over 90%, the population prevalence of PE would need to be at least 70%.

Conclusions: The fibrin monomer is not sufficiently sensitive to be used to exclude PE, even in patients with a low pre-test probability. Although this assay has a higher specificity than D-dimer, it is insufficient to be used to rule-in PE.

PB 2.64-3

PB 2.64-4

Assessment of thrombus age with contrast-enhanced MR-Venography

Arnoldussen CWKP, De Graaf R, Strijkers R, Ten Cate-Hoek AJ and Ten Cate H

Maastricht University Medical Centre, Maastricht, The Netherlands

Background: Current treatment of DVT is limited to anticoagulation and compression stockings. However, at least 20% of patients continues to have leg complaints even after 1 year of (extended) treatment. Contrast-enhanced MR-Venography allows for high detail imaging of the deep vein system. This enables us to visualize detailed thrombus characteristics. Being able to assess thrombus age may contribute to early identification of patients at risk for suboptimal treatment outcomes and safer patientmanagement.

Aims: To assess the age of thrombus with CE-MR-Venography and compare the results with the clinical estimate of the age of the DVT based on duration of complaints.

Methods: Forty-one patients (27 male and 14 female), age 17–74 years (mean 49, SD 17), underwent MR-Venography to evaluate the presence and extend of their DVT. Thrombus age was assessed at the level of the common femoral vein (35 patients). For those patients in whom the thrombus did not extend into the common femoral vein, the most proximal extension was evaluated (six patients). Thrombus age was scored, blinded to the clinical duration of complaints, as either acute, subacute or chronic. Thrombus was identified as acute if the thrombosed vein was dilated, showed a thin enhancing wall and a homogenous signal intensity. Thrombus was identified as subacute if the thrombosed vein was still dilated, with a thicker enhancing wall and signs of recanalization within the thrombus (visual as areas of lower and higher intensity within the thrombus). Thrombus was identified as chronic if the thrombosed vein was no longer evidently dilated, only partially filled with thrombus and no evident signs of residual vein wall enhancement were present. Additionally, signs of trabeculations or fibrotic strands were identified as post-thrombotic. Results of image assessment were subsequently compared to the clinical information with regard to duration of complaints.

Results: In all 41 patients the radiologist was able to distinguish the thrombus age into three categories (acute, sub acute, chronic), based on MR characteristics. Thrombus was identified as acute in patients with a mean duration of complaints of 6.5 days (range 2–13 days). Thrombus was identified as sub acute in patients with a mean duration of complaints of 13.4 days (8–18 days,). Chronic thrombus was identified in patients with a mean duration of complaints of 22.2 days (15–32 days).

Summary/Conclusions: Contrast-enhanced MR-Venography may enable differentiation between acute, sub acute and chronic thrombi. This could potentially impact treatment options in both the acute and chronic phase.

We might be able to predict suboptimal treatment outcomes, and consider more aggressive treatment options, such as catheter directed thrombolysis.

Keywords: DVT, thrombus, age, MR-venography.

PB 2.64-5

Values of pretest probability tests for diagnosis of acute symptomatic proximal DVT in Thai patients

Sermsathanasawadi N, Pumpuang T, Hongku K, Wongwanit C, Ruangsetakit C, Chinsakchai K and Mutirangura P

Siriraj Hospital, Bangkok, Thailand

Background: Clinical diagnosis of deep venous thrombosis is difficult because clinical signs and symptoms lack sensitivity and specificity. Some authors have developed pretest probability tests for diagnosis of acute DVT based on history and physical examination before confirmation by objective testing such as duplex ultrasonography or venography. These scores have not been evaluated for the accuracy of diagnosis of acute symptomatic proximal DVT in Thai patients.

Aims: To compare the accuracy of clinical predictor scores in diagnosis of acute symptomatic proximal deep vein thrombosis of lower extremity and to identify risk factors of acute proximal deep vein thrombosis of lower extremity in Thai patients'

Methods: Patients who had symptoms suspected acute deep vein thrombosis (DVT) were examined by duplex ultrasonography for detecting proximal deep vein thrombosis at common femoral veins and popliteal veins. Clinical predicting scores of acute deep vein thrombosis including Wells, Kahn, and St. Andre′ and Ambulatory constant scores were recorded. Sensitivity and specificity of all clinical scores were calculated by comparing with the result of duplex ultrasonography. We also identified the clinical predicting factors associated the diagnosis of acute symptomatic proximal deep vein thrombosis by duplex ultrasonography by univariate and multivariate analysis. In addition, we developed the new clinical predictor score (Siriraj DVT score) by using the predicting factors which had statistical significant in multivariate analysis.

Results: Five hundred patients who had symptoms suspected deep vein thrombosis were included in this study. Proximal deep vein thrombosis was confirmed by duplex ultrasonography in 133 patients (26.6%). The Ambulatory constant score was a best predictor score in diagnosis of deep vein thrombosis following by the Wells and St. Andre′ and Kahn scores respectively. According to the Ambulatory constant score, the area under the ROC curve was 0.646 (95% confidence interval [95%CI]: 0.59–0.69), for the Wells score 0.644 (95%CI: 0.59–0.69), 0.575 (95%CI: 0.52–0.63) for the St. Andre′score, and 0.540 (95%CI: 0.48–0.59) for the Kahn score. We found that history of cancer, confinement to bed, unilateral lower limb pain, local warmth, whole limb enlargement, calf enlargement more than 3 cm compared to the other sites, and previous history of venous thromboembolism were statistically significant in univariate analysis. In multivariates analysis, confinement to bed, unilateral lower limb pain, calf enlargement > 3 cm compared to the other sites and previous history of venous thromboembolism were the predicting factor which had significant statistic. We also developed the new predicting score (Siriraj DVT score) by these four parameters and the area under the ROC curve was 0.717 (95%CI: 0.67–0.77).

Conclusion: Ambulatory constant score had highest accuracy in diagnosis of acute symptomatic proximal DVT in Thai patients. Confinement to bed, unilateral lower limb pain, calf enlargement > 3 cm compared to the other sites and previous history of venous thromboembolism were the important clinical predicting factors for diagnosis of acute symptomatic proximal deep venous thrombosis in Thai patients.

PB 2.64-6

Using model-based clustering to identify patterns of INR trajectories following warfarin initiation

Tagalakis V[1], Xu CJ[1] and Ciampi A[2]

[1]Lady Davis Institute for Medical Research/Jewish General Hospital; [2]McGill University, Montreal, QC, Canada

Background: Achieving stable warfarin therapy as defined by the International Normalized Ratio (INR) being within the therapeutic range is often challenging due to intra- and inter-individual variability regarding patient response to warfarin. Characterizing patterns of INR trajectories following initiation of warfarin may help identify patients early on with stable vs. unstable INR patterns, and in turn help guide management decisions in patients with venous thromboembolism.

Aim: We aimed to identify distinct patterns of INR trajectories following initiation of warfarin therapy by applying an approach to model-based clustering of longitudinal data recently developed by the authors.

Methods: We analyzed retrospective data collected from 99 patients presenting to the anticoagulation clinic at a single tertiary-care center, who were also enrolled in a previous study. We determined INR values at the time of warfarin initiation and up to 6 months thereafter. Our approach to model-based clustering of longitudinal data treats a subject's observed trajectory as arising from a finite mixture of probabilistic models for curves, such that each component identifies a distinct pattern of time evolution (described by a mean curve and variance-covariance matrix). Our algorithm estimates from a sample of observed curves both the number of distinct patterns and the parameters describing each pattern. The algorithm also produces estimates, for each individual, the probabilities of a patient belonging to each pattern.
Results: In all, we included 99 patients with an average number of INR values per patient of 13 (Standard Deviation (SD) 4) following warfarin initiation and a mean follow-up of 189 days (SD 31). We identified two distinct patterns of INR trajectories. The most frequent pattern included 80% ($n = 79$) of the population and describes patients with favorable INR control. They achieved target INR values (between 2.0 and 3.0) early after warfarin initiation and maintained stable INR control during follow-up. The mean INR was 2.3 (SD 0.8). The less frequent pattern describes 20% of the population ($n = 20$) with less favorable INR control. In this group, INR instability was observed early during initiation of warfarin therapy with target INR values difficult to achieve and maintain. The mean INR was 2.8 (SD 1.4).
Conclusion: Our study shows that using model-based clustering can identify stable and unstable patterns of INR trajectories in patients initiating warfarin therapy. Future work is needed to verify our method in a larger population, and to determine patient characteristics predictive of INR patterns. Ultimately, predicting INR instability may help identify patients who may benefit from alternate anticoagulants.

PB 2.65-1

Clinical impact of findings supporting an alternative diagnosis on computed tomography pulmonary angiography in patients with suspected pulmonary embolism

Van Es J[1], Douma RA[1], Schreuder SM[1], Middeldorp S[1], Kamphuisen PW[2], Gerdes VEA[1] and Beenen L[1]
[1]Academic Medical Center, Amsterdam; [2]University Medical Center Groningen, Groningen, The Netherlands

Background: Computed tomography pulmonary angiography (CTPA) is commonly used as the first-line imaging test in the diagnostic work-up of patients with suspected pulmonary embolism (PE). Other CTPA findings may provide an alternative explanation for the signs and symptoms in this group of patients; however, the clinical impact of these findings is not clear.
Aims: To assess the clinical impact of findings supporting alternative findings on CTPA ordered in the diagnostic work-up for PE, in terms of diagnostic or therapeutic consequences. Besides, we investigated whether findings supporting alternative diagnoses were already established or highly suspected before CT-scanning.
Methods: In 203 consecutive patients with suspected PE, the clinical implication of abnormalities on CTPA was prospectively evaluated. Alternative diagnoses were defined on clinical grounds prior to performing CTPA; afterwards, all findings were systematically registered. Diagnostic and therapeutic consequences were assessed using *a priori* defined criteria.
Results: A total of 39 (19%) patients were diagnosed with PE and 61 (30%) had no abnormality on CTPA. Before CTPA, alternative diagnoses were suspected in 97 (48%) patients. Findings supporting an alternative diagnosis were detected in 88 (43%) patients. In 28 patients this was a new finding, in 18 patients, a conclusive alternative diagnosis for the complaints was made based on the outcome of the CTPA. Overall, findings supporting alternative diagnoses had therapeutic consequences in 10 (4.9%) patients. Incidental findings (nodules/lymph nodes) requiring diagnostic procedures were present in 17 (8.4%) patients, of which one (0.5%) had a therapeutic consequence.
Conclusion: In patients undergoing CTPA for suspected PE, findings supporting alternative diagnoses were found in almost half of the patients. However, in only few patients this had therapeutic consequences. Hence, CTPA should principally be used to find or exclude PE in high probability patients but not to establish an alternative diagnosis.

PB 2.65-2

Inter-observer agreement for Wells DVT score and empiric unstructured estimate of pretest probability

Courtney MD, Brucker K, Dore L, Chevrier A, McConnell R and Sears J
Northwestern University, Chicago, IL, USA

Background: Evaluation for potential DVT is challenging due to inadequacy of clinical exam to identify clot and lack of 24 h duplex Doppler ultrasonography in some settings. The Wells DVT score has achieved less attention by clinicians and researchers than the corresponding score for PE. Increased use of an approach to identify of low probability patients (< 10%) could facilitate increased use of D-dimer testing with improved diagnostic efficiency. Currently most patients in US EDs are evaluated primarily with ultrasonography as the primary and only diagnostic tool.
Objectives: To determine interobserver agreement among two clinicians for components of the Wells DVT score, as well as agreement for empiric clinician judgment.
Methods: We conducted a prospective, observational single site study including patients evaluated in the emergency department for possible lower extremity DVT. IRB approval was provided for human subjects research. We excluded patients with: known DVT on warfarin with INR > 2.0 or other non-aspirin anticoagulation, DVT diagnosed within last 1 month regardless of INR, or known results of duplex Doppler. Two clinicians (attending, resident or mid-level) independently evaluated each patient prior to test results and completed a web-based data collection instrument including components of the Wells Score and overall clinician empiric estimation of DVT probability (< 10%, 10–19%, ≥ 20%). Structured medical record review determined combined VTE outcome (any acute DVT or PE over 45d). Kappa statistic assessed inter-observer agreement.
Results: One hundred and thirty-six patients were enrolled; mean age was 54 years, 64% were female. The median time to obtaining a duplex Doppler was 3.4 h. Acute DVT was diagnosed in 18% (95% CI 12–26%) acute PE without DVT in 2% (5–6%). Forty-four percent of patients were pretest probability < 10% by clinician unstructured estimate and 49% were DVT unlikely by Wells. Kappa values (and agreement%) were: previous DVT 0.90 (98%), active cancer 0.85 (98%), leg immobility 0.75 (97%), bedridden or surgery 0.56 (92%), calf swelling 0.58 (81%), entire leg swelling 0.42 (77%), unilateral pitting edema 0.36 (72%), alternative diagnosis at least as likely 0.32 (70%), deep venous system tenderness 0.23 (66%), superficial collateral veins 0.15 (86%). Kappa for binary empiric unstructured gestalt (< 10% vs. ≥ 10%) was 0.42 with 71% agreement. Prevalence of acute DVT/PE in the empiric < 10% group was 8.3%. Acute DVT/PE in the Wells ≤ 1 'unlikely' group was 12.5%.
Conclusion: Highest precision exists for the patient history components of the Wells DVT score rather than physical exam components. Almost half of the patients were non-high probability, suggesting possible increased opportunity for a combined pretest probability and D-dimer testing strategy.

PB 2.65-3

Accuracy of diagnosing incidental pulmonary embolism on routinely performed contrast-enhanced CT-imaging in patients with malignancy

Van Der Hulle T[1], Den Exter PL[1], Klok FA[1], Kroft LJM[1], Huisman MV[1] and Jiménez D[2]

[1]Leiden University Medical Centre, Leiden, The Netherlands; [2]Ramón y Cajal Hospital, IRYCIS and Alcalá de Henares University, Madrid, Spain

Introduction: The routine use of modern CT scanners has led to an increased detection of incidental PE. The accuracy of diagnosing PE on normal CT scans that were not performed for diagnosis of clinically suspected PE is unknown.

Methods: Consecutive patients with active malignancy in whom incidental PE was diagnosed were included. All CT-images were reassessed in a blinded fashion by an experienced thoracic radiologist, to determine the location of the emboli, the obstruction index by the method of Qanadli and the level of confidence in diagnosis. A sample of 19 cancer patients, who had undergone staging CT-imaging, in whom no incidental PE was reported, were included to ensure blindness and control of the expert reader.

Results: A total of 62 patients with incidental PE were included. A central pulmonary embolism was diagnosed in 32.8%, and a segmental localization in 67.2%. All patients received anticoagulant treatment upon diagnosis. In only one patient (1.6%; 95% CI: 0.04–8.7%) expert reading refuted the diagnosis of PE. The Kappa level of agreement between initial reading and expert reading for the diagnosis of PE was 0.97. The median obstruction index was 17.5% (IQR: 10–30%), which was lower compared to a reference sample of 113 patients with symptomatic PE diagnosed on CTPA ($P = 0.008$).

Conclusion: This study is the first to assess the accuracy of diagnosing PE on CT-scans that were conducted for other reasons than symptomatic PE. It demonstrates an excellent agreement between initial reading and expert reading for the diagnosis of incidental PE.

PB 2.65-4

Fibrin monomer (FM) might be used as a marker for venous thromboembolism in pregnancy

Kristoffersen AH[1], Hyltoft Petersen P[2] and Sandberg S[2]

[1]Haukeland University Hospital; [2]Norwegian Quality Improvement of Primary Care Laboratories (NOKLUS), Bergen, Norway

Background: Pre-test probability of VTE combined with D-dimer measurement can be used to decide on exclusion of venous thromboembolism (VTE) or further diagnostic work-up (radiologic imaging) in non-pregnant patients when VTE is suspected. Although we have suggested a model for interpretation of D-dimer based on the within-subject variability of D-dimer in pregnancy, the usefulness of D-dimer measurement in pregnancy and post-partum period, when VTE is suspected, is complex. There is a gradual increase in D-dimer concentration during pregnancy, not returning to normal levels until about 6 weeks post-partum. Studies have suggested that fibrin monomer (FM) can be used as a biomarker for VTE. But to be used in pregnancy, FM concentration should first be shown to be stable throughout the whole pregnancy in healthy women.

Aims: The aim of this study was to compare FM concentration in healthy pregnant and non-pregnant women to evaluate if FM concentration is as stable in healthy pregnant as in healthy non-pregnant women.

Methods: Blood samples were obtained every 4 weeks in 20 healthy non-pregnant women and every 4 weeks during pregnancy in 20 healthy pregnant women. D-dimer (STA Liatest D-dimer, Stago) and FM (STA Liatest FM, Stago) were analysed on all samples. Informed consent was obtained and the study was approved by the Regional Committee of Medical Ethics (REK) of Western Norway.

Results: The median FM in non-pregnant women was 4.75 μg/mL (97.5th percentile 8.2 μg/mL) and in pregnancy 6.2 μg/mL (97.5th percentile 15.4 μg/mL), after exclusion of two pregnant women who had elevated concentrations of both FM and D-dimer in several samples (one of the women was Factor V Leiden homozygous). The median fibrin monomer concentration were slightly lower in the 1st trimester (5.7 μg/mL) compared to 6.2 and 6.8 in the 2nd and 3rd trimester, but there was a large overlap of concentrations in the three trimesters, and there was no statistical significant increasing trend from the 1st to the 3rd trimester (linear regression, $P = 0.55$). The analytical variation (CVa) based on duplicate measurements was 11% and 14% in samples from pregnant and non-pregnant, respectively.

Summary/Conclusion: The concentration of FM seems to be relatively constant during pregnancy, as opposed to D-dimer. The suitability of FM to be used in the exclusion of VTE in pregnant women should be assessed in clinical studies.

PB 2.65-5

Age adjusted D-dimer for exclusion of venous thromboembolism: results from a hospital emergency department

Scalia P, Padmore R, Wells P and Giulivi A

University of Ottawa, Ottawa, ON, Canada

Background: A clinical decision rule, the Wells score, can be used to exclude venous thromboembolism (VTE), when used in conjunction with a normal D-dimer test. The instrument/reagent combination CS2100i Sysmex coagulation analyzer along with the INNOVANCE® D-dimer is used for the conventional 500 μg/L FEU D-dimer cut-off. Higher cut-off values may provide advantage for low Wells score. An age-adjusted cut-off of the D-dimer (patient's age x 10) may increase the number of elderly patients in whom VTE can be safely excluded.

Methods: D-dimer data was collected in a hospital laboratory prospectively and sequentially over a period of 38 days. Four hundred and fifty-eight consecutive patients were included of whom 266 were > 50 years (58%). No patients were excluded. The patients in the dataset were all from the emergency department. We retrospectively assessed the presence or absence of VTE and the Wells Score using chart reviews. This included review of the hospital charts on all emergency department visits and with additional follow-up information on those patients admitted to hospital, but not on those patients discharged from the emergency department. The proportion of patients in whom VTE could be excluded, with low Wells score, combined with age-adjusted D-dimer test was calculated and compared with the conventional D-dimer cut-off of 500 μg/L and a higher cut-off of 650 μg/L.

Results: When combined with a low Wells score (0–2) the negative predictive value for negative D-dimer results is excellent (100%) for conventional, higher and age adjusted cut-offs. For patients under the age of 50, raising the conventional D-dimer cut-off to 650 μg/L yields a higher specificity than the 500 μg/L cut-off. Lastly, for patients over the age of 50, the age-adjusted D-dimer cut-off yields a modest improvement in specificity for a low Wells score and a doubling of the specificity (20% to 41%) for moderate probability Wells score, compared to using the conventional D-dimer cut-off, with no change in sensitivity.

Conclusion: Using age-adjusted cut-off yields a higher specificity for both the low and moderate (2–6) Wells scores in emergency department patients.

PB 2.65-6

Patient delay in the diagnosis of acute pulmonary embolism does not lead to higher thromboembolic burden or worse right ventricular function

Pasha SM, Klok FA, Van Der Bijl N, De Roos A, Kroft LJM and Huisman MV

LUMC, Leiden, The Netherlands

Background and Aims: It has earlier been demonstrated that the time between symptom onset and objective diagnosis of pulmonary embolism (PE) – does not influence outcome on re-thrombosis and mortality. It is unknown whether the patient's delay – defined as time between symptom onset and presentation at the hospital – is of influence on the thromboembolic burden and right ventricular function. We sought to evaluate this by measuring Qanadli-score and RV/LV-ratio in PE patients with and without patient's delay.

Materials and Methods: *Post-hoc* analysis of an observational prospective outcome study in 113 consecutive CT proven PE patients. In all patients Qanadli-score and RV/LV ratio were scored and duration from symptom onset until the clinical presentation was requested. Also mortality and hospital readmission in a 6-weeks follow-up period were collected.

Results: Twenty patients with and 93 patients without delay, defined as more than 7 days after symptom onset, with identical baseline characteristics and co-morbidities, were included. In a linear analysis, Qanadli-scores were not correlated to delay with a R^2 of 0.021 ($P = 0.130$). RV/LV-ratio had a $R^2 < 0.001$ ($P = 0.991$). Likewise, longer delay was not associated to 6-week mortality (Odds ratio: 0.65; 95%CI 0.08–5.57) or hospital readmission (Odds ratio: 0.75; 95%CI 0.15–3.65).

Conclusion: In our patient cohort, patient's delay was not associated with higher thrombus load or right ventricular dysfunction. This could provide a possible explanation for the lack of association between delay in diagnosing PE and clinical outcome as found in earlier studies.

PB 2.66-1

Oral contraceptive formulations with estetrol as an estrogen, in combination with levonorgestrel or drospirenone, show minor effects on haemostasis

Kluft C[1], Neuteboom J[1], Klipping C[2], Foidart J-M[3], Zimmerman Y[4] and Coelingh Bennink H[4]

[1]Good Biomarker Sciences, Leiden; [2]Dinox BV, Groningen, The Netherlands; [3]Estetra S.A., Grâce-Hollogne, Belgium; [4]Pantarhei Bioscience, Zeist, The Netherlands

Introduction: Current contraceptive preparations contain either ethinyl estradiol or the natural 17β-estradiol. The natural fetal estrogen, estetrol, has recently been added to the estrogen portfolio and was successfully evaluated for contraconception and vaginal bleeding patterns with either levonorgestrel or drospirenone as progestogen.

Aims: To determine the effects on haemostasis variables (in relation to estrogenicity markers) of combinations of estetrol (5, 10, 20 mg) with levonorgestrel (LNG:150 μg) and estretrol (5 and 10 mg) with drospirenone (DRSP: 3 mg) in comparison with Yaz® (20 μg ethinyl estradiol with 3 mg DRSP). All combinations were administered according to a 24–4 day regimen.

Methods: A randomised, open-label, comparative, parallel study in 111 assigned women of which 109 were actually treated with six different hormone combinations was performed with analysis of variables at the pre-treatment sample, after one cycle at day 22–23, after three cycles at day 22–23 and post treatment after 1 month. Yaz® effects were taken as reference; the third cycle data were taken for comparisons.

Results: We selected to compare the results for 10 mg estetrol with either LNG or DRSP with the results of Yaz®.

The change from baseline in the third cycle was respectively + 15% and −23% for SHBG and + 19% and −9% for angiotensinogen relatively compared to Yaz® (set at 100%) ($P < 0.001$). This indicates a low estrogenicity with DRSP and shows the estrogen-antagonistic effect of LNG.

Comparisons for important haemostatic variables shows a reduction in APC-resistance of 1% and 10% for DRSP and LNG respectively while Yaz® shows an increase of 179% ($P < 0.001$). Free TFPI shows a reduction of 17% for DRSP and an increase of 7% for LNG while Yaz® shows a decrease of 45% ($P < 0.001$). Antithrombin shows increases of 2% and 1% for DRSP and LNG respectively, while Yaz® shows a decrease of 5% (n.s.). Protein S activity showed increases of 3% and 17% for DRSP and LNG and a decrease of 27% with Yaz® ($P < 0.001$).

Most remarkable were decreases in F 1 + 2 of 3% and 10% for DRSP and LNG respectively while Yaz® showed 63% increase ($P = 0.001$), and D-dimer which showed decreases of 26% and 31% for DRSP and LNG respectively while Yaz® showed 31% increase ($P = 0.008$).

It is concluded that impact of estetrol containing preparations on markers of haemostatic activation (F1 + 2 and D-dimer) suggests a decrease in coagulation activation. This is supported by changes in the coagulation inhibitors antithrombin, protein S and TFPI showing no or less strong decreases compared to Yaz®. The APC resistance test is slightly changed in a favourable direction unlike for Yaz® where it is strongly increased.

It is suggested that the biomarker analysis of the effects of estetrol containing oral contraceptive formulations on haemostasis indicate a low increase of risk or even protection against venous thrombosis.

PB 2.66-2

Circulating nucleosomes and plasma free DNA are increased in abnormal pregnancies

Bouvier S[1], Grandemange L[2], Assie G[2], Mousty E[1], Ripart-Neveu S[1], Marès P[1], Cochery-Nouvellon E[1], Mercier E[1] and Gris J-C[1]

[1]University Hospital of Nîmes, Nimes; [2]Faculty of Pharmacy and Biological Sciences, Montpellier, France

Background: Recent data have analyzed the fundamental coupling between coagulation and innate immunity, indicating the central role of neutrophil-derived circulating nucleosomes on the promotion of coagulation and thrombus growth. Indeed, nucleosomes, as DNA/histones molecular complexes, a component of the neutrophil extracellular traps, target the proteolytic action of neutrophil serine proteases on Tissue Factor Pathway Inhibitor and factor XII, thus worsening coagulation *(Massberg S et al. 2010)*.

Pregnancy is an acquired hypercoagulability state. The placental function is central to the fetal development. Thrombotic impairments of the placental vessels may participate to placental insufficiency and may favor the related clinical complications, the so-called ischemic placental diseases (IPDs).

Aim: These data prompted us to perform an exploratory prospective study. Its aim was to compare plasma nucleosomes and cell free DNA (fDNA) concentrations between non-pregnant women, pregnant women with a normal pregnancy and pregnant women with an obvious clinical complication. Pregnancy complications, defined according to international guidelines, were diagnosed by reference practitioners and included: gravidic hypertension, IPDs (pre-eclampsia, intrauterine fetal growth restriction with evidence of placental insufficiency), venous thromboembolism, gestational diabetes, acute infections, cholestasis of pregnancy, abnormally implanted placenta, threats of premature labour and premature rupture of membrane. The study was

approved by the University Hospital of Nîmes Institutional Review Boards and Ethics Committee. This clinical investigation was performed according to the Helsinki declaration of 1975 as revised in 1996 (ClinicalTrials.Gov ID: NCT01736826). Informed consent was obtained from all patients.

Methods: Quantification of circulating nucleosomes and DNA were respectively determined by a commercially available ELISA kit and Q-PCR. Age, white blood cell (WBC) and neutrophils counts were documented for each woman. Blood samples from pregnant women were characterized by gestational age and pregnancy-related pathology, if any.

Results: We included 124 patients from October 2011 to May 2012: 35 women with a normal pregnancy, 73 women with an abnormal pregnancy and 16 non-pregnant women.

We found increased plasma concentrations of nucleosomes ($P = 0.02$) and fDNA ($P < 0.0001$) in pregnant women, concentrations being the highest in abnormal pregnancies.

Nucleosomes ($P = 0.002$) and fDNA ($P < 0.0001$) concentrations differed depending on the type and severity of pregnancy-related complications: very high rates in the ischemic placental disease group.

Nucleosomes:WBC, fDNA:WBC, nucleosomes:neutrophils and fDNA:neutrophils ratios were significantly higher in pregnant women with a symptomatic complication.

Conclusion: This preliminary study shows high nucleosomes and fDNA concentrations during pregnancy, which culminate in severe pregnancy complications. These data encourage the systematic evaluation of the pathogenic and aggravating role of circulating total nucleosomes and fDNA in ischemic placental diseases.

PB 2.66-3
Could polycythemia vera be a vascular 'risk factor' in woman?

Marton I, Pósfai ER, László Z, Széll M and Borbényi Z
University of Szeged, Szeged, Hungary

Background: The life expectancy of polycythemia vera (PV) patients is strongly affected by thrombotic events. Investigation of risk factors of thrombotic events separately in women should be prominently important, since changes in their lifetime conditions such as pregnancy or climaterium, and commonly prescribed oral contraceptives or oral hormone replacement therapies (HRT) could have an additional effect on the relatively frequent occurrence of vascular complications in these patients.

Aims: To evaluate the impact of major cardiovascular risk factors (hypertension, cigarette smoking, diabetes mellitus, obesity and hyperlipidemia) on thrombotic events in woman diagnosed with polycythemia vera.

Methods: Women with or without of thrombotic events were compared by a series of variables such as age, presence of JAK2 V617F mutation, measured platelet, red blood cell, haemoglobin and leukocyte counts at diagnosis, cardiovascular risk factors, and thrombotic events before and after diagnosis. Mann-Whitney tests were performed to explore overall effects of these variables. Multivariate binary logistic regression was also run to estimate the probability of thrombotic events.

Study participants: Fifty- eight women with median age 62 years; (range: 24–80 years) diagnosed with polycythemia vera between 1999 and 2011 at our Department, were enrolled to the study. Patients who used oral contraceptives or HRT were excluded from the study.

Results: JAK2 V617F-positivity was proven in 41 patients. Twenty-one thrombotic events were recorded in the prior history of PV patients, (before the clinical diagnosis of PV): myocardial infarction in five cases (8.6%), ischemic stroke or transient ischemic attack in nine cases (15.5%), venous thrombotic events in seven cases (12.1%). During the follow up period, six new thrombotic events were recorded: ischemic stroke or transient ischemic attack in five cases (8.6%), venous thrombotic event in one case (1.7%). Thirty-seven patients (63.8%) had high blood pressure. Eleven patients (19%) had hyperlipidaemia, nine patients (15.5%) had diabetes mellitus, and seven patients (12.1%) were cigarette smoker. Thirty-six women (62.1%) had normal weight (BMI 18.5–25), 22 (37.9%) woman were obes (BMI > 25).

The univariate analysis of the individual cardiovascular risk factors, the presence of diabetes mellitus ($P = 0.576$) or obesity ($P = 0.664$) did not show association with an increased risk of thrombosis in our study. However high blood preassure ($P = 0.053$), hyperlipidaemia ($P = 0.042$), and cigarette smoking ($P = 0.003$) are all associated with a significantly increased risk of thrombotic events. The association of cigarette smoking could be also confirmed using the multivariate binary logistic regression analysis ($P = 0.046$).

Summary/Conclusions: Based on our findings we concluded that polycythemia vera female patients, with cardiovascular risk factors (especially high blood pressure, hyperlipidemia, smoking) may have a higher risk for thrombotic events. In the future, in a prospective analysis we plan enlarge our study group for comparing the risk status of female PV patients who use or do not use oral contraceptives or HRT.

PB 2.66-4
Carbetocin increases thrombin generation after cesarean section

Testa S[1], Paoletti O[1], Dellanoce C[1], Bassi L[1], Stramezzi M[1], Spotti E[1], Mammoliti D[2] and Riccardi A[2]
[1]*Haemostasis and Thrombosis Center, A.O. Istituti Ospitalieri;* [2]*Obstetrics and Gynaecology Division, AO Istituti Ospitalieri, Cremona, Italy*

Background: Uterine atony is the first cause of haemorrhages at delivery. To prevent post partum major bleeding many strategies are adopted and uterotonic prophylactic drugs are commonly used after caesarean section. Thrombin generation, as expression of the balance between hyper- and hypo-coagulability, could give information about haemostatic assessment and modifications.

Aims: Aim of the present pilot study is to evaluate if women treated with carbetocin and oxytocin, two different uterotonic agents, show differences in thrombin generation test (TGT) after caesarean section (CS).

Methods: Twenty-eight women undergoing cesarean section, without previous bleeding or thrombotic events, were matched for age, weight, parity, race and for type of intervention (planned or emergency). Fourteen women were treated with a standard 2-h oxytocin IV infusion (10 IU) and 14 with carbetocin 100 μg IV. Blood samples for TG study and blood cell count were collected before delivery (T0), 1 h (T1) and 24 h (T2) after drug infusion. Blood samples were immediate centrifuged and poor platelet plasma (PPP) stored at −80°C. Thrombin generation was performed with a commercial assay (TGA Ceveron α, Technoclone). TG measured lag time, peak, velocity, endogenous thrombin potential (ETP). The activation of coagulation was obtained by adding small amounts of tissue factor and phospholipids. ETP results were expressed as nM-Thrombin/min.

Results: No differences were observed in TG profile between the two groups at T0, confirming homogeneity between the two groups. At T1 a significant increase in ETP was observed in the carbetocin group (ETP mean ± DS = 3810.8 ± 661.95) compared with oxytocin treated patients (ETP mean ± DS = 3588.7 ± 711.36) with $P < 0.05$. T2 showed the persistent ETP increase in carbetocin group, even if it didn't reach the statistical significance. Also other parameters like peak and velocity were significantly increased in the carbetocin compared with oxytocin group, both at T1 and T2. No differences in bleeding were observed in the two groups.

Conclusion: Our pilot study show a major ETP increase in patients treated with carbetocin, probably reflecting a much important thrombin activation associated with uterotonic action and longer half-life, in comparison with oxytocin. TGT showed to be sensitive in describing uterotonic agent effects on the haemostatic system.

PB 2.66-5

Changes in haemostatic parameters during the menstrual cycle and drospirenone-containing oral contraceptive use

Tchaikovski SN[1], Thomassen CLGD[2], Costa SD[1], Bremme K[3] and Jan R[2]

[1]Otto-von-Guericke University, Magdeburg, Germany; [2]Cardiovascular Reasearch Institute Maastricht, Maastricht, The Netherlands; [3]Karolinska Institutet, Stockholm, Sweden

Background: Oral contraceptives (OC) increase the risk of venous thromboembolism. The risk is dependent on the OC formulation and can be explained by increased thrombin generation and acquired resistance to activated protein C (APC). OC containing a new progestogen-drospirenone (DRSP-OC) associated with an increase of thrombosis risk that is similar to that during the use of third generation OC and two times higher as compared to second generation OC. There is limited information available on the effect of DRSP-OC on thrombin generation, APC resistance and other coagulation parameters.
Aim: to investigate changes in the coagulation system during the menstrual cycle and DRSP-OC use.
Methods: In a study population consisting of 14 healthy women between 21 and 33 years of age we investigated the effect of menstrual cycle and subsequent use of DRSP-OC on thrombin generation, APC resistance, the function of the tissue factor pathway inhibitor (TFPI) system and on the plasma levels of prothrombin, antithrombin, factor (F) V, FX, FVIII, protein C, total and free protein S, and full length and free TFPI.
Results: During DRSP-OC use we observed a significant increase in APC resistance (128%), thrombin generation at low (66%) and high tissue factor concentrations (40%), plasma concentrations of prothrombin (20%), FX (28%), FVIII (17%) and protein C (32%). DRSP-OC use impaired the function of the TFPI system and decreased plasma levels of antithrombin (−7%), FV (−21%), total protein S (−23%), free protein S (−21%), full length TFPI (−44%) and free TFPI (−49%). All studied parameters remained unchanged during menstrual cycle.
The changes in total and free protein S caused by DRSP-OC use correlated with $r = 0.89$ and slope 0.97 (95%CI: 0.66–1.28), indicating that the decrease of functionally active free protein S is likely due to the reduction of the levels of total protein S and not to a shift in the distribution between free and bound fractions of protein S. In contrast, although both total and free TFPI decreased during DRSP-OC use, no correlation between changes in these two forms of TFPI was detected, suggesting that DRSP-OC may influence TFPI activity at various regulatory levels, such as synthesis, cleavage, binding to lipoproteins or clearance.
Conclusions: DRSP-OC induce multiple changes in coagulation, which lead to an increase of thrombin generation, particularly at low tissue factor concentrations and which more than doubles APC resistance. The changes in anticoagulant pathways such as protein C- and TFPI-systems are more pronounced than the changes in the coagulation pathways.

PB 2.66-6

Venous thromboembolism (VTE) prophylaxis in hospitalized obstetric patients in Ireland: a multicentre cross-sectional study

Crowley MP[1], Noone C[1], Higgins JR[2] and O' Shea S[1]

[1]Cork University Hospital; [2]Cork University Maternity Hospital, Cork, Ireland

Background: VTE complicates 1–2/1000 pregnancies, and the risk increases with age, mode of delivery, and presence of co-morbidities. It continues to be one of the leading causes of maternal death. Prophylaxis with low molecular weight heparin (LMWH) is safe. Despite having a population of only 4.5 million, Ireland has 20 maternity hospitals. Given this large number, it is difficult to standardize practice with international best practice.
Aims: To assess the prevalence of VTE risk in pregnant women in the hospital setting and to determine the proportion of at-risk patients who receive effective prophylaxis.
Methods: The study period was September 2011 to November 2012. All patients admitted to the participating hospitals on the day of investigation were assessed for risk of VTE on the basis of hospital chart review. Risk was assessed in accordance with the 2009 Royal College of Obstetricians and Gynaecologist Guidelines. Patients undergoing procedures or on the labour ward at the time of review were excluded. Ethical approval was obtained from the ethics committees governing all centers.
Results: Five hundred and forty pregnancies were reviewed across 16 centers. The average age of was 31 ± 5.65 years (Range 16–47) with 21.87% (117/535) aged over 35. Twenty-two percent (118/535) had a parity of three or more. The average weight was 71.51 ± 14.482 kg (Range 42–134 kg). Data on BMI was available for 77–34% were overweight and 21% were obese. One percent (6/420) had a BMI > 40. Thirty-one percent (168/540) were antenatal and 69% (372/540) were postnatal.
Sixty-three percent (105) of antenatal patients were low risk (< 2 risk factors), 35% (59) were intermediate risk (two or more risk factors, prophylaxis should be considered) and 2% (4) were high risk. All the high risk patients were on prophylaxis at an appropriate dose. Four percent (6) of the low risk patients were on prophylaxis unnecessarily. Only 7% (4/59) of the intermediate risk patients were on prophylaxis (3/4 were on too low a dose).
Among postnatal patients, 41% (153) were low risk (< 2 risk factors), 58% (217) were intermediate risk (two or more risk factors, require prophylaxis) and < 1% (2) were high risk. Eighty percent (296) were appropriately risk stratified and put on LMWH if necessary. Fifty-nine percent (219) of patients should have been on LMWH but only 42% (157) were (92% Tinzaparin and 8% Enoxoparin). This included eight patients who were on LMWH unnecessarily. Thirty-eight percent (59/157) were on too low a dose.
Conclusion: VTE prophylaxis is an important issue in obstetrics given its prominent role in maternal morbidity and mortality and the increasing prevalence of risk factors such as obesity and increasing maternal age. It is clear that while there is good awareness of the risk in the postnatal period, there is less emphasis on risk assessment in antenatal patients where prophylaxis is rarely used. Those on prophylaxis are also likely to be on too low a dose. Given the number of maternity hospitals inIreland, there is a role for a national guideline to standardize care for all pregnant women.

PB2.67 – Inflammation: Basic – II

PB 2.67-1

Factor VII-activating protease in concert with DNase removes nucleosomes from necrotic cells

Marsman G, Stephan F, Bakker L, Bulder I, Aarden L and Zeerleder S

Sanquin Bloodsupply, Amsterdam, The Netherlands

Background: Circulating cell-free DNA e.g. nucleosomes can be a potent immune activator, which is released into the circulation during inflammation. Nucleosome levels correlate with disease severity and mortality in patients with sepsis. Little is known about the mechanism on how DNA in the form of nucleosomes is released from dead cells. It has been shown that plasma can remove nucleosomes from late apoptotic cells and the plasma serine protease Factor VII-activating protease (FSAP) is responsible for this release. FSAP circulates as an inactive single-chain protein, which is activated upon contact with either apoptotic or necrotic cells. In contrast to late apoptotic cells

however, purified FSAP is not able to remove nucleosomes from necrotic cells.
Aim: We hypothesized that upon necrosis, endogenous DNase I activity may be required to facilitate efficient nucleosome release by FSAP and aimed to investigate the role of these serum proteins in this process.
Methods: Necrotic jurkat cells were incubated with serum or serum components and nucleosome release was monitored by measuring residual DNA content by flow cytometry. In addition nucleosomes were measured in the supernatant of these samples by means of a nucleosome specific ELISA. Finally, the extent of chromatin fragmentation of these samples was determined on agarose gel.
Results: Both serum and a combination of purified FSAP and DNase I are equally efficient to release nucleosomes from necrotic cells. However, purified FSAP or DNase I alone is not able to convey nucleosome release. Furthermore, both serum in which FSAP is blocked by a neutralizing antibody and FSAP-deficient serum are unable to induce nucleosome release from necrotic cells. Finally we show that in contrast to FSAP or DNase I alone, a combination of both FSAP and DNase I can induce chromatin fragmentation.
Conclusion: FSAP and DNase cooperate in the release of nucleosomes from necrotic cells. This synergistic activity might play a crucial role in the release of pro-inflammatory nucleosomes upon inflammation or tissue damage.

PB 2.67-2
SMTP-7, a novel small-molecule thrombolytic with an anti-inflammatory potential, improves primate thrombotic stroke with reduced hemorrhage risk

Suzuki E, Matsumoto N and Hasumi K
Tokyo Noko University, Tokyo, Japan

Background: SMTP-7, a small molecule that promotes plasminogen activation through relaxation of plasminogen conformation, has excellent therapeutic activities in cerebral infarction in several rodent models, possibly due to its thrombolytic and anti-inflammatory, crebroprotective potentials.
Objective: Detailed evaluation of SMTP-7 efficacy in a primate stroke model is anticipated in view of novel, safe drug development, especially in terms of reduced hemorrhage risk.
Methods: A monkey photochemical-induced thrombotic middle cerebral artery (MCA) occlusion model, as well as several other rodent models, was utilized to evaluate therapeutic potentials of SMTP-7.
Results: In the monkey model, in which thrombotic MCA occlusion was followed by recanalization/reocclusion, Compared with saline control, SMTP-7 (10 mg/kg, iv infusion) increased post-infusion MCA recanalization rate (32.5-fold, $P = 0.043$) and ameliorated post 24-h neurological deficit (by 29%, $P = 0.02$), cerebral infarct (by 48%, $P = 0.025$), and even cerebral hemorrhage (by 51%, $P = 0.013$). In normal monkeys, SMTP-7 did not affect general physiological and hemostatic variables including coagulation and platelet parameters. Investigations on rodent models of transient and permanent focal cerebral ischemia as well as endothelial-injured arterial thrombosis and bleeding tests, suggested an importance of the drug's crebroprotective properties as well as its regulated profibrinolytic action that served as a physiological on-demand system coping with thrombotic events.
Conclusions: SMTP-7 is effective in treating thrombotic MCA occlusion stroke in monkeys, ameliorating neurological deficits, infarct size, and even hemorrhagic transformation, which may be attributable to both regulated thrombolytic promotion and neuroprotective properties as demonstrated in several other animal models.

PB 2.67-3
Oral anti-thrombin abrogates microvessel permeability during experimental ischemia

Del Zoppo GJ, Hawkins BT and Gu YH
University of Washington, Seattle, WA, USA

Background: Non-valvular atrial fibrillation (AF) increases the risk and severity of thromboembolic stroke, however prevention of thrombus formation with an anti-thrombotic agent increases intracerebral hemorrhagic risk. The RE-LY trial demonstrated significant reductions in thromboembolic stroke and intracerebral hemorrhage with the direct thrombin inhibitor dabigatran compared to warfarin. Thrombin is generated acutely in the wall and abluminal space of cerebral microvessels during focal ischemia at a time when the (blood-brain) permeability barrier is compromised, and thrombin is itself a putative mediator of increased microvessel permeability.
Aims: We hypothesized that dabigatran could decrease the risk of intracerebral hemorrhage by direct inhibition of thrombin-induced increases in microvascular permeability. These studies focus on the cellular components of the microvessel.
Methods: Based on *in vivo* work in the non-human primate focal ischemia model, we developed high-quality *in vitro* systems mimicking endothelial cell-matrix-astrocyte interactions of cerebral microvessels. Primary murine brain endothelial cells (mBEC) without or with astrocytes were exposed to purified murine thrombin (0–10 U/mL) in serum-free media for 1 h prior to measuring permeability to a molecular weight range of FITC-labeled dextrans. Co-culture with astrocytes significantly decreases endothelial permeability. Cell viability was confirmed by a propidium iodide uptake assay. Coincident expressions of endothelial cell integrin and the tight junction protein claudin-5 following thrombin exposure were measured by flow cytometry. In separate studies, experimental ischemia (oxygen-glucose deprivation, OGD) was induced by placing cells in low-glucose media in an airtight container purged with N_2 and incubating 18 h at 37°C.
Results: Thrombin increased mBEC permeability to 4 kDa FITC dextran in a concentration-dependent manner (P_{app} for control: $2.98 \times 10^{-6} \pm 0.87 \times 10^{-6}$ cm/s, for 10 U/mL thrombin $4.37 \times 10^{-6} \pm 0.39 \times 10^{-6}$ cm/s, $n = 6$, $2P = 0.0109$), without endothelial cell demise ($\leq$ 20 U/mL thrombin). Pre-treatment of mBEC with dabigatran (24 h, 500 nM) completely abrogated the effect of 10 U/mL thrombin on permeability under conditions of normoxia. The results were similar when endothelial cells and primary astrocytes were grown in apposition, and subject to thrombin ± dabigatran exposure. Thrombin-induced permeability was not due to decreased expression of beta 1 integrins or claudin-5. OGD also increased permeability of mBEC, and this effect was also abrogated by treatment with dabigatran.
Summary/conclusions: Dabigatran blocks thrombin-induced brain endothelial cell (*in vitro* microvessel) permeability. These findings indicate that thrombin increases mBEC permeability by direct modification of other tight junction protein(s) than claudin-5 or via a transcellular mechanism. They imply that the development of thrombin during an embolic ischemic stroke (in the setting of AF) contributes to increased microvessel permeability. Ongoing studies further detail the mechanisms by which thrombin increases cerebral microvascular permeability and hemorrhagic risk.

PB 2.67-4
Connective tissue growth factor (CTGF/CCN2) is over-expressed via TGF beta pathway in synoviocytes upon cell-to-cell interaction with platelets

Liverani E, Kunapuli SP, DeLa Cadena RA and Rico M
Temple University School of Medicine, Philadelphia, PA, USA

Background: CTGF/CCN2 is an important molecule for extracellular matrix development and remodeling. It has potent angiogenic prop-

erties and it is present in fibrotic tissue and on the surface of atherosclerotic plaques. In inflammatory conditions such as rheumatoid arthritis (RA), CTGF is increased in plasma and synovial fluid, and it might contribute to increase inflammation, angiogenesis and synovial fibrosis. Interestingly, CTGF is also stored in the α granules of platelets and it is released upon activation. Platelets have been shown to infiltrate into the synovial fluid during RA and contribute to the inflammation of the joint. Thus, we hypothesize that CTGF is involved in (i) worsening the formation of atherosclerotic plaque via platelet activation and granule-content release with subsequent platelet adhesion and in (ii) the perpetuation of synoviocyte hyperplasia.

Aims: (i) To evaluate platelet adhesion in the presence of CTGF/CCN2 (ii) To evaluate the potential role of platelet/synoviocyte interaction for the expression of CTGF/CCN2 and (iii) to delineate potential signaling pathways in platelets and synoviocytes leading to CTGF/CCN2 expression.

Methods: We performed *in vitro* studies on platelets and platelets/fibroblast-like synoviocytes co-cultures, analyzing CTGF/CCN2 effects by immuno-fluorescence, adhesion assay, flow-cytometry and Western blot analyses.

Results: Platelets adhere and spread on recombinant (r) CTGF-coated slides in a concentration dependent manner similar to platelet adhesion on fibrinogen. The platelet spreading area on CTGF surface (1 μg/mL) was significantly increased (8-fold) in comparison to control (BSA). Furthermore, platelets pre-treated with rCTGF (50 nM) increased ERK phosphorylation upon ADP stimulation. In contrast, pretreatment with rCTGF did not cause platelet aggregation or secretion by itself. Platelet/synoviocyte co-cultures treated with rCTGF showed an increase in cell-cell aggregates formation, assessed by flow cytometry and immunofluorescence. CTGF/CCN2 was also increased when synoviocytes were co-cultured with resting platelets in a time dependent manner assessed by Western blot analyses. In order to understand the role of synoviocytes in CTGF/CCN2 production, we analyzed the SMAD proteins, which are part of the TGFβ pathway. Activation of the TGFβ-receptor will result in phosphorylation of SMAD2, formation of a SMAD2/3 complex and subsequent CTGF/CCN2 expression. SMAD2 phosphorylation was increased in synoviocytes after co-culture with resting platelets, suggesting that synoviocytes increased CTGF/CCN2 expression.

Conclusions: Platelets adhere and spread into CTGF/CCN2 surfaces, suggesting a possible atherogenic effect for CTGF/CCN2 *in vivo*. Furthermore, CTGF/CCN2 exposure could augment platelet ability to adhere to synoviocyte. Overall, these data indicate that CTGF/CCN2 may contribute to increase and/or sustain joint inflammation, suggesting a possible target for future therapeutic strategies in RA

PB 2.67-5

Thrombin modulates the expression of a set of proinflammatory genes including tissue factor in human monocytes

Lopez Zambrano M[1], Bruges G[1], Crespo G[1], Pabon J[1], Alvarado C[1], Salazar V[1], Dittrich-Breiholz O[2], Schneider H[2], Preissner KT[3] and Schmitz ML[3]

[1]IVIC, Caracas, Venezuela; [2]Hannover Medical School, Hannover; [3]Institute of Biochemistry, JLU, Giessen, Germany

Background: Besides its role in blood coagulation, thrombin is known to act as a cell signaling molecule via activation of protease-activated receptors (PAR), thereby connecting this coagulation protease to specific cellular/inflammatory responses. Previous studies demonstrated that thrombin is capable of modulating chemotaxis of monocytes and also inducing expression of monocyte chemotactic protein (MCP-1), plasminogen activator inhibitor type 2 (PAI-2), matrix metalloproteinase-9 (MMP-9) or interleukin (IL) eight in monocytes. However, no study has analyzed the gene expression changes of thrombin-stimulated monocytes in a systematic way using microarray experiments.

Aim: The aim of this work was to evaluate the gene expression profile of thrombin-stimulated monocytes by microarray technology.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from human blood by density gradient centrifugation using Ficoll-Paque PLUS and affinity adsorption using anti-CD14 monoclonal antibody-coated microbeads combined with a magnetic cell separation system. Monocytes were stimulated with 10 U/mL human alpha-thrombin at 37 °C for 5 h, and after washing cells, total RNA was isolated using the RNeasy mini Kit (Qiagen). Labeled cRNAs were hybridized to the Whole Human Genome Oligo Microarray Kit 4x44K v2), including cRNA fragmentation, hybridization (Agilent Technologies, protocol V5.7). Slides were scanned on the Agilent Micro Array Scanner G2565CA. DAVID database (http://david.abcc.ncifcrf.gov) was used to dynamically assign gene expression data to the Gene Ontology (GO) biological-process categories.

Results: Eighty-three genes were selected which showed differential expression changes; 68 genes were up-regulated whereas 15 genes were down-regulated. Near 30% of the upregulated genes were related to the inflammatory response. Thus, genes encoding several cytokines and chemokines, associated with the recruitment and activation of leukocytes, were differentially expressed in monocytes in response to thrombin. Moreover, the gene for tissue factor was also up-regulated. Real-time reverse transcriptase polymerase chain reaction (RT-PCR) was used to confirm the microarray results of some of these genes. Moreover, higher expression of tissue factor in monocytes exposed to thrombin was also demonstrated by immunofluorescence and by shortening of clotting time.

Conclusion: Our results provide new evidences to the thrombin-mediated link between coagulation and inflammation through changes in gene expression in monocytes.

PB 2.67-6

The impact of glycation on aspirin-induced acetylation of human serum albumin: an *in vitro* study

Finamore F[1], Priego-Capote F[2], Zufferey A[1], Fontana P[3] and Sanchez J-C[1]

[1]University of Geneva, Geneva, Switzerland; [2]University of Còrdoba, Cordoba, Spain; [3]Division of Angiology and Haemostasis, Geneva, Switzerland

Background: Aspirin (ASA) acetylation is a post-translational modification that occurs through the transfer of its acetyl residue to the amino groups of proteins located at lysine and N-terminal residues. This modification plays a key role in medicine, since it improves the level of inflammation and partially prevents the risk of cardiovascular ischemic events. However, the biological effects of ASA on platelet function as well as its clinical benefit are lower in diabetic patients, a phenomenon described as 'aspirin resistance'. The effect of ASA was demonstrated in several human plasma proteins including haemoglobin, fibrinogen and serum albumin (HSA). HSA is the main transporter of drugs, hormones, fatty acids and metabolites, plays an important role in the regulation of osmotic pressure and is considered as an aspirin esterase. Considering the widespread use of aspirin, investigation of the acetylation and glycation of albumin is of interest.

Aim: The purpose of this study was to identify the albumin acetylated residues after incubation of HSA with an increasing ASA concentration by immunoblotting and mass spectrometry; and to determine whether pre-incubation of HSA with glucose inhibits ASA-acetylation.

Methods: HSA was incubated with an increasing ASA concentration (0, 0.02, 0.2, 2 and 20 mM) and the acetylation and glycation levels were measured by immunoblotting and high-resolution tandem mass

spectrometry (MS). In a second analysis, HSA was first incubated with glucose (10 mM) followed by ASA (20 mM). The acetylation and glycation levels were again measured.

Results: Incubation of HSA with ASA resulted in a dose-dependent increase of acetylated sites, among which only one was found as endogenous in native HSA, while six and 32 sites were identify at very low and very high ASA concentration, respectively. A significant decrease in the acetylation level was observed by Western blot when HSA was previously incubated with glucose. This result was confirmed by MS. Four sites were found to be common targets for both acetylation and glycation modifications.

Summary/Conclusions: We evidenced here a dose-dependent increase of the number of acetylation sites on HSA. Glycation had a major impact in decreasing the aspirin-induced acetylation process on HSA. The preferential amino acid sites for both post-translational modifications were identified as well. The influence of glycation on HSA acetylation could impair its biological functions, potentially leading to the worsening of the typical diabetes complications. This proof-of-concept study may pave the way to a better understanding of the acetylation – glycation interactions at the protein level in diabetic patients.

Keywords: aspirin, acetylation, human serum albumin, glycation.

Rhinovirus infection induces procoagulant changes in parallel with eosinophilic airway inflammation

Majoor CJ[1], Kamphuisen PW[2], Van De Pol MA[1], Meijers JC[3], Van Der Poll T[1], Nieuwland R[1], Johnston SL[4], Bel EH[1], Lutter R[1] and Van Der Sluijs KF[1]

[1]Academic Medical Centre, Amsterdam; [2]University Medical Center Groningen, Groningen; [3]Academic Medical Center Amsterdam, Amsterdam; [4]National Heart and Lung Institute, Imperial College, London, UK

Background: Asthma exacerbations are frequently triggered by rhinovirus infections. Asthma itself is associated with activated coagulation and increased risk of venous thromboembolism[1] and also respiratory viruses may activate hemostasis. *Vice versa*, a prothrombotic state in the lung can also induce or aggravate pulmonary inflammation.

Aim: To determine whether rhinovirus infection and asthmatic airway inflammation act on the local and systemic hemostatic balance in patients *in vivo*.

Methods: In a two-groups parallel study design 28 volunteers (14 patients with mild asthma (seven females, 19–26 years) and 14 healthy controls (13 females, 19–31 years)) were experimentalliy infected with low-dose rhinovirus serotype 16 (RV16). Patients with mild asthma were stable after discontinuation of their asthma medication 2 weeks prior to RV16 inoculation. Venous plasma and bronchoalveolar lavage fluid (BAL fluid) were obtained 1 day before and 6 days after rhinovirus challange to evaluate several key markers of coagulation activation in plasma and BAL fluid, as well as the coagulant features of microparticles in BAL fluid. Thrombin-antithrombin complexes (TATc), von Willebrand factor (vWF), Plasmin-antiplasmin complexes (PAP), Plasminogen activator inhibitor type-1 (PAI-1), and eosinophil cationic protein (ECP) in plasma and BAL fluid were measured by immunoassay. Endogenous thrombin potential (ETP) was analysed using the Calibrated Automated Thrombogram® and tissue factor bearing microparticles, measured by fibrin generation test (FGT). Eosinophils were counted on cytospin preparations. Comparisons and correlations were performed by non-parametric testing.

Results: In plasma, RV16 challange resulted in increased PAI-1 levels in patients with asthma after viral infection (26.5 ng/mL in patients with astma vs. 10.0 ng/mL in healthy controls, $P = 0.01$) and decreased PAP levels (318 vs. 534 ng/mL resp., $P = 0.04$). Changes in PAI-1 levels were significantly elevated in asthma than in control subjects (3.0 vs. −3.5 ng/L respectively, $P = 0.024$), while changes in TATc, D-dimer, vWF and ETP did not differ between both groups. In BAL fluid, the FGT shortened after viral infection in asthma (t = −1 day: 689s vs. t = 6 days: 516 s; $P = 0.011$), but not in healthy controls (t = −1 day: 695s vs. t = 6 days: 672 s; $P = 0.79$). The changes in TATc and PAP did not differ between both groups and vWF, D-dimer and PAI-1 were below the detection limit.

Both FGT and TATc in BAL fluid correlated (Spearman) with eosinophil counts and ECP ($r = -0.583$ and -0.682 resp. for FGT and $r = 0.535$ and 0.619 resp. for TATc, all $P < 0.01$)

Conclusion: Experimental rhinovirus infection induces procoagulant changes in patients with asthma systemically through PAI-1 and in the airways by TF-bearing microparticles. This did not lead to changes in global assays of hemostasis, probably due to the relatively mild infection in patients with mild to intermittent asthma. In the airways, microparticle-associated procoagulant changes are associated with eosinophilic inflammation, suggesting that virus infection and eosinophilic inflammation both act on the hemostatic (dis)balance during asthma exacerbations.

Role of platelets and MMP2 in osteoarthritis joint inflammation: effect of hyaluronic acid

Petito E, Falcinelli E, Momi S, Alunno A, Gerli R and Gresele P

University of Perugia, Perugia, Italy

Background: Osteoarthritis (OA) is the most common form of arthritis and, although mainly a degenerative disorder, it is now demonstrated that inflammation takes part in the early development and in the progression of this chronic degenerative joint disease.

OA is characterized by cartilage breakdown, consequent to extracellular matrix (ECM) degradation caused in particular by an increased local formation of matrix metalloproteinases (MMPs), a family of zinc-dependent endoproteinases.

Platelets are involved in different inflammatory conditions, including rheumatoid arthritis (RA), but their role in OA has not been investigated yet.

Platelets contain and release several MMPs, including MMP-2, and they enhance MMPs expression by other cell types. We have recently shown that MMP-2 contributes to joint degeneration in group B Streptococcus-induced arthritis (Puliti M. et al., Arthritis Rheum. 2012 Apr;64(4):1089–97).

Viscosupplementation by the intra-articular administration of hyaluronic acid (HA), a non-sulphated glycosaminoglycan physiologically present in synovial fluid, is a widely used treatment for OA.

Aims: Aims of our study were to evaluate the role of platelets in joint inflammation in OA patients and to assess the effect of HA on platelets and on their interaction with synoviocytes (FLS).

Methods: We collected synovial fluid (SF) from 38 patients with knee-OA (T0). Twenty-seven out of these 38 patients were re-analyzed after 5 weekly HA intra-articular administrations (T1). The following parameters were measured in SF: total cell count, platelet count and platelet-leukocyte aggregates (by flow-cytometry) and MMP-2 levels (by zymography).

Moreover, FLS isolated from SF of OA patients were co-cultured with platelets in the presence or not of HA, and MMP-2 release was measured by zymography. Platelet P-selectin was measured as an index of platelet activation.

Results: HA treatment significantly reduced total cell count (T0: 943.9 ± 144.1 vs. T1:573.1 ± 62.97 $P < 0.05$), platelet count (T0: 32.83 ± 22.31 vs. T1: 3.70 ± 1.06 $P < 0.05$), platelet-leukocyte aggregates (T0: 7.55 ± 2.31 vs. T1:2.19 ± 0.67 $P < 0.05$) and MMP-2 levels (T0: 468.1 ± 72.69 ng/mL vs. T1: 428.2 ± 68.89 ng/mL $P < 0.05$) in SF.

In vitro, platelets increased MMP-2 release by FLS (FLS: 45.27 ± 11.80 ng/mL vs. FLS + Plts: 64.76 ± 15.50 ng/mL $P < 0.05$). Platelet activation, evaluated as P-selectin expression, increased significantly after 24 h of co-culture (Plts: 8.75 ± 2.15 ng/mL vs. Plts + FLS: 20.70 ± 3.19 ng/mL $P < 0.05$). HA decreased significantly the release of MMP-2 by FLS-platelet co-cultures (FLS + Plts: 64.76 ± 15.50 ng/mL vs. FLS + Plts + HA: 20.84 ± 4.78 ng/mL $P < 0.05$).

Conclusions: Platelets are involved in OA and may participate in cartilage degradation by facilitating the expression and release of MMP-2 by synoviocytes. Platelet P-selectin contributes to this activation. Treatment with HA reduces platelet activation in synovial fluid of OA patients and reduces the release of MMP-2 by platelet-synoviocyte co-cultures.

Defining platelet function in polytrauma patients upon admission to the emergency department

Brophy DF[1], Contaifer D[1], Mohammed BM[1], Newton JC[1], Martin EJ[1], Brophy G[1], White NJ[2], Reynolds PS[1], Song J[1] and Ward KR[3]

[1]Virginia Commonwealth University, Richmond, VA; [2]Puget Sound Blood Center, Washington, DC; [3]University of Michigan, Ann Arbor, MI, USA

Background: Haemostatic function is impaired by multisystem injury and impacts survival. Recent description of Trauma Induced Coagulopathy (TIC) has found significant relationships between the onset and degree of coagulopathy and injury severity in trauma patients.

Aims: To characterize the relationships between platelet function and injury severity with clinical outcomes in response to trauma.

Methods: We conducted a prospective observational trial of clot formation in trauma patients presenting to a U.S. level I trauma center. Blood samples and clinical data were collected upon arrival to the emergency department and platelet function was determined using a comprehensive panel of tests including viscoelastic clot strength and platelet mapping, platelet-associated thrombin generation, platelet-induced clot contraction and effect on clot structure, platelet aggregation, flow cytometry, prothrombin time (PT), activated partial thromboplastin time (aPTT) and fibrinogen. Exploratory hierarchical clustering analysis of patient admission data resulted in clustering using the Injury Severity Score (ISS); mild/moderate (1–15), severe (14–24) and profound (=25). ISS groups were then used to group patients and compare compare to healthy volunteers.

Results: The ISS score was available on 94 trauma patients including 36% with mild/moderate injury; 26% with severe injury and 38% with profound injury. The presence of traumatic brain injury (TBI) was significantly greater in the profound injury group (42%) compared to the other groups ($P = 0.019$). When compared to healthy patients, the mild/moderate, severe, and profound ISS groups, respectively had relatively lower fibrinogen concentrations (median [range] 247.0 [215.75, 324.00], 226.5 [176.50, 342.00], 175.7 [114.50, 221.50] mg/dL, respectively, [$P < 0.001$]). Severe and profound injury had severe base deficits, respectively (median [range] −5.3 [−7.13, −1.15]; −4.7 [−10.45, −2.13] mEq/L). Profound injury patients had normal TEG maximum amplitude (mean [SD] 57.5 [9.3] mm), reduced collagen impedance aggregation (median [range] 12.3 [7.75, 15.00] Ω), and prolonged PT (17.5 [15.03, 21.48] s).

Summary/conclusion: All ISS groups showed signs of TIC, but only patients with severe and profound ISS classifications had significant tissue hypo-perfusion, prolonged PT and relatively reduced fibrinogen levels, suggesting a disseminated intravascular coagulopathy pattern. As there were more TBI patients in the profound ISS group, this may suggest an association between TBI and altered haemostasis. The ISS may be a useful tool to predict the degree of coagulopathy in polytrauma patients, but further prospective trials are needed.

PB 2.68-4

Changes of platelets status in pts with inflammatory cardiac pathology

Gupalo E, Buryachkovskaya L, Uchitel I, Chumachenko P and Mironova N

Russian Cardiology Research Complex, Moscow, Russian Federation

Background: Viruses are able to induce myocarditis and lead to subsequent inflammatory dilated cardiomyopathy (DCM) development. Cardiac rhythm and conduction disturbances can be direct consequence inflammation in myocardium. Coxsackie-adenovirus receptor (CAR) a protein of tight junctions generally present at the cardiac intercalated disks recently was shown on platelets in the sites of intracellular communications.

The aim of our study was to evaluate platelets property in patients (pts) with DCM/myocarditits compared to pts with conduction delays with structurally normal heart.

Methods: Platelet spontaneous and ADP-induced aggregation (studied by simultaneous analysis of the mean aggregate size changes kinetics and light transmission (LTA) using an aggregation analyzer BIOLA (Russia) as well as CAR expression was investigated in 13 pts with DCM/myocarditis and in 19 pts with different grade atrioventricular and left bundle branch block, which were diagnosed by routine clinical investigation. Diagnosis of DCM/myocarditis was confirmed according endomyocardial biopsy (EMB) data. Ten healthy subjects (HS) were included as a control. Platelets of pts of both study groups and also HS were analyzed using immunofluorescent method on CAR persistence by microscopic evaluation and also by flow cytometry. In eight pts the persistence of connexin 45 was assessed.

Results: In whole blood of nine from 13 DCM/myocarditits pts were found circulating microaggregates. These group of pts demonstrated high level of platelet activation which was induced by release reaction. The level of 1.0 μM ADP and 5.0 μM ADP induced aggregation was 43 ± 21% ($N < 25\%$) and 52 ± 24% ($N < 68\%$) respectively. Spontaneous aggregation was 3.7 ± 1.8% at the first 5 min, but to the 9–14 min its level grew up to 37 ± 17.3% similar to ADP induced aggregation ($P = 0.2$) as a result of platelet release reaction that was never observed in HS. Microaggregates persistence and high level of platelet aggregation can possible reflect microvascular changes due to inflammatory infiltration revealed by endomyocardial biopsy data in all these pts. The level of aggregation of the rest four pts was in normal ranges that can be explained by aspirin uptake according clinical indications. Similar induced aggregation was demonstrated in nine pts from group with conduction delays (1.0uM ADP was 40 ± 19.1% and 5.0uM ADP was 51 ± 17.6%, $P = 0.1$). Spontaneous aggregation was 1.76 ± 0.72 r.u.(normal range < 1.4 r.u) without release reaction. Complex of clinical investigation confirmed structurally normal heart in these pts. The estimation of platelets with CAR expression was much higher in DCM/myocarditis pts (14 ± 9.9% vs 3.5 ± 1.9% in pts with conduction delays and HS). CAR persisted predominantly at the sites of intracellular communication in the aggregated and was co-localized with connexin 45 which was firstly detected at human platelets. The level of CAR expression was higher in DCM/myocarditis pts with clinical and EMB data confirmed the sigh of active inflammation.

Summary/Conclusions: Platelet activation can reflect microvascular changes in DCM/myocarditis pts. The high level of CAR expression, its appearing in the sites of intracellular connection and co-localization with connexin 45 may indicate the role of these two receptor in platelets changes during inflammation.

PB 2.68-5

Protein chip array and thrombotic biomarker profiling of plasma samples undergoing bypass surgery

Walenga JM[1], Matsuo T[2], Wanaka K[3], Chaudhry T[1], Hoppensteadt D[1] and Fareed J[1]

[1]*Loyola University Medical Center, Maywood, IL, USA;* [2]*Hyogo Prefectural Awaji Hospital, Sumoto;* [3]*Kobe Research on Thrombosis and Haemostasis, Kobe, Japan*

Introduction: In cardiovascular surgical procedures, such as coronary artery bypass grafting (CABG) and valve repair/replacement, patients are exposed to large doses of heparin and protamine sulfate. There is a high prevalence of anti-heparin/platelet factor-4 antibodies in these patients. Although a fraction of these patients develop HIT syndrome, the role of circulating anti-heparin/platelet factor-4 antibodies is not clear. Such thrombogenic mediators as microparticle and tissue factor may be up regulated in these patients. The relevance of thrombotic mediators and inflammatory processes remains to be further explored in these patients. Recently the protein chip array approach using SELDI/TOF mass spectrometry methods have been employed to identify unique biomarkers in various diseases. The purpose of this study was to determine the protein chip array profile and various mediators of thrombotic activation in patients who have undergone coronary artery bypass surgery.
Materials and Methods: Plasma samples from 79 cardiovascular patients were collected prior to surgery and one and 2 weeks afterwards. Protein chip array profiling was carried out on a SELDI/TOF mass spectrometric method (PCS4000, BioRad; Richmond, CA) employing a gold chip array in the molecular weight range of 3000–150,000. The intensity of unique peaks was also calculated in terms of relative intensities. Cellular microparticles were measured using a functional method (Hyphen Biomedical; France) and tissue factor antigen levels were measured using an ELISA method (Hyphen). The anti-heparin/platelet factor-4 antibodies were also measured using a commercially available ELISA method (GTI; Wisconsin).
Results: Of the 79 patients, 20 showed a unique peak around 11–12 kDa in the pre-op samples, which was absent from normal controls. Seventy-seven of the patients showed this unique biomarker peak at 1 week, whereas only 48 patients exhibited the peak at 2 weeks after surgery. The relative intensity of the 11.6 kDa biomarker was much higher at 1 week (6-fold) and was decreased at 2 weeks (3-fold). In addition to this unique peak, additional biomarker peaks were noted at 15.1 and 15.8 kDa. In comparison to the normal controls, the microparticle levels were higher in the baseline sample (10.1 ± 3.2 nM) and increased to 19.3 ± 6.1 and 24.5 ± 8.1 nM. Similarly, the tissue factor levels were increased at the 2 weeks time period. The anti-heparin/platelet factor-4 titer rose 28% from the baseline at week 1 and 33% at week 2.
Conclusions: The results on the biomarker profile are consistent to one of our earlier findings, where the presence of a unique biomarker in the range of 11–12 kDa has been reported in patients with high prevalence of anti-heparin/platelet factor-4 antibodies. The increased level of microparticles and tissue factor at post-surgical periods of 1 and 2 weeks suggests endogenous activation of thrombogenic mechanisms, which appears proportional to the up regulation of the anti-heparin/platelet factor-4 antibodies. Thus, this data indicates that the non-functional anti-heparin/platelet factor-4 antibodies may result in the activation of cellular processes leading to thrombogenesis. Further characterization of the unique biomarkers identified in these patients may be useful in the understanding of the pathogenesis of thrombogenesis in cardiovascular surgery patients.

PB 2.68-6

Effect of long-term intake of serotonin reuptake inhibitors on neutrophil function in humans

Duerschmied D[1], Guenther J[1], Kontchou A[1], Stallmann D[1], Bode C[1] and Normann C[2]

[1]*Heart Center Freiburg University;* [2]*University Hospital of Freiburg, Freiburg, Germany*

Background: Blood serotonin is stored in the dense granules of platelets and released upon activation. Treatment with serotonin reuptake inhibitors (SRIs) depletes platelet serotonin levels and thus reduces serum serotonin. This reduction results in reduced leukocyte rolling and adhesion in mice.
Aims: Based on findings in mice we asked, whether long-term intake of SRIs impairs neutrophil function in humans.
Methods: We compared 29 patients treated for major depression with SRIs to seven depressive patients not treated with SRIs. A control group consisted of 17 non-depressive study subjects. Severity of depression was documented by Beck Depression Inventory II. The frequency of respiratory tract or urogenital infections, infective gastroenteritis and pharyngitis was assessed by a questionnaire. Blood cell count and CRP measurement was conducted. The concentration of serum serotonin was determined by ELISA. Expression of neutrophil surface antigens involved in neutrophil recruitment was investigated by flow cytometry, as was the production of reactive oxygen species (ROS) and intracellular calcium flux upon activation with Phorbol 12-myristate 13-acetate (PMA) and Leukotriene B4.
Results: Serum serotonin levels in patients treated with SRIs were reduced by 75% ($P < 0.02$). No difference in the frequency of infective disorders was seen. The production of ROS upon stimulation with PMA was significantly reduced in patients treated with SRIs whereas intracellular calcium flux was increased. Flow cytometry showed a trend towards higher expression levels of MAC-1 in patients treated with SRIs (mean fluorescence intensity 916 ± 253) compared to patients with no treatment (MFI 491 ± 119) and healthy study subjects (MFI 519 ± 119, Kruskal–Wallis-$P = 0.08$).
Summary: Long-term intake of SRIs was not associated with a change in the frequency of infections as assessed by a questionnaire. Flow cytometry however showed differences in calcium flux, ROS production, and surface expression of some markers, warranting further research on the influence of SRIs on immune functions.

PB 2.69-1

Haplotypes of the endothelial protein C receptor gene and circulating protein C levels

Martos L[1], Navarro S[1], Bonet E[1], Zorio E[1], Ferrando F[1], Aznar JA[1], Estellés A[1], Bertina RM[2], España F[1] and Medina P[1]

[1]*Hospital Universitario y Politécnico La Fe Campanar, Valencia, Spain;* [2]*Leiden University Medical Centre, Leiden, The Netherlands*

Background: The protein C pathway plays a crucial role in the regulation of blood coagulation, by controlling the generation of thrombin. Protein C circulates in plasma as an inactive zymogen and is activated on the vascular endothelial cell membrane by the thrombin-thrombomodulin complex, a process further enhanced when protein C binds to its membrane receptor, the endothelial-cell protein C receptor. The information about the genetic factors that determine the variation in plasma protein C (PC) levels is limited. It has been reported that, apart from the PC gene itself, the endothelial PC receptor gene (*PROCR*) and the *FOXA2* gene explain part of the variation.
Aims: To analyze the association between two of the *PROCR* haplotypes, H1 and H3, and PC plasma levels.

Methods: We determined the levels of PC and soluble (s) EPCR and analyzed the *EPCR* haplotypes H1 and H3 in 467 healthy individuals, in 358 patients with a history of venous thromboembolism (VTE) and in 225 young patients with myocardial infarction (MI). Informed consent was obtained from all subjects of the study and it was approved by the medical ethics committee of our Institution.
Results: Among controls, PC level was higher in the 81 carriers of the H3 haplotype (115 ± 22%) than in the 386 non-carriers (102 ± 18%) ($P < 0.001$), but similar in the 133 carriers of the H1 haplotype (105 ± 19%) and in the 339 non-carriers (104 ± 19%), and there was a significant correlation between PC and sEPCR levels ($r = 0.312$, $P < 0.001$). Among VTE patients, PC levels were also higher in the 64 carriers (113 ± 25%) than in the 294 H3 non-carriers (102 ± 23%; $P < 0.001$), but similar in the 114 carriers of the H1 haplotype (105 ± 23%) than in the 244 non-carriers (101 ± 24%), and there was again a significant correlation between PC and sEPCR levels ($r = 0.307$; $P < 0.001$). Finally, among MI patients the 26 carriers of the H3 haplotype had PC levels (117 ± 18%) higher than the 199 non-carriers (104 ± 18%; $P = 0.001$), with a significant correlation between PC and sEPCR levels ($r = 0.276$, $P < 0.001$).
Conclusion: These results suggest that the *PROCR* H3 haplotype is, in part, responsible of the variations in plasma PC levels. We do not know the mechanism by which the H3 haplotype influences plasma PC levels. As this haplotype is associated with elevated sEPCR levels, it has been suggested that PC may bind to sEPCR and become more stable. However, this is unlikely because the concentration of sEPCR in plasma is much lower than that of PC. We hypothesize that carriers of the H3 haplotype have less membrane-bound EPCR, either because H3 may induce a lower expression of the *EPCR* gene and/or because H3 is associated with increased shedding, or both. As part of the circulating PC is bound to the membrane-bound EPCR, less membrane-bound EPCR in carriers of the H3 haplotype will led to less PC bound to the membrane and higher free, circulating PC. These data may help to further increase the information on the physiological mechanisms involved in the regulation of PC.

PB 2.69-2

Association of haplotypes (H) 1 and 3 of the endothelial protein C receptor gene (PROCR) with venous thromboembolism

Navarro S[1], Bonet E[1], Martos L[1], Ferrando F[1], Aznar JA[1], Vayá A[1], Estellés A[1], Bertina RM[2], España F[1] and Medina P[1]
[1]*Hospital Universitario y Politécnico La Fe, Valencia, Spain;*
[2]*Leiden University Medical Centre, Leiden, The Netherlands*

Background: Protein C is a vitamin K-dependent glycoprotein that circulates in plasma as a precursor of a serine protease and is activated on the endothelial cell surface by thrombin bound to its receptor, thrombomodulin, localized on that surface. This activation is further enhanced when protein C binds to its membrane receptor, the endothelial-cell protein C receptor (EPCR). Activated protein C (APC) regulates blood coagulation by selectively inactivating factors Va y VIIIa by limited proteolysis. Several studies have reported that plasma levels of APC and soluble forms of EPCR (sEPCR) are determined by haplotypes H1 and H3 of the EPCR gene (*PROCR*), respectively. However, there are conflicting results as to the associations of *PROCR* H1 and H3 with the risk of venous thromboembolism (VTE).
Aim: To analyzed these associations in a case-control study.
Methods: We studied 676 VTE patients and 505 sex- and age-matched healthy subjects (controls). The g.4678G>C (which targets the *EPCR* H1) and the g.4600A>G polymorphism (which targets the *EPCR* H3) were genotyped by sequencing the corresponding amplified region. We also measured APC levels by a homemade ELISA and sEPCR levels with a commercial ELISA (Asserachrom sEPCR, Stago) in 461 VTE patients and 505 controls in whom adequate plasma samples was available. Informed consent was obtained from all subjects of the study and it was approved by the medical ethics committee of our Institution.
Results: The frequency of the *PROCR* H3 was similar in patients and controls ($P = 0.99$). However, the frequency of the H3H3 genotype (4600GG) was higher in patients than in controls (OR 12.7, CI95% 0.7–220.0, $P = 0.024$): eight VTE patients and none of the controls carried the 4600GG genotype. The level of sEPCR was higher in carriers than in non-carriers of the 4600G allele, both in patients and in controls ($P < 0.001$). In contrast, the level of APC was lower in the eight patients carrying the 4600GG genotype than in the 379 carrying the 4600AA genotype ($P = 0.005$). A significant difference was observed between cases and controls for the frequency of the *PROCR* H1 (OR 0.7, 0.5–0.9, $P = 0.002$). Among controls, the level of APC was higher in carriers than in non-carriers of the *PROCR* H1 ($P = 0.006$).
Conclusion: These data confirm previous result indicating that the *PROCR* H1 protects against VTE, possibly via increased APC levels. They also confirm previous reports showing that the *PROCR* H3 is not associated with the risk of VTE. However, although the number of cases is small, carriers of the 4600GG (H3H3) genotype showed an increased risk of VTE in our population (Valencia, Spain), via increased sEPCR levels and decreased APC levels, suggesting that the 4600GG genotype is associated with lower membrane-EPCR expression and lower APC generation.

PB 2.69-3

Sixteen different mutations in the SERPINC1 gene with antithrombin deficiency causing venous thrombosis

Shinozawa K, Inaba H, Hagiwara T, Otaki M, Suzuki T, Amano K and Katsuyuki F
Tokyo Medical University, Tokyo, Japan

Introductions: Antithrombin is the primary inhibitor of thrombin and other activated serine proteases in the blood coagulation system. Inherited impaired function or deficiency of this molecule significantly increases the risk of thrombosis. We previously identified 10 different mutations in the *SERPINC1* gene, which encodes antithrombin, from 10 unrelated Japanese antithrombin deficient patients with thrombotic disease. In the present study, we analyzed the *SERPINC1* gene in six newly identified patients with low levels of antithrombin activity using direct sequencing and a multiplex ligation-dependent probe amplification (MLPA) assay and performed diagnosis of the carrier detection of their family members.
Patient and Methods: The patients were unrelated Japanese adults, five of the six patients had developed deep vein thrombosis. Antithrombin activity levels were determined by amidolytic heparin cofactor assay with chromogenic substrate (S-2238) for anti-thrombin activity. Antithrombin antigen levels were determined by latex photometric immunology assay. The *SERPINC1* gene of the patients and family members was analyzed to define the diagnosis with their informed consent in our protocol, which was approved by the ethical committee of Tokyo Medical University. Genomic DNA was extracted from leukocytes. Purified PCR products from genomic DNA were sequenced using a BigDye® Terminator v3.1 Cycle Sequencing kit (Applied Biosystems). We performed a MLPA assay using SALSA P227 SerpinC 1 (MRC-Holland).
Results: Levels of both antithrombin activity and antigen in five of the six new patients were reduced to approximately half the mean normal value, and these patients were diagnosed as having type 1 deficiency. Because the remaining patient's antithrombin activity was 37% and antigen level was 95%, the patient was given the diagnosis of type 2 deficiency, a qualitative deficiency in which nearly normal antigen levels are found in association with low antithrombin. Five different mutations were identified in type 1 deficiency in the heterozygous state, two novel deletions (g.2578_2581delTTCT and g.6414delG) and three previously reported point mutations (c. 5311C>T, p. Arg161*; c. 6420C>T, p. Arg229*; and c. 7450T>C, p. Leu302Pro). In the remain-

ing patients, a previously reported point mutation (c. 5272T>C, p. Ser148Pro) in the homozygous state was identified. This missense mutation was detected in the heparin-binding site of antithrombin protein.

Discussion: Both the novel 4-bp deletion in exon 2 and the 1-bp deletion in exon 4 resulted in a frame-shift followed by a premature termination codon occurring at amino acid 113 and 282, respectively. Therefore, two frame-shift mutations caused a quantitative deficiency. The patient with a missense (p.Ser148Pro) mutation in the homozygous state was diagnosed with type 2, heparin-binding site defects type, deficiency. The mutation in the heterozygous state have been reported to associated with thrombosis (*Blood* 81, 1993). However, vein thrombosis was not observed in our patient.

Conclusion: Taken together with our previous studies, a total of 16 different mutations, comprising nine missense mutations, five nonsense mutations, and two small deletions, were analyzed in *SERPINC1* of 16 unrelated Japanese patients. Of these, 13 patients were classified as type 1 deficiency and three patients were classified as type 2.

PB 2.69-4

Novel causative and neutral mutations in a patient with protein C deficiency

Yamanouchi J, Hato T, Niiya T and Yasukawa M

Ehime University, Toon, Japan

It is often difficult to make a diagnosis of congenital protein C (PC) deficiency based on the results of hemostatic laboratory tests. Analysis of the *PROC* gene is helpful for accurate diagnosis, and a considerable number of mutations have been reported. However, it cannot be concluded that the gene mutation detected in affected patients, particularly missense mutation, is responsible for PC deficiency because the *PROC* gene has many single nucleotide polymorphisms (SNPs). In this study, we found three novel mutations in a patient with PC deficiency, and identified one causative and two neutral mutations.

A 20-year-old woman was referred to our hospital because of deep vein thrombosis. Her PC antigen and activity were 55.0% and 46.8%, respectively, suggesting type I PC deficiency. Her *PROC* gene had three missense mutations: E61Q, E375K, and V407A. To determine which mutation(s) played a causative role in PC deficiency, we established stable HEK293 cell transformants expressing wild-type or mutant PCs. Western blot analysis detected the E61Q and E375K mutant proteins in culture supernatants at the same level as wild-type PC, and their PC activities were comparable to those of wild-type PC. In contrast, the V407A protein was not detected in the supernatant or cell lysates, suggesting that V407A mutation impairs the intracellular synthesis of PC. Our study provides evidence that V407A is a causative mutation for type I PC deficiency and that E61Q and E375K are neutral mutations. Genetic information that allows differentiation between causative and non-causative mutations would contribute to accurate diagnosis of congenital PC deficiency.

PB 2.69-5

Vascular tone regulating genes polymorphism can modulate the risk of early-onset venous thromboembolism in individuals with inherited thrombophilia

Polyakova A, Shmeleva V, Soldatenkov V, Blinov M, Kargin V and Kapustin S

Russian Reseach Institute of Hematology and Blood Transfusion, Saint-Petersburg, Russian Federation

Background: Venous thromboembolism (VT) is one of the most actual multifactorial diseases in the world. Genetic predisposition plays a significant role in pathogenesis of VT. Mutations in the factor II (FII G20210A) and factor V (G1691A, FV Leiden) genes are the most frequent inherited risk factors for VT and could be detected in about 9% and 20% of VT cases, respectively, in the population of North-Western Russia. Endothelial dysfunction is an important mechanism underlying thrombosis, and it frequently occurs as a result of imbalance between vasoconstriction and -dilatation processes. Variations in the genes coding for components of the renin-angiotensin system (RAS) and endothelial NO-synthase (eNOS) can lead to changes in their structure and/or functional activity and modulate the risk of VT.

Aims: To investigate the role of angiotensinogen (AGT), angiotensin II receptor type 1 (AGTR1), angiotensin-converting enzyme (ACE) and eNOS genes polymorphism in the development of VT at young age in individuals with inherited thrombophilia.

Methods: Retrospective study involved 181 patients with early-onset VT (mean group age 34.0 $\pm$ 8.6 years) and 156 sex- and age-matched healthy controls (HC). All individuals originated from the North-Western region of Russia and gave informed consent for participation in the study. Variations in the FII (G20210A), FV (G1691A, Leiden), ACE (Ins/Del), AGT (T704C, Met235Thr), AGTR1 (A1166C) and eNOS (T−786C) genes were discriminated by PCR-RFLP method. The differences in genotype distributions between groups were estimated by Fisher's exact test.

Results: The distributions of alleles and genotypes of the vascular tone regulating genes in patients without known inherited risk factors, as well as in those having FII G20210A mutation were not significantly different from HC. At the same time, the positive association between the FV G1691A and eNOS −786CC genotypes was observed in the VT group (OR = 3.2; 95% CI: 1.3–7.5; $P = 0.01$). Homozygosity for the eNOS −786C allele was more frequently seen among carriers of FV Leiden mutation than in patients with normal FII and FV genotypes (29.7% vs. 13.1%, respectively, $P = 0.024$). The 'unfavorable' variants of the RAS genes were also over-represented in patients with FV Leiden. In particular, the simultaneous presence of the ACE Del/Del and AGT 704CC genotypes was almost 5-times more frequently seen in these individuals than in patients with normal FV and FII genotypes (15.2% vs. 3.1%, respectively, $P = 0.018$) Interestingly, neither the eNOS −786CC variant nor the 'ACE Del/Del-AGT 704CC' combination was detected in VT patients having FII G20210A mutation and normal FV genotype.

Conclusions: We suggest that polymorphism of the vascular tone regulating genes can affect the imbalance between vasoconstriction and vasodilatation processes and play a provocative role in the development of early-onset VT among patients with FV Leiden variant.

PB 2.69-6

Mutation analysis of ATIII in a small cohort of Greek patients with VTE

Kotsi P, Tsaousidou M, Thymianou S, Moschidis ZM, Chanos A, Gavalaki M and Katsarou O

Laiko General Hospital, Athens, Greece

Background: Antithrombin III (ATIII) belongs to Serpins (Serine Protease Inhibitors) and is the main inhibitor of thrombin. ATIII normal levels range between 80% and 120%. Low ATIII levels are an important cause of Venous Thromboembolism (VTE). ATIII deficiency is inherited with autosomal dominant pattern. Various mutations have been referred, that cause quantitative (type I) or qualitative defects (type II)

Aims: In this study we present preliminary results of mutation detection in ATIII gene in patients with VTE

Methods: Forty patients with VTE and reduced ATIII levels were examined. ATIII:C and ATIII:Ag mean levels were 46% (range 19–62%) and 58%, range (38–113%) respectively. Whole blood DNA was isolated (QIAGEN) and ATIII 7 gene exons were amplified either separately (PCR) or simultaneously (multiplex PCR). Amplified exons were analyzed on dHPLC (WAVE analysis). PCR products were heat denatured and then reannealed with graduate cooling in order to form

hetero-duplexes. The existing mutations are observed due to the formation of characteristic chromatograms (detection of point mutations, small deletions or insertions). Further analysis via sequencing was obtained for samples with characteristic chromatograms. Multiplex PCR was used for the detection of heterozygous exon deletions, difficult to be seen due to the existence of the normal allele.

Results: Until now 14 patients have been analysed and gave the following results:

In six patients the mutation 'Budapest III – L99', on exon 2, was identified. Five were heterozygous and 1 was homozygous. One patient carries the mutation W189 on exon 4 (transition, TGG > CGG, Trp > Arg) at the conservative position 189 in heterozygous state. One patient carries the mutation D342 on exon 5 (transition, GAT > GGT, Asp > Gly) at the conservative position 342 in heterozygous state. One patient carries the mutation R359X (CGA > TGA, Arg > STOP) on exon 6 (at position 9819) that leads to abolishment of exons 6 & 7 (thrombin binding site). One patient carries the mutation Q334X (CAG > TAG, Gln > STOP) on exon 5 (position 7711) that leads to abolishment part of exon 5, exons 6 & 7 (thrombin binding site). At the same exon, this patient carries one more synonymous point mutation in heterozygosity that causes the polymorphism GAG > GAA (codes for the amino acid Glu) that it has not been referred until now to ATIII data base. Three patients have the unknown polymorphism G > A on intron 6 and two of these patients are close family members.

One patient has a heterozygous frame shift on exon 2 that is under further investigation.

The patients that do not have any known mutation in seven exons are investigated for large exon deletions with multiplex PCR. Until now, four patients were examined and no deletion at any exon was found.

Conclusion: Mutation analysis could be one important tool in therapeutic management of patients with VTE and ATIII deficiency and that knowledge could improve care of VTE patients.

PB 2.70-1

Socioeconomic status and the risk of venous thromboembolism – the Tromsø study

Enga KF, Braekkan SK, Skjeldestad FE and Hansen JB

University of Tromsø, Tromsø, Norway

Background: Indicators of socioeconomic status (SES) usually include number of years with formal education, occupational status, personal income, and neighbourhood environment. Some, but not all, previous studies have found an inverse association between SES and risk of venous thromboembolism (VTE). However, these studies have only studied limited components of SES, and mostly refrained from investigating the impact of behavioural risk factors, psychosocial aspects and comorbidities on the relationship between SES and VTE.

Aims: We wanted to investigate the association between the Socioeconomic Condition Index (SCI) and risk of VTE, and explore how the associations were affected by behavioural risk factors, psychosocial aspects and comorbidities.

Methods: Information about the SCI components, as well as potential confounders, was collected by self-administered questionnaires, blood samples and a physical examination in 26,473 men and women (≥ 25 years) participating in the Tromsø study in 1994–95. Information about personal income was obtained from Statistics Norway. The SCI included educational level, employment status, self-perceived health, satisfaction with number of good friends, and personal income with predefined categories for each component. The total SCI score ranged from 0 to 18, and was divided into quartiles for men and women separately. Participants were followed from date of enrolment in 1994–95 until December 31, 2010. Cox proportional hazard regression models were used to estimates hazard ratios with 95% confidence intervals (CI). All analyses were stratified by sex due to statistical interaction. The study was approved by the regional committee for research ethics, and all participants gave their informed written consent to participate.

Results: There were 602 VTE events during a median follow-up of 15.8 years (incidence rate: 1.72, 95% CI: 1.59–1.86). An inverse association between SCI and risk of VTE was found among women. Women in the highest quartile (SCI 15–18) had lower risk of VTE in age-adjusted analyses (HR 0.44, 95% CI: 0.27–0.72) (*P* for trend across quartiles of SCI: < 0.001) and in multivariable adjusted analyses (HR 0.62, 95% CI: 0.36–1.05) (*P* for trend across quartiles of SCI: 0.02) compared to those in the lowest quartile (SCI 0–8). Multivariable analyses were adjusted for behavioural factors (body mass index, smoking, physical activity, alcohol and coffee consumption), psychosocial factors (feelings of happiness and optimism) and comorbidities (cancer, arterial cardiovascular disease and diabetes). All the individual components of the index displayed an inverse relation to risk of VTE, but educational level and self-perceived health were the strongest predictors for the inverse association between SCI and VTE among women. Behavioural factors, psychosocial factors and comorbidities explained 30–40% of the association between SCI and VTE (age-adjusted β coefficient: −0.31 vs. multivariable-adjusted β: −0.21). No associations were found between SCI or its individual components and risk of VTE in men.

Conclusions: We found an inverse association between the SCI and risk of VTE in women, but not in men. Behavioural factors, psychosocial factors and comorbidities explained 30–40% of the inverse association between the SCI and risk of VTE in women.

PB 2.70-2

A study to analyze the utility of PNH screening in patients with intra-abdominal thrombosis

Naseem S[1], Ahluwalia J[2], Naseem S[2], Sachdeva MUS[2], Bose P[2], Chawla Y[2], Thapa BR[2] and Varma N[2]

[1]*Postgraduate Institute of Medical Education & Research;* [2]*PGIMER, Chandigarh, India*

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is an acquired hematologic disorder, characterized by intravascular hemolysis, thrombosis or bone marrow failure. The clinical manifestations are due to deficiency of glycosyl phosphatidylinositol (GPI) anchored protein. Fluorescently labeled inactive toxin aerolysin (FLAER) binds to GPI anchor specifically and lack of FLAER binding to granulocytes, measured by multiparameter flow cytometry, indicates presence of PNH clone. FLAER testing is recommended for primary screening of PNH clones.

Thrombosis, often at unusual sites, intra-abdominal, cerebral or dermal may be the presenting feature of PNH. However there is a paucity of data on how many cases of PNH present primarily with thrombosis. Current guidelines recommend screening for PNH in patients presenting with thrombosis at unusual sites. We screened patients with intra-abdominal thrombosis for PNH clone by FLAER analysis.

Aim: To assess the utility of PNH screening in patients presenting with intra-abdominal thrombosis

Methods: Patients with intra-abdominal thrombosis -Budd Chiari Syndrome (BCS), Extra Hepatic Portal Vein obstruction (EHPVO), mesenteric, iliac or renal vasculature as confirmed by imaging studies and referred for thrombophilia workup to the department of Hematology, PGIMER, Chandigarh were included in the study. EDTA peripheral blood samples were analysed by multiparameter flow cytometry using FLAER + CD24 on neutrophils (gated on CD45 and CD15 side scatter) and FLAER + CD14 on monocytes (gated on CD45 and CD33 side scatter). Ten thousand events were acquired and analysed on the FACS Canto II (BD Biosciences). Patients with > 5% deficient neu-

trophils/monocytes were labelled positive for PNH clone and further tested for PNH clone in RBC by CD55+ CD59. Normal controls were included in each run.
Results: Eighty one (65 adults and 16 pediatric) cases of intra-abdominal thrombosis were tested for PNH clone. Mean age of these patients was 30 years (range = 1.5–65 years) and male: female ratio = 1.1:1. There were 34 (42%) cases of EHPVO and 27 (33%) of BCS. Remaining 20 (25%) cases included portal vein thrombosis, iliac vein thrombosis, superior mesenteric vein thrombosis and recurrent thrombosis
Out of the 81 patients tested only 1 (1.2%) patient was positive for PNH clone. This patient had BCS and positive PNH clone in both neutrophils (FLAER/CD24 negative cells = 82%) and monocytes (FLAER/CD14 negative cells = 62%). Further testing for PNH clone in RBC revealed 21% CD55 + CD59 negative cells. None of the 76 controls and remaining 80 patients revealed > 5% PNH positive cells.
Summary/Conclusion: In this study we evaluated the utility of PNH screening in patients with intra-abdominal thrombosis by flow cytometry with FLAER in neutrophils and monocytes. Large PNH clones were infrequent in the study population, seen in only 1 (1.2%) out of 81 patients tested. PNH with a primary thrombotic presentation is therefore rare in cases with intra-abdominal thrombosis. Our results would indicate that, in a resource limited setting, routine screening of all patients with intra-abdominal thrombosis for PNH may be of limited value.

PB 2.70-3
Impact of different measures of renal impairment on future risk of venous thromboembolism. The Tromsø study

Brodin E[1], Enga KF[1], Sigrid BK[1], Toft I[2], Brox J[1], Vik A[1] and Hansen JB[1]
[1]Hematological Research Group (HERG); [2]Department of Nephrology, University Hospital of North Norway, Tromsø, Norway

Background: Mild to moderate chronic kidney disease (CKD) is associated with increased risk of venous thromboembolism (VTE). Creatinine, the current clinical standard to detect CKD, is influenced by several factors. Thus, the most reliable equation for estimation of renal function is debatable. A recent study suggests that a combination of creatinine and cystatin C is more accurate than either marker alone for estimating glomerular filtration rate (eGFR).
Aims: The aims of this population-based cohort study were to investigate the ability of eGFR, based on serum creatinine (eGFRcrea), cystatin C (eGFRcys) and both (eGFRcrea-cys) to identify persons at risk, and to elucidate the impact of stages of impaired kidney function on risk of VTE in static and time-dependent analyses of exposure.
Methods: Cystatin C and creatinine was measured in 16,297 men and women, aged 25–84 years, who were enrolled in the fourth (1994–95) and sixth (2007–8). Survey of the Tromsø study, Creatinine, cystatin C and the combination of both markers was used to determine GFR according to the CKD-EPI equations. Incident VTE-events during follow-up were registered from the date of inclusion through the end of the study period, December, 31, 2010. Cox-regression models were used to calculate hazard ratios (HR) with 95% confidence intervals (CI) for VTE adjusted for age, sex, body mass index, diabetes and smoke. Moreover, to minimize regression dilution effects, Cox-regression was performed in subjects with two recordings of eGFR during follow-up, allowing for time-dependency of the exposure variable and important co-variates. The study was approved by the regional committee for research ethics, and all participants gave their informed written consent to participate.
Results: There were 451 incident VTE-events, of which 205 (45%) were unprovoked, during a median of 12.5 years of follow-up. eGFRcys identified 24% of the population to have mildly impaired kidney function (60–89 mL/min/1.73 m^2) and 3.2% to have moderate/severely impaired kidney function (15–59 mL/min/1.73 m^2), and the HRs for total VTE were 1.53 (95% CI 1.21–1.93) and 2.05 (95% CI 1.36–3.10), respectively, compared to those with a normal kidney function (≥ 90 mL/min/1.73 m^2). Likewise, eGFRcys-crea identified 24% with mildly impaired and 1.5% with moderate/severely impaired kidney function, with corresponding HRs for total VTE of 1.65 (95% CI 1.18–2.29) and 1.67 (95% CI 0.95–2.88), respectively. Although 26% with mildly impaired kidney function were identified, no significant associations were found between mildly impaired kidney function assessed by eGFRcrea and risk of VTE (HR 1.07 (95%CI 0.87–1.35). However, for moderate/severely vs. normal kidney function) there was an association (HR 1.83, 95%CI 1.05–3.20) between eGFRcrea and VTE. The risk estimates from the time-dependent analyses were essentially similar.
Conclusions: The present study showed that all CKD-EPI equations identified similar proportions with mild to severely impaired kidney function and that eGFRcys and eGFRcys-crea equally estimated the future risk of VTE among subjects with mildly impaired kidney function.

PB 2.70-4
Venous thromboembolism in patients undergoing shoulder surgery: findings from the Recos registry

Imberti D[1], Ivaldo N[2], Murena L[3], Paladini P[4], Castagna A[5], Barillari G[6], Guerra E[7], Castoldi F[8], Camporese G[9] and Porcellini G[4]
[1]Haemostasis and Thrombosis Center, Piacenza; [2]Acquiterme Hospital, Alessandra; [3]University of Insubria, Varese; [4]Cattolica Hospital, Cattolica; [5]Humanitas, Milano; [6]University of Udine, Udine; [7]Rizzoli Institute, Bologna; [8]Mauriziano Hospital, Torino; [9]University of Padova, Padova, Italy

Background: Sparse informations are available about venous thromboembolic (VTE) complications after different types of shoulder surgery.
Aim: The primary end-point of the study was to determine the incidence of symptomatic deep vein thrombosis (DVT) and pulmonary embolism (PE) within 90 days of follow-up in patients undergoing shoulder surgery. Risk factors for VTE and thromboprophylaxis practices were also studied.
Methods: RECOS is a prospective multicenter registry of consecutive patients undergoing shoulder surgery recruited in nine hospitals inItaly. Patients were followed-up at 7, 30 and 90 days for major clinical outcomes. Cumulative rates of VTE were estimated according to the Kaplan-Meier method; a Cox regression model was used to calculate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for some variables that were identified as potential risk factors for VTE.
Results: From June 2009 to June 2011 1366 evaluable patients (males 54.4%; mean age 55.65 ± 15.3 years) were enrolled in the registry. The shoulder surgical procedures were the following: arthroscopy (72%), arthrotomy (19.1%) total replacement (8.9%). After 90 days, the incidence rate (95% CI) of symptomatic DVT and PE was 0.7% (95CI% 0.2–11.2). Mean age of patient with VTE complications was significantly different from patients who did not displayed complications (55.6 ± 0.42 vs. 25.7 ± 0.2, $P = 0.024$). Duration of surgery > 60 min (HR: 10.99; 95CI% 1.26–95.89; $P = 0.030$) was found as independent risk factor for VTE. Pharmacological thromboprophylaxis was prescribed in 33.5% ($n = 457$) of the patients; in 95.8% of them the recommended duration of prophylaxis was > 10 days.
Conclusions: The risk of symptomatic VTE in patients undergoing shoulder surgery is not negligible. This risk and the potential need for thromboprophylaxis should be taken into account by orthopaedic surgeons.

PB 2.70-5

Thromboprophylaxis in mutliple myeloma – a tale of two cities

Czuprynska J

Taunton and Somerset NHS Foundation Trust, Somerset, UK

Background: Multiple myeloma is associated with an increased risk of thrombosis. This is greater with immunomodulatory (iMID) drug combinations and during the first 6 months of therapy. Bortezomib may have a protective effect. First-line therapy for myeloma in the UK generally comprises a thalidomide-containing regimen. This contrasts with New Zealand, where bortezomib is commonly used upfront. In both countries, lenalidomide is customarily given third-line. British guidelines recommend thromboprophylaxis with aspirin in patients receiving an iMID-containing regimen who are at moderate risk of thrombosis. The optimal strategy for high risk patients is yet to be determined.

Aims: To compare and contrast the current practice of thromboprophylaxis in myeloma patients in two centres on opposite sides of the globe: one in the United Kingdom (Musgrove Park Hospital, Somerset) and the other in New Zealand (Christchurch, Canterbury District Health Board).

Methods: Audits were performed to assess current practice of thromboprophylaxis in all patients with myeloma under active follow-up in each centre. NZ data were collected in 2012, while UK data were collected in 2013. Additionally, retrospective data were collected on live patients who had experienced a thrombotic event since being diagnosed with myeloma. Results were compared with BCSH guidelines for management of thromboprophylaxis in myeloma, which recommend that all patients for an iMID-containing regimen should have a thromboprophylaxis risk assessment, giving a gold standard of 100%. In parallel, national consultant surveys were performed to review thromboprophylaxis for myeloma patients in New Zealand and the South West of England.

Results: Ninety-eight patients with myeloma under active follow up were identified in the UK centre and 151 in the NZ centre. In each centre, approximately half of the patients on active therapy were receiving an iMID (50% in the UK and 52% in NZ). In the UK centre, 96% of patients on an iMID were in receipt of thromboprophylaxis. This figure was lower at 67% in the NZ centre meaning that thromoboprophylaxis was potentially not being adequately addressed for a third of patients on iMIDs.

Despite higher upfront use of thalidomide-containing regimens in the UK, the proportion of patients experiencing thrombosis was similar in the two centres (7% in the UK centre and 8% in the NZ centre). In the NZ cohort, 50% of these thrombotic events ($n = 6$) took place during induction therapy without thromboprophylaxis and only one patient was on an iMID. In the UK centre 43% of these events ($n = 3$) took place during induction with a thalidomide-containing regimen despite thromboprophylaxis.

Summary/Conclusions: Optimal thromboprophylaxis in myeloma is still a matter for debate although there is a greater consensus when using lenalidomide-containing therapy. Thromboprophylaxis according to an individual risk profile should be considered for every patient with myeloma, particularly at the start of treatment.

PB 2.70-6

Postoperative deep vein thrombosis in patients undergoing general, colorectal and orthopedic surgeries in Taiwan- an institutional experience

Lin CY, Shen MC, Chang IL, Chen HCh, Huang TM, Chen YL, Lee KW, Lin HY, Hsieh HN and Yang YW

Changhua Christian Hospital, Changhua City, Changhua County, Taiwan

Background: It has been believed for a long time that the incidence of venous thromboembolism is lower in Asian countries, as compared to that in Western countries. Such belief was challenged by recent studies of postoperative deep vein thrombosis (DVT) in postorthropedic surgeries.

Aim: We aimed to study the incidence of postoperative DVT following general, colorectal and orthopedic surgeries seen in middle part ofTaiwanduring August 2009 to December 2012.

Material and Methods: Patients 195 patients undergoing general surgeries [mean age 63.6 years (range 29–91 years), 118 males and 77 females], 128 patients receiving colorectal surgeries [66.2 (37–91), 77 males and 51 females] and 120 patients undergoing orthopedic surgeries including 57 total knee replacements (TKR), 23 total hip replacements (THR), and 21 Hip replacements (HR) and 17 fracture surgeries, two of them received TKR and THR concurrently[69.4 (20–95), 46 males and 74 females] were studied.

Methods: Compression ultrasonography (CUS, Philips HD11) examination was performed for each patient before and 5–10 days after operation. Thrombin generation (TG) analysis using Fluoroscan Ascent and microparticle (MP) activity test using ZYMUPHEN MP activity test kit were done before and after operation. Venography was also performed in some patients for comparison. Univariate and multivariate logistic regression analysis for the risk factors associated with development of postoperative DVT including sex, age, tumor staging (in colorectal cancer only), type of operation, anesthesia duration, operation duration, bed rest days, previous cerebral and cardiac disorders, previous DVT, TG endogenous thrombin potential and MP activity were done in each group of patients.

Results: *Validation of the CUS examination:* Twice CUSs were performed after operation including six DVTs and 60 normal veins, all showed identical results. Parallel examinations of CUS and venography were done in 19 patients including four DVTs and 15 normal veins, all showed identical results except that in one patient CUS showed partial thrombosis of left external iliac vein and common femoral vein, but venography revealed no evidence of thrombosis and external compression by left common iliac artery was suspected.

General surgery: Only 1 (0.5%) patient was found to have asymptomatic distal DVT among 195 patients received general abdominal surgery. Univariate and multivariate logistic regression analysis showed no associated risk factor.

Colorectal surgery: Among 128 colorectal cancer-surgical patients, 3 (2.3%) had proximal DVT before operation, 9 (7.0%) developed new DVT after operation, all were distal. Both univariate and multivariate logistic regression analysis showed that previous VTE patients has higher incidence of postoperative VTE.

Orthopedic surgery: Nine of 120 patients (7.5%) developed DVT, Five had proximal DVTs, four distal DVT; all detected on the operated leg. Venography was also done to confirm the diagnosis in four of them. Univariate risk analysis showed patients received TKR had significant higher risk. Multivariate logistic regression analysis showed no associated risk factor.

Conclusion: The incidence of postoperative DVT in our patients undergoing general, colorectal and orthopedic surgery was only about 4.3% (0.5%,7.0%,7.5% respectively) as low as recent reports from Asian countries (Singapore: Fong 2000, Nathan 2003, China: Lu 2007).

PB2.71 – Recurrent Venous Thrombosis – II

PB 2.71-1

Factors associated with early and late hypercoagulability after stopping anticoagulation for idiopathic venous thromboembolism

Cosmi B[1], Legnani C[1], Tosetto A[2], Pengo V[3], Ghirarduzzi A[4], Testa S[5], Prisco D[6], Poli D[6], Tripodi A[7] and Palareti G[1]

[1]S.Orsola-Malpighi University Hospital, Bologna; [2]San Bortolo Hospital, Vicenza; [3]Department of Cardiac Thoracic and Vascular Sciences, University of Padova, Padova; [4]Arcispedale Santa Maria Nuova, Reggio Emilia; [5]General Hospital, Cremona; [6]University of Florence and Centro Trombosi, A.O. U. Careggi, Firenze; [7]University & IRCCS Maggiore Hospital; A Bianchi Bonomi Hemophilia&Thrombosis Cen, Milano, Italy

Background: The recurrence rate is especially high in the 3 months after stopping anticoagulation for a first episode of idiopathic venous thromboembolism (VTE). A hypercoagulable state, as expressed by an abnormal D-dimer, in these 3 months has been shown to be a risk factor for both early and late recurrence.

Aim: To evaluate factors associated with an abnormal D-dimer within and beyond 3 months after stopping anticoagulation for a first episode of idiopathic VTE in the PROLONG II study.

Methods: in a prospective multi-center study patients underwent repeated D-dimer testing after anticoagulation suspension. D-d was measured with a qualitative method (Clearview Simplify D-dimer, Inverness Medical Professional Diagnostics, Bedford, UK) on the day of anticoagulation withdrawal and after 30 days. If D-dimer was abnormal during anticoagulation or at 1 month, patients continued or resumed VKAs, while if D-dimer was normal at 1 month after stopping anticoagulation patients did not resume treatment and repeated D-d testing every 2 months for a year.

Results: Early hypercoagulability (abnormal D-dimer in the 3 months after stopping anticoagulation) was associated with age > 65 year (odds ratio-OR: 3.6 (95% confidence interval-CI:1.9–6.7; $P = 0.0001$), the presence of comorbidities (OR: 2.7; 95% CI:1.5–5.1; $P = 0.001$) and thrombophilia (OR: 1.9; 95% CI:1.1–3.4; $P = 0.041$) when compared with a persistent normal D-dimer over a year. Late hypercoagulability (abnormal D-dimer after 3 months since anticoagulation withdrawal) was associated with the presence of comorbidities (OR: 2.8; 95% CI:1.5–5.5; $P = 0.002$) and of residual venous obstruction (RVO) (OR: 1.9; 95% CI:1.1–3.8; $P = 0.037$) when compared with a persistent normal D-dimer over a year. Late hypercoagulability was associated with male sex (OR: 2.3, 95% CI:1.1–4.7; $P = 0.029$) and age < 65 year (OR:2.2; 95% CI:1.1–4.6; $P = 0.039$) vs. early hypercoagulability.

Conclusions: Hypercoagulability after stopping anticoagulation for idiopathic VTE is influenced by age, comorbidities, thrombophilia and RVO.

PB 2.71-2

The incidence of recurrent venous thrombosis associated with different clinical risk profiles

Van Hylckama Vlieg A[1], Baglin CAC[2], Luddington R[2], Rosendaal FR[1] and Baglin TPT[2]

[1]Leiden University Medical Center, Leiden, The Netherlands; [2]Addenbrookes Hospital, Cambridge, UK

Background: Acquired, clinical risk factors are easily assessed after a patient suffers a first venous thrombotic event and may be useful in the prediction of recurrence.

Aim: The aim of this study was to assess whether the risk of recurrent venous thrombosis differed per clinical risk profile, i.e., in patients in whom the first venous thrombosis was surgery provoked, non-surgery provoked, or unprovoked.

Methods: Analyses were performed in the Thrombophilia, Hypercoagulability, and Environment and the risk of Venous ThromboEmbolism (THE-VTE) study. Between March 2003 and December 2008, patients with a first, objectively diagnosed episode of deep venous thrombosis or pulmonary embolism, aged 18–75 years, were included in the anticoagulation clinics inLeiden, NL andCambridge, UK. Controls were partners of patients. Individuals with active malignant disease were excluded. In total, 796 patients and 531 controls were included. Consent and ethical approval were obtained.

Patients were subsequently followed for recurrent thrombosis. Potential recurrences were classified as certain or unlikely based on the time between the first and recurrent event and the location of the recurrence. Patients with an unlikely recurrence were censored at the time of the event. The end of follow-up was defined as the date of recurrence, date of death, or end of follow-up.

The incidence rates (IR) of recurrence with 95% confidence interval (CI) were calculated overall and after stratification in risk groups (surgery provoked, non-surgery provoked, and clinically unprovoked first event).

Surgery provoked was defined as having had a surgical procedure in the 3 months prior to the first event. Non-surgery provoked as having had a plaster cast, injury, immobilization > 4 consecutive days, hospitalization, or hormone use in the 3 months prior to the first event. In patients with an unprovoked first event, none of the above risk factors were present in the 3 months prior to the first event. Complete information on these risk factors was available for 760 patients.

The 2- and 4-year cumulative incidences of recurrence were calculated in the before-mentioned risk groups separately.

Results: After a mean duration of follow-up of 5.1 years, 117 (14.7%) of the 796 patients developed a recurrence: IR = 29/1000 person years (py); 95% CI: 23.7–34.2.

The distribution in risk groups was as follows: surgery provoked first event $n = 135$ (17.8%), non-surgery provoked first event $n = 225$ (29.6%), clinically unprovoked first event $n = 400$ (52.6%). The incidence of recurrence was lowest in patients with a provoking factor (surgery: IR = 21.7/1000 py; 95% CI: 11.1–32.4, non-surgery: IR = 19.5/1000 py; 95% CI: 11.4–27.6). The incidence of recurrence was highest after a first clinically unprovoked event, IR = 37.8/1000 py; 95% CI: 29.3–46.3.

The difference in recurrence is present after 2 years of follow-up and remains also after longer duration of follow-up (4-year cumulative incidences: surgery provoked: 9.6%, 95% CI: 5.8–13.5, non-surgery provoked: 7.6, 95% CI: 4.1–11.0; unprovoked: 12.8, 95% CI: 9.5–16.0).

Summary/Conclusion: Assessment of clinical risk factors at the time of a first venous thrombosis predicts the risk of a recurrent event. The risk of recurrence is highest in patients with an unprovoked first event.

PB 2.71-3

Whole blood gene expression profiles to distinguish venous thromboembolism phenotypes

Lewis DA[1], Suchindran S[1], Beckman MG[2], Heit JA[3], Moll S[4], Philipp CS[5], Kenney K[2], De Staercke C[2], Pyle M[2] and Ortel TL[1]

[1]Duke University Medical Center, Durham, NC; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]Mayo Clinic, Rochester, MN; [4]University of North Carolina, Chapel Hill, NC; [5]University of Medicine and Dentistry of New Jersey, New Brunswick, NJ, USA

Background: Recurrent venous thromboembolism (VTE) occurs in 10–30% of individuals after completing a course of anticoagulant therapy for an initial unprovoked VTE. Currently, there is limited understand-

ing of the biological mechanisms that predispose patients to recurrent VTE and it would be useful to have biomarkers to help predict which patients are at a higher risk for recurrent VTE. Using clinically well-defined patient groups, we explored the use of whole blood gene expression profiles to distinguish patients with recurrent VTE as well as provoked and unprovoked VTE.

Methods: Adults with one or more VTE were recruited at four sites participating in the Thrombosis Research and Prevention Network supported by the Centers for Disease Control and Prevention. Participants were allocated into three groups: (i) 'low-risk' individuals had sustained one or more provoked VTE ($n = 34$); (ii) 'moderate-risk' individuals had sustained one unprovoked VTE (with or without provoked VTE) ($n = 33$); and (iii) 'high-risk' individuals had sustained more than one unprovoked VTE (with or without provoked VTE) ($n = 40$). Patients with antiphospholipid syndrome were excluded. Individuals with no history of VTE were enrolled as healthy controls ($n = 25$). The study was approved by the review boards at each institution and informed consent was obtained from all participants. Blood for RNA was collected in PAXgene tubes; citrated plasma and serum were collected at the same time. Total RNA was isolated and hybridized to Illumina HT-12v4 Beadchips to assay whole genome expression with over 47,000 probes. Blood levels of selected biomarkers identified by gene expression were measured by ELISA. Class prediction analysis and differential expression analysis were used to compare the groups.

Results: Class prediction analysis was able to distinguish high-risk individuals from healthy controls with good receiver operating curve characteristics (AUC = 0.88). We also distinguished high-risk individuals from low-risk individuals, moderate-risk individuals from healthy controls and low-risk individuals from healthy controls with AUC's of 0.72, 0.77 and 0.72, respectively.

Differential expression analysis identified genes that were differentially expressed when comparing the high-risk group to the low-risk group or healthy controls, and the moderate-risk group to the healthy controls. Several genes relevant to coagulation, immune response and/or vascular biology, including *SELP* and *CD46,* were differentially expressed in at least two of the comparisons. This distinction in whole blood was limited to gene expression, since plasma or serum protein levels of several of these genes did not differ between the different groups.

Conclusion: Gene expression profiles were able to distinguish individuals with recurrent, unprovoked VTE from individuals with provoked VTE only and healthy controls. In contrast, this approach could not distinguish individuals with a single, unprovoked VTE (the moderate-risk group) from patients with recurrent unprovoked VTE or patients with provoked VTE, indicating heterogeneity among the moderate risk group. Prospective studies are needed to determine whether the gene expression profiles identified by this approach will indeed distinguish patients at high-risk for recurrent VTE and thus provide a guide for which patients would benefit from extended anticoagulant therapy.

PB 2.71-4

Efficacy and safety of weight-adjusted dosing of low-molecular-weight-heparin for prevention and treatment of acute VTE in obese patients: a systematic review and meta-analysis

Ikesaka T, Le Gal G and Carrier M

The Ottawa Hospital, Ottawa, ON, Canada

Background: Obese patients are often excluded from clinical trials or are not recruited in sufficient number to assess safety and efficacy of LMWH in this population. It is unclear if standard (i.e. non-adjusted) thromboprophylaxis doses of low-molecular weight heparin (LMWH) provide adequate coverage for obese patients. Similarly, weight-adjusted dosing of LMWH is recommended for the acute treatment of venous thromboembolism (VTE). However, product monographs of different LMWH manufacturers state not to exceed their recommended maximum dosage. It is not known if using the actual weight-adjusted dose of LMWH (instead of capping the dose) is safe and effective for obese patients treated for acute VTE.

Aims: To summarize the event rates of VTE (or recurrent VTE) and major bleeding episodes in obese patients receiving weight-adjusted doses of LMWH for the prevention and treatment of VTE.

Methods: A systematic literature search was performed using MEDLINE and EMBASE. The primary outcome measures were VTE and major bleeding events. Venous thromboembolism was defined as symptomatic proximal lower limbs (popliteal vein or more proximal) deep vein thrombosis or pulmonary embolism. Major bleeding was defined as per the ISTH definition. Weight-adjusted thromboprophylactic LMWH dosing was defined as the use of higher than standard recommended dosing for obese patients. Weight-adjusted therapeutic LMWH dosing was defined as a dose calculated according to patient's weight regardless of dosage cap as per the manufacturer's instructions. Rates of the primary outcomes were generated for the indications: (i) Thromboprophylaxis in medically-ill patients; (ii) Acute treatment of VTE. Pooled proportions for the different outcomes during hospitalization (prophylaxis medically-ill patients) and up to 3 months of follow up (acute treatment of VTE) were calculated.

Results: A total of eight studies (four on thromboprophylaxis in medically-ill patients; four on the acute treatment of VTE) met inclusion criteria. Two thousand two hundred and twenty patients were included in the systematic review (1200 in thromboprophylaxis studies; 1020 in treatment studies).

Medically ill hospitalized patients receiving weight-adjusted thromboprophylactic LMWH had a VTE rate of 2.1% (95% CI: 0.1–6.7%) compared to a rate of 2.9% (95% CI: 1.7–4.4%) for patients receiving standard doses of LMWH thromboprophylaxis. The rate of major bleeding in the weight-adjusted prophylaxis studies was 1.0% (95% CI: 0.02–4.6%). None of the studies included in the systematic review reported the risk of major bleeding among obese patients receiving standard doses of LMWH thromboprophylaxis.

The 3-month risk of recurrent VTE and major bleeding in obese patients receiving weight-adjusted LMWH for acute VTE was 2.7% (95% CI: 0.7–5.9%) and 0.8% (95% CI: 0.3–1.6%) respectively. No studies have reported the risk of recurrent VTE or major bleeding among obese patients receiving capped doses of LMWH.

Summary/Conclusions: Weight-adjusted doses of LMWH seem safe and effective in the prevention and treatment of VTE in obese patients. Rates of VTE, recurrent VTE and major bleeding episodes compare favorably to previously reported rates in non-obese patients. Future studies assessing the efficacy and safety of different dosing strategies among obese patients are needed.

PB 2.71-5

Residual pulmonary embolism as a predictor for recurrent thromboembolic events after a first unprovoked episode: data from the REVERSE cohort study

Le Gal G[1], Zeng W[2], Righini M[3], Kovacs MJ[4], Tan M[5], Carrier M[6], Bazarjani S[2], Rodger M[6] and REVERSE Study Group T[7]

[1]Ottawa Health Research Institute; [2]University of Ottawa, Ottawa, ON, Canada; [3]Geneva University Hospital, Geneva, Switzerland; [4]University of Western Ontario, London, ON, Canada; [5]Leiden University Medical Centre, Leiden, The Netherlands; [6]Ottawa Hospital Research Institute, Ottawa, ON; [7]Various Centres, Various Cities, Canada

Background: We sought to assess if residual pulmonary embolism after completion of 5–7 months of oral anticoagulant therapy for unprovoked pulmonary embolism is associated with an increased risk of recurrent venous thromboembolism.

Methods: Patients with a first unprovoked venous thromboembolism were enrolled after completion of 5–7 months of oral anticoagulant therapy over a 4 year period and completed a mean of 18 months

follow-up. Patients with pulmonary embolism (with or without deep venous thrombosis) had a baseline V/Q scan performed before stopping oral anticoagulant therapy. The percentage of vascular obstruction was determined for all patients. This is a Multi-centre multinational prospective cohort study done in tertiary care centres.
Main Outcome: During follow-up off oral anticoagulant therapy, all episodes of suspected recurrent venous thromboembolism were independently adjudicated with reference to baseline imaging.
Results: Annual incidence rates of recurrent venous thromboembolism were 2.8% (95%CI 0.3–5.2%) in patients with a percentage of vascular obstruction of 0% (no residual obstruction), 6.7% per year (1.3–12.0%) in patients with percentage of vascular obstruction of 1–5%, and 11.7% per year (5.3–18.0%) for patients with a percentage of vascular obstruction > 5%.
Summary/Conclusion: In our study, the presence of residual pulmonary vascular obstruction at the time of oral anticoagulant therapy withdrawal was associated with a statistically significant higher risk of subsequent recurrent venous thromboembolism. Percentage of vascular obstruction assessment might be useful to guide duration of oral anticoagulant therapy.

PB 2.71-6
Two years outcome and features of isolated distal vein thrombosis

Sartori M, Cosmi B, Migliaccio L, Favaretto EJ, Guazzaloca G, Valdrè L, Legnani C and Palareti G

S. Orsola-Malpighi Bologna University Hospital, Bologna, Italy

Background: Isolated distal deep vein thrombosis (IDDVT) is a frequent finding in symptomatic outpatients, but its natural history is still uncertain.
Aims: To assess the long term outcome of IDDVT and ascertain the impact of IDDVT characteristics on outcome.
Methods: In a prospective, single center study we enrolled 90 symptomatic outpatients (age 60.7 ± 18.3, male 48.9%) in whom a complete real-time B-mode and color Doppler ultrasonography examination revealed an IDDVT. Among the 88 treated patients, 56 received low molecular weight heparins (LMWH) for 30 days and 32 with vitamin K antagonists for 3 months. The outcomes of the present study included death, major bleeding, pulmonary embolism, proximal deep vein thrombosis (DVT), and IDDVT. Follow-up visits were at 1, 3, 12 and 24 months.
Results: The most frequent risk factors for thrombosis in the study population were: significantly reduced mobility (34.4%), obesity (25.3%), surgery (15.7%), and previous DVT (15.7%). Cancer was present in eight patients (8.9%). During the follow-up (median 24 ± 2 months), 18 patients (20%) developed an outcome, which included one non cardiovascular death (cancer), one major bleeding (during LMWH therapy), three pulmonary embolism (two among patients with cancer), four proximal DVT (one among patients with cancer), and nine IDDVT. According to Cox regression analysis, male patients (HR 4.0 CI95%: 1.3–12; $P = 0.018$) and patients with cancer (HR 6.1 CI95%: 1.4–26; $P = 0.016$) were at higher risk for reaching the end-point, whereas the anatomical characteristics and the type (provoked vs. non-provoked) of IDDVT, the type of anticoagulant therapy, age, BMI, and history of DVT were not associated with the outcome. Normal d-Dimer values at IDDVT diagnosis were associated with lower risk of recurrent venous thromboembolism (HR 0.76 CI95%: 0.67–0.87 $P = 0.023$).
Conclusions: The risk of recurrent venous thromboembolism after IDDVT may be relevant, especially in male patients or in patients with active cancer. Larger studies are needed to address this issue.

PB2.72 – Thrombophilia – III

PB 2.72-1
FIX-Padua increases fibrinolytic resistance through a TAFI-mediated mechanism

Semeraro F[1], Ammollo CTC[1], Tormene D[1], Colucci M[2] and Simioni P[1]

[1]University of Padua Medical School, Padua, Italy; [2]Aldo Moro University, Bari, Italy

Background: Thrombin activatable fibrinolysis inhibitor (TAFI), upon activation to TAFIa, down-regulates fibrinolysis by removing plasminogen binding sites from fibrin. As thrombin is considered the main activator, TAFI represents a link between coagulation and fibrinolysis. Therefore, hypercoagulability is often associated to a hypofibrinolytic state determined by increased TAFI activation. The substitution R338L in the gene for coagulation factor IX (FIX-Padua) has been reported in a young patient with venous thrombosis as a gain-of-function mutation that causes an 8-fold increase in the clotting activity of FIX. To date, it is not known whether FIX hyperactivity can also impact on TAFI activation.
Aims: To evaluate the influence of FIX-Padua on TAFI-mediated regulation of fibrinolysis.
Methods: Blood was collected from the proband (hemizygous for FIX-Padua), two family members (mother, heterozygous, and father, normal) and six unrelated healthy controls (all providing written informed consent), and anticoagulated with citrate plus the inhibitor of the contact system corn trypsin inhibitor (CTI). Plasma clot lysis induced by 40 ng/mL t-PA was studied by a microplate turbidimetric assay. TAFI-dependent inhibition of fibrinolysis was calculated as the ratio between lysis times in the absence and in the presence of the specific TAFIa inhibitor PTCI (PTCI-ratio). TAFI activation was assessed by an ELISA specific for TAFIa and its inactive derivative TAFIai (TAFIa/ai). Thrombin generation was evaluated by calibrated automated thrombinography (CAT). In all experiments, clotting was induced by very low concentrations of tissue factor (0.05 pM) in order to better reproduce the physiological conditions.
Results: Under our conditions, in three different experiments TAFI-dependent inhibition of fibrinolysis was low in control samples (PTCI-ratio: 1.18 ± 0.22), intermediate in the heterozygous mother (1.55 ± 0.19), and high in the proband (1.92 ± 0.15) ($P < 0.001$ by one sample t-test). Thrombin generation was markedly enhanced in the proband as compared to his mother and controls, lag time being 13, 27, and 32.3 ± 4.6 min, respectively ($P < 0.001$) and endogenous thrombin potential (ETP) being 705, 320, and 186 ± 27 min ($P < 0.001$). Accordingly, TAFIa/ai accumulation at 30 min after the start of experiments amounted to 115 ng/mL in the proband as compared to 55.7 ± 14.3 in controls ($P < 0.01$). When a higher concentration of TF (5 pM) was used to make thrombin generation independent of FIX, the differences in PTCI-ratio, thrombin generation and TAFI activation between the proband and controls became much smaller and statistically insignificant ($P > 0.05$).
Conclusions: FIX-Padua increases fibrinolytic resistance by enhancing thrombin-mediated TAFI activation. This finding, on the one hand, may provide an additional explanation for the thrombotic risk of patients carrying the mutation; on the other hand, it might represent a further haemostatic mechanism encouraging the use of FIX-Padua for the gene therapy of haemophilia B.

PB 2.72-2

Audit of requests for thrombophilia laboratory tests post introduction of clinical guidelines in a referral laboratory

Byrne MB, Rafferty M, White B, Ryan K, O'Donnell J and O'Connell N

St James's Hospital, Dublin, Ireland

Background: Thrombophilia testing represents a significant portion of test requests in a tertiary referral coagulation laboratory but such testing has not been shown to be clinically useful in the acute or longterm management of the majority of patients with Venous Thromboembolism (VTE). Guidelines for laboratory testing for thrombophilia were introduced at the National Centre for Hereditary Coagulation Disorders (NCHCD) in August 2012 to assist clinicians in determining appropriate indications for thrombophilia testing. Following implementation, requests for thrombophilia tests were only processed if the clinical indication was in keeping with the guidelines or the specific clinical circumstances had been discussed with a Consultant Haematologist. Requests for testing received without clinical information or appearing to be outside the guidelines were put on hold in the laboratory until additional clinical information was received from the requesting clinician. The final decision regarding laboratory testing was made by the Consultant Haematologist.
Aim: The aim of this audit was to examine the changes in thrombophilia requesting patterns and test processing pathways in the coagulation laboratory following the introduction of thrombophilia test guidelines.
Method: Samples are received for thrombophilia testing (functional and molecular tests) from within St James's Hospital (in-patient and out-patient services), from other referral hospitals throughout Ireland and from general practitioners. Test numbers for the period September to December 2012 were compared with the same period in 2011. Total test numbers and a breakdown of requesting source were examined. An audit of all requests that had been put on hold was conducted and the review rate and final testing decision by the Consultant Haematologist was determined.
Results: There was a 56% reduction in thrombophilia test numbers following implementation of the thrombophilia testing guidelines. The greatest reduction in test numbers was seen in tests requested from external agencies and general practitioners (> 60%). A total of 129 requests were put on hold during this period awaiting further clinical information. The reason for holding the request was either lack of clinical information (n = 66) or the clinical information provided appeared to be outside the testing guideline (n = 63). Requests included full thrombophilia screen (n = 86), Lupus Anticoagulant testing (n = 25) and prothrombotic molecular testing (n = 18). Of the 129 requests on hold, additional information was received in the laboratory on 35/129 requests. Following consultant review, testing was approved in 20 of these requests consisting of full thrombophilia screen (n = 4), Lupus Anticoagulant screen (n = 14) and prothrombotic molecular analysis (n = 2). The most common reason for approval of testing was recurrent pregnancy loss and Lupus Anticoagulant testing (n = 9).
Conclusions: Guidelines for laboratory testing improve the appropriate selection of patients for thrombophilia testing and result in a significant reduction in test requests. There is however an increased administrative workload for laboratory and clinical staff in processing test requests.

PB 2.72-3

Novel mutations of antithrombin gene in inherited AT deficiency

Yu Z, Sun L, Wang C, Zhang W, Cao L and Ruan C

Jiangsu Institute of Hematology, Suzhou, China

Background: Antithrombin (AT) is a natural anticoagulant agent to produce a marked inhibitory effect on thrombin and other activated blood coagulation factors (factor Xa、IXa、XIa) and is pertained to SERPIN (serine protease inhibitor) superfamily. Inherited AT deficiency is associated with a high risk of deep vein thrombosis (DVT) and pulmonary embolism (PE), owing to the mutations of antithrombin gene. It is considered that inherited AT deficiency, as autosomal dominant inheritance, is the main cause of thrombophilia in China.
Aims: The phenotype and genotype in three propositus with DVT and their family members were analysed, in order to identify the mutations in AT gene and investigate the pathophysiologic mechanism.
Methods: The blood sample were collected from three propositus and their family members. The AT activity level in plasma, using chromogenic, were detected in our laboratory. The Protein C activity and Protein S activity were also measured. Genomic DNA was extracted from blood cells. All exons in AT gene were amplified by PCR, then PCR products were directly sequenced to further identify the genotype.
Results: The AT activity in plasma were significantly decreased in propositus and their affected family members, but the Protein C activity and Protein S activity in plasma were normal. We found three kind of heterozygous mutations in AT gene in three unrelated Chinese patients with AT deficiency, 18,390–18,391 InsCT in exon 6 leading to frameshift as to nonsense mutation (433 Thr>stop), 10446 C>T in exon 3 resulting in nonsense mutation (164 Arg>Stop), and 7747T>C in exon 2 causing 78Leu>Pro missense mutation. These mutations can cause premature termination or protein structural abnormality in AT protein. According to the antithrombin mutation database (http://www1.imperial.ac.uk/departmentofmedicine/divisions/experimentalmedicine/haematology/coag/antithrombin/type1/), we confirmed the 18,390–18,391 InsCT mutations and 7747T>C in AT gene were novel mutations.
Summary: These mutations in AT geng, found in three unrelated Chinese patients with DVT, resulted in a premature termination of AT protein or dysfunctional AT protein in plasma, which were the intrinsic reason for the occurrence of DVT.

PB 2.72-4

Inherited thrombophilia and recurrent pregnancy loss

Karimi M[1], Zolghadri J[2], Nezam M[2] and Afrasiabi A[1]

[1]Hematology Research Center, Shiraz University of Medical Sciences; [2]Infertility Research Center, Shiraz University of Medical Sciences, Shiraz, Iran

Background: Recurrent fetal loss (RFL) is a common health problem, with three or more loses affecting 1–2% and two or more losses affecting up to 5% of women at the reproductive age.
The polymorphisms G20210A of prothrombin gene (FII G 20210A), G 1691A), of factor V gene (Factor V Leiden, FVL) and C677T of methylene tetrahydrofolate reductase gene (MTHFR C677T) are the most extensively studied thrombophilic mutations in association to recurrent miscarriage.
Aim: Our aim is to compare the prevalence of FII G20210A and FVL polymorphisms and their combinations in a series of patients with three or more consecutive, miscarriages with control group.
Methods: The study group included 90 west southern Iranian patients with three or more consecutive miscarriages with the same partner in < 20 weeks gestation. We obtained medical histories, performed physical examinations, routine laboratory tests, endocrinologic examinations, and immunologic tests for auto antibodies for patients. Exclusion criteria were: anatomic abnormalities, endocrinologic dysfunction, liver function, abnormalities, inflammatory pelvic disease and PCO. The control population consisted of 44 women of similar age to the patients, with at least one live born children and no history of pregnancy loss. Functional activity of protein C & S, activated protein C resistance (APCR), FV Leiden assay by PCR and prothrombin gene mutation were assessed. The polymorphism frequencies were recorded for each of the groups and comparisons were made using odds ratios (OR), together with their 95% confidence intervals. Chi-squared or Fisher's exact test were also used for comparisons of poly-

morphism distribution between the groups. P-value < 0.05 was considered significant.

Results: The mean age of patients (29.21 years, S.D. 5.9) did not differ from that of the controls (28.75 years, S.D. 5.2) (t-test, $P = 0.66$). Four patients (4.4%) had protein C deficiency while only 1 (2.3%) of control group had protein C deficiency. The mean functional activity of protein C was 109.74 and 102.35 s for case and control groups respectively ($P > 0.05$). Protein S deficiency was detected in 9 (10%) patients. The mean functional activity of protein S was 91.32 and 85.42 s for case and control groups respectively ($P > 0.05$).

There were three homozygous and 15 heterozygous cases of Factor V Leiden in patient group. Carrier ship for Factor V Leiden did not significantly increase the risk for recurrent miscarriage (OR 2.25, 95% CI 0.41–7.55).

There were no homozygous cases in either group. Carrier ship for G20210A (homozygous or heterozygous vs. the wild type) did not significantly increase the risk for recurrent miscarriage (OR 1.95, 95% CI 0.49–13.90)

Conclusion: Factor V Leiden and FII G20210A are associated with pregnancy loss in both the first and second trimester. We found that two common thrombophilic mutations (Factor V Leiden and Prothrombin G20210A), alone or in combination, is associated with increased risk for recurrent miscarriage.

PB 2.72-5

Thrombophilia screening in patients with ocular venous thrombosis

Alrifai M, Heidinger K-S, Fischer R, Zimmermann A and Kemkes-Matthes B

University Hospitals Giessen and Marburg, Giessen, Germany

Background: Ocular venous thrombosis (OVT) is a frequent cause of visual impairment. Patients with OVT are commonly treated with anticoagulants, although no recommendations concerning anticoagulant treatment exist. We here report upon treatment of and thrombophilia screening in 90 patients with OVT.

Aims: To reveal the importance of thrombophilia screening in patients with OVT and to get an overview over anticoagulant treatment in these patients.

Methods: Ninety patients with OVT (46 male, 44 female, age: 22–75 years) were examined. At time of examination none of the patients was acutely ill. Thrombophilia parameters were determined in all patients.

Results:

1 Thrombophilia screening: antiphospholipid antibodies were detected in 12, lipoprotein (a) elevation in 19, factor VIII:c elevation in 11, antithrombin deficiency in 2, factor XII deficiency in 1, hyperhomocysteinemia and Prothrombin (G20210A) polymorphism in 2, Factor V Leiden mutation in eight patients.
2 Treatment: 56 patients were initially treated with acetylsalicylic acid (ASA), two with ADP antagonists, two with low molecular weight heparin (LMWH), 11 with vitamin K antagonists. Ten patients had no treatment at all. Eleven patients had recurrent OVT under treatment with ASA, whereas three patients developed OVT under vitamin K antagonist treatment (one of them suffering from antiphospholipid syndrome). One patient developed two consecutive OVTs under treatment with ASA (100 and 300 mg/day, respectively) despite of proved efficacy of ASA.

Conclusion:

1 Common risk factors of venous thromboembolism like Factor V Leiden mutation, Prothrombin polymorphism, antithrombin deficiency and factor VIII:c elevation were relatively rare in OVT patients, while antiphospholipid antibodies and lipoprotein (a) elevation seem to play a major role. Therefore it is questionable, whether it is necessary to perform a 'complete' thrombophilia screening in OVT patients.
2 ASA was more frequently used than vitamin K antagonists. Nevertheless, recurrence rate of OVT in patients under treatment with vitamin K antagonists was lower in comparison to patients treated with ASA.

PB 2.72-6

The course of vWF multimers and ADAMTS13 in cardiac surgery

Miesbach W[1], Reinecke I[2], Weber C[2] and Budde U[2]

[1]Goethe University, Frankfurt; [2]Medilya Laboratory, Hamburg, Germany

Introduction: Several cases of postoperative TTP following cardiovascular surgery have been recorded. It is still unclear whether the use of extracorporeal circulation (Heart-Lung Machine) during surgery has an impact on vWF multimers and ADAMTS13 and thus on the occurrence of postoperative TTP.

Methods: In order to analyse the course of vWF multimers and ADAMTS13 we included 47 patients undergoing cardiac surgery at the University Hospital Frankfurt/Main. Thirty-nine patients were operated with the use of an HLM (23 coronary artery bypass grafts, 17 cardiac valve operations). Eight patients were operated without the use of an HLM (Off Pump Coronary Artery Bypass). Six blood samples were taken from each patient; before the operation, at 60 & 120 min during operation and 2, 4 and 6 days postoperatively.

Results: We found that ADAMTS13 activity significantly decreased during surgery (from 66% to 50%, $P > 0.001$ in the HLM group, from 67.5% to 48.5%, $P = 0.02$ in the OPCAB group), as well as the ADAMTS13 antibodies. Postoperatively the antibodies rose to a maximum of 14 U/L in the HLM group but stayed lower at 7.7 U/L in the OPCAB group.

The percentage of large vWF multimers increased significantly during surgery in the HLM group from 27% to 30.8% ($P = 0.04$). The amount of vWF antigen measured did not significantly change during surgery in either group.

VWF multimers were quantified using densitometric gel analysis. To test the difference between measuring points the Friedman-Test was used with a 5% level of significance. For the vWF multimers and antigen the Wilcoxon-Matched-Pairs-Test was used.

Conclusion: Our investigations showed significant changes in ADAMTS13 activity during cardiac surgery. There is also a difference in the presence of large vWF multimers when comparing extracorporeal circulation to OBCAB surgery. These findings might support the thesis that TTP may develop after cardiac surgery with extracorporeal circulation.

PB2.73 – TTP/Thrombotic Microangiopathies – I

PB 2.73-1

Hematologic outcomes at 2 years in eculizumab-treated atypical hemolytic uremic syndrome patients with long disease duration and chronic kidney disease

Douglas K[1], Furman R[2], Babu S[3] and Bedrosian CLC[4]

[1]Beatson West Scotland Cancer Centre, Glasgow, UK; [2]Weill Cornell Medical College, New York, NY; [3]Fort Wayne Medical Oncology and Hematology, Fort Wayne, IN; [4]Alexion Pharmaceuticals, Cheshire, CT, USA

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, systemic genetic disease characterized by chronic, uncontrolled complement pathway activation leading to platelet activation, thrombosis, hemolysis, and thrombotic microangiopathy. Patients with aHUS frequently present with abnormal hematologic parameters, as well as

renal and end-organ damage. Within 1 year of diagnosis, up to 65% of patients develop permanent renal damage, end-stage renal disease, or die.[2] Eculizumab, a terminal complement inhibitor, is a humanized monoclonal antibody that binds with high affinity to the human C5 complement protein, blocking the generation of proinflammatory C5a and C5b-9. Eculizumab is the first approved treatment for aHUS in pediatric and adult patients.

Aims: Two-year hematologic and renal outcomes were investigated from a phase 2 study of eculizumab treatment in aHUS patients with long disease duration, and chronic kidney disease (CKD) with prior chronic plasma exchange/plasma infusion (PE/PI).

Methods: Twenty patients age ≥ 12 years receiving chronic PE/PI on a stable regimen with no platelet count decrease > 25% during an 8-week observation period were enrolled in the study and received eculizumab for 26 weeks; 19 of 20 patients entered the long-term extension. Patients provided informed consent and the study was approved by each center's institutional review board. Data are reported at 104 weeks unless otherwise noted.

Results: Patients (median age 28 years, 60% female, 40% with prior renal transplant) had a median time from diagnosis to screening of 48 months. All patients received PE/PI prior to eculizumab treatment. Mean ± SD hemoglobin and haptoglobin levels at baseline were 107.7 ± 16.5 and 0.9 ± 0.6 g/L, respectively. Mean ± SD baseline estimated glomerular filtration rate (eGFR) was 30.8 (19.0). By data cutoff, 18 of 20 patients (90%) achieved hematologic normalization (platelet count ≥ 150′ 10^9/L and lactate dehydrogenase [LDH] ≤ upper limit of normal sustained for at least two consecutive measurements spanning ≥ 4 weeks), 19 of 20 patients (95%) sustained LDH levels below the upper limit of normal, and only one patient (5%) required PE/PI (two fresh frozen plasma infusions) while continuing eculizumab. Mean ± SD increase in hemoglobin from baseline was 13.6 ± 16.2 g/L ($P = 0.0044$). Hemoglobin increased to a normal level in six of the 12 patients with a low level at baseline. At 100 weeks, mean ± SD haptoglobin increase from baseline was 0.2 ± 0.7 g/L ($P = 0.2770$). The eGFR increase from baseline (mean, 95% CI) was 7.2 (0.76–13.6; $P < 0.05$), an increase of 42.0% (23.2–60.7; $P < 0.0001$). Earlier eculizumab intervention (shorter duration of aHUS clinical manifestation prior to treatment) was associated with greater increases in eGFR ($P = 0.001$).

Summary/Conclusions: In aHUS patients with long disease duration and CKD with prior chronic PE/PI, treatment with eculizumab led to improvements in both hematologic and renal outcomes at 2 years. There was significant reduction in hemolysis in association with ongoing improvements in renal function. These results underscore the important role that hematologists may play in the diagnosis and management of this life-threatening disease, as well as the need for early and ongoing eculizumab treatment in aHUS patients.

PB 2.73-2

A new heterozygous mutation in the metalloprotease domain of ADAMTS13 in a patient with thrombotic thrombocytopenic purpura

De Cock E[1], Hermans C[2], Vandeputte N[1], Deckmyn H[1], De Meyer SF[1] and Vanhoorelbeke K[1]
[1]KU Leuven Kulak, Kortrijk; [2]St-Luc University Hospital, Brussels, Belgium

Background: Hereditary thrombotic thrombocytopenic purpura (TTP) is caused by mutations in the von Willebrand factor (VWF) cleaving protease ADAMTS13. ADAMTS13 deficiency prevents processing of ultra-large (UL) VWF multimers into normal, less reactive molecules. Hence, surviving UL-VWF multimers spontaneously react with platelets thereby inducing intravascular thrombosis, severe thrombocytopenia and hemolytic anemia.

Aim: We aimed at identifying the genetic defect in the *Adamts13* gene in a patient who developed TTP during pregnancy and at characterizing the functional effect of the ADAMTS13 mutation *in vitro*.

Methods: Genomic DNA was isolated from the patient's blood cells. Twenty-nine ADAMTS13 exons with exon-intron boundaries were amplified by PCR and sequenced. The identified mutation was introduced by site-directed mutagenesis in the pcDNA6.1 huADAMTS13 expression vector. Wild type and mutant ADAMTS13 were stably expressed in HEK293T cells using blasticidin selection. Recombinant proteins were partially purified using heparin chromatography. ADAMTS13 antigen levels were determined using an in house developed ELISA. ADAMTS13 activity was measured in a FRET assay. The presence of inhibitory antibodies was tested using a commercial ELISA kit.

Results: We here report the identification of a mutation in the *Adamts13* gene in a 39-year old female who developed TTP during pregnancy. In the acute phase of the disease she was diagnosed with severe thrombocytopenia and schistocytes. ADAMTS13 activity levels were severely decreased (8%, normal values in controls are > 40%). As no inhibitory anti-ADAMTS13 antibodies were found, we looked for the genetic defect in the *Adamts*13 gene of this patient. Sequence analysis of all 29 ADAMTS13 exons with exon-intron boundaries revealed three homozygous single nucleotide polymorphisms in exons 5 (c.420 C>T), 15 (c.1716 A>G) and 19 (c.2280 C>T) and a heterozygous c.559 G>C mutation in exon 6. This missense mutation changes D187 to H (p.Asp187His) in the metalloprotease domain of ADAMTS13 and has not been described before in any other patient. However, D187 was previously shown to be functionally involved in the high affinity Ca^{2+} binding site as mutating D187 to A resulted in a 10 fold reduced catalytic activity. In line with this, at an enzyme concentration of 0.5 nM, the activity of the D187H mutant as measured in the FRETS assay was abolished while wild type ADAMTS13 exhibited normal activity.

Conclusion: In this study we show that the p.Asp187His mutation leads to an inactive ADAMTS13 protein, confirming that the patient mutation, when expressed in a homozygous state, abolishes ADAMTS13 activity. The heterozygous state of the p.Asp187His mutation in our TTP patient however does not explain her severely reduced ADAMTS13 activity levels. Expression studies mimicking the heterozygous state and analyzing the contributions of the SNPs to ADAMTS13 expression levels will help to further explain this discrepancy. Nevertheless, the presence of the p.Asp187His mutation in our TTP patient supports the physiological relevance of the role of the D187 residue in the high affinity Ca^{2+} binding site of ADAMTS13.

PB 2.73-3

Atypical hemolytic uremic syndrome patients with progressing thrombotic microangiopathy treated with ongoing eculizumab have favorable hematologic outcomes at 2 years

Furman R[1], Babu S[2], Douglas K[3] and Bedrosian CLC[4]
[1]Weill Cornell Medical College, New York, NY; [2]Fort Wayne Medical Oncology and Hematology, Fort Wayne, IN, USA; [3]Beatson West Scotland Cancer Centre, Glasgow, UK; [4]Alexion Pharmaceuticals, Cheshire, CT, USA

Background: Atypical hemolytic uremic syndrome (aHUS) is caused by inherited and/or acquired defects of complement system regulators, resulting in chronic, uncontrolled complement activation that causes platelet activation, thrombosis, hemolysis, and thrombotic microangiopathy (TMA). Patients may present with end-organ damage despite plasma exchange/plasma infusion (PE/PI), frequently in association with anemia, thrombocytopenia, undetectable haptoglobin, and/or elevated lactate dehydrogenase (LDH).[1] Within 1 year of diagnosis, up to 65% of patients develop permanent renal damage or die.[2] Eculizumab, a terminal complement inhibitor, is a humanized monoclonal

antibody that binds with high affinity to the human C5 complement protein and is the first approved treatment for aHUS in pediatric and adult patients.

Aims: Hematologic and renal outcomes were investigated in this phase 2 study of eculizumab in aHUS patients with progressing TMA.

Methods: Patients age ≥ 12 years with clinical evidence of progressing TMA (platelet count < 150×10^9/L after ≥ 4 PE/PI sessions in the prior week and platelet count decrease > 25%) were enrolled and received treatment with eculizumab. Patients provided informed consent and the study was approved by each center's institutional review board. Data are reported at 104 weeks.

Results: Seventeen patients (median age 28 years, 71% female, 41% with prior renal transplant) had a median time from diagnosis to screening of 10 months. Hematologic parameters were abnormal at baseline: mean ± SD platelet count was $109.0 \pm 32.1 \times 10^9$/L, LDH level was 323.0 ± 138.2 U/L, hemoglobin level was 89.1 ± 14.0 g/L, and haptoglobin level was 0.5 ± 0.4 g/L. All patients presented with renal impairment (estimated glomerular filtration rate [eGFR] < 60 mL/min/1.73 m^2). At 104 weeks, mean ± SD platelet count increase vs. baseline was $93.9 \pm 55.5 \times 10^9$/L ($P = 0.001$), LDH decrease was 205 ± 107.2 U/L ($P = 0.013$), hemoglobin increase was 36.1 ± 30.5 g/L ($P = 0.008$), and haptoglobin increase was 0.9 ± 0.4 g/L ($P = 0.006$). The median (range) time to the start of platelet count normalization (first platelet count ≥ 150×10^9/L) was 7 days (range, 1–218). Only two patients (12%) required PE/PI after starting eculizumab, (one patient after 10 days of treatment, the other after 84 days). Significant renal improvements were observed in association with the hematologic effects: eGFR change from baseline (mean, 95% CI) was 35.2 (17.3–53.1; $P = 0.0005$), and earlier eculizumab intervention (shorter duration of aHUS clinical manifestation prior to treatment) was associated with greater increases in eGFR ($P < 0.01$). In addition, four of five patients (80%) receiving dialysis at baseline were able to discontinue after eculizumab initiation.

Summary/Conclusions: Ongoing treatment with eculizumab led to sustained improvement in hematologic outcomes at 2 years, including reduced hemolysis, in association with ongoing improvements in renal function. These results underscore the important role that the hematologist may play in the diagnosis of this life-threatening disease, as well as the need for early and ongoing eculizumab treatment in patients with aHUS and progressing TMA.

PB 2.73-4

A novel heterozygous missense ADAMTS13 mutation (G3368A) in a patient diagnosed with thrombotic thrombocytopenic purpura due to reduced ADAMTS13 activity and low titer of anti-ADAMTS 13 antibody

Calderazzo JC[1], Kempfer AC[2], Powazniak Y[3], Sánchez-Luceros A[2], Woods AI[2], Paiva JH[4] and Lazzari MA[2]

[1]Academia Nacional de Medicina, Instituto de medicina experimental (IMEX); [2]IMEX-Academia Nacional de Medicina; [3]Fundación Investigar-Argenomics; [4]IIHEMA-Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Thrombotic thrombocytopenic purpura (TTP) is characterized by microvascular thrombosis, associated with deficiency of ADAMTS13, induced by mutations in the gene and autoantibodies.

Aims: In order to explain the patient's phenotype of the ADAMTS13 deficiency, it was decided to explore the mechanistic effect of a mutation found by means of expression studies in mammalian cells.

Methods: Patient with a history of TTP episodes that began at 13 years of age. Several plasma samples were measured for ADAMTS13 activity (ac) and antigen (ag), IgG anti-ADAMTS13 antibody and VWF multimers. The wild type (WT) and the ADAMTS13 mutant (site-directed mutagenesis) construct were transiently expressed in HEK 293 cells. Culture medium and cell lysate were evaluated by ELISA kit for ADAMTS13 ac and ag levels.

Results: In the patient's plasma were detected: ag = < 0.5% (nv = 70–160%), ac = 0.6 ± 0.6% (nv = 40–130%), 26% ULVWF multimers (normal value, nv < 15%) and IgG anti-ADAMTS13 antibody = 19 ± 3 U/mL (nv < 15 U/mL). The mean ± SD of ag, ac and IgG anti-ADAMTS13 antibody from three samples of the patient was informed.

To exclude the possibility that the novel mutation (in heterozygous state) found in our patient is not a disease-related polymorphism, we screened 50 healthy donors. The '*in vitro*' expression of the ADAMTS13 mutant led to a defect of secretion (ag = 7.5, ac = 17) of protease, causing intracellular accumulation (ag = 116, ac = 83). The cotransfection of the mixtures of the mutant and the WT revealed a secretion defect of the protease (ag = 86, ac = 69). All samples were compared to WT (considered 100%).

Conclusions: Mutagenesis suggests that the novel mutation G3368A (in TPS1-8 domain, exon 25) is critical for ADAMTS13 secretion.

The patient had low antibody titers to ADAMTS13 although the levels of ac and ag always were < 1.2%.

This patient's ADAMTS13 deficiency was probably caused by a combination of the G3368A mutation (in heterozygous state) and IgG anti-ADAMTS13 antibodies, although it is unclear why the latter were present.

PB 2.73-5

Release of fibrinolytic microvesicles in atypical haemolytic-uremic syndrome

Monthé-sagan K[1], Plawinski L[2], Chatelet V[3], De ligny BHurault[3] and Anglés-cano E[4]

[1]Centre hospitalo-universitaire, Caen; [2]Equipe Imagerie Moléculaire et NanoBioTechnologie UMR CNRS 5248 C.B.M.N – Univer, Pessac; [3]Centre hospitalo-universitaire de Caen, Caen; [4]Inserm U765 Thrombosis: pathophysiology and new therapies Fac Sciences Pharmaceu, Paris cedex 06, France

Background: Complement deposition on platelets and endothelium results in increased release of microvesicles that may participate in the thrombotic microangiopathy (TMA) of atypical hemolytic-uremic syndrome (aHUS). However, activated endothelial cells may also release microvesicles with compensatory fibrinolytic activity. Treatment with eculizumab, an anti-C5 mAb, arrests the TMA process.

Aims: We hypothesized that eculizumab may modify the release of fibrinolytic microvesicles from endothelial cells. Thus, we monitored the release pattern of fibrinolytic microvesicles in a patient with aHUS treated with eculizumab.

Methods: Blood samples were drawn before and after each dose of eculizumab. Microvesicles were isolated from plasma by sequential centrifugation and their concentration was evaluated by microvolume protein quantitation (A280 nm). The fibrinolytic activity of microvesicles was detected by fibrin-agarose zymography and by measuring the generation of plasmin using a photometric microtitre play assay.

Results: Microvesicle concentration and fibrinolytic activity before eculizumab were similar to the control group. A higher concentration of microvesicles and a parallel increase in fibrinolytic activity was observed after each dose of eculizumab. This increase was sustained all along the treatment period (6 month). The plasminogen activator responsible for this fibrinolytic activity was identified as tPA, thus suggesting an endothelial origin.

Conclusions: Eculizumab induced the release of fibrinolytic microvesicles that may participate in the arrest of the TMA during the course of aHUS.

PB 2.73-6

Recurrent disease in patients with thrombotic thrombocytopenic purpura: data from Serbian TTP Registry

Saracevic M[1], Vucelic D[2], Savic N[3], Rajic Z[4], Obradovic S[5], Jevtic D[6] and Mikovic D[1]

[1]Blood Transfusion Institute of Serbia; [2]Clinic of Digestive Surgery, Clinical Centre of Serbia; [3]Clinic of Vascular Surgery, Clinical Centre of Serbia; [4]Institute of Haematology, Clinical Centre of Serbia; [5]Military Medical Academy; [6]Mother and Child Health Care Institute of Serbia, Belgrade, Serbia

Background: Thrombotic thrombocytopenic purpura is a severe multisystem disorder characterized by fever, thrombocytopenia, microangiopathic hemolytic anemia, neurologic symptoms, and impaired renal function. Despite greater understanding of pathophysiology and effective treatment with plasma exchange thrombotic thrombocytopenic purpura is still intriguing disease since mortality from acute episode as well as risk of recurrent disease in survivors remains substantial. Recurrent episodes occur in up to 50% of patients who survive initial episode, developing a chronic recurrent form of the disease

Aims: To analyze risk of recurrent TTP and treatment options in such cases.

Methods: Registry of patients with TTP was established in Blood Transfusion Institute of Serbia (BTIS) in 2004. From August 2004 to December 2012 consecutive patients with clinical diagnosis of TTP were followed up and treated in Belgrade at the University Clinical Centre of Serbia, Military Medical Academy and Mother and Child Health Care Institute of Serbia. Prospective/retrospective analysis of 51 consecutive TTP patients was performed. Patients' informed consents were obtained and the study was approved by the BTIS Medical Ethics Committee.

Results: Seven of 51 patients (12%) did not survive acute episode of the disease. Among survivors, 32/44 (72%) patients presented with their initial TTP episode, 7/44 (16%) patients presented on their relapse in the range of 5–11 years after their initial TTP episode, whereas 5/44 (12%) patients presented at our observation in remission lasting 1–5 years after the initial TTP episode. There were 32 female (73%) and 12 male (27%) patients. The age range for the initial TTP episode was from 20 to 68 years, median value 37 years. Idiopathic TTP was observed in 36 patients and secondary TTP in eight patients. In the course of the disease none of the patients with secondary TTP manifested recurrence, while recurrent disease was present in 15/36 (42%) patients with idiopathic TTP. Recurrent disease occurred with a spectrum of presentations ranging from a single relapse to several episodes developing with variable frequency. In our cohort six patients had relapse only once, five patients relapsed two times, and four patients had three recurrent episodes. The period between initial TTP episodes and relapses ranged from 2 months to 11 years, median value 53 months. Most recurrent episodes were treated efficiently by plasma infusion or therapeutic plasma exchange. Due to repeated relapses splenectomy was performed in six patients.

Summary/Conclusions: Relapses are common in patients with idiopathic TTP. Patients follow up is necessary not only immediately upon the episode because of the risk of delayed TTP recurrence. In one of our patients, we have seen the first relapse as late as 11 years after initial episode. In patients with frequent relapses splenectomy as therapeutic option should be considered.

PB2.74 – Thrombosis: Miscellaneous

PB 2.74-1

Successful management for pregnancy in three patients with Upshaw-Schulman syndrome

Matsumoto M[1], Isonishi A[1], Kajiwara M[2], Ogawa Y[3], Yamamoto Y[4] and Fujimura Y[1]

[1]Nara Medical University, Kashihara City, Nara; [2]Tokyo Medical and Dental University, Tokyo; [3]Gunma University Graduate School of Medicine, Maebashi; [4]Juntendo University, Tokyo, Japan

Background: Upshaw-Schulman syndrome (USS) is caused by a deficiency of ADAMTS13 activity (AC) due to its gene mutation. When ADAMTS13:AC is deficient, unusually large von Willebrand factor (VWF) multimers are not cleaved, which induces platelet thrombi formation in the microcirculation under high shear stress. We found nine female patients who were diagnosed with USS in their pregnancy. These pregnancies often result in premature delivery or fetal loss. Detail therapeutic protocol including FFP infusion for pregnant women with USS has not been established.

Case Series: Patients G3 (c.686 + 1 G>A/p.R1123C) was diagnosed with USS at 14 years old (yo). Her first pregnancy at 21 yo resulted in spontaneous abortion at 7 weeks of gestation (WG) without regular FFP infusion. In the second pregnancy at 22 yo, prophylactic FFP infusion was started at as following dose and intervals: 5–25 WG 5 mL/kg biweekly, 26–28 WG 5 mL/kg every 10 days, 29–33 WG 5 mL/kg weekly, after 34 WG 8 mL/kg every other days. At 35 WG, she delivered a baby girl (weighting 1446 g) with intrauterine growth retardation but no anomaly by a cesarean section (CS). Just before delivery, her platelet counts were 179×10^9/L, and ADAMTS13:AC was 34%. In her third pregnancy at 24 yo, she started FFP infusion at 7 WG. In addition to the FFP infusion of the same protocol as 2nd pregnancy, she was treated with asprin (100 mg/day) between 12 and 28 WG. She delivered a healthy baby boy (2632 g) at 37 WG by CS. Her platelet counts were 223×10^9/L, and ADAMTS13:AC was 10.5% just before delivery.

Patients K4 (p.Y304C/p.G525D) was diagnosed with USS at 25 yo in her first pregnant. After diagnosis, she received regular FFP infusion (5 mL/kg) every 3 weeks until nine WG of 2nd pregnancy at 30 yo. Between 9 and 29 WG, she received 5 mL/kg of FFP infusion biweekly. In 30 WG, she delivered a baby girl (1522 g) by CS after infusion of 9 mL/kg FFP. Her platelet counts were 179×10^9/L, and ADAMTS13:AC was 34% just before delivery.

Patients LL4 (p.C438S/p.G909R) was confirmed the diagnosis of USS at 27 yo by ADAMTS13 gene analysis. She became pregnant at 30 yo. She received 7 mL/kg FFP biweekly in 9–17 WG, 7 mL/kg weekly in 18–31 WG, and 9 mL/kg weekly after 32 WG. In addition to FFP, she was treated with aspirin (100 g/day) between 9 and 34 WG. At 39 WG, she delivered a healthy baby girl (3476 g) without anomaly. Her platelet counts and ADAMTS13:AC just before delivery was 208×10^9/L and 15%, respectively.

Conclusion: Plasma VWF level increases with progressing gestation in pregnancy. To prevent platelet thrombi in USS, much more ADAMTS13 supplementation may be necessary in the later term of gestation of USS. Therefore, we shortened the interval and increased the volume of FFP infusion with progressing gestation. This protocol brought successful delivery in four pregnancies of three patients with USS. The administration of low dose aspirin might be useful in USS pregnancy in addition to FFP infusion.

PB 2.74-2

Size of pulmonary embolism in relation to persisting symptoms

Mäkelburg ABU, Brouwers AH, Hoendermis ES, Dierckx RAJO, Veeger JGM, Nossent GD, Kluin-Nelemans HC and Meijer K
University Medical Centre Groningen, Groningen, The Netherlands

Background: Up to two third of patients experience persisting symptoms after pulmonary embolism (PE). In nearly all of them no distinct (cardiopulmonary) pathology is detected. Predicting which patients will develop persisting symptoms is difficult.
Aims: We explore whether the size of PE, as defined by amount of perfusion defects and/or level of D-dimer, is able to predict development of residual symptoms.
Methods: Consecutive patients who have participated in PE-studies, who were at least 1 year after PE and had undergone perfusion lung-scanning as part of the diagnostic test and/or in whom a D-dimer was measured at PE were eligible. They were evaluated for persisting symptoms. Perfusion defects were scored by using a validated scoring-chart. D-dimer were measured by Vidas (BioMerieux) and by Roche Modular (Roche Diagnostics)-tests. Patients were classified as having increased fatigue when they reported any increase in fatigue with or without loss of condition after PE; their daily routine had to be unchanged. Patients were classified as having decreased performance when reporting any change in daily routine due to residual symptoms following PE. All other patients were classified as having no symptoms.
Results: Of 110 patients who participated in PE-studies between January 2000 and December 2009, 85 were evaluable. In 45 patients a perfusion-scan was available, in 74 D-Dimer had been measured at PE and in 34 both tests were available.
Median age at time of PE in patients with perfusion-scan was 50.5 (range 22.6–76.5) years. Time since PE was median 4.2 (1.0–8.6) years, 44% of patients were female. Perfusion defects were median 3.00 (0.25–12.25) segments. No symptoms were reported by 16 (36%), increased fatigue by 15 (33%) and decreased performance by 14 (31%) patients.
Perfusion defects in patients without symptoms were median 1.75 (range 0.25–12.00) segments vs. 2.50 (0.50–8.25) segments in patients with increased fatigue vs. 3.88 (0.50–12.25) in patients with decreased performance, overall $P = 0.325$. When comparing asymptomatic patients with those with symptoms, number of mismatched segments was median 1.75 (range 0.25–12.00) vs. 3.25 (0.50–12.25) segments, $P = 0.307$.
D-dimers were measured from 2003 on. Median age at time of PE in the D-dimer-group was 50.3 (20.8–85.7) years, time since PE median 1.5 (1.0–5.8) years and 41% were female. No symptoms were reported by 38%, increased fatigue by 34% and decreased performance by 28% of patients. D-dimer-levels were median 3059 (581–41,870). Observed levels of D-Dimer were similar before and after change of assay. D-dimer were in patients without symptoms median 2749 (581–18259) vs. 3094 (944–41870) in patients with increased fatigue vs. 3082 (765–8859) in patients with decreased performance.
Conclusions: Median larger perfusion-defects in perfusion lung-scanning seem to be related to persistent symptoms. This relation is not strong enough to yield a useful predictor at diagnosis for development of persistent symptoms. D-dimer was not related to symptoms.

PB 2.74-3

D-dimer, factor VIII, and thrombotic burden during the acute phase of leg deep venous thrombosis and early signs and symptoms of post-thrombotic syndrome

Sartori M, Favaretto EJ, Cosmi B, Cini M, Legnani C and Palareti G
S. Orsola-Malpighi Bologna University Hospital, Bologna, Italy

Background: Post-thrombotic syndrome (PTS) is the most common complication of deep vein thrombosis (DVT). Few data are available on the time course of D-dimer, FVIII and thrombotic burden in relation with the risk of post-thrombotic syndrome.
Aim: The aim of the study was to evaluate the course of D-dimer, FVIII levels, and the burden of residual thrombus during the acute phase of proximal DVT of the lower limbs and the PTS signs and symptoms after 90 days of vit K antagonist therapy.
Methods: Fifty-eight patients with a proximal DVT of the lower limbs (age 64; range: 20–88 years; male 57%) were enrolled from the day of diagnosis with a follow-up of 90 days. All subjects received LMWH for 5–7 days, overlapped and followed by oral anticoagulation for 3 months. A complete ultrasound examination of the deep vein system of the lower limbs was conducted on the day of diagnosis (D0) and 7 (D7), 30 (D30), and 90 (D90) days afterward. On the same days, blood samples were taken for measuring D-dimer (Vidas d-Dimer, BioMerieux, France, n.v. < 0.5 μg/mL) and FVIII (chromogenic assay). Villalta scale was evaluated at D30 and D90. The thrombotic burden was defined according to a new score, which considered the number of districts with thrombi and the degree of occlusion.
Results: D-dimer was 4.1 ± 3.4 μg/mL at D0 and decreased till 0.4 ± 0.5 μg/mL $P < 0.001$ at D90. D-d levels did not correlate with thrombotic burden at diagnosis and during follow-up; FVIII levels did not change during follow-up (D0: 2.5 ± 0.7 IU/mL; D90 2.6 ± 0.6 IU/mL, P = ns) and did not correlate with thrombotic burden. At D90, nine patients had a Villaalta score ≥ 5, the mean Villalta score was 2.3 IQR 0–3 and was not correlated to D-dimer or FVIIII. Neither D-dimer nor FVIII time course correlated with Villalta score, whereas the burden of residual thrombus at D30 and D90 was correlated with the Villalta scale (rho 0.4 $P < 0.01$).
Conclusions: D-dimer decreases according to a power decay during treatment for acute DVT but is not correlated with PTS symptoms and signs. FVIII levels are stable during the acute phase of DVT. The burden of residual thrombus is correlated with signs and symptoms for PTS after 90 days of oral anticoagulation.

PB 2.74-4

The effect of initiating combined antiretroviral therapy on endothelial cell activation and coagulation markers in a south african HIV-infected cohort

Louw S
NHLS, Johannesburg, South Africa

Background: An increased prevalence of venous thrombo-embolism (VTE) including deep venous thrombosis (DVT) is observed in HIV-infected patients with an increased incidence vs. HIV negative individuals [1, 2]. A beneficial effect of anti-retroviral therapy (ART) on coagulation markers is described. [3, 4, 5, 6]. Clinical risk factors for VTE in HIV-infected patients are advanced age, immobilisation, presence of a central venous catheter, AIDS-defining opportunistic infections and a CD4 cell count < 500 cells/mm^3. Protein C, protein S or antithrombin deficiencies as well as antiphospholipid antibodies and elevated levels of factor VIII and von Willebrand factor (vWF) are associated with VTE in HIV [7].
Objectives: To examine the effect of initiating ART on endothelial cell activation and coagulation markers in a South African ART-naive HIV-infected cohort.
Patients/Methods: Prospective cohort study of 123 HIV-infected individuals. Markers of endothelial cell activation, coagulation and anticoagulation were measured at baseline (ART naive) and at follow-up (on ART) in HIV-infected individuals and compared to the levels in an HIV-uninfected control population. A venous ultrasound of both legs was performed to detect asymptomatic DVT.
Results: Before initiating ART significantly elevated von Willebrand factor and D-dimer levels, increased activated protein C resistance (APCR) and decreased protein S and C levels were observed. At follow-up all markers, except APCR, improved towards the normal range for controls without showing complete normalisation. In a subgroup of 56 patients no asymptomatic DVT was found.

Conclusions: Compared to the controls, abnormal levels of coagulation markers were observed in HIV-infected individuals before and after the initiation of ART. Most markers improved after starting ART, but remained significantly different from the controls, indicating a persistent disturbed haemostatic balance. In this cohort no increased prevalence of asymptomatic DVT was observed.

PB 2.74-6

Markers of endothelial damage are associated with successful recanalization in acute stroke

Faille D[1,2], Labreuche J[3], Huisse MG[1,2], Mazighi M[1,2] and Ajzenberg N[1,2]

[1]Inserm U698, Université Paris Diderot; [2]Department of Hematology, Bichat Hospital; [3]Department of Neurology, Bichat Hospital, Paris Cedex 18, France

Background and Purpose: We aimed to determine the association of pretreatment levels of selected endothelial biomarkers with arterial recanalization and clinical outcome in acute ischemic stroke (AIS) patients treated with recombinant tissue plasminogen activator (rtPA).

Methods: We prospectively recruited 64 AIS patients treated with intravenous and/or intra-arterial rtPA. Blood samples were collected before thrombolysis and analyzed for von Willebrand factor (vWF), soluble thrombomodulin (sTM) and soluble endothelial protein C receptor (sEPCR). Patients were divided into three groups according to documented arterial occlusion followed or not by complete recanalization (Thrombolysis In Myocardial Infarction score of 3). Favorable clinical outcome was defined by modified rankin score of 0–2 at 90-day.

Results: Of the 64 included patients, 33 had a documented arterial occlusion and 14 (42%) of them had a complete recanalization after thrombolysis. After adjustement for confounding factors, these patients presented lower levels of sTM and sEPCR than patients with a persistent occlusion (median sTM values, 21 vs. 48 ng/mL, $P = 0.008$; median sEPCR values, 78 vs. 114 ng/mL, $P = 0.018$), but similar levels than patients without documented occlusion (median sTM values 22 ng/mL; median sEPCR values 77 ng/mL). Levels of vWF did not differ between the three groups. None of the selected biomarkers were significantly associated with favorable outcome.

Conclusions: The efficacy of thrombolytic therapy to recanalize intracranial vessels is associated with low levels of sTM and sEPCR but not with vWF levels. This suggests that thrombolysis resistance might be related to the impairement of the activated protein C pathway resulting from an increased shedding of endothelial surface receptors rather than a more global endothelial dysfunction including VWF secretion. Further larger studies are warra

PB 2.74.5

Aspirin intake AM or PM?: effect on platelet reactivity in the morning

Bonten T[1], Snoep JD[1], Assendelft WJ[2], Zwaginga JJ[1], Huisman MV[1], Rosendaal FR[1], Eikenboom HCJ[1] and Van Der Bom JG[1]

[1]Leiden University Medical Center, Leiden; [2]Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands

Background: Platelets play a crucial role in the development of acute thrombotic events and platelet activity follows a circadian rhythm, with a peak in the morning. This may contribute to the observed peak of cardiovascular disease (CVD) in the morning. Aspirin is one of the cornerstones in secondary prevention of CVD and is usually taken on awakening, although evidence regarding optimal time of intake is lacking. Due to its short half life, aspirin only inhibits platelets which are present at the time of intake while new platelets formed throughout the day will not be inhibited. These uninhibited platelets contribute to the morning peak of platelet reactivity. The proportion of uninhibited platelets which are present in the morning may be higher with aspirin intake on awakening compared with aspirin intake at bedtime. Thus, the timing of aspirin intake may influence its effect on platelet reactivity during the morning hours.

Aim: We hypothesized that aspirin intake at bedtime compared with on awakening attenuates platelet reactivity in the morning.

Methods: This study is part of the Aspirin in Reduction of Tension II trial (clinicaltrials.gov number: NCT01379079), which is a randomized crossover trial comparing the effect of aspirin intake on awakening with intake at bedtime on blood pressure and platelet reactivity. Two hundred and fifty patients using aspirin for secondary prevention of CVD randomly use both aspirin on awakening and at bedtime during two intervention periods of 3 months. Blood is drawn in the morning at fixed time points for each patient at the end of both intervention periods. Platelet reactivity is measured with the VerifyNow® Aspirin assay in 125 of the 250 patients to detect a 10% reduction of platelet reactivity in the morning with aspirin intake at bedtime.

Results So Far: Until now (19 December 2012) 235 patients have been randomized, of which 109 patients have complete measurements at both time points. We expect to complete data collection of platelet reactivity measurements in March 2013, which guarantees availability of the data to be presented at ISTH 2013.

Potential Impact: Results of this study will show whether aspirin intake at bedtime attenuates the morning peak in platelet reactivity compared with intake on awakening in patients with CVD. Simply changing the time of intake could make aspirin even more effective in preventing recurrent thrombotic events in the morning without any additional costs.

PB3.21 – Antiplatelet agents: aspirin – II

PB 3.21-1

Diabetes modulates the fibrinolytic properties of aspirin without altering the platelet inhibitory actions: a possible mechanism for aspirin treatment failure

Kurdee Z[1], Mamaniat A[1], Phonix F[1], Rice P[1], Storey R[2], Grant PJ[1] and Ajjan R[1]

[1]The University of Leeds, Leeds; [2]The University of Sheffield, Sheffield, UK

Background: Aspirin is an anti-thrombotic agent that has a dual mode of action by inhibiting platelet function and modulating fibrin clot lysis. This agent is used in individuals at high risk of atherothrombosis, including those with diabetes. However, recent evidence suggests reduced clinical efficacy of aspirin in diabetes by mechanisms that are not entirely clear.

Aims: We hypothesised that hyperglycaemia in diabetes interferes with aspirin action, consequently comrpomising cardiovascular protection. Therefore, the aim of this work were to investigate the effects of short and medium term hyperglycaemia on response to aspirin therapy.

Methods: To analyse the effects of medium term hyperglycaemia on response to aspirin therapy, we investigated the ex vivo effects of this agent on platelet function and clot structure/fibrinolysis in 25 individuals with type 1 diabetes not on any treatment other than insulin. Results were compared with an age and sex matched control group of 23 individuals.

In addition, we investigated the effects of short term hyperglycaemia on response to aspirin therapy by ex vivo addition of excess glucose (20 mM) to blood samples in the presence and absence of aspirin, followed by plasma separation. Platelet function, after stimulation with different agonists, was monitored by the multiplate assay and fibrinolysis was tested using turbidimetric analysis.

Results: Platelet aggregation to arachidonic acid (AA) after treatment with 0, 1 and 10 mg/L aspirin in T1DM subjects was 62.7 ± 2.8, 54.6 ± 3.0 and 31.4 ± 3.3 AU, respectively ($P < 0.05$). However, failure to respond to low aspirin concentration was noted in individuals with poorly controlled diabetes ($n = 9$, HbA1c>9%). Excess glucose abolished the platelet inhibitory effect of low aspirin concentration but had no effect on inhibition by high aspirin concentration. Similar findings were demonstrated in 23 healthy controls with low aspirin concentration having a non-significant effect on platelet inhibition in the presence of excess glucose (69.2 ± 5.0, 64.3 ± 4.8; for 0 and 1 mg/L aspirin, $P > 0.05$ and 37.6 ± 4.7 au for 10 mg/L, $P < 0.05$). Aspirin had no effect on ADP-induced platelet stimulation in the diabetes group or controls.

Fibrinolysis in individuals with diabetes showed no difference in the presence of 0, 1 and 10 mg/L aspirin (654 ± 49, 672 ± 43.8 and 657.7 ± 41.5 s, respectively; $P > 0.1$). This was not affected by adding excess glucose to blood samples. In contrast, fibrin clot lysis was enhanced by aspirin treatment in healthy controls (600 ± 63.5, 475 ± 26.6 and 489 ± 29 s, respectively; $P < 0.05$). However, facilitation of fibrinolysis by aspirin in the control group was abolished when excess glucose was added to blood samples.

Summary: Our data indicate that medium term glycemic control and high glucose concentrations affect platelet response to low aspirin concentrations following AA stimulation. Moreover, the fibrinolytic properties of aspirin are lost in diabetes, which appear to be due to both chronic and acute elevation of blood glucose levels. Future work is warranted to investigate the relationship between clinical aspirin treatment failure and medium/short term glycaemia in aspirin-treated individuals with diabetes.

PB 3.21-2

Anti-platelet effect of aspirin in medically treated patients with acute myocardial infarction: Influence of age and gender

Santos MT[1], Valles J[2], Madrid I[3], Bonastre J[3], Moscardo A[2], Ruano M[3], Latorre AM[2] and Santos MT[1]

[1]University Hospital La Fe; [2]Research Center. University Hospital La Fe; [3]Intensive Care Unit. University Hospital La Fe, Valencia, Spain

Background: Aspirin is recommended as a first-front anti-platelet treatment for patients who present with acute myocardial infarction (AMI). The pharmacological target of aspirin in platelets is the inhibition of thromboxane A_2 (TXA_2) synthesis. Data on platelet function testing in medically managed patients with AMI without coronary interventions are scarce in the literature, particularly those testing platelet TXA_2.

Aims: To assess the effect of aspirin on platelet TXA_2 synthesis and platelet reactivity in medically treated patients with AMI and the possible influence of age and gender.

Methods: We studied 220 consecutive medically treated patients with AMI (mean 65 ± 13 years of age, range 31–91; 164 men, 56 women). Of them, 135 patients had electrocardiographic ST-segment elevation (STEMI) and 85 did not (NSTEMI). All patients were treated with aspirin and clopidogrel at the onset of the acute event, and 40% of the STEMI patients received fibrinolytic treatment. The study was approved by the Institutional Review Board of the hospital; all patients gave informed consent. Platelet function testing was performed within 48 h of the onset of the acute event. The tests, performed as described[1], included: collagen-induced TXA_2 synthesis, ^{14}C5HT release and recruitment (proaggregatory activity of the cell-free releasates) in whole blood; light transmission aggregometry (LTA)-induced by arachidonic-acid (AA, 1 mM), collagen (1 μg/mL), ADP (20 μM), U46619 1 μM and TRAP 15 μM and the occlusion times in the PFA-100 system with collagen/epinephrine (CEPI) and collagen/ADP cartridges (CADP). TXA_2 inhibition in individual patients was considered partial if > 3.5 ng/mL (< 95% inhibition compared with that of aspirin-free volunteers)[1].

Results: Partial TXA_2 inhibition was detected in 58/220 (26%) of the patients without differences between STEMI and NSTEMI or the fibrinolytic treatment. Those patients had markedly higher TXA_2 synthesis as compared to the rest of the patients (mean ± SEM 45.1 ± 4.6 vs. 0.23 ± 0.03 ng/mL, $P = 0.000$). This was associated with increased platelet dense granule release, collagen-induced aggregation and recruitment, AA-induced aggregation, and with reduced closure time in the CEPI test (in all instances $P = 0.000$). LTA-induced by ADP, U46619 and TRAP or the CADP test were unchanged. When patients were stratified according to age (< 75 years of age and ≥ 75 years of age) the older patients had 2-fold higher platelet TXA_2 synthesis (18.0 ± 4.1 vs. 9.0 ± 2.0 ng/mL, $P = 0.026$). Comparison of TXA_2 synthesis by gender indicated that men had higher TXA_2 synthesis than women (15.4 ± 2.3 vs. 2.4 ± 1.1 ng/mL, $P = 0.002$).

Conclusions: The effectiveness of aspirin for TXA_2 suppression early at the onset of the acute event is less than optimal in a relevant proportion (26%) of the medically treated patients with AMI. The aspirin effect was lower in patients more than 75 years of age and in male patients. Since this was associated with elevations of other markers of platelet reactivity, patients with partial inhibition of TXA_2 by aspirin may be at higher risk of poor outcome or recurrence.

PB 3.21-3

Low-dose acetylsalicylic acid therapy monitored with ultra high performance liquid chromatography

Rubak P, Hardlei TF, Würtz M, Kristensen SD and Hvas AM
Aarhus University Hospital, Aarhus N, Denmark

Background: Assessment of compliance in patients on low-dose acetylsalicylic acid (ASA) therapy is crucial when evaluating the antiplatelet effect of ASA. Assessment of compliance is however limited to interview, pill counting, witnessed ASA intake, and measurement of thromboxane B_2 levels.
Aims: We validated a new, sensitive ultra high performance liquid chromatography assay for analysing blood levels of ASA and the metabolite salicylic acid (SA) in order to develop a reliable and sensitive method to assess compliance in patients receiving ASA.
Methods: Ten healthy volunteers not taking any drugs containing ASA were included and had blood samples taken prior to and one, six and 24 h after intake of 75 mg ASA. Besides that, 50 ASA-treated patients with stable coronary artery disease were included and blood samples were obtained one and 24 h after intake of 75 mg ASA. Whole blood was collected into chilled Lithium Heparin tubes and plasma was separated by centrifugation at 4 °C and afterwards immediately stored at −80 °C until analysed. Before analysis plasma was mixed with acetonitrile, and 2-methylbenzoic acid was added as internal standard. After filtration, ASA and SA were quantified with ultra high performance liquid chromatography. Separation was accomplished with an isocratic flow of acetonitrile in phosphate buffer pH 2.5, and a Zorbax RRHD C_{18} analyticalcolumn. Detection was achieved with wavelength photodiode array detection set at 237 nm. The study was approved by the Danish Data protection Agency and it was conducted in accordance with the Helsinki II declaration.
Results: The ASA- and SA-assay showed linearity ($r^2 > 0.999$) within the range of 0.2–200 μg/mL, with detection limits in plasma of 170 and 53 ng/mL, respectively. Limits of quantification in plasma were estimated to be 0.2 μg/mL for both ASA and SA. The intra- and inter-day imprecision for ASA and SA were 2.2–5.9%, 3.4–11.7% and 1.8–8.0%, 3.8–9.4%, respectively. Recovery was between 89% and 103% for both assays. More than 60 coadministered drugs were investigated for interference, and only one drug interfered with the ASA-assay whereas none of the coadministered drugs interfered with the SA-assay. ASA was measurable 1 h after intake of 75 mg ASA in most participants (54 of 60), and SA was measurable 1 and 6 h after ASA intake in all participants. No difference in ASA or SA concentrations was found between healthy volunteers and coronary artery disease patients (*P*-values of 0.13 and 0.27, respectively). Inter-individual variance of 31–52% was observed for both ASA and SA after low dose ASA intake.
Conclusion: We developed a new, fast and reliable ultra high performance liquid chromatography assay with a high sensitivity and selectivity, suitable for monitoring compliance in patients treated with low-dose ASA.

PB 3.21-4

Aspirin response: how to explain striking differences in serum TxB2 levels across clinical studies and what use for serum TxB2?

Reny J-L[1], Brun C[1], Frelinger AL[2], Daali Y[3], Zufferey A[1], Michelson A[2], Combescure C[3], Fontana P[1] and Reny J-L[1]
[1]Geneva University Hospital and Geneva Platelet Group, Thonex, Switzerland; [2]Children's Hospital Boston, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; [3]Geneva University Hospital, Geneva, Switzerland

Background: Quantification of serum thromboxane B_2 (TxB_2) is a highly specific assay to assess the biological response of platelets to aspirin. Data on the prognostic value of higher levels of TxB_2, in compliant patients, are conflicting while mean TxB_2 can display up to 10-fold differences in different cohorts
Aims: To identify factors responsible for differences in TxB_2 in two different cohorts of cardiovascular patients originally tested with two different Elisa assays.
Methods: TxB_2 levels in two sets of serum samples ($n = 39$ and $n = 34$) from representative subgroups of aspirin-treated patients from the ADRIE study[a] ($n = 656$) and from the BOSTON study[b] ($n = 562$) were quantified with both of the original assay (GE and RD Elisas) and also with liquid chromatography and tandem mass spectroscopy (MS) as the gold standard. The concordance between the two assays and with the MS was evaluated. Variables known to affect TxB_2 were compared between both population subgroups and further included in a multiple linear regression model. TxB_2 was log-transformed for linear regressions
Results: The median TxB_2 in the entire ADRIE and BOSTON study populations were respectively 7 ng/mL (IQR 3–12) and 0.6 ng/mL (IQR 0.2–1.4) as originally tested with a GE and RD Elisa assays respectively. This difference persisted in the selected subgroups for MS-TxB_2: medians were 6.1 ng/mL (IQR 2.4–16) and 0.6 ng/mL (IQR 0.2–1.2) in the ADRIE and BOSTON subgroups, respectively ($P < 0.0001$). Concordance between the GE and RD assays was poor raising the possibility of assay bias. Several clinical factors with a potential impact on MS-TxB_2 were unbalanced in the two cohorts (aspirin dose, diabetes, gender, statin use, hypercholesterolemia, clopidogrel use, SSRI use, CRP, BMI, all with $P < 0.05$) but some of these variables were tightly linked to the study (eg aspirin dose was 81 or 325 mg in BOSTON and 100 mg in ADRIE) precluding a proper regression model on pooled data from both subgroups. Multiple regression performed independently in each subgroups showed that between 27% and 59% (R^2) of the variance of Log (MS-TxB_2) could be explained by variables such as BMI, diabetes, statin, acute coronary syndrome at inclusion. Complementary analyses on the whole cohorts (1218 TxB_2 samples) will help derive a proper model to assess the respective contribution of the different factors to the difference in TxB_2 levels between the two cohorts.
Conclusions: Differences in serumTxB_2 levels in different cohorts of aspirin-treated cardiovascular patient are important and. The differences may not only be explained by a potential bias between Elisa assays but rather by differences in individual factors. In view of such differences and in the absence of clinical trials, relying on serum TxB_2 levels to adjust the antiplatelet regimen is discouraged.

PB 3.21-5

Aspirin efficacy is reduced following off-pump coronary bypass operation

Würtz M, Modrau IS, Kristensen SD and Hvas AM
Aarhus University Hospital, Aarhus, Denmark

Background: Aspirin is widely used to preserve graft patency and prevent thromboembolic complications including graft closure following coronary artery bypass surgery. Conventional 'on-pump' bypass surgery transiently reduces the *in vitro* antiplatelet effect of aspirin, but it is unclear whether this is true for modern 'off-pump' bypass surgery performed through a minimally invasive J-hemisternotomy. If so, this may be explained by a postoperative increase in platelet turnover or thrombopoietin production.

Aims: To investigate if minimally invasive off-pump bypass surgery reduces the effect of aspirin and, if so, to identify potential explanatory mechanisms related to platelet turnover and platelet production.
Methods: We performed a prospective non-interventional single-center study including 41 aspirin-treated patients undergoing off-pump bypass surgery. Blood samples were obtained 8–10 days before surgery during aspirin 75 mg maintenance treatment and at first postoperative day (8 a.m.) following an aspirin bolus of 300 mg. The effect of aspirin was evaluated by VerifyNow® Aspirin and Multiplate® Analyzer (agonist: arachidonic acid 1.0 mM). The immature platelet fraction was used as a marker of platelet turnover. Thrombopoietin was measured by ELISA to reflect the regulation of platelet production. Serum thromboxane B_2 was measured with ELISA and used to confirm compliance with aspirin.
Results: All patients were compliant with aspirin according to serum thromboxane B_2 levels (all below 13.7 ng/mL). Postoperative platelet aggregation was significantly higher than preoperative platelet aggregation according to VerifyNow® Aspirin ($P = 0.002$), but not to Multiplate® Analyzer ($P = 0.19$). Platelet turnover was increased postoperatively as indicated by an increased immature platelet fraction ($P = 0.03$). Thrombopoietin levels were also significantly increased postoperatively ($P < 0.0001$), whereas platelet count was significantly reduced ($P < 0.0001$).
Summary/Conclusions: Off-pump bypass surgery reduces the antiplatelet effect of aspirin according to VerifyNow® Aspirin. This finding may reflect that the operation, although much less invasive than conventional bypass surgery, triggers an increased platelet turnover and an up-regulation of platelet production. Using the Multiplate® Analyzer showed no difference between pre- and postoperative platelet aggregation, which is likely explained by the considerable perioperative reduction in platelet count.

PB 3.21-6

Association between the GPIIIa gene polymorphism and the response to acetylsalicylic acid in patients with type 2 diabetes mellitus

Duarte RCF[1], Gonçalves LH[2], Alves MT[1], Fernandes AP[1], Gomes KB[1], Dusse LMS[1], Bosco A[3] and Carvalho MG[1]
[1]Federal University of Minas Gerais; [2]Rede Sarah de Hospitais; [3]Santa Casa Hospital, Belo Horizonte, Brazil

Background: Type 2 diabetes mellitus (DM2) is a metabolic disorder associated with cardiovascular complications and hyperactivation of platelets. Acetylsalicylic acid (ASA) is an antiplatelet agent used in the prevention of atherothrombotic events by inhibition of platelet cyclooxygenase-1, thus blocking the formation of thromboxane A_2. The effect of ASA can be determined by the plasma levels of 2,3-dinor-thromboxane B_2 (2.3-dinor-TXB_2). The β3 subunit (GPIIIa) of the platelet glycoprotein GPIIb/IIIa can present a polymorphism at position 33 which consists in a replacement of a leucine (PI^{A1}) by a proline (PI^{A2}) resulting from a single nucleotide transition in the GPIIIa gene (C^{155} à T). Previous studies reported that this polymorphism is associated with increased platelet aggregation and may contribute to ASA resistance. However, this association is still controversial.
Aim: To investigate the association between 2.3-dinor-TXB_2 plasma levels and GPIIIa gene polymorphism in patients with DM2 using ASA for primary prevention of atherothrombotic events.
Methods: Blood samples from 65 patients with DM2 were collected in two distinct moments, the first immediately prior to initiation of treatment with ASA and the second, at the fifteenth day of treatment with 100 mg of this medication daily. Patients with DM2 were selected in the Santa Casa Hospital, Belo Horizonte, Brazil. These samples were analyzed to determine plasma levels of 2.3-dinor-TXB_2. Furthermore, the GPIIb/IIIa (PI^A) gene polymorphism was studied using a polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) technique. Statistical analysis was performed using Pearson Chi-Square test and was considered statistically significant when $P < 0.05$.
Results: During treatment with ASA, 29 patients (44.6%) had a higher or equal to 75% reduction in the 2.3-dinor-TXB_2 levels. The PI^{A2} allele of GPIIIa gene was found in 25.9% of the participants (23.5% heterozygous and 2.5% homozygous). It was observed that the PI^{A2} allele of GPIIIa gene was present in higher frequency in patients who had a reduction of 2.3-dinor-TXB_2 higher or equal to 75% ($P = 0.032$).
Conclusions: These results suggest that the presence of PI^{A2} allele in GPIIIa gene may be associated with a better response to ASA intake in patients with DM2.

PB3.22 – Platelets: Point-of-Care Tests

PB 3.22-1

A 96 well plate-based whole blood assay assessing multiple platelet activation pathways appears promising in the evaluation of antiplatelet therapy

Dovlatova N[1], Algahtani M[1], Lordkipanidzé M[2], May J[1], Watson SP[2] and Fox SC[1]
[1]University of Nottingham, Nottingham; [2]University of Birmingham, Birmingham, UK

Background: Platelet function testing to assess the efficacy of antiplatelet drugs is increasingly being used. A variety of assays have been developed; however few offer the advantage of assessing multiple platelet activation pathways simultaneously. Recently, adaptations based on 96 well plate formats have attracted attention as they require significantly smaller volumes of blood and can provide extensive concentration-response ranges to multiple platelet agonists. We have developed a 96-well plate-based assay carried out in whole blood, where flow cytometry is used to assess the decrease in single platelets as a measure of platelet aggregate formation.
Aims: To investigate the sensitivity of the 96-well plate-based whole blood assay to platelet inhibition by aspirin and cangrelor, a P2Y12 receptor inhibitor.
Methods: Platelet function was assessed in whole blood obtained from healthy volunteers, using 96 well plates coated with 4 μL of the following agonists: arachidonic acid (AA, 0.03–1 mM), ADP (0.3–30 μM), collagen (0.1–10 μg/mL) and TRAP (0.1–10 μM), or vehicle. Whole blood was incubated with aspirin 10–100 μM, cangrelor 1–1000 nM or vehicle. Forty-six microlitre of whole blood was added to each well and the plate was shaken for 5 min at 1000 rpm at 37 °C; a fixative solution (Platelet Solutions, Nottingham) was applied to stop platelet aggregation and stabilize samples for up to 9 days and allow analysis in a central laboratory where samples were labeled with FITC-conjugated CD42a and assessed by flow cytometry. Aggregation was calculated as (Platelet count in vehicle-treated sample – Platelet count in agonist-stimulated sample)/Platelet count in vehicle-treated sample × 100.
Results: In 20 healthy volunteers, aggregation assessed in duplicate was robust and reproducible (CV < 10%). As expected, cangrelor induced a profound inhibition of ADP-induced aggregation. Aspirin dose-dependently inhibited platelet responses to AA; however, a significant drop in single platelet count was seen at the highest AA concentration (1 mM) indicating full aggregation. Addition of cangrelor 1 μM to these samples prevented the drop in platelet count, suggesting that ADP is responsible for the aggregation seen with AA 1 mM in the presence of aspirin. One possible explanation for the appearance of ADP could be some degree of red cells lysis caused by high AA concentration as previously reported in the literature. Collagen- and TRAP-induced aggregation were also impaired to a different extent by *in vitro* treatment with either antiplatelet agent, and resulted in a right shift of dose-response curves.

Conclusions: The present optimization study has shown that a 96-well plate-based whole blood aggregation assay could be used to assess platelet function and the effect of commonly used antiplatelet agents. However, AA at concentrations > 0.5 mM should be used with caution in whole blood to assess the effect of COX inhibition as the latter could be underestimated potentially due to the effect of ADP. Further work to explain this observation and evaluate the utility of the assay to detect platelet inhibition in patients requiring antiplatelet therapy is warranted.

PB 3.22-2

A simple colorimetric assay provides a novel platelet activation endpoint and distinguishes between responses to different physiological agonists

Prechel M, Escalante V, Lohmeier J and Walenga JM

Loyola University Medical Center, Maywood, IL, USA

Background: Our laboratory has demonstrated that a relatively simple dye reduction assay is comparable to the complex ^{14}C-serotonin release assay (SRA) in detecting Fc-receptor mediated platelet activation by antibodies diagnostic for heparin-induced thrombocytopenia (HIT) (Platelets 23:69,2012). The aim of these experiments was to investigate this novel activation assay using other platelet agonists. Previous literature has suggested that immune stimulation of platelets results in a higher degree of activation than other physiological agonists (Platelets 10:319,1999) and that strong platelet activation leads to apoptosis (Blood Rev 26:51,2012).

Methods: This study evaluated platelet responses to hemostatic agonists, a pro-apoptotic stimulus and platelet-activating antibodies, using the colorimetric assay in comparison to traditional platelet activation endpoints. Platelet activation by thrombin and/or collagen was compared to immune-mediated stimulation with HIT antibody plus 0.1 U/mL heparin or a commercial monoclonal antibody to CD9, and to the apoptotic agent, ABT737. The non-physiologic calcium ionophore, A23187, was included as a control. Washed donor platelets were incubated with agonists or antibodies on a rotary shaker (600 rpm) for 15–30 min prior to assessment of activation. Platelet activation endpoints included dense granule release, monitored using platelets pre-incubated with radio-labeled serotonin, platelet aggregation detected spectrophotometrically, and depletion of mitochondrial membrane potential assessed by flow cytometry using fluorescent dye (JC-1). For colorimetric assay, platelets were incubated 60 min with CellTiter 96 Aqueous One Reagent (Promega, Madison WI) at 37 °C and dye reduction measured as optical density at 490 nm (OD). With this dye, moderate platelet activation results in an increased OD, while a highly activated state results in lack of ability of platelets to metabolize the dye to its dark product, reflected by a low OD reading.

Results: Both hemostatic and immune activators caused maximal platelet aggregation and serotonin release. However, antibody-mediated platelet activation resulted in an extreme loss of metabolic potential matched only by A23187, while platelets activated by high doses of thrombin and/or collagen retained significant metabolic capacity. The colorimetric assay paralleled the loss of mitochondrial membrane potential evaluated by JC-1 uptake dye. Surprisingly both thrombin-activated and HIT antibody-activated platelets showed loss of mitochondrial membrane potential, yet only the immune-activated platelets lost dye reduction capacity. Stimulation of platelet apoptosis by ABT737 did not result in platelet aggregation, and caused increased metabolic activity as detected by increased dye reduction. In contrast platelet-activating antibodies and A23187 caused maximal aggregation and a rapid loss of metabolic activity.

Conclusion: The results of this study demonstrate that while many features indicative of apoptosis are also characteristic of highly activated platelets, the metabolic pathway to these endpoints differs. The colorimetric assay is rapid and relatively inexpensive and allows a range of doses of multiple agonists to be evaluated simultaneously in a microtiter format. The precise mechanism that is reflected in the colorimetric response will require further study. In the interim, this method may be used empirically to provide a finer distinction in the level of platelet activation compared to current methods.

PB 3.22-3

Development of a novel high throughput 96 well plate-based whole blood assay for investigation of platelet function in healthy volunteers and patients with clinically diagnosed bleeding disorders

Lordkipanidze M[1], Dovlatova N[2], Lowe GC[3], Watson SP[3] and Fox SC[2]

[1]University of Birmingham, Birmingham; [2]University of Nottingham, Nottingham; [3]Birmingham Platelet Group, Birmingham, UK

Background: The current gold standard in platelet function testing, light transmission aggregometry (LTA), is time- and labor-intensive, and uses platelet-rich plasma (PRP) which makes it sub-optimal for high throughput testing. We have previously investigated the utility of a 96-well plate aggregation assay (*Optimul*) in assessing platelet function with promising results (presented at the SSC2012-HDC04). However, this method still relied on PRP preparation. In order to reduce blood manipulation prior to platelet function testing and to study multiple platelet activation pathways simultaneously, we have developed a 96-well plate-based assay carried out in whole blood, where aggregation is measured as a decrease in the number of single platelets – a method we previously described (Fox et al. *Platelets* 2004; 15:85–93).

Aims: To investigate whether a 96-well plate-based whole blood assay can be used to assess platelet function.

Methods: Healthy volunteers (n = 20) and participants with clinically diagnosed excessive bleeding (n = 15) were recruited to the Genotyping and Phenotyping of Platelets study (GAPP, ISRCTN 77951167) from October 2012 to January 2013. This study was approved by the National Research Ethics Service Committee and all participants gave written informed consent. Platelet function testing was carried out by LTA, used as a reference method, and in whole blood using 96 well plates coated with 4 μL of the following agonists: arachidonic acid (0.03–1 mM), ADP (0.3–30 μM), collagen (0.1–10 μg/mL) and TRAP (0.1–10 μM), or vehicle. After addition of 46 μL of whole blood, the plate was shaken for 5 min at 1000 rpm at 37 °C; a fixative solution (Platelet Solutions, Nottingham) was applied to stop platelet aggregation and allow analysis in a central laboratory. Fixed whole blood samples were labeled with FITC-conjugated CD42a and assessed by flow cytometry. Aggregation was calculated as (Platelet count in vehicle-treated sample – Platelet count in agonist-stimulated sample)/Platelet count in vehicle-treated sample x 100.

Results: Normal ranges of platelet aggregation response on the 96-well plate were determined based on the results obtained from 20 healthy volunteers. Intra-individual variability was minimal (CV < 10%). Dose-response curves were readily assessable for all agonists tested. In patients with bleeding symptoms both assays agreed on diagnosis in 80% of cases (κ = 0.587, P = 0.013). However, while 7 (47%) participants had a platelet defect according to LTA, the 96 well plate assay found a defect in 4 (27%). Discrepancies were seen in mild Gi-type defects and possible partial COX defects which were diagnosed due to kinetic information available with LTA, and were missed with the whole blood endpoint assay.

Summary/Conclusions: Evaluation of the 96 well plate-based whole blood aggregation assay suggests it might be useful for investigation of platelet function, especially in individuals where blood sample volume is limited, such as children or those requiring multiple other blood tests. Additional developments of the assay to look at the expression of platelet activation markers in addition to single platelet counting are underway. Further investigation to determine the clinical utility of the assay in detecting acquired and inherited defects in platelet function is warranted.

PB 3.22-4

Point-of-care platelet testing accurately displays platelet dysfunction in chronic renal insufficiency, but fails to predict bleeding after kidney biopsy

Kuiper JAJM, Houben R, Verhezen WM, Lancé MD, Christiaans MHL, Ten Cate H and Henskens YMC
Maastricht UMC+, Maastricht, The Netherlands

Background: The risk of major complications in kidney biopsies is low with only minor bleeding complications in 24% of the cases. Low platelet count, low hematocrit, and high uremia are found to contribute to this bleeding risk in renal failure patients. Ivy bleeding time (IBT) is under debate whether it adequately predicts this bleeding risk.
Aims: We assessed if Multiplate (MEA) and/or PFA-100 (PFA) could predict bleeding complications after kidney biopsy in renal patients more accurately than the IBT. Low platelet count and low hematocrit in MEA and PFA testing, however, produce false positive results. Therefore, a full range of reference intervals was calculated by measuring healthy volunteer blood under *in vitro* lowered conditions.
Methods: Venous blood was drawn from healthy volunteers, diluted by replacing platelet rich plasma with platelet free plasma and hereafter resuspended to obtain platelet counts of around 20, 50, 100, and 150×10^9/L (PLTlow). In order to lower hematocrit (HTlow) to around 0.25, 0.30, 0.35, 0.40, and 0.45 L/L, red blood cells were replaced by platelet free plasma and resuspended. Platelet function was assessed with MEA (agonists: TRAP, ADP, COL, and ASPI) in hirudin anticoagulated blood and PFA-100 (cartridges: COL/ADP and COL/EPI) in citrate anti-coagulated blood according to the manufacturers protocols. Using Graphpad Prism V5.0a non-linear 95% prediction bands were calculated as reference intervals for the full range of results.
Renal patients for kidney biopsy were analyzed pre-biopsy with Ivy bleeding time, PFA-100, Multiplate, complete blood count, renal function parameters, and post-procedure hemoglobin. Bland-Altman plots were calculated for IBT vs. PFA tests.
Results: Using 20 healthy volunteers per condition (MEA/PLTlow, MEA/HTlow, PFA/PLTlow, PFA/HTlow) 95% prediction bands could be calculated. MEA showed lower area under the curve (AUC) for lower platelet counts, while AUC remained equal for lower hematocrit for all agonists. In PFA both lower platelet counts and lower hematocrit gradually prolonged the closure time for both cartridges.
In total 142 patients were included. With PFA 5 (3.5%) and 6 (4.2%) patients showed prolonged results for COL/EPI and COL/ADP respectively, all others were normal in comparison to healthy volunteers. For MEA low AUC was seen in 13 (9.2%), 4 (2.8%), 33 (23.2%) and 11 (7.7%) patients for TRAP, ADP, COL, and ASPI, respectively. IBT prolongation over 4 min was seen in 7 (4.9%) patients.
Bland-Altman analysis showed for IBT vs. COL/ADP a sloping trend (bias: 38 s; SD 52) and for IBT vs. COL/EPI a widening trend (bias: 11 s; SD 58).
Median hemoglobin drop after kidney biopsy was 0.4 mM (IQR: 0.2–0.6). No transfusions were needed in any of the patients. After correcting for uremia and/or serum creatinine levels hemoglobin drop after biopsy could not be predicted with IBT, MEA, or PFA.
Conclusion: Using diluted healthy volunteer blood non-linear reference intervals were calculated for low platelet counts and hematocrit levels for Multiplate and PFA-100 tests. Although a portion of renal patients show lower Multiplate and/or prolonged PFA-100 response, none of these tests together with Ivy bleeding time could predict a significant hemoglobin drop after kidney biopsy.

PB 3.22-5

Platelet aggregation in whole blood by multiplate system is a rapid and suitable assay to evaluate platelet function in stored blood for transfusion therapy

Tartari CJ[1], Marchetti M[1], Russo L[1], Vignoli A[1], Diani E[1], Verzeroli C[1], Gargantini C[1], Coffetti N[2], Rosti A[3] and Falanga A[1]
[1]Hospital Papa Giovanni XXIII, Bergamo; [2]Bolognini Hospital, Seriate (BG); [3]Treviglio-Caravaggio Hospital, Treviglio (BG), Italy

Background: Multiplate analyzer represents a quantitative, easy-to-use, point-of-care device with minimal technical variables. This method has been standardized for analysis of whole blood samples collected in Na-citrate or Hirudin as anticoagulants, but not for blood samples anticoagulated with citrate-phosphate-dextrose (CPD) as in blood bags from healthy donors.
Aims: The present study evaluates for the first time the applicability of Multiplate device to assess platelet aggregation in whole blood samples derived from donation bags. The influence of the ABO blood group, age, and two-day storage (at 4 °C) on the platelet aggregation is also analyzed.
Methods: Whole blood samples (300 μL) were obtained from 259 donation bags collected in CPD (242 Male/17 Female). As a comparator blood samples in Na-citrate 0.105M (9 vol.: 1 vol.) were obtained from 40 healthy control subjects (20M/20F). Platelet aggregation was assessed by Multiplate (Roche) after stimulation with ADP (6.4 μM), collagen (COLL, 3.2 μg/mL), thrombin-receptor-activating-peptide (TRAP-6, 32 μM), and arachidonic acid (AA, 0.5 mM). Pre-assay expression of platelet surface CD62P was assessed by cytofluorimetric analysis (FACS Canto, Becton Dickinson).
Results: CPD samples showed lower ($P < 0.05$) aggregation values compared to the Na-citrate samples in response to the different agonists. Specifically, in CPD samples, platelet aggregation induced by ADP and TRAP-6 was higher ($P < 0.05$) than that induced by COL or AA. Furthermore, platelet aggregation induced by ADP and COLL was significantly higher ($P < 0.01$) in the O phenotype compared to both the A and B phenotypes. No significant correlations were found between the aggregometry results and the CD62P expression or the donor age. Platelet aggregation evaluated in a subgroup of 20 blood bags stored for 2 days at 4 °C showed a significant ($P < 0.05$) reduction in platelet aggregation capacity induced by ADP, COLL and TRAP-6 as compared to fresh bags.
Summary/Conclusions: The aggregation response of CPD blood samples by Multiplate analysis, although significantly lower compared to Na-citrate samples, is retained and can be quantified after stimulation by all different agonists. An influence of the ABO phenotype on aggregation can also be detected. Therefore, the Multiplate assay can be a valid tool to monitor platelet function in blood stored for transfusion therapy.

PB 3.22-6

Optimizing whole blood impedance aggregometry in severe thrombocytopenia

Skipper MT, Rubak P, Stentoft J, Hvas AM and Larsen OH
Aarhus University Hospital, Aarhus, Denmark

Background: Information on platelet function in thrombocytopenic patients could be of high value in order to predict the risk of bleeding episodes. However, evaluation of platelet function by impedance aggregometry is currently not possible in patients with thrombocytopenia.
Aim: This study aimed to investigate a novel approach for evaluating platelet aggregation in severe thrombocytopenia, using whole blood impedance aggregometry seeking to adjust for the platelet count and optimize the amount of applied agonist.

Methods: Following informed consent, citrated whole blood was obtained from 12 healthy volunteers, seven cancer patient with chemotherapy induced thrombocytopenia, and 12 patients with primary immune thrombocytopenia (ITP). Thrombocytopenia was induced in the healthy whole blood employing a previously validated method. Platelet aggregation was evaluated by whole blood impedance aggregometry (Multiplate®), and expressed as area under the curve (AUC).
Results: Following titration experiments a final concentration of collagen 8 μg/mL was applied as agonist providing the strongest aggregation response in thrombocytopenia. Platelet counts in the range of 10–39 × 10^9/L was obtained in whole blood from healthy volunteers. In this range, linear regression analysis displayed a strong positive correlation between platelet count and platelet aggregation ($R^2 = 0.84$) in whole blood from healthy volunteers. The prediction equation of normal platelet aggregation in thrombocytopenia was: $y = 19.9x-145$ (y = platelet aggregation (AUC), x = platelet count). The platelet aggregation response was then indexed relatively to the prediction estimate of normal platelet aggregation. The obtained platelet aggregation index was 106% (64–130) [median (interquartile range)] in thrombocytopenia modelled from healthy whole blood, 10% (7–13) in cancer patients and 170% (158–188) in ITP patients. The difference in aggregation index observed between ITP and cancer patients was highly significant ($P = 0.002$; Mann–Whitney U-test). Aggregation in ITP patients was significantly increased ($P < 0.001$) whereas aggregation in cancer patients was significantly reduced ($P < 0.001$) when compared to the platelets from healthy volunteers.
Conclusion: The findings suggest that whole blood impedance aggregometry can be optimized to detect differences in platelet function even at very low platelet counts. This may provide valuable information for prediction of bleeding risk in thrombocytopenic patients.

PB3.23 – Platelet Inhibition

PB 3.23-1
Prednisolone inhibits platelet function through targeting of the RhoA/ROCK signalling pathway

Naseem KM[1], Banerjee S[1] and Perretti M[2]
[1]*University of Hull, Hull;* [2]*Queen Mary College, University of London, London, UK*

Background: The synthetic glucocorticoid prednisolone is widely used as an anti-inflammatory, and immunosuppressive drug. Platelets are pivotal in regulating haemostasis, but can precipitate atherothrombosis associated to cardiovascular diseases. Previously, we have shown that prednisolone inhibits platelet aggregation and adhesion under conditions of flow, although the mechanisms have remained unclear.
Aims: In the present study examined the mechanisms responsible for the inhibitory effects of prednisolone, with a particular emphasis on RhoA/RhoA kinase signalling.
Methods: Washed Platelets (WP) treated with prednisolone prior to stimulation with thrombin. Platelet function was examined using light-transmission aggregometry, signalling mechanisms were studied using Western blotting and Rho A activity was detailed using a pull-down assay.
Results: Prednisolone caused concentration-dependent inhibition of thrombin-induced platelet aggregation. Threshold inhibitory responses were observed at 0.01 μM, while maximal effects were observed with 10 μM where thrombin (0.02 U/mL) induced aggregation was reduced from 56 ± 8% to 12 ± 7% ($P < 0.05$). The inhibition of aggregation by prednisolone was reversible, suggesting that this was a non-toxic effect. Thrombin caused 58 ± 8% aggregation but after 5 min incubation with pred this was reduced to 23 ± 11% ($P < 0.05$), but had returned to 61 ± 8% after 15 min. In order to understand the molecular mechanism underpinning these inhibitory effects we examined RhoA/ROCK pathway. Stimulation of platelets with thrombin led to the RhoA/RhoA kinase (ROCK) dependent phosphorylation of myosin light chain (MLC). Pretreatment of platelets with pred caused a concentration-dependent inhibition of phosphorylation of MLC-ser19. The inhibition was transient lasting for up to 5 min before returning to the level of phosphorylation found with thrombin alone. Consistent this observation, prednisolone also prevented the inhibitory phosphorylation of myosin light chain phosphatase (MLCP) at two key residues thr696 and thr853 in its MYPT1 subunit, suggesting that pred inhabits RhoA/ROCK signalling in platelets. In all cases the effects of pred were inhibited by the glucocorticoid receptor antagonist, RU486.
Conclusions: Prednisolone inhibits platelet activation by targeting RhoA/ROCK signalling events following thrombin stimulation. Modulation of the RhoA activity represents on of the no-genomic effects of this synthetic glucocorticoid on platelets.

PB 3.23-2
Natriuretic peptides and platelets: evidence of a localised cGMP synthesis

Borgognone A, Lowe K, Watson SP and Madhani M
University of Birmingham, Birmingham, UK

Background: Cyclic guanosine-3′,5′-monophoshate (cGMP) is the common second messenger for the cardiovascular effects of nitric oxide (NO) and natriuretic peptides (NPs), which activate soluble and particulate guanylyl cyclases (sGC and pGC), respectively. pGC activity is carried by two membrane receptors for NPs, NPR-A and NPR-B. A third receptor, NPR-C lacks the cyclase domain and acts as a clearance receptor although it has been shown to have some signalling activity. In platelets the role of NO in regulating cGMP concentration and the consequent inhibitory effects is well established. On the contrary, contrasting data have been reported in the past supporting a role for NPs in the regulation of platelet function.
Aims: To investigate the effects of atrial natriuretic peptide (ANP), B-type natriuretic peptide (BNP), C-type natriuretic peptide (CNP) and the NPR-C agonist $cANF^{4-23}$ on platelet function.
Methods: We used platelet aggregation and dense granule secretion to evaluate the effects of NPs on platelet responses involved in haemostasis. PAR-1 peptide, collagen and ADP were used as agonists. Phosphorylation of the cyclic nucleotide-dependent protein kinase A (PKA) and G (PKG) substrate vasodilator-stimulated phosphoprotein (VASP) was studied as a readout of the kinase activation. Experiments were performed in the absence or presence of the non-selective cGMP and cAMP phosphodiesterase (PDE) inhibitor, 3-isobutyl-1-methylanxthine (IBMX).
Results: None of the NPs used in this work, even at high micromolar concentration, affected platelet aggregation or dense granule secretion in response to PAR-1 peptide, collagen and ADP either on their own or in the presence of a low concentration of IBMX. On the other hand, VASP phosphorylation at Serine 239 (mainly PKG substrate), was increased by concomitant treatment with NPs or $cANF^{4-23}$ and IBMX compared to IBMX on its own, thus indicating a small localised PKG activation. On the contrary, platelet aggregation, dense granule secretion and VASP phosphorylation at Serine 157, mainly dependent on PKA, measured under the same conditions, were not affected.
Summary/Conclusions: We conclude that treatment with NPs in platelets is able to trigger PKG activation, but that the magnitude of activation *per se* is not sufficient to exert functional inhibition of platelet involvement in haemostasis. However we cannot exclude that it would affect other platelet responses. The increase in VASP phosphorylation obtained following treatment with $cANF^{4-23}$ and IBMX suggests that the effects on PKG activation may be dependent on the NP clearance receptor (NPR-C) expressed on platelet membranes, through a not yet identified mechanism.

PB 3.23-3

Decreased phosphorylation of the linker for activated T-cells (LAT) is associated with impaired collagen activation of neonatal platelets

Israels SJ, McMillan-Ward E and McNicol A
University of Manitoba, Winnipeg, MB, Canada

Background: Collagen is an important early activator of platelets under physiological conditions. Cross-linking of glycoprotein (GP) VI by collagen leads to the Fyn/Lyn-mediated phosphorylation of an ITAM motif on the Fcγ receptor, and sequential phosphorylation of downstream targets, including the transmembrane protein LAT. These serve as the platform for the formation of a membrane raft-based signalosome that includes phospholipase Cγ2 (PLCγ2), the activation of which mediates intracellular calcium mobilization and full platelet activation. Platelets from newborn infants demonstrate impaired function, although platelet number and ultrastructure do not differ from those of older individuals. Umbilical cord blood platelets show impaired *in vitro* responses to collagen stimulation, including decreased PLCγ2 activation, calcium mobilization, granule secretion and aggregation.
Aim: To determine whether deficient collagen activation in neonatal platelets results from decreased GPVI-coupled signaling.
Methods: Cord blood was collected by umbilical venipuncture from uncomplicated term deliveries (gestational age ≥ 37 weeks, $n = 10$), and blood was drawn by venipuncture from healthy adult volunteers ($n = 10$) into citrate/citric acid/dextrose anticoagulant. Washed platelet suspensions were prepared, lysed and separated by SDS-PAGE before immunoblotting with commercial monoclonal antibodies to GPVI and GPIbα. Resting and collagen-stimulated (2 μg/mL and 10 μg/mL) cord blood and adult control platelets were lysed and immunoblotted with polyclonal anti-LAT and anti-phospho-LAT. Membrane rafts were separated from platelet lysates by sucrose density-gradient centrifugation; fractions from the gradient were separated by SDS-PAGE, followed by immunoblotting with anti-LAT antibody. Immunoblot band intensities were quantitated by scanning densitometry.
Results: The maximum aggregation of cord blood platelets was significantly less than the maximum aggregation of adult control platelets in response to collagen 10 μg/mL (31 ± 6% vs. 63 ± 8%, $P \leq 0.01$), and 2 μg/mL (9 ± 4% vs. 46 ± 12%, $P \leq 0.01$). GPVI immunoblots of whole platelet lysates did not show significant differences in mean band intensities in neonatal platelets compared to adult platelets (1944 ± 145 vs. 1961 ± 480 intensity units, n.s.). The distribution of LAT in the low-density membrane (lipid raft) fractions of the sucrose gradient was the same in adult and cord blood platelets. This distribution was not altered by collagen-stimulation. Comparison of the mean band intensities of LAT in immunoblots of platelet lysates showed no difference between cord blood and adult platelets (1218 ± 290 vs. 1428 ± 114 intensity units, n.s.). Following stimulation with 10 μg/mL collagen there was significantly less phospho-LAT in cord blood platelets than in the adult control platelets (522 ± 285 vs. 1173 ± 283 intensity units, $P < 0.05$); the ratio of phospho-LAT to total LAT was 0.82 in collagen-stimulated adult platelets, and 0.42 in collagen-stimulated cord blood platelets.
Summary/Conclusion: Comparing cord blood and adult control platelets, no difference was detected in in the level of GPVI, or in the quantity or distribution of LAT in membrane rafts. However, collagen-stimulated phosphorylation of LAT was significantly decreased in cord blood platelets, and was associated with decreased downstream platelet activation. Examination of events upstream of LAT in the GPVI signaling pathway, including Fcγ receptor ITAM phosphorylation and activation of Syk may identify the basis for the impaired collagen response in neonatal platelets.

PB 3.23-4

Tangeretin regulates platelet function through dual inhibition of phosphoinositide 3-kinase and cyclic nucleotide signalling

Vaiyapuri S, Ali MS, Moraes LA, Sage T, Jones CI and Gibbins JM
University of Reading, Reading, UK

***Background*:** The relationship between diet and risk factors for cardiovascular diseases has long been appreciated. Indeed, several epidemiological studies have suggested that the regular intake of dietary flavonoids reduce the risk for cardiovascular diseases. But the mechanisms of action of these dietary flavonoids in reducing cardiovascular risks are poorly understood. Tangeretin, a flavonoid abundant in the peels of citrus fruits has been demonstrated to have several beneficial effects in human health.
***Aims*:** This study was performed to determine whether tangeretin is able to modulate the function of platelets and to characterise mechanisms of its actions.
***Methods*:** The effects of tangeretin at a range of concentrations on the function of platelets were tested through measurement of platelet aggregation, fibrinogen binding, calcium mobilisation and granule secretion upon stimulation with agonists. Tangeretin was also tested for its ability to modulate human plasma clot retraction and haemostasis in mice using tail bleeding assay. The effect of tangeretin on *in vitro* thrombus formation was analysed under arterial flow conditions perfusing human whole blood over collagen-coated Vena8 biochips. To explore the mechanism of action of tangeretin on platelet function, the phosphorylation of proteins involved in GPVI, PI3K and cyclic nucleotide mediated signalling pathways was analysed in the presence and absence of tangeretin.
***Results*:** Tangeretin inhibited agonist-induced human platelet activation in a concentration-dependent manner. It inhibited integrin αIIbβ3 mediated inside-out signalling, intracellular calcium mobilisation and granule secretion. Inclusion of tangeretin reduced the plasma clot retraction indicating reduced integrin αIIbβ3-mediated outside-in signalling. Tangeretin also inhibited human platelet adhesion and subsequent thrombus formation on collagen-coated surfaces under arterial flow conditions *in vitro* and reduced haemostasis in mice. The characterisation of potential mechanisms by which tangeretin inhibits platelet function revealed dual inhibitory targets in platelets. Tangeretin was found to inhibit phosphoinositide 3-kinase (PI3K) mediated signalling and increase the phosphorylation of VASP at S239, consistent with elevated cyclic nucleotide signalling.
Conclusions: This study provides support for the ability of dietary flavonoids, particularly tangeretin, to modulate platelet signalling and function, which may impact on the risk of thrombotic disease.

PB 3.23-5

Targeting of type 1 protein kinase A to lipid rafts is required for competent platelet inhibition by the cAMP-signaling pathway

Naseem KM[1], Raslan Z[1], Aburima A[1], Magwenzi S[1] and Tasken K[2]
[1]*University of Hull, Hull, UK;* [2]*University of Oslo, Oslo, Norway*

Background: Cyclic adenosine monophosphate (cAMP)-dependent signalling modulates platelet function at sites of vascular injury. The foremost effector of cAMP signalling in platelets is protein kinase A (PKA), which acts by phosphorylating numerous platelet proteins. In platelets two PKA isoforms are present, type I (PKAI) and type II (PKAII). In other cell types, PKA isoforms are specifically targeted to distinct subcellular compartments by a family of proteins called A-Kinase Anchoring proteins or AKAPs allowing them to mediate non-redundant biological effects.
Aim: To determine the role of AKAPs in platelet inhibition by cAMP signalling.

Methods and results: Under basal conditions we observed a pool of PKAI, but not PKAII, was specifically localised into platelet lipid rafts. To establish the mechanism that facilitated localisation of PKAI we used an established cell-permeable peptide inhibitors of PKAI/A-kinase anchoring protein (AKAP) interactions called RI anchoring disruptor (RIAD-Arg_{11}). Inhibition of PKAI-AKAP interactions displaced PKAI from lipid rafts with resultant loss of PKA activity in these microdomains. Using Far-Western blotting and PKA pull-down assay followed by mass-spectrometry we established that the cytoskeletal protein moesin acted as an AKAP that bound PKAI and localised the pool of PKAI to platelet lipid rafts.

To clarify the importance of the localization of PKAI to lipid rafts we examined platelet activity. PGI_2 inhibited platelet aggregation by vWF and platelet accrual on immobilised vWF under flow. Disruption of PKAI-AKAP interactions with RIAD-Arg_{11} reduced platelet sensitivity to the inhibitory actions of PGI_2. The phosphorylation of GPIbb, a known PKA substrate and a raft protein, is though to contribute to platelet inhibition of vWF-mediated responses by PGI_2. Treatment of platelets with PGI_2 resulted in the phosphorylation of GPIbb in the lipid raft fraction. Isolation of PKAI from its potential AKAPs by RIAD-Arg_{11}, resulted in a significant decrease in raft localised phosphoGPIbβ, demonstrating that this phosphorylation is a PKAI-dependent event.

Conclusion: We show that selective localisation of PKAI into lipid rafts is required for competent platelet inhibition by cAMP. Furthermore, we identify the lipid raft-residing GPIbb as the first PKAI-specific substrate in platelets and moesin as the first platelet AKAP.

PB 3.23-6

Characterization of the effects of losartan on human platelets

Jiang P, Loyau S and Jandrot-Perrus M

Inserm U698, Paris Cedex 18, France

Background: Losartan, a selective, competitive inhibitor of the angiotensin II type I receptor, is routinely used to treat hypertension. It has been reported to have antithrombotic effects in animal models dependent on NO/prostacyclin and direct antiplatelet effects were described *in vitro*: competitive inhibition of U46619 binding to the thromboxane A2 receptor (TPR) (Guerra-Cuesta JI et al. *J Hypertens 1999*) and interaction with GPVI (Grothusen C et al. *Arterioscler Thromb Vasc Biol*, 2007; Ono K et al. *J Med Chem* 2010).

Aims: This study was aimed to better characterize *in vitro* the effect of losartan on platelets and to elucidate its mechanism of action.

Methods: Experiments were performed on PRP and washed platelets from healthy donors who had not taken medication for at least for 10 days. Samples were preincubated with increasing concentrations of Losartan (0–50 μg/mL) before measuring platelet aggregation and P-selectin exposure. Platelet activation was triggered by arachidonic acid (AA, 1.5 mM), APD (10 μM), thrombin-receptor activating peptide (TRAP 20 μM), the thromboxane A2 analogue U46619 (1 μM), type I collagen (Horm, 1 μg/mL), convulxin (Cvx, 0.5 nM), or the anti-FcgRIIA antibody IV.3 cross-linked by anti-mouse IgG Fab'2. Platelet adhesion to immobilized collagen was analysed using whole anticoagulated blood in flow conditions (1500/s). GPVI binding to collagen was measured using recombinant soluble dimeric GPVI (GPVI-Fc). GPVI dimerisation/clustering was analysed by flow cytometry using the specific antibody 9E18 *(Loyau S et al. Arterioscler Thromb Vasc Biol 2012)*.

Results: Losartan up to 50 μg/mL had no effect on AA, TRAP or Cvx-induced platelet aggregation and P-selectin exposure. Losartan (50 μg/mL) inhibited the second wave of aggregation in response to ADP and dose-dependently inhibited U69919- and collagen-induced platelet aggregation. However, the losartan IC50 was six times higher for U46619 than for collagen-induced platelet aggregation (18 vs. 3 μg/mL) suggesting that the inhibition of collagen-induced platelet activation was partly independent of the effect of losartan on TPR. This was confirmed by the observation that losartan still inhibited the collagen-induced residual platelet aggregation of indomethacin-treated platelets. When blood preincubated with losartan (10 μg/mL) was perfused over collagen, less platelet aggregates were formed as compared to control conditions. Losartan up to 100 μg/mL slightly reduced the binding of the anti-GPVI monoclonal antibody 9O12 to GPVI-Fc and had no effect on the high affinity binding of GPVI-Fc to collagen suggesting that losartan does not occupy the collagen-binding site on GPVI. However, interestingly, losartan (10 μg/mL) inhibited the binding of the 9E18 antibody to platelets incubated with collagen suggesting that losartan blocks collagen-induced GPVI clustering.

Conclusion: Losartan inhibits collagen-induced platelet adhesion, activation and aggregation. This effect is, at least partly, independent of TPR inhibition, and does not rely on the inhibition of the protein tyrosine kinase pathway since it does not impact FcgRIIA activation. Our data suggest that the inhibition, by losartan, of collagen-induced GPVI clustering could reduce platelet reactivity and contribute to its antithrombotic effect. The relevance of this effect in losartan-treated patients is under investigation.

Time-resolved phosphorylation patterns of human platelets upon treatment with Iloprost reveal novel insights into platelet inhibition

Zahedi R[1], Beck F[1], Geiger J[2], Gambaryan S[3], Walter U[4] and Sickmann A[1]

[1]Leibniz-Institut für Analytische Wissenschaften – ISAS – e.V., Dortmund; [2]Institut für Klinische Biochemie und Pathobiochemie, University of Würzburg, Würzburg, Germany; [3]Sechenov Institute of Evolutionary Physiology and Biochemistry, St. Petersburg, Russian Federation; [4]Center for Thrombosis and Hemostasis (CTH), Mainz, Germany

One of the most important physiological platelet inhibitors is endothelium-derived prostacyclin which stimulates the platelet cAMP/PKA signaling cascade and inhibits virtually all platelet activating key mechanisms. Using quantitative mass spectrometry, we analyzed time resolved phosphorylation patterns in human platelets after treatment with Iloprost, a stable prostacyclin analogue, for 0, 10, 30 and 60 s to characterize key mediators of platelet inhibition and activation in three independent biological replicates.

Starting from only 100 μg of protein per condition, in total we quantified more than 2700 different phosphorylated peptides of which 360 peptides show a significant (two-fold) up/down regulation upon stimulation.

For the first time, our data provide time-resolved insights into phosphorylation-dependant processes during platelet inhibition. Some of the signaling proteins detected in this study represent so far unknown key players and signaling nodes of platelet activation and inhibition – novel candidates for monitoring functional defects or impaired responsiveness of human platelets to anti-platelet treatment, imposing an increased risk for severe cardiovascular or other adverse secondary effects.

In conjunction with our recently published first comprehensive and quantitative protein composition of human platelets [1], our novel quantitative data on platelet phosphorylation provide a rich source for further functional research and represent another step towards a deeper understanding of the mechanisms contributing to platelet physiology as well as pathophysiology.

PB 3.24-2

Proteomic comparison of platelets with high and low mean platelet volume

Thiele T, Steil L, Wiersbitzky S, Fuerll B, Gesell Salazar M, Hammer E, Völker U and Greinacher A

Greifswald University, Greifswald, Germany

Background: It has been supposed that platelet size is a determinant of platelet age; however, there is a lack of data to support this concept.
Aim: This study applies highly sensitive quantitative proteomics to compare the protein constitution of platelet subpopulations with high and low mean platelet volume (MPV).
Methods: Platelets were separated from whole blood ($n = 3$) by density gradient centrifugation using a percoll density gradient. Residual leukocytes were removed after labeling with magnetic CD45 beads through a magnetic column (Milteny Biotec). Platelets were washed and separated by MPV using differential centrifugation to obtain a large and a small platelet fraction. MPV was determined using a Sysmex™ cell counter. Platelets were analyzed by differential in gel electrophoresis (DIGE) and label free LC-ESI-MS/MS.
Results: Mean platelet volumes were 11.2 fL (10.6–12.2) in the large and 9.0 fL (8.2–10.0) in the small platelet fraction. The comparison of 1187 proteins revealed no significant differences in platelet proteins using the LC-ESI-MS/MS approach, whereas 76 out of 1265 protein spots displayed significantly altered abundances in the DIGE-experiment. Identification of 41 spots by MALDI-TOF-MS revealed that large cells contained more fragments of highly abundant cytoskeletal proteins such as talin, kindlin-3, and filamin.
Conclusion: The relative abundances of platelet proteins appear similar in platelet subpopulations with high and low MPV. Protein differences detected by DIGE indicate fragmentation of cytoskeletal proteins in platelets with high MPV.

PB 3.24-3

A proteomics study of the neonatal platelet plasma membrane

Schlagenhauf A, Obrist B, Leschnik B, Birner-Gruenberger R and Muntean W

Medical University of Graz, Graz, Austria

Background: Neonatal platelets are hyporeactive *in vitro* to a variety of agonists. The nature and degree of this impairment is diverse, depending on the type of agonist. Poor response to thrombin and epinephrine is due to decreased numbers of respective receptors, while hyposensibility to TXA_2 is not associated with decreased receptor numbers, but a result of impaired signal transduction.
Nevertheless, primary hemostasis is not affected, as newborns are not prone to easy bruising. Additionally, we observed that adult and neonatal platelets support thrombin generation to the same extent. Both observations seem discrepant with *in-vitro* hypoaggregability of neonatal platelets.
Aims: We wanted to adopt proteomics to get an integrated picture of neonatal platelet peculiarities and focused on the plasma membrane, because it contains the majority of targets for platelet activation and inhibition.
Methods: Platelets of adult blood and umbilical cord blood were isolated, washed and lysed in their resting state. Enrichment of plasma membranes was performed by partitioning in an aqueous two-phase polyethylene glycol/dextran system followed by two-fold extraction with sodium carbonate. Proteins were subjected to a bottom-up proteomics workflow including tryptic digestion. Semiqantitative comparison was achieved by stable isotope dimethyl labeling on the peptide level. Differentially labeled pools containing five adult or neonatal samples respectively were combined and subtracted to SCX prefractionation prior to analysis with high resolution LC-MSMS. The experiment was repeated three times with pools containing different samples. Analysis of semiquantitative data was done using Thermo Proteome Discoverer 1.1.0. Gene ontology classification and enrichment analysis was performed using the database for annotation, visualization and integrated discovery (DAVID) v6.7.
Results: Semiquantitative comparison with adult samples revealed 321 differentially regulated features in neonatal platelets. The most consistently upregulated proteins are all known to be involved in platelet signalling, such as GPIbα, GP9, PECAM1, CD36, and integrin alpha 6. Notable downregulated proteins were $G_{i\alpha}$, integrin-linked kinase, and pro-platelet basic protein. Gene ontology classificaton and enrichment analysis confirmed enrichment of proteins integral or intrinsic to plasma membrane in all samples. Functional annotation clustering revealed significant enrichment of proteins involved in cell signaling and cell adhesion in the neonatal samples.
Conclusion: Higher levels of GPIbα in the neonatal samples are in agreement with our previous findings using Western blot analysis and argue for increased binding to high molecular von Willebrand factor present in neonatal blood. Additionally, higher levels of several integrins speak for increased cell-cell interaction and support of platelet adhesion reflected in the results of functional annotation clustering. Lower levels of $G_{i\alpha}$ are of particular interest, because several inhibitory signaling pathways could be affected. These impairments might not be observable with *in-vitro* platelet function testing using strong activators, but could potentially explain some controversial clinical findings.

PB 3.24-4

Towards a better characterization of the platelet secretory granule proteome

Zufferey A[1], Schvartz D[1], Nolli S[2], Reny J-L[2], Sanchez J-C[1] and Fontana P[2]

[1]University of Geneva; [2]University of Geneva and University Hospitals of Geneva, Geneva, Switzerland

Background: Platelets are anucleated cell fragments involved in haemostasis. They contain four types of secretory granules, which are different in term of morphology, number and content: alpha granules, lysosomes, dense granules and T granules. Granules are a cornerstone in the platelet activation and aggregation processes as well as in atherosclerosis progression and its thrombotic complications. Subcellular fractionation techniques allow enriching organelles of interest and are a promising strategy to dissect the proteome of platelet granules.
Aims: The present project aims to further characterize the protein composition of the platelet secretory granules.
Methods: Platelet granules were enriched by sucrose gradient and analyzed by tandem mass spectrometry in gas-phase fractionation mode. The presence of selected proteins was verified in the granule-enriched sucrose fraction by western blot and their localization confirmed by confocal microscopy.
Results: We identified more than 800 proteins, among which the vast majority is involved in pathways ranging from platelet granule biogenesis to secretion. A pathway analysis comparing the proteomes of the granule-enriched fractions with the whole platelets showed enrichment in ERK signaling and MHC I related pathways. Western blot confirmed the presence of Syk and Lyn, which are members of the ERK pathway. In addition, MHC I was shown to co-localize with the alpha granule marker von Willebrand factor by confocal microscopy.
Conclusion: To our knowledge, this work constitutes the largest characterization of the platelet secretory granule proteome. It identified proteins never shown in platelet secretory granules so far. Among them, ERK and MHC I related pathways have been localized in platelet granule-enriched fractions and alpha granules, suggesting a role in the plate-

let granule machinery biogenesis and cargo secretion. This work constitutes a new insight in the understanding of the platelet secretion.

PB 3.24-5

A 2D-DIGE-based proteomic analysis reveals differences in the platelet releasate depending on the platelet stimulus

Vélez P, Rosa I and García A

CIMUS, Universidad de Santiago de Compostela, Santiago de Compostela, Spain

1 Undesired platelet activation and formation of arterial thrombi are implicated in many diseases, such as myocardial infarction and stroke. Once activated, platelets release a high number of proteins and other biomolecules, which is known as releasate. There are clear indications that proteins secreted by platelets are found in the atherosclerotic plaque contributing to its pathogenesis [Coppinger JA et al. Blood. 2004;103:2096–2104]. In recent years there have been several groups focusing on the study of the releasate, analyzing the effect of different agonists and antiplatelet agents such as aspirin [Coppinger JA et al. Blood. 2007;109:4786–4792].

2 Our main objective was to test the hypothesis that the platelet releasate might vary depending on the platelet stimulus.

3 We activated platelets with collagen or thrombin and compared the proteome of the releasate. Platelets were isolated from healthy volunteers and activated *in-vitro* to obtain the releasate. Proteome analysis was based on two-dimensional in-gel electrophoresis (2D-DIGE) and mass spectrometry (MALDI-MS/MS and LC-MS/MS). Validations were by 1D- and 2D-western blotting.

4 We detected 1742 spots per gel, 131 of which appeared differentially regulated between both conditions. Spots were filtered based on two parameters: fold change ≥ 2 and $P < 0.05$. So far we successfully analyzed 72 differentially regulated spots by mass spectrometry. We detected two main arrays composed of fibrinogen (12 spots) overexpressed in the releasate of collagen-activated platelets, which was somehow expected due to the ability of thrombin to transform fibrinogen into fibrin. We identified another 25 unique proteins (13 overexpressed in collagen, 11 in thrombin and one in both conditions). The identified proteins were secreted in a similar proportion by both classical and non-classical secretory pathways (58% and 42%, respectively), and some of them had not been reported previously in platelet releasate or microparticle proteome studies. Those include nucleosome assembly protein 1-like 1 (NP1L1), Myosin regulatory light chain 12B (ML12B), and cardiotrophin-like cytokine factor 1 (CLCF1). The latter is a cytokine with B-cell stimulating capability. 1D- and 2D-western blotting validation experiments demonstrated it is secreted in higher amounts by thrombin-activated platelets. On the other hand, the adhesive glycoprotein thrombospondin-1, which mediates cell-to-cell and cell-to-matrix interactions, was found to be up-regulated in the collagen-induced releasate.

5 We demonstrated the platelet releasate varies depending on the specific stimulus. This could have pathological implications given that some platelet-related diseases involve a primary role of some particular receptors and platelet secreted proteins. For example, in a recent study we showed a higher activation state of GPVI signaling in platelets from patients with acute myocardial infarction [Parguiña AF et al. Arterioscler Thromb Vasc Biol. 2011;31:2957–64]. Our results may also have pharmacological implications, assuming the platelet releasate might be modulated with anti-platelet drugs.

PB 3.24-6

What do platelets release?

Scholten A[1], Wijten P[1], Van Holten TC[2], Bleijerveld OB[2], De Groot PG[2], Heck AJ[1] and Roest M[2]

[1]Utrecht University; [2]University Medical Centre Utrecht, Utrecht, The Netherlands

Background: Platelet activation and subsequent release of α-granule content plays an important role in healthy hemostasis, but also in many cardiovascular pathologies. Although some of these factors are routinely assayed, there is an eminent need to estimate more accurately the identity, and the protein concentrations within the releasate. In addition, it was suggested that the platelet releasate varies with different activation routes. Currently, such data is only based on single protein assays, but would benefit from a more systems-wide method.

Aim: It is our aim to develop methodology to establish an unambiguous quantitative map, including identity and quantity (ng/mL), of the platelet releasate under various stimulatory conditions.

Methods: To establish and quantify the platelet releasate we isolated platelets from healthy individuals ($n = 3$) and split each sample into two halves. One half was left to rest, while the other was fully stimulated using collagen (CRP) and thrombin (TRAP). After a standard proteomics sample preparation, each half was labeled with a different stable isotope tag (dimethyl labeling) and the samples were again combined. These mixes were analyzed with an optimized workflow incorporating 2-dimensional chromatography and LC-MS/MS analysis on an Orbitrap Velos operated with a decision tree algorithm to optimally choose ETD or HCD fragmentation for each peptide. The stable isotopes aided in the elucidation of the released proteins as these were found significantly reduced in the activated sample ($P < 0.05$). The normalized spectral index was used to establish the copy number and subsequently the released concentrations of each protein in ng/mL.

Results: Thus far, qualitative, mass spectrometry-based investigations into the platelet releasate have not exploited the power of quantitative proteomics and have yielded ambiguous results due to insufficient depth and the identification of many false positives due to uncontrolled platelet lysis. We monitored almost 4500 platelet proteins for their release characteristics and estimated copy number. We observed that full stimulation leads to the consistent ($n = 3/3$) and significant release of only 124 proteins ($P < 0.05$). At this depth, the released proteins span a concentration range of at least five orders of magnitude, as confirmed by ELISA. These released proteins contained all known factors at high concentrations (> 100 ng/mL, e.g. Thrombospondin, von Willebrand factor and Platelet factor 4). Interestingly, in the lower concentration range (< 1 ng/mL) of the releasate many novel factors were identified. With this methodology we are now ready to take on the next challenge, i.e. monitor differential release upon different platelet activation routes.

Summary/Conclusion: We have generated a quantitative map of the platelet releasat, which contained all known important factors, many novel proteins. Compared to previous work, the releasate turned out to be much smaller than anticipated.

PB3.25 – Platelet Disorders: Loss-of-Function

PB 3.25-1

Variability in clinical and biological manifestations of anti-GPVI autoantibodies: about four new patients

Loyau S[1], Fiore M[2], Latger-Cannard V[3], Baccini V[4], Dumont B[1], Pillois X[2], Lecompte TP[3], Alessi M-C[4] and Jandrot-Perrus M[1]
[1]Inserm U698, Paris Cedex 18; [2]Laboratoire d'Hématologie, Centre de Référence des Pathologies Plaquettaires, Pessac; [3]Service d'Hématologie Biologique, Centre de Compétence Nord-Est des Pathologies, Nancy; [4]Inserm U1062/U1260 Inra/AMU, Marseille, France

Background: Chronic immune thrombocytopenia (ITP) is an autoimmune disorder manifested by immune-mediated platelet destruction and decrease in platelet production. There are only rare reports of ITP patients with antibodies against GPVI-FcRγ, the major platelet receptor for collagen. Due to scarce observations, many questions are still pending: (i) do these antibodies mediate clearance of GPVI-FcRγ by shedding or internalization, (ii) are they able to activate or inhibit platelets, (iii) and are they associated or not with bleeding?
Aims: Our goal was to collect as many data on patients with anti-GPVI antibodies to conduct a study that would offer a real understanding of the natural history of this rare platelet disorder.
Methods: Light transmission aggregometry (LTA) using standard agonists; Surface expression of platelet glycoproteins analysis by flow cytometry; Plasma anti-GPVI antibodies detection by ELISA; Platelet content in GPVI and FcRγ by immunoblot analysis; Sequencing of the *GP6* gene.
Results: Four patients with identified anti-GPVI antibody were explored. All cases (numbered P1–P4) are females. At diagnosis, their age was 46, 35, 25 and 16 years; their platelet counts were of 30–40, 60, 150 and 360 G/L respectively. Bleeding manifestations were variable, from none (P1) to mild (ecchymosis, epistaxis and/or gingival bleeding). The platelet defect started during pregnancy (P2) but was not associated to an identified event in other cases. Platelet-associated immunoglobulins were detected in P1 and P4 who were positive in MAIPA for anti-GPIIbIIIa. In P1-P3, LTA revealed no or profoundly reduced collagen- and convulxin-induced platelet aggregation and normal responses to other agonists, leading to the suspicion of a GPVI deficiency which was confirmed by flow cytometry; in P4 the GPVI deficiency was identified by flow cytometry and confirmed by LTA. Cross-tests (patient's PPP mixed with control platelets) evidenced either an inhibitory effect on collagen and convulxin- induced platelet aggregation (P1), or an activating effect (P2) or no effect (P3 and P4). Platelet GPVI content was very low as indicated by immunoblot analysis and the expression of the FcRγ chain was variably reduced: as GPVI (P2) or less than GPVI (P1, P3 and P4). The GPVI cytoplasmic fragment was undetectable in all cases. An anti-GPVI immunoglobulin was evidenced in the plasma of the four patients. In P2, purified IgGs bound to GPVI and induced platelet activation. Finally, sequencing of the GP6 gene (P1, P3, P4) ruled out a genetic disorder and identified common polymorphisms.
Conclusion: The comparative study of these four new cases of acquired immune GPVI deficiency and confrontation with literature confirm the variability of their clinical manifestations (thrombocytopenia and bleeding), which are most often mild, leading to underestimate the occurrence of GPVI deficiency. The apparent absence of GPVI shedding suggests that antibody-triggered GPVI internalization and degradation could be a current process. More systematic research of anti-GPVI antibodies using a standard protocol would help to identify whether the different mechanisms of action and manifestations could be linked to specific target areas on GPVI.

PB 3.25-2

Platelet dense granule but not alpha granule secretion defect in cystic fibrosis patients

Kerrigan SW, McGivern TJP, Molloy K, McElvaney NG and Moran N
Royal College of Surgeons in Ireland, Dublin, Ireland

Background: Cystic fibrosis (CF) is an autosomal recessive disorder caused by mutations of the CF transmembrane conductance regulator (CFTR) gene. It is the most common genetically inherited disease worldwide affecting more than 70,000 individuals. Airway inflammation in concert with chronic infection accounts for progressive, suppurative pulmonary disease. Platelets are critical elements in linking and modulating thrombosis, inflammation and tissue repair. Platelets orchestrate the inflammatory response by undergoing a series of highly controlled intracellular signaling events that lead to the release of its stored intracellular granules.
Aims: We therefore investigated if platelets from CF patients have an altered responsiveness to agonists compared to platelets from normal healthy donors.
Methods: Informed consent was obtained from all participants (healthy and CF) and ethical approval to carry out the study was obtained from the RCSI and Beaumont Hospital Ethics committees. Platelet aggregation was assessed by light transmittance. Alpha granule secretion was measured by flow cytometry and dense granule secretion was measured by luminometry using a luciferin/luciferase assay.
Results: CF patients ($n = 7$) and healthy control ($n = 7$) populations were equivalent in terms of age and platelet counts. There was no statistical difference in platelet aggregation betweenhealthy control and cystic fibrosis patients when stimulated with a range of concentrations of Thrombin Receptor Activating Peptide (TRAP), thromboxane mimetic, U46619, collagen related peptide (CRP) or arachidonic acid (AA) ($n = 7$). Alpha granule secretion, determined by surface expression of CD62P, was also similar between the healthy control patients and CF patients with all agonists and concentrations tested ($n = 7$). In contrast to these results, platelets from CF patients had a significantly reduced secretion from dense granules, when stimulated with strong agonists TRAP ($P < 0.01$), CRP ($P < 0.0001$), but not weak agonists U46619 and AA (P = NS). In order to confirm a dense granule secretion defect rather than reduced levels of bioactive cationic molecules present in the dense granules of CF patients, we measured the total ATP and ADP content in platelet dense granules. There was no significant difference in the total ATP or ADP levels found in healthy vs. CF patient platelets (P = NS).
Conclusion: Our results suggest that platelets from CF patients exhibit a decreased platelet dense-granule secretory response to activation signals. This may lead to a muted response in terms of inflammatory cell mobilization. Thus, drugs that suppress platelet responses such as non-steroidal anti-inflammatory drugs, should be used in a limited fashion in CF patients, as such drugs will further suppress inflammatory responses.

PB 3.25-3

Is molecular analysis of the MYH9 gene helpful in the diagnosis of May-Hegglin anomaly and related disorders?

Mitchell MJ[1], Alamelu J[2], Austin S[3] and Cutler J[4]
[1]GSTS Pathology LLP; [2]Evelina Hospital, Guy's & St. Thomas' NHS Trust; [3]St. Georges' Hospital NHS Trust; [4]GSTS Pathology, London, UK

The autosomal dominant giant-platelet disorders, May-Hegglin anomaly, Sebastian syndrome, Epstein syndrome and Fechtner syndrome, are now collectively referred to as *MYH9*-related disease (MYH9-RD); following identification of causative mutations in *MYH9*, the gene coding for the heavy chain of non-muscle myosin-9. These disor-

ders are characterised by macrothrombocytopenia and, usually, leukocyte inclusions. There is also variable association with sensorineural hearing loss, presenile cataracts and renal disease. These non-haematological clinical manifestations may arise or worsen later in life and it is important to be aware of the possibility and offer surveillance to patients. For these reasons a definitive diagnosis is important and molecular analysis of the *MYH9* gene may help provide this. MYH9-RD is most commonly misdiagnosed as chronic ITP but may also be confused with Bernard-Soulier syndrome (BSS), Paris-Trousseau syndrome/Jacobson syndrome, X-linked macrothrombocytopenia or Gray platelet syndrome.

We have screened the *MYH9* gene in a total of 24 patients referred for possible MYH9-RD. In 13 of the 24 a causative mutation was identified, whilst in the other 11 no causative mutation was identified following sequencing of the entire coding region of *MYH9*. Of the 13 in whom a causative mutation was identified, 10 were previously reported mutations whilst three were novel (p.Leu89Arg, p.Arg1165Ser and p.Asp1941Metfs*7). Eleven different variants were identified in the 13 patients, with the previously reported p.Lys373Asn and p.Glu1841Lys mutations each being reported in two patients, confirming the heterogeneity of *MYH9* mutations. However, it is interesting to note that, despite *MYH9* being a relatively large gene (41 exons encoding a 1960 amino acid protein), there is apparent clustering of mutations at particular loci. Four different amino acid substitutions have been reported at Asp1447, three at Arg702, Arg1165 & Asp1424 and two at Trp33, Ala95 & Thr1155. That is a total of 19 different amino acid substitutions, out of a total of < 40 unique missense/nonsense mutations reported, at just seven different loci. This suggests that these regions must be either critical to function or more susceptible to mutation.

Although referral information was sometimes less than comprehensive, the referrals could roughly be categorised into Strong, Possible and Weak candidates for an *MYH9* gene mutation. Of the 11 considered strong candidates a mutation was identified in 10 with one being negative and possibly worthy of further investigation. The nine possibles resulted in three patients with an *MYH9* mutation and six negative, whilst all four patients considered to be weak candidates for a mutation were indeed negative.

A definitive diagnosis of MYH9-RD is clinically important and molecular analysis of *MYH9* can play an important role in achieving this. Our experience confirms that appropriate referral criteria are important for molecular analysis to be a practical part of the diagnostic process. However, the criteria should not be too strict or *de novo* cases, with no family history of thrombocytopenia, may be missed. For example, we confirmed the diagnosis of MYH9-RD in an 18 month old child with a *de novo MYH9* mutation. Definitive diagnosis will enable monitoring of his developmental milestones with early intervention as necessary.

PB 3.25-4

Increased total platelet TFPI and higher surface expression of TFPI in activated platelets may be involved in the pathogenesis of mild bleeding disorders (MBD) of undefined cause (BUC)

Panes O, Zuniga P, Valencia R, Kovacs P, Quiroga T, Pereira J and Mezzano D

Pontificia Universidad Catolica de Chile, Santiago, Chile

Background: Inherited mild bleeding disorders (MBD), usually manifested with skin and mucous bleeding are heterogeneous in nature, involving different pathogenic mechanisms, including platelet function defects, decreased amount and function of plasma VWF, mild defects of clotting factors and also, increased fibrinolysis. However, up to 60% of all the patients with MBDs have abnormal bleeding of undefined cause (BUC). Platelets contain TFPI, but its function is poorly understood.

Aims: To analyze the expression of TFPI in resting and activated platelets from controls and patients with BUC.

Methods: Platelet TFPI was analyzed by flow cytometry in washed platelets (Panes et al. Blood 2007;109:5242) without previous stimulation and stimulated with VWF-Ristocetin or Thrombin Receptor Activating Peptide (TRAP). TFPI protein was measured in platelet lysates by ELISA. Measurements were performed in Control individuals and patients with inherited mucous and skin bleeding who had normal plasma VWF, normal platelet aggregation and ^{3}H-serotonin secretion and normal hemostasis screening tests. Exposure of anionic phospholipids was assessed by annexin V binding, by flow cytometry.

Results: TFPI protein measured in platelet lysates of 41 patients with BUC (mean age 19 ± 9 years, 32 women) was 36 ± 14 ng/mg protein, significantly higher than that of 40 Controls (ages 22 ± 6, 31 women) who had 25 ± 12 ng/mg protein (mean ± SD, $P = 0.0041$). In 16 of these patients and 17 Controls, platelet surface TFPI was measured. No difference in the% of labeled was observed in Patients and Controls in non-stimulated platelets (59.5 ± 15% vs. 53 ± 23%, P = NS) and in VWF-Ristocetin stimulated platelets (35 ± 24% vs. 35 ± 23%). However, stimulation with TRAP resulted in a significant fall in TFPI-labeled platelets in Controls but not in BUC patients (13 ± 13% vs. 34 ± 23%, $P = 0.0007$, non-paired '*t*'test). Annexin V binding was significantly increased after platelet stimulation with VWF-Ristocetin and TRAP, but no significant differences were observed between Patients and Controls.

Conclusions: (i) Platelets from patients with MBDs of undefined cause contain more TFPI protein than normal. (ii) TFPI is detectable on more than 50% of the platelets in normal individuals. After activation with VWF-Ristocetin, but mainly with TRAP, a significant drop to 12% of TFPI-labeled platelets is observed. In contrast, more than 1/3 of the platelets from patients still express TFPI after TRAP stimulation. (iii) No significant differences were observed in Controls and Patients regarding annexin V binding. (iv) We have observed that the mean thrombin generation in PRP in patients with BUC is decreased as compared to controls (another Abstract in this Meeting). Taken together, our current observations strongly suggest that some patients with BUC might have a defective platelet procoagulant activity, which could be pathogenically related with the bleeding symptoms. (FONDECYT 1110404 and 1130853).

PB 3.25-5

HPLC-based assay to measure platelet serotonin (5-HT) secretion in specialized hemostasis laboratories: comparison with the current 'gold standard' radioisotopic test

Mezzano D, Vásquez L, Araya E, Aranda E, Goycoolea M, Panes O, Pereira J and Quiroga T

School of Medicine, Catholic University of Chile, Santiago, Chile

Background: The underlying defect of most mild platelet function disorders (PFD) is a primary secretion defect. Moreover, a proportion of the patients with PFDs have isolated secretion defects with normal aggregation. The 'gold standard' assay for measuring platelet secretion is radioisotopic 5-HT release. However, radioactivity has been displaced from clinical labs and currently, the best assay licensed to perform both measurements is PRP-lumiaggregometry. This has been criticized because it potentiates the aggregation of platelets and the ATP release has high coefficient of variation (CV). So, new tests are being developed to improve the diagnosis of PFDs.

Aims: To measure concomitantly the aggregation and 5-HT secretion of platelets by an HPLC-based assay, comparing it with the ^{3}H-5-HT release test. Also, to measure total platelet 5-HT in the same assay.

Methods: Platelet ^{3}H-5-HT release was measured as described (Holmsen, et al. Methods: Enzymol1989;169:205). 5-HT secretion by HPLC coupled to electrochemical detection (HPLC-ED) was performed in platelet lysates, obtained after stopping the aggregation test with ice-cold EDTA, rapid centrifugation in the same cuvette and lysis of the platelet pellet by three freezing-thawing cycles. HPLC-ED assay was

done as described (Kumar, Life Sciences 1990;47:1751). Initially, secretion tests by both methods were done in separate cuvettes, assessing the variability of aggregation tracings and secretion assays. Then, we performed a study in volunteers before and 2 h after intake of 300 mg uncoated aspirin, recording aggregation in a single cuvette and measuring released ^{3}H-5-HT in supernatant plasma and endogenous 5-HT retained in the platelets by HPLC-ED. Agonists used were arachidonate, epinephrine, ADP and collagen, using saline as blank (100% 5-HT).

Results: HPLC-ED was highly sensitive (around 1×10^{7} platelets injected in the column). Retention time was 7.5 min. Mean CVs for Blank, Epinephrine and ADP were 2.99%, 2.72% and 3.7%, respectively. Parallel assays showed almost identical maximal aggregation in both aliquots (74 ± 13% and 75 ± 13%); HPLC secretion was higher than the isotopic one (46 ± 15% vs. 34 ± 11%, $P < 0.0001$, $n = 130$ samples). The same was observed in volunteers before aspirin (42 ± 12% vs. 35 ± 12%, $P < 0.0001$, $n = 78$). Spearman correlation between both secretion assays was $r = 0.913$; 95% CI: 0.8799–0.9377; $n = 141$ paired samples, including post-aspirin samples). Aspirin dampened 5-HT secretion to a median (range) of 0.0% (0.0–40) and 0.0% (0.0–33) for HPLC and isotopic determinations, respectively ($n = 69$ pairs of samples). Analysis of individual agonists was also concordant. Total 5-HT content in platelets was 586 ± 138 ng $\times 10^{-9}$ platelets ($n = 27$).

Discussion: (i) 5-HT is abundant, specific of platelets and ideal marker to assay platelet secretion. (ii) 5-HT measurement by HPLC-EC is highly specific, sensitive and accurate, has very low CV, not requiring duplicates. (iii) It allows simultaneous measurement of total platelet 5-HT content to assess dense granule content and recognition of PFDs characterized by isolated secretion defects. (iv) After an initial expensive investment, the reagents used are cheap and ideally the instrument should be a dedicated one, side by side with the aggregometer. (v) Results can be obtained overnight. (vi) Radioactive compounds are eliminated. (vii) The adapted test can measure 5-HT release for diagnosing HIT.

PB 3.25-6

Prevention of intracranial hemorrhage in fetal/neonatal alloimmune thrombocytopenia: Identification of risk factors

Bertrand G, Martageix C and Kaplan C
INTS, Paris, France

Background: Fetal/neonatal alloimmune thrombocytopenia is the most common cause of severe thrombocytopenia in the fetus and newborn. The major risk is intracranial hemorrhage (ICH), with neurological sequels in 20% of reported cases or death in 10%. We previously have shown that maternal anti-HPA-1a antibody concentration measured before any treatment and before 28 weeks of gestation was predictive of the fetal status (Bertrand et al. *Blood* 2011).

Aims: Although the relationship between thrombocytopenia and hemorrhage is obvious, not every severe thrombocytopenic child is affected by ICH, and predictive parameters would be helpful.

Methods: Two cohorts of severely thrombocytopenic index cases at diagnosis were retrospectively analyzed: Group I, $n = 52$ pregnancies without ICH; Group II: $n = 27$ pregnancies with ICH. Informed consent was obtained according to the Declaration of Helsinki.

Results: Only 48% women were multigravida in Group I comparatively to 81% in Group II ($P = 0.007$). Mean neonatal platelet count was significantly lower for Group II (7.10^{9} platelets/L comparatively to Group I (14.10^{9}/L; $P = 0.018$). In the absence of ICH the outcome was favorable. In group II, ICH led to fetal/neonatal death in 59% of the cases ($P < 0.001$). Moreover a statistically significant difference between the two groups was observed for maternal alloantibody concentration measured at time of diagnosis: 40 IU/mL in Group I and 89 IU/mL in Group II ($P < 0.001$).

Conclusions: Gynecologic history (abortions or successive pregnancies) and maternal anti HPA-1a alloantibody concentrations may be considered as predictive risk factors for ICH in severe cases.

PB3.26 – Platelet Acquired Dysfunctions

PB 3.26-1

Platelet function and blood loss during coronary artery bypass surgery

Van De Kerkhof D[1], Mezger S[2], Van Der Stokker A[1], Lanen P[1] and Van Straten B[1]
[1]*Catharina Hospital;* [2]*Eindhoven University of Technology, Eindhoven, The Netherlands*

Background: Coronary artery bypass surgery (CABG) is associated to blood loss. Transfusion of platelets and plasma is often applied anticipating on heparinisation, extracorporal circulation (ECC) and use of platelet inhibitors during surgery. To prevent blood loss during surgery, clopidogrel is often stopped at least 5 days before surgery.

Aims: In this study coagulation and platelet function were monitored during the CABG procedure in a population that stopped clopidogrel use 5 days before the procedure (Group A) and in a population that continued clopidogrel through the procedure (Group B).

Methods: Patients undergoing standard CABG on ECC were included ($n = 60$, Group A 38, Group B 22). Analyses were performed pre-surgery, during surgery and within 2 h after arrival at the Intensive Care Unit. Thrombocyte function was analysed with Light Transmission Aggregometry (LTA), Multiple Electrode Aggregometry (MEA) and GPIIb/IIIa-expression with flowcytometry. Also, routine coagulation testing and thromboelastrography was performed with platelet mapping. Blood loss and transfusion was registered.

Results: No signficant difference was present in hemoglobin concentration, blood loss and transfusion between Group A and B. Platelet aggregation with ADP was reduced in Group B, while strong agonists as collagen and TRAP not significantly different. The aggregation response of all agonists was decreased during the surgical procedure and returned to pre-operative values at the time of arrival at the ICU. Coagulation assays showed no significantly different results during the procedure.

Conclusion: As most transfusions are applied at the ICU, this study shows that the use of clopidogrel during the procedure is a weak parameter for clinical decision making on transfusion. Platelet function is reduced during surgery, but is restored to pre-operation values at the time of arrival at the ICU.

PB 3.26-2

The microstructure of clots formed via the extrinsic pathway: effects of shear induced platelet activation

Hambly RJ[1], Chan HH[2], Thornton CA[1], Williams PR[1], Evans PA[1] and Hawkins KM[1]
[1]*Swansea University;* [2]*Calon Cardio Technology, Swansea, UK*

Background: Platelet activation (PA) is known to be one of the earliest precursors to the formation of an incipient blood clot but little is known about its effect on clotting time and clot microstructure. Excessive PA *in-vivo* might lead to the rapid formation of a thrombus with a 'dense' microstructure and increased elasticity which is more difficult for the body to reabsorb by fibrinolysis and could therefore cause a blockage leading to thromboembolic complications and potentially death.

Aims: This study aims to find how the repression of the contact pathway affects the incipient clot microstructure and clotting time using the rheological detection of the gel point in coagulating whole blood.

Furthermore, we aim to quantify the incipient clot formation time and resultant clot microstructure in clots formed, *in-vitro*, under different levels of shear induced PA.

Methods: Whole fresh blood was mixed with Corn Trypsin Inhibitor (CTI), to inhibit the contact pathway, and immediately confined between two parallel plates (at a gap of 400 μm) of an AR-G2 Controlled Stress Rheometer. The Gel Point was found by the attainment of a frequency independent phase angle (ratio of viscous response to elastic response) during the evolution of viscoelasticity of the clot. Fractal analysis of this data provides a method of quantifying clot microstructure in terms of a fractal dimension d_f (Evans et al., 2010). Furthermore, the application of pre-shearing regimes (at different periods and levels of shear rates) allows us to manipulate levels of platelet activation prior to monitoring the formation of the clot. Flow cytometry was used to measure platelet activation on a small aliquot of sample following pre-shearing.

Results: Our preliminary data shows that the presence of CTI significantly delays the onset of the incipient clot, with clot formation time increasing approximately eight-fold compared to previous data obtained using unaltered whole blood. Furthermore, the value of d_f significantly decreased in the presence of CTI, indicative of a more 'open' or 'loose' clot microstructure. In this paper we will also report the ongoing studies of how different levels of shear induced platelet activation effect incipient clot formation time and resultant clot microstructure.

Summary: Suppression of the contact pathway of coagulation, via the addition corn trypsin inhibitor to whole blood, significantly delays the onset of incipient clot formation as measured by the rheological detection of a Gel Point. This allows us to explore the effects of platelet activation on clotting times and resultant microstructure by the application of pre-shearing regimes. The results are important for understanding clot formation *in-vivo*, in particular in instances of regions of high shear flow such as stenotic vessels, and also in ventricular assist devices.

PB 3.26-3

Plasma LDL-cholesterol lowering by LDL apheresis induces acute changes in platelet properties

Korporaal SJA[1], De Angelis V[1], Sjouke B[2], Van Der Stoep M[3], Bochem AE[2], Hovingh K[2], De Groot PG[1] and Van Eck M[3]

[1]University Medical Center Utrecht, Utrecht; [2]Academic Medical Center, Amsterdam; [3]Leiden Academic Centre for Drug Research, Leiden, The Netherlands

Background: Arterial thrombosis is modulated by lipoproteins by altering the platelet response to activating agents. Accordingly, platelets of familial hypercholesterolemia (FH) patients who are characterized by elevated low-density lipoprotein cholesterol (LDL-C) levels due to a molecular defect in the *ldlr* gene are hyperreactive both *in vivo* and *in vitro*. For those patients who are unresponsive to or intolerant for oral lipid lowering therapy, i.e. statins, LDL-apheresis is warranted to adequately lower LDL-C levels.

Aim: To elucidate the impact of selective LDL particle removal by LDL apheresis on the responsiveness of platelets from hypercholesterolemic patients.

Methods: Experiments were performed with platelets from three statin intolerant hypercholesterolemic patients, who underwent four weekly LDL apheresis procedures performed with absorption columns of the direct adsorption of lipoprotein (DALI) system. Blood was collected prior to each session to prevent possible platelet activation induced by the apheresis procedure. Platelet reactivity after agonist stimulation was assessed in whole blood by flow cytometry by measuring fibrinogen binding and surface expression of P-selectin. The study was approved by the international review board of the Academic Medical Center, Amsterdam. All participants provided written informed consent.

Results: The mean plasma LDL-C concentration after LDL apheresis was calculated by the Kroon formula taking into account the rebound of LDL-C levels after each apheresis session. This showed a mean reduction of the plasma LDL-C level by 40 ± 6% (from 10.1 ± 2.0 to 6.8 ± 0.6 mM, respectively). The reduction of the plasma LDL-C level was associated with an increase in the platelet count from 261 ± 17 × 10^9 platelets/L to 334 ± 19 × 10^9 platelets/L ($P < 0.05$). In addition, fibrinogen binding and P-selectin expression, induced by adenosine 5′-diphosphate (ADP) or the glycoprotein (GP) VI-specific collagen peptide mimetic, cross-linked collagen-related peptide (CRP-XL), were normalized after LDL apheresis.

Summary/Conclusions: Our findings indicate that lowering of plasma LDL-C levels by LDL apheresis induces acute changes in platelet count and normalizes platelet reactivity.

PB 3.26-4

The role of platelets in vitamin K antagonist-associated bleeding

Van Der Meijden PEJ, Bouman A, Feijge MAH, Van Oerle R, Spronk HMH, Hamulyak K, Ten Cate-Hoek AJ, Ten Cate H and Heemskerk JWM

Maastricht University Medical Center, Maastricht, The Netherlands

Background: Recurrent bleeding can complicate the treatment of patients with vitamin K antagonists (VKA), even at a well-regulated level of anticoagulation. Bleeding at mucocutaneous sites is frequently reported in these patients, which may point to defects in primary hemostasis.

Aim: In this proof-of-principle study, we investigated whether defects in platelet function or von Willebrand factor (vWf) contribute to a bleeding phenotype in patients on VKA therapy.

Methods: A case–control study was performed with 33 well-regulated patients without bleeding events (controls) and 33 patients with recurrent bleeding (cases). Patients have a well-regulated anticoagulation level when the International Normalised Ratio (INR) is ≥ 65% of the time within the target range. Cases and controls were matched for age, gender and INR target range. Thrombin generation and vWf levels and function were determined in plasma. Platelet function was assessed by light transmission aggregometry and flow cytometry using a validated panel of agonists.

Results: Thrombin generation was similarly reduced in controls (median ETP: 361 nM/min) and cases (median ETP: 387 nM/min), in comparison to normal plasma. This confirmed no difference in the degree of anticoagulation between the controls and cases. The plasma level of vWf was higher than 150%, the upper limit of the normal range, in 85% of the controls and 67% of the cases. Platelet aggregation in response to ADP, epinephrine, arachidonic acid, PAR1 agonist SFLLRN, collagen or ristocetin was in the normal range for almost all patients irrespective of the type of agonist. However, in response to a low collagen dose, platelets from 21% of controls and 27% of cases showed diminished responses. Agonist-induced secretion of α- and δ-granules or integrin αIIbβ3 activation were similar in platelets from controls and cases.

Conclusion: Recurrent bleeding in well-controlled patients on VKA therapy is not explained by defective platelet or vWf function.

PB 3.26-5

An analysis of the hemostatic response using a hybrid computational and experimental approach

Tomaiuolo M, Stalker T, Welsh J, Diamond SL and Brass LF
University of Pennsylvania, Philadelphia, PA, USA

Background: Recent evidence shows that the hemostatic response to penetrating vascular injuries produces a markedly heterogeneous structure in which a stable core of tightly packed, fully-activated platelets is overlaid with an unstable shell of less-activated and less densely packed platelets (Stalker, et al. Blood 2013). The development of such a structure is shaped by the interaction of biological and physical factors that include blood flow and the movement of plasma-borne solutes such as pro- and anticoagulant proteins within the complex geometry of the deposited platelets.
Aims: Our goal in this study was to apply a computational approach to understand the clinically-relevant question of how the movement of solutes affects, and is affected by the heterogeneous structure of the hemostatic thrombus that we have observed.
Methods: We started by engineering different architectures to simulate platelet accumulation from the early stages to the stable form of a hemostatic mass. Each architecture represents a hemostatic plug with a different number of platelets and different packing density. For each architecture we used fluid dynamics to simulate the flow of blood around and within the hemostatic mass. We then simulated solute transport into and out of the platelet mass using Convection-Reaction-Diffusion. The results of the simulation were compared to data obtained by observing the movement within the thrombus of albumin linked to a caged fluorophore.
Results: Our results show that the platelet mass slows solute movement, helping to facilitate its biological action. This deceleration is regulated by the platelet packing density. Based on the computational analysis, we estimated the residence time of a species. For an arteriole 30 μM wide with average blood velocity of 2 mm/s, the residence time of a protein like albumin, is about 0.5 ms in the lumen, 4 ms in the shell and 9 ms in the core, a conclusion in good agreement with the experimental evidence. We then manipulated critical parameters such as the packing density of the platelets, the production of thrombin and the release of ADP. We observed the interaction of two main effects, dilution and residence time. In the case of thrombin, for instance, we observed that a two-fold increase in production rate translates into a 50% larger area of action, defined as the region of space where the concentration of thrombin exceeds that needed to activate platelets.
Conclusions: From these theoretical findings a picture emerged in which the potency of agonists that are produced or released at the bottom of a platelet mass, decreases as they percolate through the mass. This decrease is due both to dilution and to an increase in the removal rate as the agonists encounter regions of reduced packing density, and thus the sheltering action of deposited platelets plays a fundamental role in solutes transport. In summary studying solute transport in the complex geometry of a platelet mass can teach us important lessons about the spatiotemporal function and activation of platelets. It offers a novel way to study the evolving environment surrounding a platelet during hemostasis.

PB 3.26-6

Pattern and management of bleeding complications with new oral anticoagulants. Results of the Prospective Dresden NOAC Registry (NCT01588119)

Beyer-Westendorf J, Ebertz F, Gelbricht V, Förster K, Köhler C, Tittl L and Werth S
Dresden University Hospital, Carl Gustav Carus, Dresden, Germany

Background: Novel oral anticoagulants (NOAC) have been approved for anticoagulation for venous thromboembolism (VTE) and stroke prevention in atrial fibrillation (SPAF). In large trials, bleeding complications were the most frequent side effect, at in general similar frequency as with respective comparators. However, little is known about the distribution pattern, management and outcome of NOAC-related bleeding complications in daily care.
Aims: To evaluate the pattern and management of bleeding complications during NOAC therapy in daily care.
Patients and Methods: The Dresden NOAC registry is a prospective, non-interventional registry. A network of more than 230 physicians from private practice and hospitals enrol eligible patients, who are centrally followed by the registry office. Inclusion criteria are: (i) indication for therapeutic NOAC anticoagulation > 3 month; (ii) age > 18 years; (iii) written informed consent; (iv) availability for follow-up. No Exclusion criteria apply. In the registry, up to 2000 patients will receive prospective follow up by phone visits at day 30 day and quarterly thereafter for up to 3 years to collect efficacy and safety data.
Results: Until December 31th 2012, 1665 patients were enrolled into the registry. Of these, 1356 patients received rivaroxaban (372 for VTE, 968 for SPAF, 16 off-label) and 309 received dabigatran (303 for SPAF and six off-label). During follow-up (635.4 patient years) a total of 400 patients reported 474 bleeding complications (61.8% minor bleeding, 32.9% non-major, clinically relevant (NMCR) and 5.3% major bleeding according to ISTH definition).
For non-major bleeding, mucosal (epistaxis, gingival, conjunctival) were the most common bleeding sites (37.8% of all bleedings), followed by bruises and traumatic skin bleeds (27.8%), genitourinary (14.1%) and gastrointestinal (11.2%). For major bleeding, gastrointestinal bleeding was the most common manifestation (2.5%), followed by intracranial (0.4%) and a variety of other manifestations.
Most patients (96.0%) either did not need any treatment or received conservative treatment with compression, tamponade or red blood transfusion (RBC) alone. Surgical or interventional treatment was used in 4% of all bleedings (0.3% of minor, 7.1% of NMCR and 28% of major bleedings).
Transfusion of RBC or fresh frozen plasma (FFP) was only observed in patients with major bleeding (4.2& and 0.8% of all bleedings; 76.0% and 16.0% of all major bleedings, respectively). Prothrombin complex concentrate (PCC) was used in 1.3 of all bleedings (24% of all major bleedings) and no patient received recombinant factor VII.
Fatal bleeding was observed in two patients (0.4% of all and 8.0% of all major bleedings), in both cases due to major intracranial bleeding.
Conclusion: Bleeding complications are common in daily care NOAC patients treated and are usually managed by conservative treatment. Only 5% of all observed bleedings fulfil the ISTH criteria of major bleeding (mainly RBC transfusion criterion) and are managed using interventions, FFP or PCC. Overall, only a very small proportion of NOAC-associated bleeding complications in daily care are fatal, indicating that available management strategies are sufficient.
For presentation at the ISTH meeting, updated results from this ongoing project will be provided.

PB3.27 – Platelet Calcium Signaling

PB 3.27-1

Simultaneous real-time imaging of fibrinogen binding and intracellular calcium reveals a role for Rac1-dependent synergy between P2Y1 and P2Y12 receptors

Bye AP, Evans RJ and Mahaut-Smith MP
University of Leicester, Leicester, UK

Background: In platelets, ADP stimulates inside-out activation of integrin $\alpha_{IIb}\beta_3$ through co-activation of Gq-coupled P2Y1 and Gi-coupled P2Y12 receptors. These receptors operate synergistically via mechanisms that remain incompletely understood. The megakaryocyte (MK) serves as a bona fide model of platelet purinergic signalling and allows the dynamics of $\alpha_{IIb}\beta_3$ activation to be followed by imaging of fluorescently tagged fibrinogen (Tolhurst *et al.* Blood, 2005;106, 1644). We

have developed this approach further to simultaneously record Ca^{2+} waves and fibrinogen binding. We also explore the role of the small GTPase Rac1, an important mediator of positive feedback in platelets.
Aims: To explore in real time the spatiotemporal relationship between P2Y receptor-evoked elevations of cytosolic Ca^{2+} and downstream $\alpha_{IIb}\beta_3$ activation using fluorescence imaging of single primary MKs. To combine this approach with immunocytochemistry (ICC) to investigate the role of the small GTPase Rac1 in P2Y-evoked responses.
Methods: Primary rat MKs were isolated as described previously (Mahaut-Smith *et* al 1999 J. Physiol. 515, 385), loaded with the Ca^{2+} indicator Fluo-3 (2 μM Fluo-3 AM for 60 min) and imaged on a confocal microscope (Olympus FV1000) at 5.3 Hz in the presence of 60 μg/mL alexa fluor 647-tagged fibrinogen. P2Y1/P2Y12 receptors were stimulated with 100 μM ADPβS. Rac-1 was inhibited with 100 μM EHT1864. For ICC, MKs were fixed with 2% paraformaldehyde prior to staining of activated Rac1 with a mouse anti-Rac1-GTP antibody.
Results: ADPβS stimulated a series of transient Ca^{2+} increases in the form of waves spreading rapidly across the MK. Each Ca^{2+} wave was followed by a single, incremental increase in fibrinogen binding to the cell periphery. The fibrinogen bound uniformly at first, but in many cells developed a polarized appearance within 4 min that correlated with the average direction of the Ca^{2+} waves (computed from vectorial analysis). BAPTA-loading abolished the fibrinogen binding. Selective inhibition of either P2Y1 or P2Y12 receptors virtually eliminated fibrinogen binding as reported previously in murine MKs (Tolhurst et al. 2005). Although P2Y1 receptors were essential for the Ca^{2+} response, P2Y12 receptors were also required for more than a single initial Ca^{2+} spike. Inhibition of PI3K or Rac mimicked the effects of P2Y12 blockade on Ca^{2+} signalling and fibrinogen binding. Active (GTP-bound) Rac1 accumulated at the periphery of ADPβS-stimulated megakaryocytes and was abolished by inhibition of P2Y12, PI3K or Rac1.
Summary/Conclusions: In the MK, P2Y receptors generate multiple transient Ca^{2+} waves that efficiently couple to peripheral $\alpha_{IIb}\beta_3$ receptor activation. P2Y receptors also generate polarised fibrinogen binding that correlates with the direction of the Ca^{2+} waves. Sustained Ca^{2+} oscillations require co-stimulation of both P2Y1 and P2Y12 receptors, extending previous observations in platelet suspensions (Hardy *et al*. Blood, 2004;104:1745; van der Meijden *et al*. FEBS J, 2008;275:371). As described in platelets, the synergistic mechanism in the MK was blocked by PI3K inhibition suggesting the existence of a PI3K-dependent Ca^{2+} signalling pathway. We also provide evidence for the involvement in this pathway of Rac1, which is known to have a role in the development of polarity in other cell types.

PB 3.27-2

The role of plasma membrane STIM1 and Ca^{2+} entry pathways in platelet aggregation

Authi KS[1], Ambily A[1], Kaiser J[2], Pierro C[1], Chamberlain EV[1], Li Z[1], Kassouf N[1], Jones CI[2], Gibbins JM[2] and Authi KS[1]
[1]King's College London, London; [2]Uinversity of Reading, Reading, UK

Background: Ca^{2+} is an essential messenger in platelet activation that is released from intracellular stores and enters from the extracellular medium. The contributions of Ca^{2+} release and Ca^{2+} entry to individual platelet activation events are not established. IP_3 receptors release Ca^{2+} from intracellular stores. STIM1 senses
Ca^{2+} in the endoplasmic reticulum and activates Orai channels following Ca^{2+} release allowing store-operated Ca^{2+} entry (SOCE). TRPC6 and P2X1 entry channels allow non-SOCE Ca^{2+} entry.
Aims; STIM1 has also been reported in the plasma membrane (PM) but its role here is not understood. The effects of SOCE and non-SOCE inhibitors on platelet activation have not been fully described.
***Methods*:** We examined the effects of the antibody GOK/STIM1, which recognises the N-terminal region of STIM1, on SOCE, agonist-stimulated Ca^{2+} entry, surface exposure, *in vitro* thrombus formation and aggregation in human platelets. In addition we determined novel binding partners of STIM1 using proteomics. We also tested the effects of SOCE and non-SOCE inhibitors (BTP2 and LOE-908 respectively) on platelet aggregation.
Results: The neat GOK/STIM1 antibody reduced thapsigargin (TG)- and agonist-mediated Ca^{2+} entry in Fura2-labelled cells, but failed to do so following dialysis of the preparation to remove preservatives. Using flow cytometry we detected surface exposed STIM1. The dialysed GOK/STIM1 antibody reduced thrombus formation by whole blood on collagen-coated capillaries under flow and platelet aggregation induced by collagen. The SOCE inhibitor BTP2 reduced TG induced platelet aggregation but not that by thrombin, collagen or OAG. The non-SOCE inhibitor LOE 908 reduced OAG and collagen induced aggregation but not that by thrombin or TG. In immunoprecipitation experiments followed by proteomic analysis, STIM1 was found to extract a number of proteins including myosin, DOCK10, thrombospondin-1 and actin suggesting novel binding partners.
Conclusion: These studies suggest that PM STIM1 may facilitate platelet activation by collagen through novel interactions at the platelet PM while the essential Ca^{2+}-sensing role of STIM1 is served by the protein in the ER. SOCE is not essential for aggregation induced by thrombin however non-SOCE contributes to aggregation induced by collagen.

PB 3.27-3

The attachment of integrin aIIbβ3 and GpIb to the platelet cytoskeleton is disrupted in the phosphatidylserine-positive platelets as a result of calpain activation

Artemenko E, Ataullakhanov F and Panteleev MA
Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Background: The exposure of phosphatidylserine (PS) to the surface of activated platelets is an essential hemostatic mechanism allowing binding of procoagulant proteins and dramatic acceleration of coagulation reactions. The PS-negative activated platelets have active form of integrin $\alpha_{IIb}\beta_3$ on their surface, and PS-positive platelets do not have active form of integrin $\alpha_{IIb}\beta_3$ on their membranes. In the resting platelets, integrin $\alpha_{IIb}\beta_3$ is attached to the cytoskeleton with special proteins, and their degradation is supposedly controlled by a calcium-dependent protease calpain. Early studies suggest that calpain also regulates the activation of integrin $\alpha_{IIb}\beta_3$.
Aims: We investigated the attachment of integrin $\alpha_{IIb}\beta_3$ and GpIb to the cytoskeleton in platelet subpopulations. Additionally we analyzed the effect of calpain on the activation of integrin $\alpha_{IIb}\beta_3$.
Methods: Platelets were isolated from whole blood by centrifugation and gel-filtration. Then they were activated with physiological agonists such as thrombin or collagen-related peptide. We investigated the status of intergin $\alpha_{IIb}\beta_3$ and attachment of integrin $\alpha_{IIb}\beta_3$ to the cytoskeleton in activated platelets by flow cytometry. The status of intergin $\alpha_{IIb}\beta_3$ was detected with fluorescently labeled PAC-1 binding. The attachment of membrane glycoproteins (integrin $\alpha_{IIb}\beta_3$ and GpIb) to the cytoskeleton was estimated by fixing the platelet with paraformaldehyde after activation in the presence of fluorescently labeled antibody CD61 (or CD42b) to surface $\alpha_{IIb}\beta_3$ (or GpIb) and treating fixed platelets with detergent. Additionally the status of cytoskeletal proteins was evaluated by electrophoresis.
Results: We observed a loss of membrane surface glycoproteins only in the PS-positive platelets (fixed platelets after detergent treatment), but not in the PS-negative activated platelets and resting platelets. This effect was prevented by calpain inhibitors (calpeptin and MDL28170). These results suggest that the degradation of cytoskeletal proteins that provide attachment of integrin αIIbβ3 to the platelet cytoskeleton occurred in PS-positive platelets. Preincubation of platelets with the calpain inhibitors significantly inhibited the degradation of cytoskeletal proteins proceeds at activation of platelets as shown by electrophoresis. It follows that the proteolytic degradation of cytoskeletal

proteins in platelets is controlled calcium-activated protease calpain. While preincubation of platelets with calpain inhibitors before activation did not lead to changes in the expression of the active form of integrin $\alpha_{IIb}\beta_3$ on the membrane of PS-negative platelets, or the lack of the active form of integrin αIIbβ3 in the PS-positive platelets.
Conclusions: Inhibition of calpain resulted in a significant decrease in the proteolytic degradation of cytoskeletal proteins, suggesting that calpain is involved in the regulation of the attachment of integrin $\alpha_{IIb}\beta_3$ and GpIb to the cytoskeleton of platelets. However, calpain inhibition did not lead to changes in the expression of the active form of the integrin $\alpha_{IIb}\beta_3$, this suggests that calpain is not involved in regulating the activation of integrin $\alpha_{IIb}\beta_3$.

PB 3.27-4

Reduced expression of SERCA3 isoform in platelet from patient with morbid obesity inhibits platelet functions

Bobe R[1], Coupaye M[2], Lopez JJ[1], Kondratieff A[1], Pepin M[1], Teillet[2], De Prost D[1] and Stepanian A[1]
[1]Inserm, Le Kremlin-Bicetre; [2]APHP, Hôpital Louis Mourier, Colombes, France

Background: Obesity is a recognized cardiovascular risk factor. Platelets play an pivotal role in pathogenesis of atherothrombosis. In obese subjects, platelet activity is often described as increased and their sensitivity to antiplatelet agents is reduced. Such dysfunctions are often associated with a disruption of calcium homeostasis. Sarco/Endoplasmic Reticulum Ca^{2+} ATPase (SERCA1, 2 & 3) are proteins involved in cytosolic Ca^{2+} transport to the Endoplasmic Reticulum and regulation of calcium homeostasis.
Aims: A pilot study comparing nine subjects with severe obesity and five normal weight subjects, showed a collapse of expression of SERCA3 isoforms, whereas expression of SERCA2b remained unchanged. We hypothesized that in obese subjects, a decrease of platelet SERCA3 induced disruption of calcium signal and abnormal platelet function. To test this hypothesis, we analyzed the expression of SERCA3 in a larger group of obese subjects whose platelet functions were explored and calcium signal measured and compared to control donors.
Methods: Monocentric case/control study. Cases were women with body mass index (BMI) ≥ 35 kg/m^2, without hypertension, diabetes, dyslipidemia, cancer, sepsis or inflammation. Control subjects were women with BMI > 18.5 and < 25 kg/m^2, without the same exclusion criteria and matched to the cases for age $\pm$ 3 years. SERCA levels were measured by immunoblotting. Aggregation was examined in static conditions in washed platelets stimulated with various agonists. Activity of thrombin-stimulated platelet was measured by flow cytometry using PAC-1 (activated GPIIbIIIa). BAPTA Oregon-green (calcium fluorescent marker) loaded platelets were analyzed for calcium mobilization and influx in response to different agonists by flow cytometry and or video microscopy.
Results: We included 40 cases and 40 control subjects. Platelets from obese subjects displayed a reduced level of SERCA3 expression. This was associated to a lower calcium mobilization in response to agonists (Thrombin, collagen, PAR4-AP), while calcium influx was nearly unchanged. Such decreased sensibility was further observed in aggregation studies where higher agonist concentrations were needed to obtain similar level of aggregation. Finally, platelet activity after thrombin stimulation assessed by flow cytometry was also higher in control platelets than in platelet from subjects with morbid obesity.
Conclusion: In obese subjects, washed platelets displayed a reduced sensitivity to agonists; this was associated to a lower calcium response and a decrease in SERCA3 expression. We suggest that this SERCA3 decrease might be a physiological response to reduce the rate of spontaneous activation of platelets. Whether it is reversible after weight loss is under investigation.

PB 3.27-5

Contributing factors influencing the platelet activation time between platelet adhesion on Von Willebrand factor, detected by an increase in intraplatelet calcium ion

Tamura N[1], Goto S[1], Tomita A[2], Shiozaki S[1] and Nanazawa Y[1]
[1]Tokai University; [2]Tokai University School of Medicine, Isehara, Japan

Purpose: To clarify intra-platelet signaling factors contributing to platelet activation initiated by its interaction with von Willebrand factor (VWF), the time was measured between platelet adhesion on immobilized VWF to the start of an increase in intracytosolic calcium ion ($[Ca^{2+}]i$), in the presence or absence of specific inhibitors.
Method: In whole blood specimen in the presence of specific thrombin inhibitor, Argatroban (100 μM), platelets were rendered fluorescent with the Ca2+-sensitive dye fluo-3 AM. The $[Ca^{2+}]i$ of individual platelet, which adhered on immobilized VWF was measured as fluorescence changed. Whole blood was perfused on VWF in the presence or absence of phospholipase C (PLC) inhibitor U73211 (5 μM), a mixture of PI3K inhibitors (LY294002 and Wortmannin [10 μM, 100 nM respectively]), and ADP receptor $P2Y_{12}$ inhibitor AR-C69931MX (100 nM). The time from platelets adhesion to the start of increased $[Ca^{2+}]i$ was measured in 20 randomly selected platelets.
Result: In control, the time taken from platelet adhesion on VWF to the start of an increase in $[Ca^{2+}]i$ was 9.5 ± 3.8 (s). The time was significantly longer in the presence of U73211 (21.2 ± 6.6 (s), $P < 0.01$ as compared to control), however, the time taken in the presence of LY294002/Wortmannin of 9.9 ± 5.5 (s) and AR-C69931MX of 7.7 ± 5.0 (s) were not different from controlled conditions. In control, $[Ca^{2+}]i$ of platelets increased from 32.0 ± 9.4 (nM) to 397.3 ± 97.8 within 0.56 ± 0.12 s after first noting an increase in $[Ca^{2+}]i$. Maximum $[Ca^{2+}]i$ in the presence of $P2Y_{12}$ inhibitor of AR-C69931MX of 221.8 ± 115.6 (nM) was significantly lower than that in control ($P < 0.01$). The Maximuma $[Ca^{2+}]i$ in the presence of PLC inhibitor of U73211 of 328.2 ± 107.5 (nM) or the PI3K inhibitor of LY294002/Wortmannin of 332.9 ± 97.3 (nM) were not significantly different from controlled conditions.
Conclusion: It takes 9.5 ± 3.8 (s) from platelet adhesion on VWF to the start of an increase in $[Ca^{2+}]i$. This time delay is regulated by the activity of PLC, and not by PI3K since the delay was increased only when the function of PLC was blocked.

PB 3.27-6

Systems biology of platelet activation: a stepped hierarchy of responses arises from the calcium interplay between cytosol, dense tubular system and mitochondria

Golomysova A and Panteleev MA
Lomonosov Moscow State University, Moscow, Russian Federation

Background: Activated platelets have two major functions, aggregation and acceleration of plasma coagulation. Different activation levels lead to a hierarchy of responses, three major steps of which include ability to aggregate, granule release and shape change, and phosphatidylserine (PS) exposure. The last step, which dramatically increases the rate of blood thrombin generation, leads to formation of distinct subpopulations. This stepped hierarchy of platelet responses suggests existence of one or several decision-making mechanisms in the platelet's intracellular signaling network.
Aim: The goal of this study was to investigate, by means of *in silico* systems biology analysis, how a uniform increase in the agonist concentration could be transformed into a stepped platelet response.
Methods: A mathematical model of the platelet's signal transduction was developed. As calcium signaling is at the heart of the platelet acti-

vation, we primarily targeted the structures involved in it. The model includes several compartments: the cytosol, the dense tubular system (DTS) and the mitochondria. DTS and cytosol interacts through calcium pumps (SERCA) and signal-dependent channels, and the mitochondrion has several specific calcium-regulating mechanisms, a uniporter, an exchanger and a permeability pore. The activation level was simulated by varying the concentration of the PAR1 agonist. The set of ordinary differential equations was integrated using the COPASI software (http://www.copasi.org).

Results: Computer simulation shows that the stable resting state of platelet is maintained by a balance between calcium pumps and leaks trough the DTS and plasma membranes. At very low agonist levels, the stationary concentration of cytosolic calcium is maintained at ~0.01 μM, and weak activation leads to a slight increase up to ~0.05 μM with a subsequent return to the baseline. Two-fold increase in the agonist concentration leads to rapid activation of the SERCA. More powerful pumping-in causes long-lasting oscillations in the cytosolic calcium concentrations with a magnitude of ~0.2 μM, almost independent of the agonist concentration, in good agreement with experimental observations. Another two-fold increase in the agonist level induces activation of the mitochondrial uniporter and the bulk of calcium goes from DTS into mitochondria which causes collapse of mitochondrial membrane potential. Simultaneously, the cytosolic calcium concentration becomes stationary high. This occurs only in a fraction of platelets leading to the PS exposure in a subpopulation of them.

Conclusion: For the first time, it is demonstrated how the uniform increase of the platelet activation level can be converted into a stepped response hierarchy corresponding to several distinct platelet functions. The main mechanism controlling platelet stability at low agonist concentrations and activation threshold is the intense membrane leaks. Medium activation triggers the appearance of oscillations of cytosolic calcium that are controlled by means of the DTS calcium pump. Ultimately, the interplay of DTS and mitochondria at the high activation level triggers the mitochondria collapse with the consequent divergence of subpopulations.

P21-activated kinase regulate directional migration and cytoskeletal organization in human neutrophils

Itakura A[1], Aslan JEJ[1], Kusanto BT[1], Phillips KG[1], Nan X[1], Insall RH[2], Chernoff J[3] and McCarty OJT[1]

[1]Oregon Health & Science University, Portland, OR, USA; [2]CRUK Beatson Institute for Cancer Research, Glasgow, UK; [3]Fox Chase Cancer Center, Philadelphia, PA, USA

Background: Neutrophils serve as a first line of defense in innate immunity owing in part to their ability to rapidly migrate towards chemotactic factors derived from invading pathogens. As a migratory function, chemotaxis is regulated by the Rho GTPases including Rac, Cdc42 and RhoA. These Rho family members mediate the cytoskeletal rearrangements that underlie chemotaxis through the p21-activated kinase (PAK), a well-established effector of Rac and Cdc42. In neutrophils, rapid phosphorylation of PAK has been observed after the treatment with various agonists. To date, however, little is known about functional roles of PAK in primary human neutrophils.

Aims: We aimed to characterize the role of PAK downstream of Rho GTPases in cytoskeletal remodeling and chemotactic processes of human neutrophils.

Methods: Using chemotaxis assays, primary human neutrophils were allowed to migrate toward a source of the chemoattractant, f-Met-Leu-Phe (fMLP). Neutrophil directionality, morphological polarization and motility were monitored by time-lapse imaging in the presence or absence of pharmacological inhibitors of key signaling molecules including Rac, PI3K and PAK. We examined the expression of PAK isoforms in human neutrophils by Western blot. In addition, immunofluorescence microscopy was performed to characterize the activation and subcellular localizations of PAK, Rac, RhoA and cytoskeletal components such as F-actin and myosin.

Results: PAK inhibition led to a loss of directionality, increased spreading and decreased migration speed in neutrophil chemotaxis, whereas Rac or PI3K inhibition resulted in impaired directionality or polarization, respectively. PAK inhibition was associated with dysregulated intracellular Ca^{2+} release. Our data show that PAK2 is activated and accumulates at the neutrophil leading edge in response to fMLP to support Rac-mediated actin dynamics in a localized manner. In addition, PAK inhibition abrogated the subcellular localization of active RhoA and increased surface contacts via vinculin-rich complexes.

Conclusions: PAK kinase activity plays a critical role in chemotaxis of human neutrophils. Together, our data suggests that PAK establishes a 'frontness' signal by negatively regulating surface adhesion and Rho-dependent 'backness' signals in human neutrophils, thus providing a mechanism for the crosstalk between Rho-family GTPases in neutrophil cytoskeletal dynamics and cell migration.

PB 3.28-2

Correction of endothelial dysfunction by hepatocyte-specific Dyrk1a gene transfer in hyperhomocysteinemic mice

Janel N[1], Tlili A[1], Garcia Perez A[1], De Koning L[2], Dubois T[3], Paul J-L[4], De Geest B[5] and Delabar J-M[1]

[1]University Paris diderot; [2]RPPA platform, Institut Curie Department of Translational Research; [3]Breast Cancer Biology Group, Institut Curie Department of Translational Research; [4]AP-HP, Hôpital Européen Georges Pompidou, Service de Biochimie, Paris, France; [5]Center for Molecular and Vascular Biology, University of Leuven, Leuven, Belgium

Background: Hyperhomocysteinemia, defined by elevated plasma homocysteine level, is well recognized as an independent risk factor for cardiovascular diseases, including coronary artery, cerebrovascular, and peripheral occlusive disease even among people with normal cholesterol levels. The increased synthesis of homocysteine, a product of methionine metabolism involving B vitamins, and its slower intracellular utilization cause increased flux into the circulation. Hence, plasma homocysteine level is an important reflection of hepatic methionine metabolism and the rate of processes modified by B vitamins as well as different enzyme activity. Reduction of homocysteine levels is the key objective in treatment of hyperhomocysteinemia. Vitamin B6 in pharmacological doses in combination with folic acid or vitamin B12 or both is the treatment of choice for cystathionine beta synthase deficiency. However, approximately 50% of hyperhomocysteinemic patients due to cystathionine beta synthase deficiency are biochemically responsive to pyridoxine (vitamin B6). Therefore, effective treatments to reduce homocysteine levels are needed, and gene therapy could provide a novel approach.

Aims : We recently found a negative correlation between plasma homocysteine level and the hepatic expression of an anti-inflammatory serine/threonine kinase, Dyrk1a. We decided to use a gene transfer strategy with a specific hepatic adenoviral vector over-expressing Dyrk1a and analyzed the effect of a selective homocysteine lowering therapy on markers of hepatic and vascular function by reverse phase protein array.

Results: we found normalisation of plasma homocysteine level after hepatic Dyrk1a gene transfer in a genetically modified murine model with hyperhomocysteinemia. Specific hepatic Dyrk1a gene transfer

corrected the decreased hepatic and plasma paraoxonase 1 activities, and the decreased plasma apo A-I level which is associated with increased hepatic protein level. Paraoxonase 1 and HDL exert potent protective effects, including the prevention and correction of endothelial dysfunction. Targeted hepatic Dyrk1a gene transfer abolished the negative effect of hyperhomocysteinemia on PI3K/Akt/mTOR pathway, a cell signaling pathway that plays a key role in cellular homeostasis through its role in regulation of apoptosis, cell growth, cell cycle and angiogenesis, and the decreased protein level of cyclin D1. Commensurate with the positive effect on PI3K/Akt activation, the hepatic Dyrk1a gene transfer also resulted in GSK3 inhibition, which can prevent endothelial dysfunction in aorta of mice.

Summary/Conclusions: The positive effect on plasma homocysteine and aortic signaling pathways demonstrates that this gene therapy can constitute a useful approach for prévention of cardiovascualr diseases linked to hyperhomocysteinemia. This approach might also benefit other diseases in which hepatic homocysteine metabolism is affected and vascular alterations are prevalent.

PB 3.28-3

The novel NOX inhibitor 2-acetylphenothiazine impairs collagen-dependent thrombus formation in a GPVI-dependent manner

Pula G and Vara DS

University of Bath, Bath Spa, UK

Background: Besides classical agonist-induced signal transduction pathways, platelet activation is also regulated by reactive oxygen species (ROS). In particular, superoxide ions from exogenous and endogenous sources increase collagen-dependent aggregation and thrombus formation. NADPH oxidases (NOXs) play a critical role in the generation of superoxide ions in platelets and contribute to platelet activation, although their mechanism of action remains largely unknown. Therefore, NADPH inhibitors may represent novel potential candidates for the development of anti-platelet agents.

Aims: In this project, we studied the effect of the novel NOX inhibitor 2-acetylphenotiazine (2-APT) on human platelet functional responses and intracellular signalling pathways.

Methods: The generation of superoxide ions was assessed by single cell imaging on adhering platelets using dihydroethidium (DHE), while cumulative ROS generation was detected with 5-(and-6)-carboxy-2′,7′-dichlorodihydrofluorescein diacetate (CM-H2-DCFDA). Whole blood thrombus formation, washed platelet aggregation, integrin αIIbβ3 inside-out signalling, Syk phosphorylation, and protein kinase C (PKC) activation were analysed to understand the functional consequences of NOX inhibition by 2-APT in platelets.

Results: Superoxide ion generation stimulated by platelet adhesion on collagen and fibrinogen was significantly inhibited by 2-APT in concentration-dependent manner within the submicromolar range, whereas this pharmacological agent did not affect cumulative ROS generation. 2-APT impaired washed platelet aggregation in response to collagen but not thrombin and abolished whole blood thrombus formation stimulated by collagen but not fibrinogen. The activation of integrin αIIbβ3 and protein kinase C in response to the GPVI-specific agonist collagen-related peptide (CRP) was significantly reduced, whereas the same responses to thrombin were not significantly affected by 2-APT. Finally, Syk activation in response to collagen but not thrombin was inhibited by 2-APT, which suggests a stimulatory role for NOX-generated superoxide ions in the early events of the signalling cascade of GPVI.

Summary/Conclusions: Taken together, our results suggest that 2-APT attenuates GPVI-specific signalling and is a novel inhibitor of collagen-induced platelet activation. Therefore, 2-APT can represent a novel candidate for the development of anti-thrombotic drugs and NOXs are promising new targets for anti-thrombotic drug discovery.

PB 3.28-4

The polyamines regulate intestinal epithelial barrier function through AMP-activated protein kinase and the nuclear accumulation of c-Myc

Xu L and Zhu X

Anhui Provincial Hospital, Hefei, China

Backgroud: Epithelial cells line the gastrointestinal mucosa and form an important barrier that protects the subepithelial tissue against a wide array of noxious substances, allergens, viruses and luminal microbial pathogens. Restoration of mucosal integrity following injury and various environmental stresses requires epithelial cell decisions that regulate signaling networks controlling gene expression, survival, migration and proliferation. Our previous studies have shown that Polyamines regulate expression of E- cadherin and play an important role in control of intestinal epithelial barrier function, but the exact mechanism is still unknown. The AMPK (AMPk- activated protein kinase), an enzyme involved in responding to metabolic stress, was recently found to be involved in the regulation of epithelial tight junction assembly.

Aims: The current study was designed to determine whether polyamines modulate the nuclear accumulation of c-Myc by AMPK and then regulate E-cadherin transcription.

Methods: The IEC-6 cell line was purchased from the A.T.C.C at passage 13. The levels of cellular polyamines were decreased as a result of inhibiting ODC with DFMO (D,L-alpha-difluoromethy lornithine). The AMPKα activity, the nuclear levels of c-myc and E-cadherin levels were detected by Western Blotting after polyamine deletion in IEC-6 cells. Then the cells were overexpressed AMPKα by infection with adenovirus-AMPKα, the nuclear level of c-Myc protein, the mRNA and protein levels of E-cadherin were detected, the E-cadherin immunostaining of IEC-6 cells were observed under confocal microscopy, and the E-cadherin promoter activity was analysis by luciferase assays. To further determine whether c-Myc had the effect on E-cadherin transcription activity, two experiment were performed. First, we used small interfering RNA(siRNA) targeting the c-Myc mRNA(siMyc) to reduce c-Myc levels and thus directly examine its role in the observed changes in E-cadherin transcription activity. Second, c-Myc has the binding site on E-cadherin promoter, so we used the different E-cadherin promoter mutation on Myc binding site to detect the effect of AMPKα on E-cadherin promoter activity.

Results: Polyamine depletion by DFMO decreased the levels of AMPKα, the nuclear level of c-Myc protein and E-cadherin. AMPK activation by overexpression of the AMPK gene increased the nuclear levels of c-myc and reversed the barrier function as indicated by increasing E-cadherin promoter activity, mRNA levels and protein levels. Decreased c-myc by transfection with c-myc siRNA could inhibit the effect of AMPK on E-cadherin promoter activity. And further researches showed that deletion and point mutations of E-pal, the binding site of c-Myc on E-cadherin promoter, prevented the increase of E-cadherin promoter activity after overexpression of AMPKα.

Conclusions: These findings confirm that polyamines regulate intestinal epithelial barrier function through AMPKα and the nuclear accumulation of c-Myc.

PB 3.28-5

Therapeutic application of activated Protein C epigenetically constrains the redox-enzyme p66shc in diabetic nephropathy

Bock F[1], Shahzad K[1], Wang H[1], Madhusudhan T[1], Dong W[1], Esmon C[2], Nawroth P[3] and Isermann B[1]

[1]Insitut für Klinische Chemie, Magdeburg, Germany; [2]Oklahoma Medical Reserach Foundations, Oklahoma City, USA; [3]Universitätsklinikum Heidelberg, Heidelberg, Germany

Introduction: Mice with genetically increased levels of activated Protein C (aPC) are protected against diabetic nephropathy and have decreased

glomerular expression levels of the mitochondrial-targeted redox enzyme p66shc. In mice therapeutic application of aPC ameliorates indices of diabetic nephropathy and podocyte damage. The therapeutic mechanism and how intermittent application of a plasma protein with a half life of ~25 min modifies nephropathy remain unknown.
Methods: Unilaterally nephrectomized WT mice were STZ-injected. After 4 weeks of diabetes a subgroup was i.p.-injected every other day for 4 weeks with 1 mg/kg aPC (Elli Lilly, Xigris®) or with aPC preincubated with an antibody (HAPC1573) to block its anticoagulant function. In parallel a subgroup of aPC-injected mice were orally treated with sodium butyrate for 4 weeks. *In vitro* immortalized murine Podocytes were treated with 2 nM aPC and methylation-specific PCR (MSP) and ChIP were applied to analyze promoter methylation and acetylation of p66shc.
Results: Exogenous application of aPC and aPC-HAPC1573 ameliorates indices of diabetic nephropathy in diabetic wild-type mice. Glomerular accumulation of oxidative stress markers and of p66shc are reversed in aPC-treated diabetic mice. Renal Histone H3 acetylation and p66shc expression was increased upon diabetes and reversed with aPC-treatment. The histone H3 hyperacetylating agent sodium butyrate reversed the suppression of p66shc by aPC and abolished the beneficial effects of aPC. *In vitro* aPC reversed the glucose induced increase of the H3-acetyltransferase GCN5 and the hypomethylation and H3-hyperacetylation of the p66shc-promoter, which was abolished with sodium butyrate treatment.
Conclusion: Therapeutic application of aPC epigenetically suppresses the red-ox enzyme p66shc and through this indirect mechanism aPC has antioxidative and cytoprotective properties that are independent of its anticoagulant function.

PB 3.28-6

Protease-activated receptor-2 triggers epithelial to mesenchymal transition: potential relevance in pulmonary fibrosis and cancer

Borensztajn KS[1], Von Der Thüsen JH[2], Peppelenbosch MP[3] and Spek A[2]
[1]*Inserm U700, Paris, France;* [2]*Academic Medical Center, Amsterdam;* [3]*Erasmus Medical Center, Rotterdam, The Netherlands*

Background: Idiopathic pulmonary fibrosis (IPF) constitutes the most devastating form of fibrotic lung disorders and remains refractory to current therapies. Fibroblast foci are the histological hallmark of IPF, and these have been shown to (partially) originate from lung epithelial cells via epithelial-mesenchymal transition (EMT). The extracellular signals and cellular receptors triggering EMT in IPF remain incompletely understood. However, aberrant reactivation of the WNT signaling pathway, which is crucial in developmental programs regulating lung development and morphogenesis, is thought to play a role in IPF.
Aims: We have recently shown that deficiency of protease-activated receptor 2 (PAR-2) affords protection in bleomycin-induced pulmonary injury. Here, we explore the role of PAR-2-induced EMT in pulmonary fibrosis.
Methods and Results: Immunostaining of lung biopsies of IPF patients revealed prominent PAR-2 expression in the fibrotic regions of the lungs of these patients, with especially strong PAR-2 overexpression by epithelial cells overlying fibroblast foci. Double immunostaining revealed that PAR-2 co-localizes with epithelial cells expressing both epithelial (cytokeratins) and mesenchymal (vimentin) markers, suggesting a role of PAR-2 in EMT in IPF. We also observed *in vitro* that, following incubation with PAR-2 agonist peptide (AP), type II lung epithelial cells (A549) acquired a fibroblast-like morphology. Moreover, western blots performed on lysates of A549 cells stimulated with PAR-2 AP, demonstrated that PAR-2 activation induces the expression of the myofibroblast markers vimentin and α-SMA, as well as collagen secretion. Additional western blots showed that PAR-2 activation of epithelial cells triggers the WNT signaling pathway, leading to β-catenin accumulation, and immunofluorescence analysis of cells stimulated by PAR-2 AP confirmed the translocation to the nucleus of β-catenin.
Summary/Conclusion: Taken together, our results strongly suggest that PAR-2 directly triggers EMT in epithelial cells via WNT signaling pathway activation. Because EMT is a mechanism common to both IPF and cancer, these results could suggest involvement of PAR-2 driven EMT in both pathologies, and inhibition of the PAR-2-coagulation axis may therefore be clinically relevant in both diseases.

Continuous platelet production in the bloodstream is regulated by von Willebrand factor

Poirault-Chassac S[1], Nguyen KA[1], Pietrzyk A[1], Casari C[2], Veyradier A[2], Denis CV[3] and Baruch D[2]
[1]*Université Paris Descartes, Paris;* [2]*Inserm, Bicetre;* [3]*Inserm U 770, Bicetre*

Introduction: It is established that pre/proplatelets are formed from mature megakaryocytes (MK) as intermediates before platelet production. We have previously identified a new mechanism showing that exposure of MKs to a high shear rate (1800 s^{-1}) on von Willebrand factor (VWF) in an *ex vivo* flow model could accelerate proplatelet formation and platelet release. MK underwent microtubular rearrangementsto form proplatelets, breaking into several elements, still linked to one another via tubulin shafts; finally, pre/proplatelet reorganization could lead to the release of single, isolated platelets. Our findings therefore imply that, during the late stages of thrombopoiesis, continuous reorganization of proplatelets into platelets could be affected by their contact with VWF present on the vessel wall.
Aim: Recently, the transition of condensed platelets into multibodied proplatelets was described in circulating blood platelets in the absence of exposure to VWF and shear. The purpose of the present study was to investigate ex vivo and *in vivo* whether exposure to VWF in flow conditions was involved in the appearance of multibodied proplatelets in circulating blood.
Methods: A mouse model of severe von Willebrand disease, the *Vwf*-/- mice was used to mimick a situation of blood cells circulating in a vascular tree devoid of VWF. Cytoskeletal modifications of washed platelets from *Vwf*-/- and wild-type (*Vwf*+/+) mice were compared in an established flow model allowing the observation of rapid changes resulting from (pro)platelet adhesion to VWF. Proplatelets (designated as newly formed platelets) proportion was determined using washed platelets from murine blood, exposed to VWF at 1800 s^{-1} in a microfluidic platform and characterized by videomicroscopy, flow cytometry and activation studies.
Results: Newly formed platelets were visible within 5 min, representing up to 38% of the total number of platelets at 12 min. 1.8-fold more newly formed platelets were produced *ex vivo* in blood from *Vwf*-/- than *Vwf*+/+ mice, suggesting a potential role of VWF *in vivo*. Expression of VWF in *Vwf*-/- mice by hydrodynamic gene transfer decreased the percentage of proplatelet formation back to wild-type levels. Platelets collected at the exit of the flow chamber remained fully activable by thrombin, demonstrating that newly formed platelets were not pre-activated. Similar observations were obtained from a patient with severe von Willebrand disease. Young immature post-chemotherapy platelets also produced a 2-fold higher percentage proplatelets than control untreated mouse blood, following exposure to 1800 s^{-1} on VWF.
Conclusion: A direct role of VWF in the transition of condensed platelets into multibodied proplatelets was demonstrated *ex vivo* and *in vivo*. This suggests a new function for VWF as a regulator of bloodstream thrombopoiesis

PB 3.29-2
IL-21 promotes the expansion of primary human megakaryocytes *in vitro*

Benbarche S, Strassel C, Gachet C, Lanza F and De La Salle H
UMR_S949, INSERM, Université de Strasbourg, EFS-Alsace, Strasbourg, France

Background: Chronic inflammatory diseases are the most frequent cause of reactive thrombocytosis. Several inflammatory cytokines (TNFα, IL-1β, IL-6 and IL-4) are known to regulate megakaryopoiesis. Gene profiling studies indicate that *in vitro* differentiated megakaryocytes express the receptor for IL-21, another cytokine produced during immune responses.
Aims: The aim of this study was to assess the role of IL-21 on *in vitro* human megakaryopoiesis.
Methods: Megakaryocytes were generated by cultivating adult peripheral blood CD34+ cells obtained from leukoreduction filters with informed consent and written agreement from the donors. In our standard culture conditions we used thrombopoietin and proliferative cytokines (stem-cell factor, IL-6 and IL-9) for 7 days (phase 1) and then, thrombopoietin alone for 5 days (phase 2). In the test experiments, IL-21 was also added at phase 1 and/or phase 2. The expression of the IL-21 receptor was confirmed by RT-PCR and flow cytometry. The effect of IL-21 was checked by evaluating cell proliferation and phenotype and measuring platelet generation. In addition, the activity of thrombopoietin and IL-21 receptors was followed by assaying the phosphorylation of Stat-3 and -5 proteins by flow cytometry.
Results: RT-PCR experiments and flow cytometry demonstrated that the IL-21 receptor was absent in peripheral CD34+ cells, but was progressively induced during the differentiation. The presence of IL-21 did not modify the expression of its receptor and appeared to be beneficial to the cell culture only when added in the second phase. The numbers of megakaryocytes differentiated after 12 days of culture was increased, provided IL-21 was added during phase 2, this, in a concentration-dependant manner, up to 1.8 ± 0.2 fold when IL-21 was used at 100 ng/mL. The phenotypes of the cells were similar, whether IL-21 was added or not, as judged by the expression of the megakaryocytic specific receptors GPIIbIIIa, GPIb and GPV, and by the ploidy of GPIIbIIIa+ cells. Morevover, platelet production was not modified by the addition of IL-21. Stimulation of the IL-21R induced Stat-3 phosphorylation in the megakaryocytes, while thrombopoietin, preferentially phosphorylated Stat-5. Thus, the two cytokines appeared to induce complementary signal transduction pathways in these cells.
Conclusion: The proliferative effect of IL-21 on megakaryocytes and the well-known implication of this cytokine in some chronic inflammatory diseases, suggest a potential role of IL-21 in reactive thrombocytosis. In addition, our observations question whether IL-21 might be useful for platelet recovery after myelodysplasia.

PB 3.29-3
Megakaryocyte regulatory pathway mediated by NMDA receptors

Kalev-Zylinska ML[1], Kamal T[1], Green T[1], Morel-Kopp MC[2], Baguley B[1], Teague L[3], Christopher W[2] and During M[4]
[1]University of Auckland, Auckland, New Zealand; [2]Royal North Shore Hospital, Sydney, Australia; [3]Starship Children's Hospital, Auckland, New Zealand; [4]Ohio State University, Columbus, Ohio, USA

Background: Novel treatment strategies are required to improve outcomes of patients with megakaryocytic malignancies. To enable progress we need better understanding of disease mechanisms and new therapeutic targets. The *N*-methyl-D-aspartate glutamate receptors (NMDARs) have arisen as potential regulators of megakaryocytic maturation but their specific roles remain unknown. Intriguingly, in other cells NMDARs are thought to help balance processes of cell death and survival and contribute to the development of cancer.
Aims: We hypothesised that similar to other cells, megakaryocytic NMDARs are involved in cell fate decisions and may therefore influence malignancy phenotype. The main aim of this study was to investigate if NMDARs regulate growth and differentiation of megakaryocytic cells.
Methods: Well-established inhibitors of neuronal NMDARs (memantine, AP5, MK-801 and DCKA; 5–100 μM) and NMDAR agonists (NMDA and glycine; 1–100 μM) were used to investigate effects on proliferation and differentiation of Meg-01 and Set-2 megakaryocytic cell lines, including after differentiation with PMA (phorbol-12-myristate-13-acetate). Phenotypic end-points were read in the MTT cell viability and proliferation assay, thymidine incorporation assay and by flow cytometry on CD41a and CD61.
Expression of all NMDAR subunits, including splice variants, was investigated in Meg-01 and Set-2 cells using RT-PCR (including real-time), Western blotting, flow cytometry and immunostaining. In a pilot study, marrow samples from patients with essential thrombocythaemia (ET), myelofibrosis (MF) and acute megakaryoblastic leukaemia (AMKL) (n = 3 of each) were tested for expression of the obligate NMDAR subunit 1 (GluN1) using immunohistochemistry. Blasts from one AMKL patient were tested for expression of all NMDAR transcripts using RT-PCR.
Results: We found that NMDAR agonists (1–100 μM) increased and NMDAR antagonists (5–100 μM) reduced proliferation of Meg-01 and Set-2 cells. NMDAR antagonists did not interfere with Meg-01 and Set-2 differentiation. Instead, mild increases in CD41a and CD61 expression were observed in Meg-01 cells treated with NMDAR antagonists.
Prototypic NMDARs in the brain are very diverse but always contain two GluN1 components that typically combine with another two (identical or different) GluN2 (A, B, C or D) subunits. The GluN3 subunits (A and B) can also be present, but are less common. We found that both Meg-01 and Set-2 cells contained transcripts for all NMDAR subunits, except for GluN2B. By real-time PCR, transcripts for GluN 2D and 3B predominated in Meg-01, and 2D and 3A in Set-2. Further, Meg-01 and Set-2 contained a similar combination of GluN1 splice variants but differed in GluN2A splicing pattern. At the protein level, we confirmed the presence of GluN 1, 2A and 2D proteins in Meg-01 and Set-2 cells, both on cell surface and intracellularly. Upon differentiation with PMA, NMDAR expression increased both in Meg-01 and Set-2, supporting receptor relevance during megakaryocytic differentiation.
Studies on human bone marrow showed that megakaryocytic cells in ET, MF and AMKL all expressed GluN1. Blasts from the singular AMKL patient who was tested by RT-PCR contained all NMDAR transcripts.
Summary/Conclusions: Human megakaryocytic cells contain complex NMDARs that influence cell phenotype. Further studies to determine how NMDARs regulate megakaryocyte biology are warranted.

PB 3.29-4
Effect of three-dimensional hydrogel scaffolds on megakaryocyte differentiation and platelet production

Pietrzyk A[1], Poirault-Chassac S[1], Aid R[2], Derkaoui SM[2], Letourneur D[2], Le Visage C[2] and Baruch D[1]
[1]Inserm U765; [2]Inserm U698, PARIS, France

Background: Hematopoietic stem cells (HSC) differentiate into megakaryocytes (MK) whose function is to terminally release platelets, which are absolutely essential for bleeding arrest. Growth in 3D conditions may replicate the bone marrow microenvironment necessary for HSC proliferation and MK differentiation. So far, information is lacking on the influence of a 3D structure on both megakaryopoiesis and thrombopoiesis.
Aim: The aim of the study was to determine the effect of porous polysaccharide-based hydrogels on MK and platelet production from

human umbilical cord blood HSC. HSC proliferation and differentiation into MK were analyzed inside 3D hydrogel scaffolds and compared to cultures in liquid conditions (2D).
Methods: Porous hydrogels composed of polysaccharides (pullulan-dextran, 3:1 ratio) with 200 μm macropores were used. This optically transparent hydrogel material allowed for a direct observation of live cells. HSC were cultured in the presence of thrombopoietin for 16 days in 2D and for 36 days in 3D scaffolds. Confocal microscopy provided identification of megakaryocytic progenitor cells by staining of CD41a and CD42b markers, and of cell ploidy by YOYO-1 staining. Following extraction of cells embedded in the scaffolds by enzymatic lysis, the differentiation markers (CD34, CD41a and CD42b) and ploidy were also quantitated by flow cytometry. Clonogenic assay was performed to study CFU-MK potential. Platelet production from mature MK exposed to physiological shear rates in Bioflux200® was studied by videomicroscopy.
Results: Rehydrated 3D scaffolds were organized in a complex network structure where proliferating cells seeded at an optimal density of 0.5×10^5 cells/cm^2 were visible inside the pores. Small spherical cells characteristic of immature cells were visible at day 2. At day 9, MK progenitors appeared as larger cells followed by proplatelet-forming MK with pseudopodial elongations at day 12. From day 12, these three cell types were observed inside pores. Finally, 36 days after initial seeding, i.e. 20 days after the end of cell survival in 2D, high cell numbers were still observed in 3D. Up to day 16, flow cytometry analysis of extracted cells grown in 3D indicated similar MK differentiation as in 2D. Between day 16 and day 36, in 3D, high proportions of immature cells were present while mature MK persisted. At day 16, the number of CFU-MK in 3D was significantly increased compared to 2D ($P < 0.05$). In 3D, most cells displayed increased 4N (30.5% ± 2.34; $P < 0.05$) and >8N (4.4% ± 0.96) ploidy classes. Functional platelet-forming mature MK were obtained for a longer period in 3D (day 36) than in 2D (day 14) as shown by separate flow experiments.
Summary/Conclusion: 3D hydrogels provide a structure to prolong the duration of HSC ability to differentiate into fully mature and platelet-producing MK and thus may mimick the bone marrow environment. Clusterization of cells in pores of scaffolds may favor their proximity and allow concentrating soluble factors. Three-dimensional hydrogels appear as a powerful tool to further unravel the physiological mechanisms of megakaryopoiesis and thrombopoiesis and the coupling with a bioreactor could strengthen this *in vitro* model of bone marrow structure.

PB 3.29-5
Impact of COX-2 deletion on platelet and megakaryocyte phenotypes

Barbieri SS[1], Petrucci G[2], Amadio P[3], Tarantino E[3], Ranelletti F[2], Gianellini S[1], Rocca B[2], Patrono C[2] and Tremoli E[1]
[1]Centro Cardiologico Monzino, Milano; [2]Università Cattolica, Rome; [3]Università degli Studi di Milano, Milan, Italy

Background: Cyclooxygenase (COX)-1 or -2 and prostaglandin (PG) synthases catalyse the formation of PGs (including PGI_2 and PGE_2) and thromboxane (TX) A_2 playing a key role in the maturation of different cell types. While mature platelets express almost only COX-1, megakaryocytes contain both COX-isoforms. *In vitro* studies showed that pharmacologic inhibition of COX-2 activity might influence megakaryocyte maturation and platelet formation. The production of platelets by megakaryocytes requires an intricate series of remodeling events; abnormalities in this process can result in clinically significant disorders.
Aims: We investigated the role of COX-2 in megakaryocytopoiesis analysing platelets and megakaryocytes from cyclooxygenase-2 knockout (COX-2KO) mice in terms of phenotype and/or function.
Methods: Platelet and megakaryocyte phenotypes were assessed by cytofluorimetry, immunohistochemistry and/or functional tests.
Results: COX-2KO platelets showed increased expression of P-selectin and GPIIbIIIa, enhanced binding to fibrinogen and adhesion to endothelial matrix compared to WT platelets. Levels of TX synthase in platelets were similar in both groups of animals, whereas levels of COX-1 were higher in platelets from COX-2KO together with an increased ability to produce TXA_2. While platelet count in COX-2KO mice was slightly lower than in WT mice (WT:1121 ± 274 vs. COX-2KO:1031 ± 263 K/μL), platelet size was larger (WT: 71.10 ± 3.87 vs. COX-2KO:91.27 ± 5.48; $P < 0.01$), and there was a higher percentage (WT: 7.62 ± 0.59 vs. COX-2KO:13.27 ± 1.01; $P < 0.01$) of reticulated, young platelets. In the bone marrows of COX-2KO mice, megakaryocyte number was significantly reduced, with phenotypic features of poor differentiation, such as high nucleus/cytoplasm (N/C) ratios and reduced positivity for lineage antigens such as CD42b (GpIb). At variance with bone marrows, megakaryocytes were significantly increased in the spleen of COX-2KO mice, with a reduced N/C ratio and hyperexpression of lineage markers, whereas few, poorly differentiated megakaryocytes were present in the WT spleens. In addition, COX-2 deletion decreased expression of the prostacylin receptor (IP) and PGE_2 production, concomitantly with increases in PGI_2 production, resulting in a reduced PGE_2/PGI_2 ratio in the bone marrow. Opposite results were obtained in the spleen, where we observed upregulation of the expression of IP, significant reduction of PGI_2 levels, and an increase in the PGE_2/PGI_2. Levels of TXA_2 measured both in the BM and in the spleen were similar in WT and COX-2KO mice.
Remarkably, splenectomy, carried out in COX-2KO and in WT mice, decreased the number of circulating platelets by about 40%, and reverted the hyper-reactive phenotype observed in COX-2KO platelets.
Summary/Conclusions: COX-2 deletion appears to delay megakaryocytopoiesis in the bone marrow, consistently with previous *in vitro* reports. The spleen megakaryocyte hyperplasia in COX-2KO mice is likely to represent a compensatory response to defective bone marrow megakaryocytopoiesis. Finally, the young and hyper-reactive platelets in COX-2KO mice, derived from compensatory spleen megakaryocytopoiesis, might contribute to an increased thrombogenicity *in vivo*.

PB 3.29-6
The cholinergic system in cord blood derived megakaryocytes and megakaryocytic lineages

Bugert P[1], Kaiser K[2], Lorenz F[2], Starigk J[2], Sarin A[2] and Schedel A[2]
[1]DRK-Blutspendedienst; [2]Institute of Transfusion Medicine and Immunology, Mannheim, Germany

Background: In former studies we have shown that platelets and their precursors express nicotinic α7 acetylcholine receptors (nAChRα7) that are involved in platelet function. We could also demonstrate that in-vitro megakaryocytic differentiation of MEG-01 cells can be modulated via cholinergic drugs targeting nAChRα7.
Aims: In this study, we have investigated additional megakaryocytic lineages and cord blood derived megakaryocytes for the presence of additional receptors of the cholinergic family (nAChRα4, nAChRβ2, nAChRα7) and the acetylcholine esterase (AChE). Furthermore, we were interested in the effect of cholinergic drugs which are in clinical use on *ex vivo* megakaryocytic differentiation.
Methods: Expression of nAChRs and AChE was investigated in four megakaryoblastic celllines (M07, CMK, Dami and MEG-01), cord blood derived TPO-differentiated megakaryocytes at different time points of differentiation and in platelets. Expression levels of the components were investigated by quantitative real-time PCR (qRT-PCR) and Western blot analysis. Cord blood derived CD34+ cells were differentiated with TPO for up to 14 days and the effect of the AChE-inhibitor donepezil (100 nM, 1 μM, 10 μM) on the differentiation and proliferation process was investigated by flow cytometry and micrsocopy.
Results: nACHRα7, nAChRα4, nAChRβ2 and AChE gene transcripts could be identified on all cell lines and cord blood derived megakaryocytes during all stages of differentiation. This could be confirmed at

protein level. While platelets express nAChRα7, they lack expression of nAChRα4, nAChRβ2 and AChE. The TPO-induced differentiation process and proliferation was significantly inhibited by the AChE-Inhibitor donepezil in a concentration dependent manner.
Conclusions: In addition to nAChRα7, precursor cells also express nAChRα4, nAChRβ2 and AChE which are down regulated during megakaryopoesis. AChE-Inhibitors are frequently used as treatment of dementia in elderly people. Since the megakaryocytic differentiation process impaired in the presence of AChE-Inhibitors patelet function in these patients could be affected.

PB3.30 – Microparticle assays

PB 3.30-1
Towards standardized protocols for preparation and detection of microparticles

Yuana Y, Böing AN, Hau CM, Grootemaat AE, Sturk A and Nieuwland R
Academic Medical Centre, Amsterdam, The Netherlands

Background: Results from studies on microparticles (MP) are difficult to compare between laboratories because no standard protocols are available for collection, handling, storage, and isolation of MP. Recently, novel technologies such as resistive pulse sensing (RPS) and single particle tracking (SPT) have become commercially available. Both technologies enable detection of *single* particles directly in solution.
Aims: In this study, we aim to develop standard protocols for collection, handling, storage, and isolation of MP. Flow cytometry (FCM), RPS and SPT are used to measure the concentration and size distribution of particles in samples prepared using these protocols.
Methods: MP were isolated from erythrocytes and platelets using different centrifugation protocols, in which the centrifugation force (18,890 ***g*** and 100,000 ***g***) and centrifugation time (0.5–2 h) were varied. Isolated MP were reconstituted in phosphate buffer saline (PBS) or in autologous vesicle-depleted human plasma (VDP) and measured directly or before snap-frozen in liquid N_2 and storage at −80 °C.
Results: RPS and SPT detect 1000–10,000-fold more particles in all MP preparations than FCM. In general, the particle concentration and diameter in all MP preparations are more affected by the single freeze/thaw cycle than by centrifugation conditions. Importantly, the effect of single freeze/thaw cycle on particle concentration and diameter are markedly different for MP prepared from erythrocytes and platelets. After single freeze/thaw cycle, the particle concentration and typical particle diameter of erythryocyte MP reconstituted in VDP are comparable to the freshly prepared samples (2.4×10^{10} particles/mL and 200 nm), but not for those reconstituted in PBS (9.9×10^{9} particles/mL and 164 nm). In contrast, regardless the reconstitution solution used, the particle concentration of samples prepared from platelets increases about 2-fold (5.8×10^{9} to 1.2×10^{10} particles/mL) and the particle diameter decreases (160–140 nm) after single freeze/thaw cycle compared to the freshly prepared samples.
Conclusions: To develop a single protocol for starting materials containing MP of different cellular origin, such as plasma, may be very challenging because each type of vesicle behaves differently especially after freezing/thawing.

PB 3.30-2
Effect of filtration on the particle concentration and diameter of microparticles

Yuana Y, Grootemaat AE, Sturk A and Nieuwland R
Academic Medical Centre, Amsterdam, The Netherlands

Background: Although many investigators use filtration to remove larger particles from suspension of vesicles, the effects of filtration are not thoroughly investigated.
Aim: To investigate the effect of filtration on the detection of MP.
Methods: Microparticle (MP)-containing samples were prepared from erythrocyte concentrates. The concentrate was diluted two times with phosphate buffer saline (PBS) and centrifuged twice at 1550 ***g*** for 20 min at 20 °C. The supernatant was measured directly or filtered using 0.8 μm (mixed cellulose esters, Millex-AA; Merck Millipore, MA, USA) and 0.22 μm (polyethersulfone, Millex-GP, Merck Millipore) syringe-disc filters. Particles were measured by flow cytometry (FCM), resistive pulse sensing (RPS), and single particle tracking (SPT). PBS was used as negative control in the filtration experiments. Finally, PBS was analysed before and after filtration by transmission electron microscopy (TEM).
Results: Erythrocyte MP (CD235a-positive) are undetectable by FCM after filtration by a 0.22 μm filter or a 0.8 μm filter. In contrast, the particle concentration detected by RPS are 5.6×10^{9} particles/mL before filtration, 5.0×10^{9} after filtration by a 0.8 μm filter, and 0 particles/mL after filtration by a 0.22 μm filter respectively. Using SPT, there is a 4-fold increase in the particle concentration measured after filtration by a 0.8 μm filter. In PBS, almost no particles after filtration by 0.22 μm filter are detectable by FCM, RPS, or SPT. Surprisingly, in PBS filtered through 0.8 μm filter, there are particles detected by FCM (5.8×10^{3} particles/mL), RPS (3.1×10^{7} particles/mL), and SPT (4.6×10^{6} particles/mL). In this sample, EM also detects particles which are likely to be debris released from the filter, and such debris was not detectable in unfiltered PBS or after filtration by a 0.22 μm filter. When PBS was first filtered through a 0.2 μm filter and then a 0.8 μm filter, similar debris was present.
Conclusions: Filtration through 0.8 μm filter affects mainly the particle concentration. Filtration through a 0.8 μm syringe-disc filter is not recommended because such filter releases debris that will contaminate particle analyses.

PB 3.30-3
Effect of inflammatory cytokines and coagulation factors on endothelial microparticle formation and content

Meiring MS, Le Roux E and Louw V
University of the Free State, Bloemfontein, South Africa

Background: The role of microparticles in inflammatory and thrombotic disorders is still not fully understood. Endothelial microparticle formation is altered in inflammatory and thrombotic disorders like sepsis, atherosclerosis and thrombotic thrombocytopenic purpura. It is however not known if these microparticles are the cause or the consequence of these disorders.
Aims: We aimed to study the effect of inflammatory cytokines and coagulation factors as well as combinations thereof on endothelial microparticle formation and on microparticle von Willebrand factor (VWF) and its regulating protease ADAMTS-13. We also measured the microparticle thrombin generation in patients with HIV-associated TTP.
Methods: In this study microparticle formation in cultured human umbilical vein endothelial cells (HUVEC) was stimulated by different inflammatory agents IL-6 (100 ng/mL) IL-8 (100 ng/mL) and TNF-α (100 ng/mL), coagulation factors TF (2 μL/mL) and thrombin (2 U/mL) and combinations thereof. The number of endothelial microparticles formed was determined using flow cytometry. Von Willebrand factor (VWF) and ADAMTS-13 levels of the microparticles were assessed by ELISA's and the microparticle thrombin generation was measured by thrombin generation assays. Von Willebrand factor multimers were visualized by a Western blot technique. Microparticle thrombin generation was measured in the plasma of 20 patients with HIV-associated TTP.
Results: Interleukin-6 did not show any effect on HUVEC derived microparticles due to the lack of the receptor for IL-6 on these cells. Interleukin-8 only had a small increasing effect on microparticle VWF and ADAMTS-13 levels. TNF-α showed a significant effect on micro-

particle numbers and contributed to almost 80% of the thrombin generated, but has almost no effect on the VWF levels in the microparticles. Tumour necrosis factor alpha is thus a potent stimulus of endothelial cells and might be responsible for the thrombotic tendency in thrombotic and inflammatory disorders. The coagulation factor TF on the other hand showed the highest increase in microparticle VWF levels and had a huge effect on microparticle numbers. It however has no effect on the thrombin generation of microparticle. Tissue factor in combination with TNF-α also induced an increase in microparticle VWF and a little decrease in ADAMTS-13 levels. Tissue factor may thus contribute to the increased VWF levels that are commonly found in TTP patients where inflammation and thrombosis occur. To proof this, we found that microparticles contribute to more than 70% of the thrombin potential in the patients with HIV-associated TTP. Interestingly, thrombin shows a protective effect on the intact HUVEC whereby microparticle formation was prevented. The combination stimuli of thrombin and cytokines also showed a protective effect on HUVEC. This highlighted the regulatory role of thrombin in intact endothelial cells on haemostasis and in protection against thrombosis in extremely inflammatory environments.

Conclusion: Endothelial microparticles can thus be detrimental or beneficial with different stimuli and in different environments. Inflammatory and coagulation stimuli may however pose a great risk for clotting by altering microparticle quantity and content. This study contributes to the understanding of the role that endothelial derived microparticles plays in inflammation and thrombosis.

PB 3.30-4

The procoagulant phospholipids clotting time assay as a routine functional test for measuring circulating microparticle activity

Campello E[1], Luca S[1], Claudia MR[1], Sabrina G[1], Barry W[2] and Paolo S[1]

[1]Department of Cardiologic, Throcacic and Vascular Science, University of Padua, Padova, Italy; [2]HaemaCon Ltd, Bromley, UK

Background: Microparticles (MP) are now considered as critical effectors involved in numerous biological processes (coagulation, inflammation, vascular biology). Two major complementary approaches are available to monitor circulating MP in a clinical setting. The MP can be measured using a quantitative and descriptive approach by flow-cytometry or by a functional approach assessing MP biological activities by a FXa based clotting assay. Flow cytometry can be used to determine the cellular origin of the different MP, although there are concerns about the detection limit of this approach. Functional assays measure only the procoagulant activity of isolated MP and give no information on the cellular source or the physical properties of the MP. The advantage of the functional assays is that the assays use well-defined reagents and they are readily automated with high sensitivity and simplicity. Ideally, a combination of methods is needed to characterize MP.

Aim: Here we report a correlation between Annexin V-MP (AMP) enumeration by cytometry and the assessment of their procoagulant activity by FXa based clotting assay, in a number of different clinical settings.

Methods: This study analyzed 60 patients with active cancer of different type (M/F 30/30, age 40–92), 60 patients with a BMI >25 kg/m^2 (M/F 30/30, age 18–66), and 49 carriers of Factor V Leiden (FVL) and prior venous thromboembolism (VTE) (M/F 19/30, age 26–64). Samples were only collected after obtaining informed consents from the patients consecutive referred to our Medicine and Thrombotic Unit. All these patients had been previously enrolled in studies by our group. MPs levels were assessed by flow-cytometry (Beckman Coulter, USA) using calibrated beads of defined diameter and annexin V-fluorescein isothiocyanate staining. MP activity was assessed by a FXa based procoagulant phospholipid dependent clotting assay (Diagnostica Stago, France) using a phospholipid depleted substrate plasma. In this assay a reduction of the clotting time reflects increased procoagulant activity of the sample. Correlation analyses were performed by Spearman's rank correlation test.

Results: Flow-cytometry analysis of AMP counts was compared with MP activity measured by the procoagulant clotting assay (PPL). In all three groups of patients tested we found the same inverse correlation between the flow-cytometry analysis of AMP counts compared with PPL: in cancer patients r −0.685, $P < 0.001$, in obese patients r −0.478, $P < 0.05$ and in FVL patients who had had a previous VTE r −0.521, $P = 0.0043$.

Conclusions: The two different methods for MP detection showed good correlations with one and other even if the basis for the MP analysis was completely different. Even if flow-cytometry is considered the 'gold standard'of MP detection there are still many technical limitations reducing its wide spread use relating to the complexity of the assay and concerns about detection of the small MP. The PPL assay is much simpler to perform. The PPL assay could be a useful initial automated screening test to detect patients with abnormal MP activity. Only the abnormal samples would then need to be further evaluated by flowcytometry.

PB 3.30-5

Procoagulant phospholipid in stored erythrocyte concentrates

Smith SA, McMichael MA, Ngwenyama T, Herring JM, O'Brien MA, Corsi R, Galligan A and Swanson KS

University of Illinois, Urbana, USA

Background: Transfusion of erythrocyte concentrates may cause adverse effects in the recipient, which include inflammatory and procoagulant responses. Pre-storage removal of leukocytes and platelets (leukoreduction) improves clinical outcome in the human recipient.

Aim: To evaluate the impact of leukoreduction (LR) on the development of procoagulant phospholipid (PL) in canine erythrocyte concentrates as a function of storage time.

Methods: Whole blood units were collected from healthy dogs and processed with LR ($n = 5$, using integral LR filter) and without LR (NLR, $n = 5$, using standard triple bag). Plasma was removed from all units via standard centrifugation, separation, and storage methodology. Aliquots were aseptically collected from the erythrocyte concentrate units on storage days 0, 7, 14, 28, and 35. Samples were centrifuged at 1850 $\boldsymbol{g} \times 20$ min to remove cells. Procoagulant PL in supernatants was quantified using STA Procoag-PPL on a STart4 coagulometer against a standard curve of liposomes containing 20% phosphatidylserine. PL-dependent thrombin generation was also evaluated using calibrated automated thrombography (CAT) with addition of supernatants to PL-depleted pooled normal human plasma.

Results: Procoagulant PL (range 6.9–42.1 μg/mL) was detected in all supernatant samples using the PPL assay. Concentrations were similar between LR and NLR units on storage days 0, 7 and 14, but were significantly higher in non-LR units on days 21, 28, and 35. Thrombin generation via CAT was minor in the absence of supernatants [Mean (SD) peak: 13.5 (10.9) nM]. Mean (SD) peak thrombin was similar between LR and NLR supernatants on day 0 [LR: 20.1 (7.8) nM; NLR: 23.2 (17.1) nM], day 7 [LR: 20.5 (10.2) nM; NLR: 24.4(18.6) nM], and day 14 [LR: 24.4 (7.9) nM; NLR: 25.3 (18.3) nM], but higher in NLR units on day 21 [LR: 34.3 (7.7) nM; NLR: 64.9 (35.6) nM], day 28 [LR:37.5 (14.9) nM; NLR: 138.2 (163.6) nM], and day 35 [LR: 80.3 (95.3) nM; NLR: 197.0(60.2) nM].

Conclusion: Procoagulant PL is present in stored canine erythrocyte concentrates. Pre-storage LR reduces the amount of procoagulant PL that develops as a consequence of storage, and delays the significant increase in procoagulant PL.

PB 3.30-6

In vitro microparticle-dependent clot formation mainly depends on platelet-derived microparticles and not on other subtypes

Bouriche T[1], Judicone C[1], Lacroix R[2], Bernit E[3], Harti K[3], Albanese J[3], Dignat-George F[3] and Poncelet Ph[1]
[1]*BioCytex;* [2]*Inserm UMR S1076, Aix-Marseille University;* [3]*La Conception Hospital, APHM, Marseille, France*

Background: Microparticles (MP) are blebs of submicron sizes derived from various cell types including platelets, erythrocytes, leucocytes, endothelial or tumor cells (resp. PMP, Ery-MP, Leu-MP, EMP and tumor-MP). Due to the expression of procoagulant phospholipids (PPL), mainly phosphatidylserine (PS), they can be characterized by annexin V binding or/and thrombin generation. The amount of PPL can also be measured in whole plasma using chronometric assays where clotting time (CT) is related to total PS+ MP (TMP) content (1,2).
Aims: Check whether or not all MP subsets are equivalent PPL sources in MP-based clotting assays.
Methods: STA-Procoag-PPL (Stago, Asnières, F) was used to measure PPL- dependent clotting time, CAT with PRP Reagent (Thrombinoscope, NL) to monitor PPL-dependent TG and high sensitivity flow cytometry (FCM, Gallios, Beckman-Coulter) to differentially count the three major MP subsets. TMP were also measured using a capture assay coupled with TG (Zymuphen, Hyphen-Biomed, F). Platelet free plasma (PFP) samples included (i) MP-free plasma (MPFP) spiked with purified MP of various origins, (ii) PFP issued from normal citrated blood samples with/w.o. agitation prior to the 1st centrifugation (in order to artificially modulate MP content, ref. 3), (iii) PFP specifically depleted from resp. PMP, Ery-MP and/or Leu-MP using immuno-magnetic separation (IMS) (iv) PFP samples from sickle cell disease (SCD) patients and (v) PFP samples from septic patients, both as sources of distorted MP contents.
Results: In all types of samples, covering large ranges of PMP, Ery-MP and Leu-MP counts, due to either a pathology, IMS depletion or blood agitation, CT always correlates well with log [PMP]. On the contrary, Ery-MP and Leu-MP counts are poorly correlated with CT in all upper-cited plasma categories (a to e), as observed by comparison with FCM counting and confirmed by spiking experiments using pure MP, although TG levels correlate well with MP counts for all MP subtypes. In a reconstituted plasma model where MPFP was spiked with similar amounts of both PMP and Leu-MP, IMS-based removal of >90% spiked PMP clearly increased CT whereas selectively removing Leu-MP had no effect, independent of the order of the sequential IMS depletions. Re-incoporating PMP linked to IMS beads into MPFP resulted into shorter CT (e.g. 106 s down-to 35 s) whereas no effect came with Leu-MP. In pathological PFP, removing both Leu-MP and Ery-MP together had no effect on CT in contrast to removing PMP.
Conclusions: In a MP-dependent clotting assay the high correlation between PMP counts and CT was confirmed whereas low correlation values were observed with other MP subsets. Despite a tight correlation between MP counts of any type and TG, effective clotting is not only linked to PS expression but seems to require properties for clot elongation that are not provided by MP subsets other than PMP. In this respect, automatized clotting assays such as STA-Procoag-PPL may be considered as PMP-specific and used as such (4).

PB3.31 – Endothelium: miscellaneous

PB 3.31-1

Molecular mechanisms of *S. aureus* mediated endovascular infection under fluid shear conditions

McDonnell C[1], McLoughlin A[2], Cummins PM[2] and Kerrigan SW[1]
[1]*The Royal College of Surgeons in Ireland;* [2]*Dublin City University, Dublin, Ireland*

Background: The adherence of *Staphylococcus aureus* to human endothelial cells is an important step in the pathogenesis of systemic *Staphylococcal* infections such as sepsis, meningitis and infective endocarditis. Adhesion to endothelial cells is critical in the pathogenesis and dissemination of the infective process. A major limitation in our current understanding of bacterial-endothelial cell interactions stems from the fact that previous studies have been carried out under static conditions. It has been argued in the literature that data obtained *in vitro* using static binding assays may not be relevant to the fluid dynamic environment encountered in the vasculature. The local fluid environment of the circulation critically affects the molecular pathways of endothelial cell-cell interactions and therefore may affect *S. aureus* binding.
Aim: The aim of this study was to investigate the interaction between *S. aureus* and endothelial cells subjected to physiological shear under resting and activated conditions.
Methods: Human aortic endothelial cells (HAEC's) were grown in Endothelial Cell Growth Medium MV supplemented with 5% Foetal Bovine Serum at 37 °C under either static conditions or conditions that mimic arterial shear rates experienced in the vasculature. Endothelial cells were treated with media or Human recombinant TNF-α (10 ng/mL) for 4 h followed by preincubation with heparinized plasma for 1 h at 37 °C. *S. aureus* were fluorescently labeled using a DNA stain and added to endothelial cells for 1 h.
Results: Tumour necrosis factor alpha is a major cytokine released from various immune cells and from the endothelial cells themselves in response to infection. TNF-α treatment of the HAEC's led to a significant increase in adhesion of *S. aureus* over resting HAEC's (128% increase, $P < 0.005$, $n = 3$). Clumping factor A (ClfA) is the most abundant protein expressed on the surface of *S. aureus* and has been implicated in the pathogenesis of Infective Endocarditis. Deletion of ClfA from the parent strain of *S. aureus* failed to have any effect on adhesion to the resting HAEC's (P = NS, $n = 3$), however significantly reduced adhesion to HAEC's treated with TNF-α (70% reduction compared to parent strain, $P < 0.001$, $n = 3$). We have previously demonstrated that ClfA binds plasma proteins in order to bridge the *S. aureus* to the host cell. Consistent with this removing plasma from the assay significantly reduced *S. aureus* from binding to the HAEC's (85% reduction in the absence of plasma, $P = 0.0001$, $n = 3$). Deletion of another major cell wall protein, protein A failed to have any effect on adhesion compared to parent strain (P = NS, $n = 3$)
Conclusion: Results presented here suggest that *S. aureus* have the propensity to bind to sheared endothelial cells that have been exposed to TNF-α over resting endothelial cells. The major cell wall protein ClfA bridges *S. aureus* to the TNF-α activated endothelial cell via an as yet unidentified plasma protein. A greater understanding in the area of vascular infection will aid in the development of novel therapies to treat this infection.

PB 3.31-2

Coagulation profile in patients with acute leukaemia receiving myeloablative or reduced-intensity conditioning regimens for allogeneic hematopoietic stem cell transplantation

Rupa-Matysek J, Czyz A, Gil L, Wojtasinska E, Zajdel K, Ciepluch K and Komarnicki M

Poznan University of Medical Sciences, Poznan, Poland

Background: Preparative regimens are critical elements in allogeneic hematopoietic stem cell transplantation (HSCT). Depending on intensity, preparatory regimens can be divided into myeloablative (MA) destroying host hematopoiesis with profound cytopenia and reduced-intensity (RIC) with minimal toxicities and immune mediated effects. Total body irradiation (TBI) regimens increase toxicity but improve eradication of leukaemia cells.

Blood coagulation, especially protein C anticoagulant system and inflammatory pathways are closely linked processes. There is also a relation between endothelial dysfunction and organ damage. Dysregulation of this process and endothelial injury may contribute to the pathogenesis of transplant complications.

Aims: Our aim was to evaluate the effects of the intensity of preparatory regimens on coagulation and endothelial cell activation in patients with acute leukaemia undergoing HSCT. Secondary was to identify coagulopathy abnormalities after TBI.

Methods: Fifty patients (29 males and 21 females, median age 34, range 18–63) transplanted with allogeneic stem cells after myeloablative (n = 15) or reduced-intensity (n = 35) conditioning regimen, followed by infusion of HSCs from a related donor (n = 17) or match-unrelated donor (n = 33) with peripheral blood stem cells (n = 26) and bone marrow stem cells (n = 24) were enrolled in the study. Underlying diseases included: acute myeloid leukaemia (n = 32) and acute lymphoblastic leukaemia (n = 18). TBI was applied in 36%. Graft vs. host disease prophylaxis consisted of cyclosporine A and methotrexate, while antithymocyte globulin (ATG-Fresenius) was additionally used in MUD.

We investigated citrated blood samples from 50 patients before the conditioning regimen (day −10), on the day of stem cell infusion (day 0) and on day +14 and +28 after HSCT for the following parameters: antithrombin (AT), protein S (PS), protein C (PC), thrombomodulin (TM), soluble endothelia protein C receptor (EPCR), C4 binding protein (C4BP), activated protein C resistance (APCR), factor VIII (FVIII), von Willebrand factor (vWF) and C-reactive protein (CRP). The mean values of all the parameters of both regimen groups were analyzed.

Results: There was no significant difference in the mean plasma level of the analyzed parameters between MA and RIC group at baseline (day −10 before HSCT), except for higher vWF and lower APCR ratio in RIC. On day −10, day 0 and day +14 after HSCT vWF antigen was higher in RIC than in MA group. Except for the lower PS in the RIC group (58.235 ± 21.233 vs. 76.041 ± 15.181; P = 0.0114), other parameters did not differ on day 0. In both groups, decreased PC and TM activity was shown between days 0 and +14 after HSCT, and differed significantly between the groups (P = 0.0146 and P = 0.0334, respectively). Neither the MA nor RIC group differed on day +28 with respect to coagulation and endothelial markers.

In patients conditioned with TBI, a significant decrease in PC, PS and FVIII between day −10 and day 0 was observed. Patients after ATG had significantly increased TM and AT on day 0 in comparison to patients with a related donor. CRP was similar with regard to intensity of preparatory regimen or radiation.

Summary: In our cohort, in patients with acute leukemia subjected to HSCT, a distinctive pattern of coagulation abnormalities was observed.

PB 3.31-3

Prior intracerebroventricular administration with endothelin-1A receptor antagonists reduces hypercoagulable state and systemic inflammation, and result in survival time prolongation in rat heatstroke

Yang TH, Shih MF, Tsai ML and Liu CC

Chia Nan University of Pharmacy and Science, Tainan city, Taiwan

Endothelin (ET)-1 was increased in the plasma and cerebrospinal fluid of patients with cerebral ischemia, stroke, brain trauma or heatstroke. Endothelial cell activation/injury also occurred in heatstroke victims. Several lines of evidence indicate that animals share with humans almost the same heatstroke syndromes. In the rodent heatstroke model, significant decrements in both mean arterial pressure (MAP) and cerebral blood flow (CBF), but increments of hypercoagulable state and systemic cytokine levels are obtained during heatstroke. ET-1 mechanisms might be involved in heatstroke-induced circulatory shock, cerebral ischemia injury, hypercoagulable state and systemic inflammation. ET-1A receptor antagonism has been shown to be of benefit in the treatment experimental cerebral ischemia and injury. In the present study, we purpose that intracerebroventricular (icv) pretreatment with ET-1A receptor antagonists act to diminish the hypercoagulable state and reduce overproduction of pro-inflammatory cytokines, and eventually improve the arterial hypotension, cerebral ischemia and damage in rats of heatstroke. The results indicate that all heat-stressed rats displayed systemic inflammation and activated coagulation, evidenced by increased tumor necrosis factor-α and interleukin-1β, prothrombin time, activated partial thromboplastin time, and D-dimer, and decreased platelet count and protein C. Biochemical markers evidenced cellular ischemia and injury/dysfunction: plasma levels of blood urea nitrogen, creatinine, glutamic oxaloacetic transaminase, glutamic pyruvic transaminase, and alkaline phosphatase, and striatal levels of glycerol, glutamate, and lactate/pyruvate were all elevated during heatstroke. In contrast, the values of MAP, plasma levels of interleukin-10, and striatal levels of local CBF were all significantly lower during heatstroke. The circulatory dysfunction, systemic inflammation, hypercoagulable state, and cerebral ischemia and damage during heatstroke were all significantly suppressed by prior icv injection with ET-1A receptor antagonist (BQ 610, 0.05 mg/mL, 10 μL) at cerebral lateral ventricle. These findings indicate that pretreatment with ET-1A receptor antagonist via icv injection may ameliorate heatstroke victims by attenuating activated coagulation, and systemic inflammation during heatstroke.

PB 3.31-4

Pulmonary embolism that causes tricuspid regurgitation is associated with impaired L-arginine metabolism

Kline JA[1], Watts JA[2], Lee YY[2], Hwang S[2], Courtney MD[3] and Fulkerson M-B[2]

[1]Indiana University, Indianapolis, IN; [2]Carolinas Medical Center, Charlotte, NC; [3]Northwestern University, Chicago, IL, USA

Background: Reduced L-arginine availability to the lung can disrupt nitric oxide biosynthesis and increase pulmonary vascular resistance. Most pulmonary vasodilation comes from NO made by eNOS, with L-arginine as its substrate. L-arginine is degraded by arginase-1, which is found in high concentrations in erythrocytes. eNOS is inhibited by dimethylated arginine (DMA) metabolites. We hypothesize that pulmonary embolism (PE) with pulmonary hypertension and tricuspid regurgitation (TR+) causes intracardiac hemolysis that increases plasma arginase-1, decreases plasma L-arginine and increases total DMA in plasma.

Methods: Case-control study of normotensive patients with suspected PE who underwent CT pulmonary angiography to evaluate for PE. All patients had transthoracic Doppler-echocardiography. TR+ was defined as a jet velocity >2.7 m/s. Patients diagnosed with PE and TR+ had follow-up measurements 3 months later. Plasma L-arginine was assayed by HPLC, arginase-1 concentration by ELISA, and asymmetric dimethylarginine (aDMA) with mass spectrometry. Erythrocytic carbonic anhydrase-1 concentration was measured with ELISA as a biomarker of hemolysis.
Results: We enrolled 96 patients, including 65 with no PE on CT angiography and 31 with PE+ and TR+. The following comparisons show data first for without PE vs. patients with PE+ and TR+ (PE- vs. PE+TR+). Patients with PE+TR+ had significantly elevated mean values of arginase-1, (24 ± 8 ng/mL for vs. 42 ± 12 ng/mL, $P < 0.01$ unpaired *t*-test), elevated total DMA (0.15 ± 0.04 μM vs. 0.27 ± 0.08 μM $P = 0.04$), lower plasma L-arginine (121 ± 8 vs. 65 ± 6 μM $P < 0.01$) and elevated plasma carbonic anhydrase-1 (45 ± 12 μg/L vs. 71 ± 27 μg/L). Patients without PE but who had TR+ for other reasons, did not have increased arginase-1, decreased L-arginine or elevated carbonic anhydrase values compared with patients without PE and no TR. At 3 month follow-up, the plasma arginase-1 and L-arginine concentrations were normal or near normal in the PE+TR+ patients (16 ± 15 μg/L and 105 ± 26 μM, respectively, $P < 0.001$ paired *t*-test).
Conclusions: Pulmonary embolism that causes significant tricuspid regurgitation is associated with increased plasma arginase-1 and reduced plasma L-arginine concentrations. These abnormalities corrected after 3 months of anticoagulation. These data support the hypothesis of disrupted L-arginine availability to the lung vasculature in acute severe PE. Hemolysis from tricuspid regurgitation and intrapulmonary shear forces manifested prior to treatment remain a possible causative factor.

PB 3.31-5
Structure-function relationship and action mechanism of Krait Natriuretic Peptide (KNP)

Sridharan S and Kini MR
National University of Singapore, Singapore, Singapore

Background: Hemodynamics is regulated by the interplay of several hormones and neuro-transmitters. Among the factors involved in lowering blood flow or vasodilation, natriuretic peptides (NPs) are a vital and potent class of peptide hormones. NPs lower blood pressure via vasodilation and increased renal water and salt excretion. Three NP isoforms- ANP, BNP and CNP- have been identified from mammals. NPs bind to their respective membrane bound guanylyl cyclase receptors to evoke cGMP as secondary messenger to elicit their function. These peptides have similar structures with a 17-residue ring and a short (5–6 residues) or no C-tail. The ring is associated with receptor binding, while the tail confers specificity. In this report, we have described the characterization of KNP from krait venom. In contrast to mammalian NPs, KNP has an extensively long 38- residue C-tail. Compared to elapid NPs, C-tail of KNP is predicted to form an α-helix compared to elapid NPs.
Aims: To understand the structure-function relationship and action mechanism of KNP.
Methods: KNP was heterologously expressed in *E. coli* and purified. KNP or ANP was infused into euvolemic rats through the femoral vein and the mean arterial pressure (MAP) was measured using a pressure transducer introduced into the femoral artery. The urine output of measured simultaneously. Further, the ability of KNP to relax endothelium-intact and denuded aortic strips was evaluated. Various truncated KNPs were synthesized and tested for their abilities to relax aortic strips.
Results: In experimental rats, infusion of KNP caused a prolonged drop in blood pressure (8 ± 2.3 mmHg) that continued after the infusion was stopped. Recovery time was 60 min, in contrast to ANP, which showed a sudden and potent (10.83 ± 1.92 mmHg) decrease in blood pressure with a recovery time of 25 min. The ex-vivo organ bath studies showed that the ability of KNP to relax the pre-contracted aortic strips was weaker than that of ANP, and KNP acts via a different mechanism. KNP evokes vasodilation via endothelium-dependent pathways in contrast to ANP, which mediates via endothelium-independent mechanisms. Nitric oxide, prostacyclin and hyperpolarization are necessary effectors of KNP-mediated vasodilation. The putative helical segment showed an equipotent vasorelaxation in an endothelium-dependent manner, while only the ring of KNP showed similar vasorelaxation as ANP in an endothelium-independent manner. Deletion of the C-terminal helical segment abrogates KNP's activity, suggesting it has a definitive role in vasorelaxation.
Conclusion: KNP causes a prolonged reduction in blood pressure when compared to ANP. The present results show that KNP has two pharmacologically active segments- the ring and the C-tail which elicit vasodilation through distinct means. The tail of KNP confers function to the full length KNP.

PB 3.31-6
Increase of angiogenic and angiostatic mediators in patients with idiopathic pulmonary fibrosis

Smadja D[1], Juvin K[1], Valeyre D[2], Crestani B[3] and Israel-Biet D[1]
[1]Paris Descartes University, Paris; [2]AP-HP, Bobigny; [3]AP-HP, Bichat Hospital, Paris, France

Objective: Idiopathic pulmonary fibrosis (IPF) is strongly associated with abnormal vascular remodeling. The aim of the present study was to investigate a potential dysbalance between angiogenic and angiostatic factors in this disease.
Methods: Sixty-four subjects with IPF and 10 healthy control subjects (60–70 years old) were prospectively included in this multicenter study. Plasma levels of vascular endothelial growth factor (VEGF), stem cell factor (SCF) and thrombospondin-1 were determined by ELISA. Comparisons between IPF and controls were made using the Mann-Whitney test. We also analysed these soluble mediators according to IPF severity (DLCO <40% or >40% predicted) through the same test.
Results: Plasmatic levels of the angiogenic VEGF were increased in IPF vs controls ($P = 0.0008$) as well as those of the angiostatic thrombospondin-1 ($P = 0.008$), irrespective of the severity of the disease as reflected by the DLCO threshold. No difference was either observed in SCF levels.
Conclusions: Molecular factors modulating angiogenic responses are dysregulated in patients with stable IPF with increases in VEGF and thrombospondin. The serial assessment of VEGF/thrombospondin-1 during the follow-up and the search for potential relationships with the functional and hemodynamic evolution of our cohort will give us hints to clinical implication of these results.

PB 3.32-1
Novel network biomarkers profile based coronary artery disease risk stratification in Asian Indians

Vangala RK, Ravindran V, Madan G, Madhavan O and Kakkar VV
Thrombosis Research Institute, Bangalore, India

Background: Multi-marker approaches for risk prediction in Coronary Artery Disease (CAD) have been inconsistent due to biased selection of specific know biomarkers. We have assessed global proteome of CAD affected and unaffected subjects and developed a pathway network model for elucidating the mechanism and risk prediction for CAD.
Aim: In this study we analyzed global proteome of CAD affected and unaffected serum samples to identify new biomarkers for risk assessment and their network in the CAD.

Methods: 252 age and gender matched subjects (112 CAD affected without family history and 140 true controls) were selected for a case control study from ongoing Indian Atherosclerosis Research Study (IARS). The information regarding inclusion, exclusion criteria and process of sample collection, and data storage have been published (Indian Heart J, 2010;6:286–95). All the blood samples were collected after overnight fasting of 12–14 h and stored at −80 °C. All the serum samples were analyzed by Surface-Enhanced Laser Desorption/Ionization time of flight mass spectrometry (SELDI-TOF-MS) using CM10 cationic chips and tagident software was used for identification of specific protein peaks. The spectra of 112 subjects with CAD and 140 controls were analyzed. 56 CAD affected and 70 control samples were used as test set and same number as validation set in blind test. Support Vector Machine based feature selection method was used for risk assessment algorithm development. ELISA assay was performed for validation of HSP27 as potential risk predictor marker.
Results: A total of 67 m/z clusters were obtained of which 36 were significantly (P value <0.05) differentially expressed in the SELDI-TOF MS analysis. The network profile analysis was performed for all 67 proteins and we found that 17 proteins did not have any network partners, suggesting that these could be new proteins identified in CAD affected subjects. The SVM base risk assessment algorithm identified nine potential biomarkers from 36 identified proteins. These nine biomarkers represent seven different pathways related to stress and immunity (HSP27, Leukocyte specific transcript-1), coagulation (Plasminogen precursor activating peptide, Vitronectin10, Pallidin gene Isoform 2), infection and inflammation (Interferon Alpha 2), mitochondrial damage (Farataxin Chain 3), Calcium binding (Calmodulin like protein 4 isoform 3) and cell cycle (Cyclin dependent kinase 4 inhibitor B). Of the nine peaks used in the risk assessment model, the m/z corresponding to 22,859 was identified as stress related protein HSP27 with an odds ratio of 3.47 (95% CI 1.41–8.56, P value 0.007).
Conclusions: Based on our data, proteome profiling with SELDI-TOF MS and SVM feature selection Methods: Can be used for biomarker discovery and risk stratification in CAD. We also validated HSP27 for potential use in risk assessment for CAD.

PB 3.32-2

Human macrophages spontaneously differentiated from blood monocytes are heterogeneous and show distinct proteome profiling

Eligini S[1], Brioschi M[1], Crisci M[1], Tremoli E[2], Banfi C[1] and Colli S[2]
[1]Centro Cardiologico Monzino I.R.C.C.S; [2]Università degli Studi di Milano, Milano, Italy

Background: Tissue macrophages are key players in many aspects of human physiology and diseases. Their biological activities include phagocytosis, killing of pathogens, antigen presentation, chemotaxis, and release of inflammatory and healing mediators. Classically, most resident macrophages are derived from circulating monocytes that, according to the microenvironment, differentiate into subpopulations that are phenotypically distinct. As an example, macrophage subpopulations evidenced within the atherosclerotic lesions contribute in a different way to plaque development/progression and even regression. Since human tissue macrophages are not easily accessible for isolation, various *in vitro* models are currently used. These models, however, mainly represented by monocytic cell lines or by monocytes differentiated in the presence of colony stimulating factors (CSFs), do not adequately reflect the heterogeneity and plasticity of tissue macrophages. With respect to monocytic cells, the type and duration of differentiation treatment heavily impact on the functional profile. On the other hand, monocyte exposure to CSF/cytokines directs macrophages to polarization into distinct phenotypes that have been classified as classical or alternatively activated (M1-pro-inflammatory and M2-non-inflammatory, respectively). These phenotypes, however, represents the extremes of a 'continuum' in a universe of activation states and do not necessarily reflect the functional skewing that occurs '*in vivo*'. We previously reported that human macrophages spontaneously differentiated from adhered monocytes (MDM) show two dominant and distinct morphotypes, that is, round- and spindle-shaped, co-existing in the same culture.
Aim: To delineate the proteome of these distinct MDM morphotypes.
Methods: Mononuclear cells were isolated from venous blood of healthy donors by Ficoll-Paque Plus and plated on Duplex-Dish50 mm. After 90 min non-adherent cells were removed and the adherent were cultured for 7 days in medium 199 supplemented with 10% autologous serum. MDM were then fixed and the distinct morphotypes were circumdissected and dislodged from the plate by means of a laser capture microdissection system (PALM MicroLaser Technologies, Germany). Cellular proteins were extracted from a total of 6000 MDM/morphotype (n = 10 different donors) and their proteome was determined and compared, both qualitatively and quantitatively, by a label-free mass spectrometry-based method. Briefly, proteins were digested with trypsin and peptides were analyzed in triplicate, in a data independent manner, by means of a nanoUPLC-ESI-qTOF instrument (Synapt-HD, Waters, Manchester, UK).
Results: One hundred-thirty two proteins were identified and quantified. Among them, 28 were more abundant in round and 28 in spindle MDM. More in detail, 11 proteins were unique in round- and 27 were unique in spindle MDM. Of shared proteins 17 were up-regulated in round and only one in spindle MDM. Specifically, distinctive bioprofiles were observed for proteins involved in lipid metabolism, cell motility, clearance of apoptotic cells and protection against stress condition.
Conclusions: We have delineated distinct reference protein maps that discriminate between the two MDM morphotypes. In particular the protein profile of round MDM is reminiscent of an non-inflammatory and reparative phenotype. Results obtained provide a consistent basis for comparative studies of macrophages in health and disease and make available a useful tool to address the effect of environment and drugs on macrophage proteome.

PB 3.32-3

Detection of protein S in necrotic core of atherosclerotic plaque and of lipoprotein-associated protein S in plasma

Baroni M[1], Mascoli F[2], Cremonini E[3], Cervellati C[3], Zagatti M[4], Meneghetti S[3], Bernardi F[1] and Marchetti G[3]
[1]University of Ferrara; [2]Unit of Vascular and Endovascular Surgery, S. Anna University-Hospital Ferrara; [3]Department of Biomedical and Specialty Surgical Sciences, University of Ferrara; [4]Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy

Background: The internalization of lipoproteins in the vessel wall is an important step in the atherosclerotic plaque formation. Plasma PS is characterized by high affinity for negatively charged and oxidized phospholipid surfaces. Nevertheless, experimental evidence for interaction between PS and HDL and LDL is scanty, mainly due to methodological limitations.
Aims: To investigate the presence of PS in the atherosclerotic plaque, and the association of PS and plasma lipoproteins.
Methods: PS from the necrotic core of plaques obtained from patients who underwent carotid endarterectomy was investigated after (i) detergent-based extraction; (ii) liposome (80/20% and 100/0% phosphatidylcoline/phosphatidylserine) -and Hepes buffer- mediated recovery. LDL- and HDL-associated PS was obtained from fresh plasma samples (10 patients with chronic obstructive artheriopaty and 10 healthy subjects) by immunodepletion in microplates coated with antibody against ApoB100 (LDL) or SAA2 (inflammatory HDL). Plaque PS or lipoprotein-associated PS was evaluated by Western blot analy-

sis (WB) with polyclonal Ab. PS plasma levels were measured by ELISA.

Results: PS was clearly detected by WB in the necrotic core of plaques either after detergent extraction or phosphatidylserine rich-liposome recovery. Improved recovery of PS using liposomes displaying negative charged phospholipids may suggest the presence of not grossly misfolded PS molecules. Interaction of PS with plasma LDLs and HDLs, hypothesized to carry circulating PS into the vessel wall, was investigated. Levels of LDL- and inflammatory HDL-associated PS showed ample variation among patients (LDL-PS = 2.49 ± 3.19 μg/mL; HDL-PS = 3.19 ± 2.37 μg/mL) and healthy subjects (LDL-PS = 0.87 ± 0.59 μg/mL; HDL-PS = 1.13 ± 0.81 μg/mL). In patients, positive association with lipoprotein levels (LDL, $r^2 = 0.85$, $P = 0.0002$) was observed. Total-PS plasma levels did not differ between patients and healthy controls (55.2 ± 10.0 μg/mL and 52.5 ± 14.9 μg/mL). With the limitation of the assay we roughly estimated that lipoprotein-associated PS was a small fraction of total circulating PS in patients (mean PS-LDL = 4.4%, mean PS-HDL = 5.6%) and in healthy subjects (mean PS-LDL = 1.7%, mean PS-HDL = 2.1%).

Conclusions: These methodological approaches permitted to detect PS protein (i) from the necrotic core of plaques and (ii) associated with circulating lipoproteins. In this experimental setting a small and variable amount of total PS appeared to be associated to LDL and inflammatory HDL, and positive relation with lipoprotein levels was detectable in plasma of atherosclerotic patients. The hypothesis that alteration in the composition/oxidative state of the lipids might influence the amount of lipoprotein bound PS, and its delivery within plaque, deserves further investigation.

PB 3.32-4

Fractalkine is expressed in early and advanced atherosclerotic lesions and supports monocyte recruitment via CX3CR1

Stolla M[1], Pelisek J[2], Von Bruehl M-L[2], Schaefer A[3], Barocke V[2], Heider P[2], Bauersachs J[3], Bray PF[4], Massberg S[2] and Schulz C[2]

[1]University of Rochester, Rochester, NY, USA; [2]Klinikum Rechts der Isar, Technische Universitaet Muenchen, Muenchen; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]Thomas Jefferson University, Philadelphia, USA

Background: Rupture of carotid artery atherosclerotic plaque causes transient ischemic attack and stroke. Chemokines play a central role in atherogenesis and support the development of an unstable plaque phenotype in manifest lesions. The membrane-bound chemokine fractalkine (CX3CL1, FKN) is expressed in the inflamed vascular wall and absence of FKN reduces atherogenesis.

Aim: Whether FKN is expressed throughout all stages of atherosclerotic disease and whether it directly contributes to monocyte recruitment to atherosclerotic lesions is not known and therefore addressed in the present study.

Methods: We collected human atherosclerotic plaque material and blood samples from patients with carotid artery disease undergoing endarterectomy. Plaques were analyzed by immunohistochemistry and qPCR. Soluble FKN levels were measured by ELISA. To determine the role of the FKN-CX3CR1 axis for monocyte adhesion *in vivo* we then performed intravital videofluorescence microscopy of the carotid artery in ApoE−/− mice.

Results: We found that FKN is expressed at all stages of atherosclerotic lesion formation, and that the number of FKN-expressing cells positively correlates with the number of CX3CR1-positive cells in human carotid artery plaques. In the circulation, soluble FKN levels are significantly elevated in the presence of high-grade (sub-occlusive) stenosis. Notably, FKN-CX3CR1 interactions are critical for recruitment of circulating monocytes to the injured atherosclerotic vascular wall.

Conclusion: The soluble form of FKN appears to be a useful biomarker for patients with unstable atherosclerotic disease of the carotid artery. In addition, FKN is directly involved in the recruitment of monocytes to unstable, subocclusive atherosclerotic lesions, which renders this chemokine dyad an attractive therapeutic target.

PB 3.32-5

UPA/UPAR and vascular repair in atherosclerotic vessel wall

Lugano R, Peña E, Casani L, Badimon L and Padro T

Cardiovascular Research Center (CSIC-ICCC) IIBSantPau, Barcelona, Spain

Migration of vascular smooth muscle cells (VSMC) within the arterial wall is a crucial event for progression of atherosclerotic plaques as well as in vascular repair. LDL infiltrated in the vessel wall become aggregated (agLDL) and retained in the intima by binding matrix proteoglycans. agLDL are internalized by VSMC in a LRP-1 mediated process impairing vascular remodeling due to changes in cytoskeleton-dynamics and migration-kinetics. The urokinase (UPA)/UPA-receptor (UPAR) system plays a relevant role in human VSMC function during remodelling. The aim of this study was to investigate whether UPA-ligand binding is involved in the mechanism underlying the impairing effects of the agLDL in VSMC migration.

The effect of high LDL levels on VSMC migration were analyzed in aortic explants of rats fed high-fat diet in presence/absence of angiotensin II (angII, 200 ng/kg/min). An *in vitro* model of wound repair was used to investigate the role of UPA in the migration of human VSMC exposed to atherogenic levels of agLDL (100 μg/mL). UPA expression was knocked down by small interfering RNAs (siRNA) and UPA function blocked by specific antibodies. Protein subcellular localization during cell migration was assessed by confocal microscopy. For analysis of gene and protein expression real-time PCR and western blot were carried out.

Rats fed a high fat diet for 14 days had 10-fold higher cholesterol-LDL plasma levels, >60% decrease in aortic UPA protein expression ($P < 0.05$ vs. normolipemic group), and VSMC with significant lower capacity to migrate from the aortic explants (50% reduction vs. control group after 6 days in culture, $P > 0.05$). The administration of angII increased UPA-aortic levels and accelerated VSMC migration from the vascular explants. Using the *in vitro* model of wound repair we showed that agLDL inhibited human VSMC migration by a UPA-dependent mechanism. Exogenous native UPA (2 μg/mL) increased >2 fold ($P < 0.01$) cell migration of agLDL-VSMC without affecting migration kinetics of control VSMC. UPA-gene silencing reduced migration of control cells to the levels of agLDL-VSMC (>50% reduction vs. random siRNA transfected cells, $P < 0.05$). UPA levels (mRNA, protein) were significantly reduced in migrating VSMC exposed to agLDL. Confocal microscopy showed a 52% decrease in UPA-labelling at the leading edge of the migrating agLDL-VSMC compared to controls ($P < 0.05$), and a decrease from 32% to 23% in the colocalization with its receptor UPAR ($P > 0.05$). Rescue experiments showed that UPA (either by enhanced endogenous expression or by exogenous additions) acting as UPAR-ligand restored migration capacity of lipid-loaded cells to control levels. UPA effect on migration of agLDL-loaded cells occurs through an LRP-1 mediated mechanism.

UPA-ligand binding regulates VSMC migration, a process that is interfered by LDL. Thus tissue infiltrated LDL, through the abrogation of UPA function reduces VSMC-regulated vascular repair.

PB 3.32-6

Immunological tolerance to a combination of ApoB and HSP60 peptides decreases markers known to be associated with plaque instability in mice model of atherosclerosis

Mundkur AL, Mukhopadhyay R, Varma M, Samson S, Chen D, Lu X and Kakkar V

Thrombosis research Institute, Bangalore, India

Background: Atherosclerosis is a progressive, inflammatory disease characterized by accumulation of lipids, inflammatory cells and cytokines in the arterial wall. Clinical complications of atherosclerosis occur due to rupture of unstable plaques, responsible for 90% of fatal heart attacks and represent the most urgent unmet clinical need. Current treatments including lipid lowering drugs are not totally effective in stabilizing a vulnerable plaque and thus preventing their rupture. An effective immune based therapy will be the one that can stabilize the plaque in addition to reducing its development and progression. Vulnerable plaques are characterized by thin fibrous cap, higher expression of biomarkers such as tissue factor, calprotectin (Mrp8/14), matrix metalloproteases (MMPs), inflammatory cytokines, and apoptosis of intimal cells, leading to an expansion of a lipid-laden necrotic core. Mice models have provided valuable insights into pathological mechanisms of atherosclerosis but the occurrence of spontaneous plaque rupture is very rare in mice. We studied expression of markers associated with plaque instability in mice after prolonged hyperlipidaemia.

Aim: The objective of the present study was to assess the efficacy of mucosal tolerance to a combination of ApoB and HSP60 peptides on markers associated with plaque instability in double-gene knockout ($Apob^{tm2Sgy}$ $Ldlr^{tm1Her}$/J) mouse model.

Methods: Groups of $ApoB^{tm2Sgy}$/$Ldlr^{tm1Her-}$ mice were fed a high-fat diet for 10 weeks, to establish atherosclerotic lesion. In the last 2 weeks, animals were orally dosed with combination of ApoB and HSp60 peptides or KLH and continued on high fat diet for another 10 weeks. Quantification of atherosclerotic lesions was carried out in the aortic sinus sections stained with Elastic van Geison (EVG). Plaque necrosis was quantified by measuring the size of the hematoxylin and eosin-negative acellular area. Immunohistochemical analysis were carried out by indirect immunofluorescence, and gene expression was quantified using real time polymerase chain reactions.

Results: Prolonged hyperlipidaemia for 20 weeks resulted in significant increase in the serum lipid concentrations in control as well as treated animals. Oral tolerance to peptides resulted in a 60.8% reduction in the necrotic core area in lesion compared with KLH (6.5 ± 1.4% vs. 16.6 ± 2.9%, $P = 0.012$) though the total lesion area did not change significantly in both the groups. Expression of biomarkers of plaque instability and rupture MMP9 ($P = 0.035$), tissue factor ($P = 0.028$), and Mrp8/14 ($P = 0.045$) were significantly decreased in the tolerized animals compared to control. Oral tolerance to peptides was associated with increased number of smooth muscle cells (SMC) and collagen content in the lesion, while SMC apoptosis found to be significantly lower in peptide treated mice (16.55 ± 0.95 vs. 31.15 ± 2.97, $P < 0.001$), suggesting features of plaque stabilization. Tolerance was associated with increase in Treg cells and significant reduction in inflammatory cytokines in the lesion suggesting immune regulation.

Conclusions: Our results suggest that oral tolerance to combination of ApoB and HSP60 peptides promotes multiple features of atherosclerotic plaque stability, including increased plaque SMC and collagen content and reduction in markers associated with plaque instability and induce regulatory immune response to control inflammation

PB3.33 – ADAMTS13: Basic – I

Pharmacokinetics of a recombinant ADAMTS13 in mice, rats and macaques

Höllriegl W[1], Schiviz A[1], Höbarth G[1], Kubik S[1], Plaimauer B[2], Scheiflinger F[1] and Muchitsch EM[1]

[1]Baxter Innovations GmbH; [2]Baxter Innovations, Vienna, Austria

Deficiency of ADAMTS13, a von Willebrand factor (VWF)-cleaving protease, is the key factor in the pathogenesis of thrombotic thrombocytopenic purpura (TTP), a life-threatening thrombotic microangiopathy. Baxter is developing a recombinant ADAMTS13 (rADAMTS13, a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13) for potential prophylaxis and treatment of TTP. The presented studies evaluated the pharmacokinetics of rADAMTS13 in mice, rats and macaques.

Ten ADAMTS13 ko mice (B6.129-$ADAMTS13^{tm1Dgi}$) per time point were administered rADAMTS1340 at 80 or 200 U/kg as an intravenous bolus injection and were bled by cardiac puncture 5 min to 42 h after dosing; Sprague Dawley rats ($n = 10$) received 80, 200 or 400 U/kg. Blood samples were taken from the tail artery before and 5 min to 72 h after dosing. Macaques ($n = 8$) received 200 U/kg followed by a dose of 1790 U/kg (limit dose) after a washout period of 2 weeks. Blood samples were taken from a suitable vein before and 5 min to 60 h after each dosing.

Citrated plasma samples were analyzed for ADAMTS13 activity (FRETS-assay) and ADAMTS13 antigen (ELISA). $AUC_{0\text{-tlast}}$ (the area under the concentration vs. time curve from 0 to the last measured time point), *in vivo* recovery (IVR), mean residence time (MRT) and terminal half-life (HL) were evaluated.

Results for activity and antigen were similar. For ADAMTS13 activity, dose-adjusted $AUC_{0\text{-tlast}}$ [hmkg] ranged from 0.098 in mice dosed with 40 U/kg to 0.401 in macaques dosed with 1790 U/kg. In mice, IVR was 51.9–62.8%, HL was 10.0–17.3 h and MRT was 13.6–21.1 h. In rats, IVR was 60.2–65.7%, HL was 16.7–25.6 h and MRT was 22.8–30.8 h. In macaques, IVR was 80.9–90.0%. Terminal HLs (24.6–27.9 h) and MRTs (29.6–36.2 h) were comparable between day 1 and day 15 for combined sexes for both analytes. The dose-adjusted pharmacokinetic curves of ADAMTS13 activity after doses of 200 or 1790 U/kg overlap well, suggesting a dose-proportionality in macaques for this dose range. The preclinical pharmacokinetic profile of Baxter's rADAMTS13 suggests that it is a promising drug candidate for future clinical trials.

PB 3.33-2

Preclinical safety of Baxter's recombinant ADAMTS13

Piskernik C, Dietrich B, Horling F, Kubik S, Ruthsatz T, Scheiflinger F, Schwarz HP, Muchitsch EM and Schiviz A

Baxter Innovations GmbH, Vienna, Austria

Baxter has developed a recombinant ADAMTS13 (rADAMTS13, a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13) product for treatment and routine prophylaxis of acute episodes of thrombotic thrombocytopenic purpura (TTP) in ADAMTS13 deficient patients. TTP is caused by excessive aggregation of platelets and accumulation of unusually large von Willebrand factor (VWF) multimers in small organ vessels, resulting in platelet thrombosis in the circulation followed by ischemic organ damage.

The preclinical safety of Baxter's rADAMTS13 was characterised in a 1-month repeat dose toxicity study in rats, an escalating dose and pilot 4-week repeat dose toxicity study in macaques, and a 1-month repeat dose toxicity study including cardiovascular/pulmonary safety pharmacology in macaques. Local tolerance was assessed in rabbits. Species suitability was demonstrated by VWF analysis *in vitro* and *in vivo*

under native conditions to present a worst case scenario for repeat dose toxicity studies.
Baxter's rADAMTS13 was well tolerated in rats at intravenous doses of 80, 400 and 800 FRETS-U/kg administered every third day for 1 month; thus, the NOAEL was the highest dose of 800 FRETS-U/kg. Intravenous treatment with rADAMTS13 at 800 FRETS-U/kg once weekly for 5 weeks (pilot repeat dose study) showed no adverse effects in macaques; the NOAEL for the escalating dose phase of the study was 1790 FRETS–U/kg. Treatment of macaques with rADAMTS13 at doses of 80, 200, and 400 FRETS-U/kg via bolus injection once weekly for 29 days did not reveal adverse findings; the NOAEL was the highest dose of 400 FRETS-U/kg. No adverse effects on respiratory and cardiovascular function in macaques were observed up to and including a dose of 400 FRETS-U/kg/day/week. As expected for a heterologous human protein drug, repeat doses of rADAMTS13 resulted in the formation of anti-drug antibodies specific for human ADAMTS13, and in neutralising human ADAMTS13 activity in animal models. No injection site reactions were observed in animals of either species. In rabbits, rADAMTS13 was well tolerated after intravenous (intended clinical administration route), intraarterial and paravenous administration.
In conclusion, no toxicity was observed for Baxter's rADAMTS13 in rats, macaques and rabbits even at the highest dose levels tested.

PB 3.33-3

Human umbilical vein endothelial cells, platelets and human tumor cell lines express isoforms 2 and 3 of ADAMTS13

Kempfer AC[1], Powazniak Y[2], Calderazzo JC[1], Paiva JH[3], Alonso D[4], Sanchez-Luceros A[1] and Lazzari MA[1]
[1]IMEX-Academia Nacional de Medicina; [2]Fundación Investigar-Argenomics; [3]IIHEMA-Academia Nacional de Medicina; [4]Laboratorio de Oncología Molecular, Universidad Nacional de Quilmes, Buenos Aires, Argentina

Background: ADAMTS13 contains 29 exons and spans 37 kb on chromosome 9q34. It has 1427 amino acids, 180 kDa of molecular weight and consists of a signal peptide, a propeptide, a metalloprotease and a disintegrin-like domain, a thrombospondin type 1 (TSP1) motif, a cysteine-rich domain, seven TSP1 repeats and two CUB domains. ADAMTS13 appears to be synthesized in the liver, particularly in hepatic stellate cells. Recent reports have shown that ADAMTS13 is synthesized and released from human megakaryocytes and platelets. ADAMTS13 mRNA is detected in almost every organ tissue by reverse transcriptase-polymerase chain reaction (RT-PCR), suggesting that the vascular endothelium may also be the source of plasma ADAMTS13. Given the large surface area of vascular endothelial beds, even a few endothelial cells producing ADAMTS13 at any moment may produce a significant contribution to plasma levels of ADAMTS13 activity. Therefore, any small change at the site of ADAMTS13 syntheses may be crucial in the pathogenesis of TTP and possibly other thrombotic diseases.
Aims: We analyzed alternative splicing of ADAMTS13 in Human Umbilical Vein Endothelial Cells (HUVEC), platelets and human tumor cell lines.
Methods: Experiments were performed in primary HUVEC obtained with 0.1% collagenase type 1. Platelets were isolated by differential centrifugation from total blood of healthy donors. Human cancer cell lines: Hep3b hepatoma and breast cancer cell lines (MCF-7 and MDA-MB-231).
RNA extraction and RT-PCR. Total RNA was extracted from cells using TRIzol reagent. The integrity of RNA was verified by 260/280 optical density ratios. The RNA sample was treated with DNase I, followed by phenol/chloroform extraction. The RNA was reverse transcribed into cDNAs using random primers. In our PCR experiments, we used the primers to amplify the portion of ADAMTS13 that is present in all the known isoforms, the expected size of ADAMTS13 isoform 1 was 610 bp, isoform 2 and 3 were 442 bp, and isoform IR25 was 1075 bp. We used Hep3b as a positive control for isoforms 2 and 3 mRNA expression.
The ADAMTS13 and β-actin mRNA was amplified for 30 cycles in the same reactions. The PCR products were analyzed on an agarose gel containing SYBR Safe.
Results: All PCR performed, except the controls, were positive for β-actin, showing the presence of amplifiable cDNA. We have detected, in our view for the first time, isoforms 2 and 3 in HUVEC and human platelets. In both breast cancer lines isoforms 2 and 3 mRNA were found to be strongly expressed in comparison to those of HUVEC and platelets, although they didn't reach the expression levels of Hep3b cells.
Conclusion: The presence of isoforms 2 and 3 in HUVEC and platelets from normal donors that we detected will enable us to assess the importance of the presence of ADAMTS13 alternative splicing products in tumor line cells and whether there is a correlation between the levels of expression of the isoforms and thrombotic events.

PB 3.33-4

FRET rather than CBA reflects ADAMTS13 proteolytic activity in thrombotic thrombocytopenic purpura patients with discordant measurements

Mancini I[1], Valsecchi C[1], Lotta LA[2], Pontiggia S[1], Bajetta MT[1], Deforche L[3], Palla R[4], Vanhoorelbeke K[3] and Peyvandi F[1]
[1]Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinico; [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milano, Italy; [3]Laboratory for Thrombosis Research, KU Leuven Kulak, Kortrijk, Belgium; [4]University of Milan, Milan, Italy

Background: Collagen binding assay (CBA) and fluorescence resonance energy transfer (FRET) are two widely adopted methods for the measurement of the plasmatic activity of ADAMTS13, the von Willebrand factor (VWF) cleaving-protease. Accurately measuring ADAMTS13 plasmatic activity is essential in the management of thrombotic thrombocytopenic purpura (TTP), a thrombotic microangiopathy (TMA) often characterized by severely reduced ADAMTS13 activity. The finding of severely reduced ADAMTS13 activity (activity below 10%) has important prognostic implications, being associated with a 10-fold increased risk of disease recurrence. Despite a good agreement between the two assays in the measurement of normal plasmas, discrepant results have been reported in up to 10% of TMA cases. The cause for the observed discrepancies is unknown, but it has been suggested that the use of a denaturing agent (<i.e. urea) in CBA may dissociate complexes between ADAMTS13 and anti-ADAMTS13 antibodies, thus generating erroneously high ADAMTS13 activity results.
Aims: To determine whether FRET or CBA results reflect ADAMTS13 activity levels *in vivo* in samples from autoimmune TTP patients with discordant results between the two assays. To evaluate the role of denaturing agents in the determination of discrepant results.
Methods: We analyzed up to 20 discordant samples (FRET <10% and CBA >20%) and 11 concordant samples (FRET and CBA <10%) with anti-ADAMTS13 antibodies from patients with autoimmune TTP, selected from the Milan TTP Registry (URL: http://www.ttpdatabase.org/). The analysis of the VWF multimeric pattern on discordant samples collected during disease remission (n = 13) and the measurement of ADAMTS13 activity under flow conditions (n = 10) were performed. FRET assay in presence of urea 1.5 M was performed in 19 discordant and 11 concordant samples.
Results: All discordant samples showed a ratio of high molecular weight VWF multimers higher than normal, due to the presence of ultra large VWF multimers. Under flow conditions, all tested samples showed reduced ADAMTS13 activity (range: 0–29%). In FRET experiments performed in presence of urea, ADAMTS13

activity level became detectable and/or overcame the 10% activity cut-off in 11 out of 19 discordant samples, whereas it remained undetectable in all 11 concordant samples tested (Fisher's exact test, $P = 0.0016$).

Summary/Conclusions: The presence of ultra large VWF multimers and the reduced ADAMTS13 activity observed under flow conditions in discordant TTP samples indicate a deficiency of the enzyme, supporting FRET over CBA results. This study showed that the presence of urea in CBA could lead to spurious and misleading results in measuring ADAMTS13 activity. ADAMTS13 activity assays, which do not require any denaturing agents, should be considered more reliable when assessing the presence of severe ADAMTS13 deficiency in patients with autoimmune TTP.

PB 3.33-5
The research of ADAMTS13 binding to human microvascular endothelial cells

Wang A, Wu J, Ding K, Liu X, Cai X, Zhu W and Sun Z
Anhui Provincial Hospital Affiliated to Anhui Medical University, Hefei, China

Background: ADAMTS13, as a specific VWF cleaving protease, could prevent the microvascular microthrombus formation caused by regulated release of ultra-large vWF multimers (UL-VWF), Previous studies mostly research ADAMTS13 function base on the large and medium-sized vascular endothelial cells. Our recent study found that ADAMTS13 could bind to the surface of human microvascular endothelial cells. Which maybe play an important role in the microvascular microthrombus formation. However, the binding mechanism remains unclear.

Aims: our study is aim to preliminary investigate that which domains of ADAMTS13 participate in the binding to the surface of human microvascular endothelial cells.

Methods: We used Hela cells to transfect and permanent express the full-length and C-terminal domain truncated types of human ADAMTS13 recombinant protein. Collected and concentrated cell supernatants, and purified recombinant proteins, then we used flow cytometry to detect the binding between recombinant ADAMTS13 proteins and human microvascular endothelial cells. We also used thrombopondin-1(from 0 to 200 nM) as a block factor, observed whether thrombospondin-1 influence the binding.

Results: We found that full-length ADAMTS13 protein could bind to the surface of human microvascular endothelial cells, the binding rate was up to 49.1%, While, the binding of full-length ADAMTS13 protein to these cells would drop to 26.5% with 200 nM thrombospondin-1 blocking. If we truncated C-terminal domain of ADAMTS13 (from tsp8), the binding was just down 4.8%.

Conclusions: The study suggests that ADAMTS13 could bind to the surface of human microvascular endothelial cells, and this binding maybe rely on the N-terminal and thrombospondin-1 repeats domains of ADAMTS13 protein.

PB 3.33-6
Characterization of IgG anti-ADAMTS13 autoantibodies isolated from patients with acquired TTP and a healthy donor pool

Turecek PL[1], Grillberger R[1], Skalicky S[1], Schrenk G[1], Plaimauer B[1], Knöbl P[2], Zheng LX[3], Rottensteiner H[1] and Scheiflinger F[1]
[1]Baxter Innovations GmbH; [2]Medical University of Vienna, Vienna, Austria; [3]Children's Hospital of Philadelphia, Philadelphia, USA

Background: ADAMTS13-neutralizing IgG autoantibodies are the major cause of acquired thrombotic thrombocytopenic purpura (TTP). So far, the properties of such antibodies have only been assessed using plasma samples of patients with acquired TTP.

Aim: We sought to functionally characterize affinity purified anti-ADAMTS13 antibodies of the IgG class from patients with acquired TTP, and a healthy donor pool as control.

Methods: Plasma collected after plasma exchange from three patients with acquired TTP and a plasma pool from 45 randomly selected healthy blood donors (HD) were used to isolate anti-ADAMTS13 IgG antibodies. Purification was carried out by a two-step procedure using an ADAMTS13 affinity matrix followed by protein G chromatography. Total IgG antibody yield, isotype distribution and ADAMTS13 specificity were determined by commercial or in-house enzyme-linked immunosorbent assays (ELISA). The binding kinetics of the isolated IgGs to ADAMTS13 were evaluated by BIAcore and ELISA. Their inhibitory activity towards ADAMTS13 was analyzed using FRETS-VWF73 assay and residual collagen-binding activity assay (CBA). The ADAMTS13-VWF binding assay was employed to assess the competitive inhibition constants (Ki) of the purified antibodies. Interaction studies with fragments of ADAMTS13 were used to determine the domains of ADAMTS13 that these IgGs target.

Results: IgGs specific to ADAMTS13 were recovered from the three TTP patients as well as from the HD plasma pool. All four subclass isotypes were present, with IgG2 being the dominant subclass, followed by IgG1 and either IgG3 or IgG4. Biacore measurements led to calculated K_D values for the IgGs isolated from TTP patients towards ADAMTS13 of around 1 nM. Anti-ADAMTS13 IgG subclass-specific ELISA revealed apparent K_D values in the nanomolar range for all IgG subclasses of these IgGs. Significantly lower affinities were determined for the IgGs from the HD pool. The TTP-associated IgGs displayed inhibitory activity ranging from 0.1 to 0.6 BU/μg IgG whereas the HD IgG did not inhibit ADAMTS13 activity in either of the two methods applied. Furthermore, only the IgGs from the TTP patients interfered with the interaction of ADAMTS13 and VWF, with a mean Ki of 0.35 nM. Epitope mapping revealed a polyclonal nature for all of the antibodies tested.

Conclusions: We present the first comprehensive study on affinity-purified anti-ADAMTS13 IgG autoantibodies from patients with acquired TTP. We also provide evidence that a subpopulation of healthy individuals possesses non-inhibitory ADAMTS13-specific IgG autoantibodies, suggesting that preexisting natural anti-ADAMTS13 B cell clones could be expanded during the development of acquired TTP.

PB3.34 – Fibrinolytic system: Basic – III

PB 3.34-1
Fractal kinetic models of plasmin-catalyzed dissolution of fibrin

Varjú I[1], Kolev K[1], Keresztes Z[2], Pap A[3], Tenekedjiev K[4] and Machovich RA[1]
[1]Institute of Medical Biochemistry, Semmelweis University; [2]IMEC, Research Centre for Natural Sciences, Hungarian Academy of Sciences; [3]ITPMS, Research Centre for Natural Sciences, Hungarian Academy of Sciences, Budapest, Hungary; [4]N.Y. Vaptsarov Naval Academy, Varna, Bulgaria

Background: Intravascular fibrin clots are resolved through the proteolytic action of plasmin acting at the interface of gel-phase substrate and fluid-borne enzyme. The classic Michaelis-Menten (MM) kinetic scheme cannot describe satisfactorily this heterogeneous-phase proteolysis, because it assumes homogeneous well-mixed conditions. A more suitable model for these spatial constraints, known as fractal kinetics, includes a time-dependence of the Michaelis constant $Km = Km0.(1 + t)\exp(hF)$, where hF is a fractal exponent of time, t. Furthermore, a realistic kinetic model should take into account

sequestration of plasmin due to kringle binding to C-terminal lysines (CTL), newly exposed during fibrin degradation.
Aim: The aim of the present study is to build up and experimentally validate a mathematical model that adequately describes the kinetics of plasmin-catalyzed fibrin dissolution and thus contributes to a better understanding of the factors that influence plasmin efficiency at the fluid-gel interface.
Method: Two modifications of the basic MM scheme were introduced: a term reducing the enzyme concentration through rapid equilibrium binding of plasmin to continuously increasing unproductive sites including an association constant *Ka* and a fractal exponent, *hF* resulting in apparent *Km*, which accounts for the time-dependent clustering of the enzyme. A broad range of biochemical (fibrin turbidimetry, densitometry of electrophoretic samples, amidolytic assay on synthetic plasmin substrate) and imaging (atomic force microscopy, AFM; confocal laser microscopy, CLM) techniques were applied to test the predictions of the fibrinolytic model. The power of the predictions was assessed using known modifiers of fibrinolysis; ε-amino caproic acid (EACA) which blocks the kringle-dependent binding and carboxypeptidase B (CPB) which removes CTLs. The clustering of plasmin was evaluated with AFM using nanogold-labeled anti-plasmin antibodies in an experimental setup where plasmin was applied to a mica surface decorated with fibrinogen using microcontact printing and with CLM using fluorescent protein-fusion derivative of plasminogen.
Results: Using a range of fibrin and plasmin concentrations, variants of the kinetic model were fitted to the turbidimetric data for lysis of fibrin by plasmin applied to the surface of the clots. A global fit to 32 time-course curves with 90 measured points each yielded four model parameters with optimal values $Km0 = 1.5\ \mu M$, $hF = 0.25$, $Ka = 1.3\ \mu M^{-1}$ and $k_{cat} = 32.4\ min^{-1}$. Addition of 1 mM EACA or 8 U/mL CPB increased the lysis rate, which could be satisfactorily explained with unchanged *Km0* and k_{cat} model parameters accompanied by a decrease in *hF* to 0.031 and in *Ka* to $0.001\ \mu M^{-1}$ in line with the interpretation of these parameters as measures of spatial clustering (*hF*) and sequestration of enzyme molecules in solution (*Ka*). This concept gained further support from imaging techniques. AFM images revealed significant changes in plasmin distribution on the patterned fibrinogen surface: the ratio of surface occupied by plasmin/intact substrate area decreased by 25% over a 5-min interval in line with the time-dependent clustering of fluorescent plasminogen in CLM.
Conclusion: These data, from multi-faceted, complementary approaches, support a mechanism for time-dependent loss of plasmin activity resulting from spatial redistribution in this heterogeneous system. Thus, plasmin-CTL binding retards lysis, opposing the stimulatory effect of CTLs in plasminogen activation.

PB 3.34-2
DNA methylation and regulation of t-PA gene expression

Kruithof E and Dunoyer-Geindre S
HUG, Genève 4, Switzerland

Background: Tissue-type plasminogen activator plays an important role in the removal of intravascular fibrin deposits and has several important physiological roles and pathological activities in the brain. Its expression by many other cell types and the diversity of regulatory mechanisms impacting on t-PA gene expression suggests that t-PA has many roles outside the vascular and central nervous system. For an understanding of these roles it is important to better understand the relationship between cell-type specific epigenetic gene modifications of the t-PA gene and regulation of t-PA gene expression.
Aim: To determine whether there is a relation between basal (unstimulated) t-PA gene expression and DNA methylation at the proximal t-PA promoter and at the multi-hormone responsive enhancer (MHRE) located 7 kbp upstream.
Methods: The methylation state of 16 CpG residues in the proximal t-PA gene promoter (from −647 to +94 with respect to the transcription initiation site) and of 12 residues in the MHRE (from −7466 to −7227) was determined by direct sequencing of bisulfite treated DNA, obtained from five primary human cell types (umbilical vein endothelial cells, monocytes, astrocytes, fibroblasts, and hepatocytes, and from five human transformed cell lines (Bowes melanoma, HT1080 fibrosarcoma, NB4 acute promyelocytic leukemia and HepG2 and HuH7 hepatoma). Basal t-PA expression was assessed by measuring t-PA antigen in 24 h cell conditioned media.
Results: Expression of t-PA by Bowes melanoma cells was 50 fold higher than in the second highest t-PA producer cell type. Melanoma DNA was fully unmethylated both in the proximal t-PA gene promoter and the MHRE region. Expression of t-PA was low in monocytes, hepatocytes, HuH7 hepatoma cells and NB4 cells and DNA of these cells was mostly methylated in the proximal promoter. Intermediate levels of t-PA expression were observed with the other cell types. In these cells, the nine CpG's in the promoter region from −121 to +94 were unmethylated, whereas the seven CpG's from −647 to −366 were in general methylated, except in HT1080 cells, in which CpG's −366 and −537 were methylated and the intervening two CpG's (at −452 and −421) unmethylated. The pattern of CpG methylation in the MHRE was more complex, with highly methylated CpG's often adjacent to unmethylated CpG's. No relation between basal t-PA gene expression and CpG methylation at the MHRE was evident.
Conclusions: Our results suggest that an unmethylated state of the promoter region from −121 to +94 is required for enabling t-PA gene expression. An unmethylated state of the upstream promoter region (from −647 to −366) was associated with extremely high t-PA expression in melanoma cells. The methylation state of the MHRE is very complex and may change from one CpG residue the other. There is no clear-cut relation between basal t-PA gene expression and methylation state of individual CpG's in the MHRE.

PB 3.34-4
Covalently linking heparin to antithrombin diminishes the protective effect of fibrin on plasmin

Chander A, Atkinson HM, Berry LR, Stevic I and Chan AK
Thrombosis and Atherosclerosis Research institute/McMaster University, Hamilton, Canada

Background: Antithrombin (AT) is the major regulator of coagulation enzymes *in vivo*. We have previously demonstrated that AT, in the presence of unfractionated heparin (UFH), can inhibit free plasmin, as well as reduce generation of plasmin from purified plasminogen. Additional studies utilizing a covalent complex of AT and UFH (ATH) revealed that plasmin generation in the presence of a fibrin clot was reduced to a greater degree by the ATH compared to AT + UFH. Furthermore, it is well known in literature that fibrin protects plasmin from inhibition by inhibitors such as α2-antiplasmin. However, little is known about the ability of AT + UFH, or ATH, to inhibit plasmin in the presence of fibrin.
Aim: To determine the rate of inhibition of plasmin in the presence of fibrin by AT + UFH vs. ATH.
Methods: Discontinuous second order rate constant assays were used to determine the overall *k2* values for inhibition of plasmin ± fibrin by AT + UFH vs. ATH. Briefly, 200 nM fibrinogen was converted to fibrin by reaction with 0.6 U/mL Ancrod for 15 min at room temperature. Fibrin was then reacted with 10 nM plasmin in six different wells of a 96-well plate, followed by addition of inhibitors (100 nM AT + 3000 nM UFH or 100 nM ATH) at specific time intervals (buffer was added to the last well as a control). The reactions were neutralized by the simultaneous addition of polybrene and S-2236 in buffer. Residual plasmin activity was measured at 405 nm for 10–30 min, and *k2* values determined from plots of $\ln(v_t/v_o)$ vs. time.
Results: The *k2* values ($x10^6$ M/min) for inhibition of free plasmin by AT + UFH and ATH were 5.74 ± 0.28 and 6.39 ± 0.59, respectively.

However, when fibrin was placed in the system, a mild protective effect by the fibrin was observed for ATH reactions ($k2$ value = 3.28 ± 0.36, $P < 0.006$). Whereas for AT + UFH, the $k2$ values were barely measurable when fibrin was present ($k2 < 0.1$). This suggests that fibrin almost completely blocks plasmin from inhibition by AT + UFH.
Summary/Conclusion: From our study, we demonstrate that fibrin almost completely protects plasmin from inhibition by AT in the presence of excess UFH. Moreover, covalently linking UFH to AT, as in ATH, diminishes the protective effect and restores the inhibition rates to approximately 50% that of free plasmin. Similar to our previous work, this suggests that the UFH in AT + UFH can dissociate and form non-productive complexes with fibrin. Such interactions may result in either repulsive effects that prevent additional AT + UFH from inhibiting plasmin or the AT being left in a non-activated state. However covalent linkage of UFH to AT, assists access and subsequent inhibition of plasmin bound to fibrin.

PB 3.34-5

Zinc inhibits fibrinolysis by attenuating plasminogen activation and fibrin degradation

Background: Tissue plasminogen activator (tPA) initiates fibrinolysis by converting plasminogen (Pg) to plasmin (Pn), which then degrades fibrin (Fn). This process is regulated by Fn, which promotes Pg activation, and by plasminogen activation inhibitor 1 (PAI-1) and antiplasmin, which inhibit tPA and Pn, respectively. Zinc (Zn), which circulates at a concentration of 10–20 μM, modulates platelet activation and coagulation. Whether Zn affects fibrinolysis is uncertain.
Aim: To examine the effect of Zn on fibrinolysis.
Methods: To determine the affinity of Zn for fibrinolytic proteins, Zn was bound to FluoZin-1 and fluorescence was monitored as the mixture was titrated with the protein of interest. Chromogenic or fluorogenic assays were used to examine the effect of Zn on tPA and Pn activity, and the rates of their inhibition by PAI-1 and antiplasmin, respectively. Turbidity was monitored as fibrinogen (Fg) was clotted with thrombin and degraded by tPA/Pg, Pn or trypsin in the absence or presence of Zn. A Pn-directed substrate was included to examine the effect of Zn on the kinetics of Pg activation.
Results: Zn bound Fg, tPA, and Pn with K_d values of 0.91, 0.14, and 0.05 μM, respectively, but did not bind Pg. Zn had no effect on Pn or tPA chromogenic activity, or on rates of Pn or tPA inhibition by antiplasmin and PAI-1, respectively. Nonetheless, Zn produced a significant ($P < 0.05$) 2-fold reduction in the catalytic efficiency of Pg activation by tPA in the absence or presence of Fg or Fn, mainly reflecting a decrease in k_{cat}. Time to lysis of Fn clots by Pg/tPA or by Pn was significantly ($P < 0.05$) prolonged by 24% and 17%, in the presence of 2 μM Zn compared with that determined in its absence. In contrast, Zn had no effect on lysis times with trypsin.
Summary and Conclusions: Although Zn binds tPA and Pn, it does not affect their chromogenic activity nor does it impair their inhibition by PAI-1 and antiplasmin, respectively. However, Zn inhibits tPA activation of Pg and delays lysis of Fn clots by tPA/Pg. Lysis of Fn clots by Pn also is delayed in the presence of Zn. This likely reflects modulation of Pn activity rather than altered Fn structure because Zn has no effect on Fn lysis by trypsin. Thus, Zn modulates fibrinolysis; an effect that may be particularly important at sites of injury where Zn is released from activated platelets.

Plasma proteins and soluble proteins from red blood cells cooperatively regulate wound healing process

Hayashi M, Ikeda M, Asai M and Shimonaka M

Tokyo University of Science, Tokyo, Japan

Background: The wound healing process is triggered by the restoration of endothelium and is regulated by various factors including plasma proteins and blood cells. The process involves endothelial cells, blood vessel constituting cells, such as smooth muscle cells and fibroblast cells, and extracellular matrices. We have previously reported that plasminogen accelerated the recovery of endothelial cells from scratch wounding using perfusion cell culture system. And this process was controlled by a temporal interaction between the endothelial cells and plasminogen. Other recent studies showed that the lysate of red blood cells affected the wound healing process by modulating the expression levels and activities of extracellular matrix components.
Aims: To investigate the effect of proteins from red blood cells on the process of wound healing, we examined the effects of fractionated proteins derived from red blood cells on the growth and motility of endothelial cells, smooth muscle cells, and fibroblast cells. We also investigated the behavior of smooth muscle cells and fibroblast cells in responding to the fractionated proteins under perfusion cell culture system.
Methods: Soluble proteins from red blood cells were subjected to ammonium sulfate precipitation to eliminate hemoglobin, and the resultant solution was fractionated by ion exchange column. The fractions were applied to the culture media, then the proliferative effect on each cells were examined. Motility activities on those cells were measured by Modified Boyden Chamber assay and the collagen gel contraction assay was also performed. In addition, proteinase activities of cultured media were measured by use of synthetic substrates and gelatin zymography. We also performed perfusion cell culture to investigate the effects of the fractions on smooth muscle cells.
Results: We found that one of the fractions suppressed the growth and motility activities of endothelial cells, on the other hand the same fraction extensively and weakly promoted those activities on smooth muscle cells and fibroblast cells, respectively. The same fraction stimulated the collagen gel contraction induced by fibroblast cells, meanwhile it inhibited the recovery of endothelial cells from wounding under perfusion culture conditions. These bioactive fractions also influenced protease activities such as matrix metalloproteinases. By using perfusion culture system, co-culture of smooth muscle cells and endothelial cells resulted in activation of protease activities including matrix metalloproteinases. In addition, the proteins from red blood cells induced the morphological changes of smooth muscle cells under perfusion culture conditions. This suggests that smooth muscle cells play a role in reconstitution of blood vessel.
Conclusions: Our result suggests that red blood cells contain some proteins which regulate the process of wound healing by affecting the function of blood vessel constituting cells, namely, endothelial cells, smooth muscle cells and fibroblast cells. And these processes are influenced by protease activities of various plasma proteins.

DDAVP treatment: clinical efficacy and molecular mechanisms of response in mild haemophilia A patients. A single center experience

Tagliaferri A[1], Di Perna C[1], Riccardi F[1], Franchini M[2], Rivolta GF[1] and Pattacini C[1]

[1]Regional Reference Centre for Inherited Bleeding Disorders, Parma; [2]Department of Hematology and Transfusion Medicine, Hospital of Mantova, Italy, Mantova, Italy

Background: Although desmopressin (DDAVP) is considered the treatment of choice for a large number of patients with mild hemophilia A for its safety and effectiveness, and several thousands of them have been treated with this synthetic compound worldwide during the last 35 years, several aspects of DDAVP therapy are still unclear such as the rate and type of response and the molecular and clinical determinants of its efficacy.

Aims: In order to elucidate these issues, we have conducted a retrospective study on all mild hemophilia A patients followed at the hemophilia treatment center (HTC) of Parma and treated with DDAVP.

Methods: We included in the study all consecutive patients with mild hemophilia A (basal FVIII:C levels >5 to 40%) regularly examined at the HTC of Parma since 1985 and with DDAVP test. Age of patients at DDAVP test was evaluated and the disease characteristics included the basal level of the deficient factor and molecular diagnosis (F8 mutation).

Our DDAVP test protocol consisted in a test dose of 0.3 mg/kg body weight administered i.v. from 1984 to 1995 and since 1996 by subcutaneous route. Patients were defined as complete responders with FVIII:C 50 IU/dL or higher after DDAVP; partial responders with FVIII:C lower than 50 IU/dL but increased at least 3-fold and with levels >30 IU/dL; and non-responders with neither criterion.

The definition of clinical efficacy of DDAVP treatment was defined as follows: *complete efficacy* resolution of bleeding after one DDAVP treatment; *partial efficacy*: resolution of bleeding after 2–4 DDAVP treatments; *no efficacy*: need for FVIII concentrate use. All side effects related to DDAVP infusion were also recorded. Statistical analysis was performed using Student *t* or Chi-square tests. A P value <0.05 was considered significant.

Results: Seventy-five patients were enrolled and underwent to DDAVP test with a complete or partial response in 76% (57/75) of them. The response to DDAVP was significantly correlated with patients' age (median age of responders and non-responders: 24 years and 18 years, respectively; $P = 0.04$), with the type of mutation (all the 10 patients with the mutation in the promoter region were non-responders) and with basal FVIII:C levels (complete responders had higher median than partial responders 0.18 IU/mL vs. 0.11 IU/mL). During the 12-years follow-up period, 82 of the 237 (35%) bleeding episodes occurring in 27 responder patients were treated with 246 DDAVP infusions with an overall complete or partial efficacy of 92% (75/82). Overall 142 events (30 traumas, 11 surgeries, 67 dental procedures, 17 invasive procedures, 17 home treatment post-FVIII concentrates) were managed with 253 prophylaxis DDAVP infusions with an hemostatic efficacy in 96% of the cases. No severe adverse reactions to DDAVP administration were recorded during the study period.

Conclusions: In conclusion, the results of our study clearly document the safety and efficacy of DDAVP as treatment or prevention of bleeding in mild hemophilia A patients and encourage the even more widespread use of such therapeutic strategy among physicians operating at the HTCs.

Clearance during continuous infusion of recombinant factor VIII products to 27 patients with hemophilia A at Nagoya University Hospital

Suzuki N, Kishimoto M and Matsushita T

Nagoya University, Nagoya, Japan

Background: Coagulation factor products are usually administered to hemophiliacs as a bolus injection. However, for cases of massive bleeding and major surgery, these drugs are increasingly being administered by continuous infusion to maintain coagulation factor activity at a constant level.

Aims: Determination of the clearance (CL) value is very important for undertaking continuous infusion more safely and ensuring reliable hemostasis management. We reviewed factor that influenced CL value.
