Method: We used recombinant factor VIII (FVIII) products for continuous-infusion hemostatic therapy in 33 cases of hemophilia A (27 patients). We calculated CL values and analyzed factors impacting CL values. The equation used for the calculation was CL = infusion rate (U/kg/h)/FVIII factor level (U/mL). Because the drug concentration needs to be assessed in the steady state, we calculated CL using activity values measure at ³70 h after starting continuous infusion. Factors that were analyzed for possible impacts on CL were the type of administered FVIII product, patient age, severity of hemophilia, presence/absence of infection (Hepatitis C Virus [HCV] and Human Immunodeficiency Virus [HIV]) and duration of continuous infusion. Fifteen cases were administered second-generation full length recombinant products, while 18 received third-generation full length recombinant products. For age strata, 1 case was in the 20s, 3 in their 30s,10 in their 40s, 9 in their 50s, 7 in their 60s, 2 in their 70s and 1 in their 80s. Disease severity was severe in 27 cases, moderate in 2 and mild in 4. Twenty cases were HCV-positive, including nine with cirrhosis, and 13 were negative. Nine cases were positive for HIV, while 24 were negative.

Result: Adequate hemostatic management was achieved in all cases. No cases developed adverse experiences, such as bacterial infection, thrombophlebitis, etc. In the analysis of factors possibly impacting CL, a significant difference ($P < 0.05$) in mean (±standard deviation) CL was found between administered drug products: 2.9 ± 1.0 mL/kg/h for second-generation full length recombinant products; and 4.1 ± 1.9 mL/kg/h for third-generation full length recombinant products. No other analyzed factors showed any significant impact. For three cases, the pharmacokinetics were analyzed and CL values were calculated and compared with CL values during continuous infusion. In each case, CL values obtained by pharmacokinetic analysis were lower than values during continuous infusion.

Summary: These findings reveal a large difference in CL as a function of the specific FVIII product used for continuous infusion treatment of hemophiliacs. We conclude that there is a need to set continuous infusion dosages. Moreover, CL values determined by pharmacokinetic analysis may not accurately reflect CL values during continuous infusion.

PB 3.35-3

NO-PEACKS: Non-interventional observations of practical implementation, efficacy, and safety of continuous infusion with full-length recombinant factor VIII formulated with sucrose in surgery

Meijer K[1], Schinco P[2], Santagostino E[3], Platokouki H[4], Schutgens REG[5], Valeri F[2], Brunn M[6], Tueckmantel C[6] and Rauchensteiner S[6]

[1]University Medical Center Groningen, Groningen, The Netherlands; [2]SSCVD Mal. Trombotiche/Emorragiche, Molinette Univ. Hospital, Turin, Italy; [3]Ospedale Maggiore Policlinico, Milan, Italy; [4]Hemophilia Centre and Haemostasis Unit, Aghia Sophia Children's Hospital, Athens, Greece; [5]University Medical Center Utrecht, Utrecht, The Netherlands; [6]Bayer HealthCare Pharmaceuticals, Berlin, Germany

Background: Continuous infusion (CI) of full-length recombinant factor VIII formulated with sucrose (rFVIII-FS) during surgery has been shown to be effective in preventing high peaks and low troughs of FVIII levels in a clinical trial setting. However, there is controversy regarding whether CI along with surgery or surgery in general would trigger FVIII inhibitors and whether CI is feasible in real practice.
Aims: The objective of this non-interventional, observational, prospective study was to collect data on the feasibility, efficacy, and safety of CI with rFVIII-FS in the real-practice setting, and to monitor for inhibitor formation.
Methods: Patients with severe hemophilia A (FVIII <1%), >150 exposure days to FVIII, and no positive inhibitor history from seven European countries who were administered CI with rFVIII-FS during and after surgery were enrolled. The observation period covered the entire course of CI and up to 3 months after surgery. Information such as infusion rates, number of used vials, additional blood product use, and FVIII measurements were recorded. Efficacy and tolerability of CI with rFVIII-FS were assessed. All adverse events (AEs) and results of inhibitor assays were documented. Informed consent was obtained by all study participants. The study was approved by the relevant ethics committees or authorities.
Results: Twenty-eight surgery cases were analyzed from 25 enrolled patients (median age, 49.4 years; range, 10–75 years). Of these patients, 64% had comorbidities. Median in-hospital stay due to the surgery was 9.0 days (range, 1–23 days). Median surgery duration was 120 min (range, 20–331 min). Twenty-six surgeries were elective; two were performed for emergency reasons. The majority (n = 21, 75%) were orthopedic operations. Median blood loss during surgery was 200 mL (orthopedic surgeries, 300 mL; non-orthopedic surgery, 0 mL). Median duration of CI was 128 h (range, 9.0–430.8 h). Median total rFVIII-FS consumption with CI was 376.0 IU/kg (range, 157.9–3605.6 IU/kg). One or two additional bolus injections were required during six orthopedic surgeries (21.4% of all surgeries). During three orthopedic surgeries (10.7% of all surgeries), a maximum of two blood transfusions was required. A median of nine FVIII level measurements per surgery were performed (range, 2–23). For all cases, the proportion of all FVIII level measurements in expected range per case was higher than 50%. Efficacy was considered good or excellent in 89.3% of cases, and tolerability was good or excellent in 100% of cases. Four non-drug-related AEs were the only AEs reported. Of these, two were considered serious AEs: a post-procedural hemorrhage and a peripheral artery aneurysm. None of the patients developed inhibitors during or after surgery.
Summary/Conclusions: The results of the study indicate that CI with rFVIII-FS was feasible, effective, and safe in the analyzed surgical cases. No inhibitors or drug-related AEs occurred in this CI study.

PB 3.35-4

Knowledge, attitudes, and behaviors of adolescents in developing world hemophilic population: a survey

Sachdeva A, Ramzon M, Gulati R and Yadav S

Sir Ganga Ram Hospital, Delhi, India

Background: Hemophilia patients must receive care from healthcare workers with expert knowledge of the bleeding disorder. In developing country like India many barriers have to be overcome to improve quality of life in hemophiliacs.
Aim: This survey focuses on knowledge about, attitudes towards and behaviors associated with key prevention activities among adolescents with hemophilia in India.
Methods: A team composed of experts working directly in hemophilia care conducted various hemophilia awareness camps for general population as well as for medical fraternity in previous 2 years. A survey form which included a set of questionnaire including both structured and open-ended questions were filled by these patients.
Results: The 167 (Hemophilia A and B-150 and 17 respectively) adolescents survey respondents ranged in age from 10 through 14 years were 109 (65.26%) and 15–19 years were 68 (40.7%) patients. Severe, moderate and mild hemophilia were 120 (71.8%), 31(18.56%) and 10 (5.9%) patients respectively. 82 patients had family history of hemophilia 36/167 (21.5%) patients did not know their blood group. Joint disease (target joint) in 116 (69.4%) followed by bleeding episodes in 12.5% were the primary concerns of most of the adolescents. Only two patients reported hepatitis C as a primary concern and none showed any concern for HIV or Hepatitis B. More than a three fourth (80%) of the adolescents believed that joint disease is not preventable; only 10% said it is an extremely preventable. Although hepatitis was a clear threat to this hemophilic cohort, majority of adolescents (90%) were unaware about the transmission route of Hepatitis B and C. Only10% of the respondents treated bleeding episodes within 1 h. Only 4.1% had facility of factor at their home in case of emergency situation. Majority (>90%) of being treated on demand therapy, that is also for severe bleeds only. They did not believe the episode was serious enough to require treatment. This finding was also related to the most prevalent response among the adolescents: that they did not always recognize a bleeding episode when it occurred.12 (7.1%) patients were on secondary prophylaxis and none was on primary prophylaxis. Icepacks were used by 115/167 (68.8%) of patients for their joint bleeds and tranexemic acid for mucosal bleeds by 60% of patients. Majority of adolescents managed hemophilia by avoiding physical activity and did not engage in any strenuous or moderate physical activity on aregular basis. More than 90% knew the diagnosis (name) of their disease and had informed their respective schools and collages about the same, but hardly anybody knows about the course of their disease.
Conclusions: Adolescents with hemophilia need help understanding that they can prevent complications especially joint damage. We emphasize messages for a hemophilia prevention campaign, including course of disease, recognition of bleeds, exercising to ensure healthy joints and treating bleeding episodes early and adequately.

PB 3.35-5

Bleeding risks in male patients and carriers with the valine to alanine 2016 form of mild hemophilia A

Phua CW, Park S, Scully M-F, Barrett B and Xie Y

Memorial University of Newfoundland, St. John's, Canada

Background: The phenotypic expression of mild hemophilia A differs significantly with moderate-severe form of hemophilia A. The difference in clinical impact of the disease has led to delays in diagnosis and treatment neglect resulting in potential serious morbidity and mortality. The valine to alanine 2016 (Val2016Ala) form of mild hemophilia A is an X-linked recessive disease with a high prevalence in Newfoundland and Labrador.

Aims: To determine the clinical manifestations and bleeding risks of affected male patients and carriers with the Val2016Ala form of hemophilia A.
Methods: 61 affected male patients with the Val2016Ala mutation, 44 unaffected males, 88 carriers and 65 unaffected females were recruited for analysis. Participants were scored based on a modified bleeding score from the previously published MCMDM-1 VWD score. Each category was scored as per data collected from a bleeding history questionnaire and chart audit. Additional data for health care utilization such as emergency room (ER) visits for bleeding, amount of packed red blood cell (PRBC) transfusion and number of hospitalizations for bleeding were also recorded. Separate analysis was carried out for each gender group.
Results: Affected males had significantly higher mean cumulative (27.64 vs. 82) and non-cumulative bleeding scores than control males (14.31 vs. 0.84) ($P < 0.01$). They also had a much higher likelihood of requiring surgical hemostasis, blood transfusions and/or replacement therapy for the following symptoms: (i) tendency to bruise (21.3% vs. 0%), (ii) gum bleeds (21.3% vs. 0%), (iii) gastrointestinal (GI) bleeds (18% vs. 0%), (iv) muscle hematoma (13% vs. 0%), (v) hemarthrosis (17% vs. 0%) and (vi) abnormal blood loss from dental work (55.7% vs. 0%), (vii) surgery (42.6% vs. 2.3%), and (viii) injury or trauma (50.8% vs. 0%). There were no significant differences for central nervous system (CNS) bleeds (3.3% vs. 0%) ($P = 0.4$). Affected males were also more likely to require hospitalizations, ER visits and PRBC transfusions for bleeding ($P < 0.05$). Carriers did not have a statistically significant difference in comparison with control females in any of the bleeding categories.
Summary: With the usage of a modified previously published bleeding score, we were able to evaluate the clinical characteristics of patients with the Val2016Ala from of hemophilia A. The affected male cohort unequivocally had significantly higher rates of bleeding as compared to the unaffected male cohort. Contrary to prior studies on mild hemophilia A, carriers status does not seem to confer any higher risk of bleeding in our cohort.

PB 3.35-6
Retrospective analysis of 1226 Chinese patients with haemophilia in a single medical centre

Xuan M[1], Xue F[1], Fu R[2], Yang Y[1], Li H[2], Zhang L[1], Mengsu T[1] and Yang R[1]
[1]Chinese Academy of Medical Sciences & Peking Union Medical College; [2]PUMC, Tianjin, China

Background: Haemophilia is an X-linked congenital disorder caused by deficiency of coagulation factor. Being the most populous country, China also has a large potential population of haemophilia patients. No studies have been published regarding the hemophilic epidemiology and medical situation of contemporary China.
Aims: The primary aim of this research was to achieve contemporary information of PWH in China, describe the prevalence, complications, as well as replacement therapy-related side effects of haemophiliacs for this decade.
Methods: A retrospective study was conducted in patients with haemophilia (PWH) visited in Tianjin haemophilia centre between 2002 and 2012. We evaluated the correlation between the severity of haemophilia and bleeding, analyse the inhibitor development in PWH of each severity group and treated with different clotting factor products.
Results: Over the past decade, a total of 1226 PWH (1019 HA and 207 HB) were identified in Tianjin single centre. Most of them came from north and northeast regions of China. Although a trend was observed towards lower Hb among more severe HA, the difference was not statistically significant ($P > 0.05$). APTT, age at initial bleeding and diagnosis showed association with the disease severity, but no correlations in the time of delayed diagnosis was found in each severity group of HA and HB. Our data did not offer sufficient evidences of any relationship between disease severity and risk or site of haemorrhage. Haemophilia related hemarthroses occurred in 65.7% HA (669/1019) and 56.5% HB (117/207). The most involved joints in HA are, in order, knee, elbow and ankle. Additionally patients with HB usually suffered from pain of hip. The overall incidence rate of inhibitors was 15.4% in HA and 9.8% in HB, and the prevalence of inhibitor was 18.8% in severe HA and 18.8% in severe HB. The prevalence of inhibitor and HTI were both associated with the severity haemophilia. In HA the incidence of inhibitor of using single each generation of rFVIII product was 10.5%, 8.8% and 2.9%, respectively. While the rate of inhibitor was 15.0% in PWH treated with pdFVIII, 8.1% in patients treated with both formulations simultaneously. In 21 haemophiliacs with HB by using single rFIX in a clinical trial, we found that three patients developed inhibitor following usage of recombinant factor.
Conclusions: We assessed the prevalence and treatment of haemophiliacs identified in Tianjin haemophilia centre. Although the present study highlights some of stepwise improvements in diagnosis and therapy of PWH, also reflects some challenges in contemporary China.

PB3.36 – Haemophilia A: Clinical – X

PB 3.36-1
FVIII neutralization kinetics – a complimentary tool for individual assessment of inhibitor patients

Livnat T[1], Azar-Avivi S[1], Zivelin A[1], Altisent Roca C[2], Brutman-Barazani T[1], Martinowitz U[1] and Kenet G[1]
[1]Institute of Thrombosis and Hemostasis and the National Hemophilia Center, Tel Hashomer, Israel; [2]Department of Haemophilia, Ciudad Sanitaria Valley de Hebrón, Barcelona, Spain

Background: Treatment of Hemophilia A patients with inhibitors is challenging, as correlation between inhibitor level and hemostatic response to therapy may be limited. The Bethseda unit (BU) titer assay reflects the inhibitory capacity for FVIII neutralization following long incubation of patient's plasma but does not express the kinetic behavior of the inhibitor. Furthermore, standard plasma derived FVIII is used for the test whereas most patients are currently treated by recombinant FVIII products.
Aims: We aimed to define the inhibitor affinity against various FVIII sources and asses FVIII inhibitory kinetics as a potential tool for therapy tailoring.
Methods: Blood was taken from 14 hemophilia patients aged (0.8–68 years) with inhibitors. All subjects or their guardians gave their informed consent to blood drawing for study purposes. The study was approved by the institutional ethical committee in accordance with the declaration of Helsinki. Inhibitor activity was determined against human rFVIIII (Kogenate), plasma derived FVIII (pd FVIII-Optivate) or recombinant porcine FVIII (pFVIII-Inspiration Biopharm Inc.) and compared to the titer measured by the BU. To test FVIII neutralization profile, patients' PPP was spiked with 2 U/mL rFVIII, pdFVIII and pFVIII and sequential measurements of residual FVIII activity was measured over 120 min. FVIII activity was measured by one stage PTT assay with Sysmex CA-1500 (Siemens Healthcare Diagnostics). All inhibitor (including the BU assay) and kinetics assays were performed on the same sample simultaneously.
Results: Variability of inhibitor activity against different FVIII sources was noted for all patients and did not necessarily correlate with the BU assay. For example, in a patient whose inhibitor titer was measured as 22BU, inhibitor activities of 16.8, 10 and 1.8 were detected for rFVIII, pdFVIII and pFVIII, respectively. All patients demonstrated individual FVIII source dependent neutralization curves. When rFVIII neutralization kinetics was analyzed over time, no obvious correlation was found between the measured BU titer and the rate of rFVIII neutralization. Interestingly, for some patients with high responding

inhibitors slow and incomplete FVIII neutralization was noted at 2 h after incubation, whereas some patients with low responding inhibitor titer showed fast and complete FVIII neutralization within 15 min.
Conclusion: Our assays suggest that FVIII source dependent neutralization kinetics may be applied as a complimentary tool for future therapy tailoring in inhibitor patients. The assay may depict the inhibitor patients that may benefit from FVIII therapy (regardless of inhibitor BU titer) and identify the best potential FVIII source for treatment.

PB 3.36-2

Low inhibitor incidence in previously untreated patients with severe haemophilia A treated with octanate – Update from the PUP-GCP clinical trial

Jansen M[1], Klukowska A[2], Komrska V[3], Laguna P[2] and Vdovin V[4]
[1]Octapharma, Vienna, Austria; [2]Medical University of Warsaw, Warsaw, Poland; [3]Motol University Hospital, Prague, Czech Republic; [4]Ailovsky Children's Hospital, Moscow, Russian Federation

Background: Octanate is a highly purified, double virus inactivated, human plasma-derived factor VIII (FVIII) concentrate with all coagulation FVIII bound to its natural stabilizer VWF in a VWF:RCo/FVIII:C ratio of approximately 0.4. Five prospective GCP studies with octanate were conducted in 77 previously treated patients (PTPs) with severe haemophilia A. None of these 77 PTPs developed an inhibitor.
Aim: To assess the immunogenicity in previously untreated patients (PUPs), a prospective clinical trial has been initiated in 2000. This included 48 PUPs with severe hemophilia A after treatment with octanate for an observational period of 100 exposure days and at least 6 months.
Methods: Patients with severe haemophilia A without previous exposure to FVIII or FVIII containing products were enrolled. Efficacy and tolerability are assessed by a 4-point verbal rating scale. Inhibitor assay, according to modified Bethesda method is tested pre-treatment, every 3–4 exposure days (ED 1-20) and every 10 EDs (ED 21-100) but at minimum every 3 months.
Results: Two of 48 (4.2%) subjects receiving treatment developed clinically relevant inhibitor titers over the course of the study. Another two displayed inhibitors that disappeared spontaneously without change of dose or dosing interval. All inhibitors developed under on-demand treatment and before ED 50. From the 48 subjects, 42 had exceeded 50 EDs at the time of this analysis. octanate was well-tolerated and the adverse event profile was consistent with the population studied. The haemostatic efficacy in prophylaxis and treatment of bleeding were generally rated as 'excellent' and no complication was reported for any surgical treatment.
Conclusion: Despite frequent inhibitor testing and predominant on-demand treatment, octanateshowed a low rate of clinically relevant inhibitor formation (4.2%) in this cohort of patients.

PB 3.36-3

A European certification system for haemophilia centres

Calizzani G[1], Menichini I[1], Candura F[1], O'Mahoney B[1], Giangrande P[2] and Makris M[3]
[1]European Haemophilia Consortium, Brussels, Belgium; [2]Oxford Haemophilia & Thrombosis Centre, Oxford, UK; [3]University of Sheffield, Sheffield, UK

Background: There are 409 facilities in Europe, of widely varying size and expertise calling themselves 'Haemophilia Centres'. Although a small number of countries have accreditation systems the majority do not. The European haemophilia community of professionals and patients has agreed the principles of haemophilia care. Care delivery is challenging due to the rarity and expense of treatment of the disease. We set to provide EU Member States (MS) with guidelines on a European certification system (CS) for Haemophilia Centres (HCs), in order to improve haemophilia care and to ensure equity of treatment throughout Europe.
Aims: To draw up a Guideline document establishing quality standards for European HCs and setting criteria for their certification and designation as European Comprehensive Care Haemophilia Centres (i.e. expert) and European Haemophilia Treatment Centres (i.e. non-expert).
Methods: The drafting of the Guideline document was performed by a panel composed of haemophilia experts and consultant methodologists. The methodology includes the following steps: (i) collection of the available MS regulations on HCs certification system by administering a questionnaire to key European stakeholders (physicians, patient representatives, institutions) (ii) systematic review of literature and MS regulations on HCs certification (iii) definition of a proposal of criteria and principles to be adopted for the production of the standards and launch of a consultation process involving key European stakeholders (iv) validation of criteria and principles for the production of the standards (v) standards production (vi) design of a HCs evaluation and certification system (vii) launch of a consultation process on standards and HCs evaluation and certification system (viii) approval of standards and evaluation/certification system.
Results: The first draft sets the standards for the designation of European HCs of two levels: European Haemophilia Comprehensive Care Centres, that provide specialized and multidisciplinary care and function as tertiary referral Centres, and European Haemophilia Treatment Centres, that provide local routine care. The standards apply to both adults and paediatric patients. They focus on organizational issues and cover: (i) general requirements (facility; general policy and objectives; information about the Centres; organization and staffing; policies and procedures; record-keeping and data collection; personnel appraisal and continuing education; supply and management of therapeutic products, reagents and medical devices; quality planning, evaluation and improvement; participation in registries; participation in clinical research), (ii) patient care (awareness, information and education of patients and their families; diagnosis and therapy of haemophilia and other related bleeding disorders and all the forms of acquired haemophilia; periodic clinical and multi-disciplinary review; genetic services; outcome indicators), (iii) advisory service, (iv) laboratory; (v) networking of clinical and specialised service.
Conclusions: The haemophilia standards have been developed following consultation and in 2013 all European haemophilia centres will be invited to apply for certification. A panel of physicians, patients and nurses will assess the applications. Once implemented across EU MS, the certification system will contribute to the reduction of health inequalities through the standardization of quality of care provided by HCs.

PB 3.36-4

Patient and parent preferences for efficacy, inhibitor risk, safety, and infusion frequency associated with prophylactic Factor VIII treatment

Mohamed AF[1], Lin VW[2], Posner JD[1] and Epstein JD[2]
[1]RTI Health Solutions, Research Triangle Park; [2]Baxter BioScience, Westlake Village, USA

Background: As new options become available for Factor VIII prophylaxis treatment, research is needed to understand a patient's willingness to accept tradeoffs among treatment attributes such as effectiveness, inhibitor risk, safety, and infusion frequency.
Aims: To quantify patient and parent preferences for prophylactic Factor VIII treatments and compare the relative importance of treatment attributes.

Methods: Adult patients and parents of children with severe hemophilia A in the United States were recruited and completed a web-enabled, discrete-choice experiment survey. The survey presented a series of 10 choice questions, each including a pair of hypothetical prophylactic Factor VIII treatment profiles. Each profile was defined by average number of bleeds per year, risk of developing an inhibitor, infusion frequency, and track record of product safety. The majority of levels for each attribute were identified based on the literature or clinical trial results. Choice questions were based on a predetermined experimental design with known statistical properties. Preference weights for attribute levels were estimated using random-parameters logit. The survey was tested to help inform attribute selection and ensure respondent comprehension in 10 face-to-face interviews. All respondents provided online informed consent and the study complied with the Declaration of Helsinki, receiving ethics board approval.
Results: The final sample included 76 adult patients and 86 parents. Mean age for adult patients was 32 years and the mean age for children was 8 years. 47% of adult patients and 41% of parents reported prophylactically infusing three times a week. Statistical tests indicated that the two samples could not be pooled due to different preferences ($P < 0.01$). For parents, the most important attribute was average number of bleeds per year and was assigned a mean relative importance score of 10.0. The remaining attributes in descending order of importance were track record of product safety (8.1), risk of developing an inhibitor (8.0), and infusion frequency (6.0). For adult patients, risk of developing an inhibitor was the most important attribute (10.0). The remaining attributes in descending order of importance were average number of bleeds per year (7.3), infusion frequency (6.3), and track record of product safety (4.5). Both patients and parents significantly ($P < 0.05$) preferred 0–1 bleeds per year over five bleeds per year and a track record of 4–10 years of product safety over a product new to market. There were significant ($P < 0.05$) differences between a 0%, 1% and 2% risk of inhibitor development as there were between infusions three times per week and infusions two times per week. Parents and adult patients revealed that achieving zero bleeds per year (relative to five bleeds) was 2.4 and 1.7 times more important than being able to infuse two times per week over three times per week, respectively.
Conclusion: While these results suggest that adult patients and parents of children with severe hemophilia A have different preferences, both were not willing to trade off having several bleeds per year to infuse less frequently. Healthcare providers are encouraged to take these preferences into account when prescribing Factor VIII prophylaxis.

PB 3.36-5

Comprehensive assessment of hemorrhagic phenotype and cardiovascular risk profile in carriers of severe haemophilia

Mingot ME, Rodriguez-Martínez M and Heiniger Mazo A
Regional Universitary Hospital Carlos Haya, Málaga, Spain

Background: There are few studies about bleeding phenotype in haemophilia carriers. All of them describe haemophilia carriers with low factor VIII (FVIII) levels without bleeding problems and on the other hand an haemorrhagic tendency in some of these women even with factor VIII (FVIII) plasma levels almost in a normal range.
Aims:
- To evaluate hemostasis in severe hemophilia carriers.
- To identify symptomatic carriers.
- To descrige this group bleeding profile.
- To exclude other concomitant haemostasis disorders supporting this bleeding profile.
- To evaluate this population cardiovascular risk profile and its influence on the bleeding profile.
- To analyze the quality of life of this population.

Method: This is a descriptive cross-sectional, non-interventional, single center study. Ethics Committee evaluation and Informed Consent are requested. The target population are severe Haemophilia A carriers from our center, there is no exclusion criteria. We will evaluate family bleeding, ischemic and thrombotic antecedents, individual hemostasis profile using Tosetto bleeding score (TBS) and pictorial blood assessment chart (PBAC), FVIII genetic study, complete blood count, basic biochemistry, haemostasis (aPTT, PT, fibrinogen, platelet function tests, FVIIIc, FvWAg and FvWRCo, FXIII, homocysteine, resistence to activated protein C, antithrombin, protein C and S, 20210A prothrombin mutation), cardiovascular risk throughout Framingham score and Systematic Coronary Risk Evaluation Project. We will study quality of life using SF-36 questionary. Anxious and depression disorders will be evaluated with Goldberg score. To describe continuous variables we will use mean, median, standard deviation, maximum and minimum. For categorical variables, it will be used the percentage of every category. Statistical techniques are used to ensure compliance with statistical assumptions to use non parametric tests.
Results: Since julio 2012, we have studied 31 severe haemophilia A carriers. Median age is 43 years-old (range, 14–73 year-old). Media FVIII: C level is 82 ± 32% (range, 35–152%). There is no difference in FVIII levels with regard to bleeding profile or FVIII gene mutation. Tosetto bleeding score is higher than 3 in 42% of the group (13/31). Abnormal bleeding in surgery, postpartum or menorrhagia were described in 26% (8/31) of cases. PBAC is higher than 100 in 70% of the group (22/31), a higher rate than general population. Three of these patients have low levels of VWF: RCo and VWF: Ag. Farther studies let us classify them as von Willebrand disease patients appart from haemophilia carriers. We find no other associated haemostatic disorder. There is no thrombophilia, nor correlation between cardiovascular risk score and bleeding profile, although serie is still short.
Conclusion: Severe haemophilia A carriers can suffer from abnormal bleeding because of low FVIII levels or association of other haemostatic difects. There is short information on general population bleeding events incidence apart from metrorrhagia. This makes difficult to verify and to prove that the incidence of bleeding in haemophilia carriers with FVIII levels over 40% is higher, particularly since these seem to occur with bleeding hemostatic levels of FVIII and no other hemostasis defect.

PB 3.36-6

Do inhibitors, treatment regimen and bleed frequency impact haemophilia treatment centre and provider utilisation: an analysis of adults with haemophilia in the HERO study

Iorio A[1], Nugent D[2], Stain AM[3], Gregory M[4], Pericleous L[5] and Cooper D[6]
[1]McMaster University, Hamilton, Canada; [2]Children's Hospital of Orange County, Orange, USA; [3]Kiddies Health Care Inc, Toronto, Canada; [4]UK Haemophilia Society, London, UK; [5]Novo Nordisk A/S, Bagsværd, Denmark; [6]Novo Nordisk Inc., Princeton, USA

Background: Congenital haemophilia is primarily treated through comprehensive care at a haemophilia treatment centre (HTC) by a variety of specialised practitioners. Little is known about the relationship of HTC utilisation to the presence of inhibitors, on-demand vs. prophylactic treatment or bleed frequency.
Aims: To describe the relationship between HTC and healthcare professional utilisation, inhibitor status, treatment regimen and bleed frequency in adults with haemophilia in the Haemophilia Experiences, Results and Opportunities (HERO) Study.
Methodology: A post-hoc descriptive analysis of data from adults ≥18 years in eight countries with home treatment. Annual bleed frequency was categorised for analysis (0, 1–5, 6–10, 10–20, >20 bleeds).
Results: Overall, 515 adults (431 without inhibitors, 84 with inhibitors) responded, with treatment distributed between on-demand (without

inhibitors 141, with inhibitors 39) and prophylaxis (without inhibitors 174, with inhibitors 29). The distribution of adults among each annual bleed frequency category (0/1–5/6–10/10–20/>20) was 54/144/63/57/75. Median age (years) of those on prophylaxis was younger than those patients on on-demand for adults without inhibitors (36 vs. 41) but not for adults with inhibitors (35 vs. 35). There was no consistent trend in median age across bleed frequencies (45/40/36/35/40). Overall, 64% of adults were full-time, part-time or self-employed; rates of employment were similar in adults without inhibitors (on-demand 65%, prophylaxis 58%), with inhibitors (on-demand 76%, prophylaxis 73%) and with increasing annual bleed rate (65%/63%/74%/63%/53%). Higher risk activities were reported more commonly by those on prophylaxis (without inhibitors 16%, with inhibitors 10%) vs. on-demand (without inhibitors 10%, with inhibitors 3%) and by those with lower annual bleed rates (15%/10%/17%/7%/9%). Mean/median bleeds per year were higher for adults without inhibitors on prophylaxis (14.9/5) vs. on-demand (10.3/2) but were lower for adults with inhibitors on prophylaxis (5.6/2) vs. on-demand (15.6/7). Mean/median number of HTC visits per year were higher for adults on prophylaxis (without inhibitors 4.5/2, with inhibitors 5.4/4) vs. on-demand (without inhibitors 3.5/2, with inhibitors 4.8/3). There were no differences seen in relation to bleed rates. Nurses were more frequently involved in haemophilia care in adults with inhibitors on prophylaxis (without inhibitors 55%, with inhibitors 69%) vs. on-demand (without inhibitors 45%, with inhibitors 44%) and with increased bleed frequency (37%/54%/54%/65%/57%), while social worker involvement was more common in adults without inhibitors on prophylaxis (20% vs. 8% on-demand) but less common in adults with inhibitors on prophylaxis (17% vs. 44% on-demand), and increased with bleed frequency (9%/15%/19%/30%/32%). Physiotherapist involvement was similar in adults on prophylaxis (without inhibitors 39%, with inhibitors 41%) and on-demand (without inhibitors 31%, with inhibitors 46%) but increased based on bleed frequency (20%/38%/41%/35%/37%).

Conclusions: For adults, employment was relatively high irrespective of the presence of inhibitors, current treatment regimen and increasing bleed frequency. Reported bleed frequency was higher in adults without inhibitors on likely secondary prophylaxis but lower in those with inhibitors on prophylaxis. HTC utilisation was slightly higher in adults on prophylaxis vs. on-demand. Bleed frequency did not seem to impact utilisation. Involvement of physiotherapy and social work in comprehensive care was generally less than expected.

PB3.37 – Haemophilia A: Clinical – XI

PB 3.37-1

Outcomes of total knee and hip arthroplasty for hemophilic arthropathy

Holderness BM, Goto Y, McKernan LJ, Bernini PhM and Ornstein L

Dartmouth-Hitchcock Medical Center, Lebanon, USA

Background: Hemophilic arthropathy results in joint pain and dysfunction and significant disability in people with bleeding disorders. Total joint arthroplasty (TJA) carries substantial bleeding risk, but may also be associated with increased risk for venous thromboembolism (VTE). Our practice is to ensure normal hemostasis using coagulation factor concentrates perioperatively while administering pharmacologic thromboprophylaxis concurrently to prevent VTE. Our center is one of the few to employ this management strategy for TJA in this population; the aim of the current study was to assess safety and efficacy of this practice.

Methods: We performed a retrospective chart review to identify patients with congenital bleeding disorders who underwent TJA between 1987 and 2012. We collected data on range of motion (ROM) and pain before and after surgery and on early and late complications (bleeding, infection, thrombosis). Data are presented descriptively using median values and ranges where appropriate.

Results: We identified 38 procedures (29 knees (TKA) and 9 hips (THA) in 28 patients (26 male, 2 female) with hemophilia A ($n = 21$), hemophilia B ($n = 4$), factor 11 deficiency ($n = 1$) and von Willebrand disease ($n = 2$). Median age at operation was 42 years (range, 17–74) for TKA and 45 years (range, 18–71) for THA. Inhibitors were present in one patient with hemophilia A (1.5 B.U.) and one patient with factor 11 deficiency (0.5 B.U.). All patients were treated with hemostatic agents appropriate to their disorders for up to 4–6 weeks post-operatively. Complete data at 2 months post-operatively are available for 27 TKA patients, of whom, 7 (23%), demonstrated improvement in ROM (median 15 degrees, range 5–25). At 1.5 years post-operatively, 17/29 (59%) TKA patients showed improvement in ROM (median 15 degrees, range 4–58) and 100% reported decreased knee pain. All nine THA patients demonstrated improved ROM at 2 months post-operatively. Eight (89%) demonstrated gains in internal rotation (median, 45 degrees, range 15–45), 9 (100%) in external rotation (median 30 degrees, range 15–45), 5 (56%) in flexion (median 35 degrees, range 27–55), 7 (78%) in extension (median 15 degrees, range 3–95), and 7 (78%) in abduction (median 15 degrees, range 10–25). Low molecular weight heparin was administered post-operatively in 29 of 38 procedures (76%). Thromboprophylaxis was discontinued in three patients for non-joint bleeding (one hematuria, two cases of hypotension and anemia). There were no symptomatic VTE. Early complications included five cases of cellulitis and two hemarthroses in patients not receiving thromboprophylaxis. Late complications included two patients with aseptic loosening in prosthetic knees leading to TKA revisions, one with a subsequent joint infection requiring surgical debridement and one patient with a worsening flexion contracture requiring TKA revision.

Conclusions: While there are risks associated with TJA in patients with bleeding disorders, our data suggest they are outweighed by the benefits manifesting as decreased pain and improved function. Pharmacologic thromboprophylaxis appears safe in this population; whether it is necessary is unknown and should be a subject of future trials.

PB 3.37-2

European Haemophilia Network (EUHANET)

Makris M[1], Calizzani G[2], Fischer K[3], Gatt A[4], Hollingsworth R[5], Lambert T[6], Lassila R[7], Mannucci PM[8], Peyvandi F[9] and Windyga J[10]

[1]University of Sheffield, Sheffield, UK; [2]European Haemophilia Consortium, Rome, Italy; [3]University Medical Centre Utrecht, Utrecht, The Netherlands; [4]Mater Dei Hospital, Msida, Malta; [5]MDSAS, Manchester, UK; [6]Paris AP-HP Haemophilia Treatment Centre, Paris, France; [7]Helsinki University, Helsinki, Finland; [8]EAHAD, Milan, Italy; [9]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [10]Institute of Haematology and Transfusion Medicine, Warsaw, Poland

Background: Inherited bleeding disorders are rare and care for patients is provided by specialist haemophilia centres. The quality of care varies enormously between countries and in different centres within countries. It is difficult for patients to select which centre to attend due to lack of information about the quality and level of care offered. There is limited independent information available for patients about their disorders and there is no uniform system to collect adverse events of their treatment.

Method: EUHANET is a European Commission funded project with additional support from industry. There are five main partners and 84 collaborating haemophilia centres participating. The project uses information technology extensively and centres collaborate on several projects including the certification of haemophilia centres, the development of a new website, the expansion of the adverse event reporting

system (EUHASS) and a prospective registry of patients with afibrinogenemia and FXIII deficiency and their management.
Results: (a) Certification
We have identified 409 facilities that call themselves haemophilia centres in Europe. After review of the currently available literature and guidelines from individual countries, we have proposed the standards required for European Comprehensive Care Haemophilia Centres (expert) and European Haemophilia Treatment Centres (non-expert) certification. All European centres will be able to apply for certification from 1st June 2013.
(b) Haemophilia Central website
A new publically available website (www.haemophiliacentral.org) contains frequently updated news stories as well as information on guidelines, clinical trials, concentrates and a locator listing all haemophilia centres and organisations in Europe. Patients can find the nearest haemophilia centre from anywhere in Europe.
(c) Adverse event reporting
The EUHASS adverse event reporting system has been expanded to include platelet disorders and acquired bleeding disorders due to inhibitors. So far in the first 4 years of the system 952 individual reports from centres have been submitted. These included 101 allergic or acute reactions, 197 first ever inhibitors, 26 recurrent inhibitors, 103 thromboses (of which 62 occurred within 30 days of concentrate administration), 207 malignancies and 310 deaths.
(d) Prospective registry for afibrinogenemia and FXIII deficiency
A new project has started where all cases of afibrinogenemia and FXIII deficiency in the participating centres are registered and data on number of bleeds and concentrate usage are prospectively provided every 6 months.
Conclusion: Although in its early days, the EUHANET project aims to improve the collaboration of European haemophilia centres and the success of the ongoing EUHASS project is a demonstration of what can be achieved with such collaboration.

PB 3.37-3

Osteoporosis and osteopenia in patient with severe and moderate type hemophilia A

Chen YC[1], Cheng S-N[2], Pan R-Y[3], Li TY[4] and Hu SH[5]
[1]Hemophilia Care and Research Center, Divison of Hematology/Oncology; [2]Department of Pediatrics; [3]Division of Sports Medicine, ; [4]Department of Physical Medicine and Reha; [5]Hemophilia Care and Research Center, Taipei, Taiwan

Background: Hemophilia patients have been found to have lower bone mineral density (BMD) as compared to normal healthy subjects. The pathophysiology of the development of osteoporosis in hemophilia patients is not exactly known.
Aim: The aims of this study were to realize the percentage of osteoporosis in hemophilia patients and to analyze the correlation of osteoporosis with some clinical factors and a biomarker in hemophilia A patients.
Patients and Methods: We prospectively enrolled 30 consecutive adult hemophilia A patients (23 severe and seven moderate type) with hemophilic arthropathy from January to December, 2011 for this study. The median age of patients was 38.5 years old with a range of 21–66 years. Each patient's clinical informations including age, disease severity, body mass index (BMI), anti-HCV positivity, Pettersson score of the X-ray of six index joints and dual-energy X-ray absorptiometry (T score) for femoral neck and lumbar spine and tartrate-resistant acid phosphatase isoform 5b level were collected for correlation analyses.
Results: The percentage of osteopenia determined by T score of femoral neck and lumbar spine in our cohort patients was 70% and 28%, respectively. The percentage of osteoporosis in femoral neck and lumbar spine was 12% and 4%, respectively. There were good correlation between patients' BMI and T score of either femoral neck ($r = 0.635$, $P = 0.0046$) or lumbar spine ($r = 0.690$, $P = 0.002$). The BMD of femoral neck and lumbar spine between patients with and without HCV were not significantly different.
Conclusion: Our study demonstrated there was a high percentage of osteopenia measured by T score of femoral neck and BMI has significantly good correlation with BMD of femoral neck and lumbar spines in this cohort of hemophilia patients.

PB 3.37-4

Haemate® P for the treatment of vWD and haemophilia A: new results of a pharmacovigilance project

Krause M[1], Von Depka Prondzinski M[2], Halimeh S[3], Wermes C[4], Kemkes-Matthes B[5], Gutowski-Eckel Z[6] and Auerswald G[7]
[1]German Clinic for Diagnostic, Wiesbaden; [2]Transfusion Medicine, Werlhof-Institute, Hannover; [3]Medical Thrombosis and Haemophilia treatment Center, Duisburg; [4]Paediatric Haematology and Oncology, MHH, Hannover; [5]Haemostasis Center, University Hospitals Giessen and Marburg GmbH, Gießen; [6]CSL Behring GmbH, Marburg; [7]Prof. Hess Childrens Hospital, Klinikum Bremen-Mitte, Bremen, Germany

Haemate® P(CSL Behring, Marburg) is a factor concentrate that contains von-Willebrand-Factor (vWF) and Factor VIII (FVIII). It is indicated for the treatment of von Willebrand disease (vWD), haemophilia A and ITT. This pharmacovigilance surveillance should collect data on the long-term efficacy, tolerability and safety of Haemate® P in clinical routine situations.
All patients treated with Haemate® P could be enrolled (vWD and haemophilia A-patients, PUPs and PTPs). Patients are routinely screened every 3–12 months. The following parameters were documented (non-interventional design): overall clinical response, bleeds, adverse drug reactions including the incidence of inhibitors, laboratory safety parameters, virus safety, relevant concomitant diseases, and relevant concomitant medication.
Up to now, 91 patients were included into this study and data from 330 visits were available for this analysis. 87 patients suffered from vWD (57 patient with Type 1, 18 patients with Type 2, and 11 patients with Type 3), and four patients from haemophilia A. The median age was 36 years (range 0.4–84.3).
In all vWD patients the median number of bleeds per year was 2.34 (in the vWD-Type 1-group median 7.74 bleeds, in the vWD-Type 2-group median 1.76 bleeds, in the vWD-Type 3-group median 0.97 bleeds). This is correlated to a higher percentage of patients with 'on demand' treatment in Type 1 patients.
Four patients with haemophilia A are enrolled in the study. One patient with known risk factors (afro-american origin) developed a low titer inhibitor, an ITI was started and successfully completed. The results included in this interim analysis confirm the very good efficacy, tolerability and safety of Haemate® P.

PB 3.37-5

Safety and pharmacokinetics of a recombinant fusion protein-linking coagulation factor VIIa with albumin (rVIIa-FP) in healthy volunteers

Veldman A, Easton R, Jung K, Moises T, Lawo JP, Joch C, Daehler A and Bensen-Kennedy D
CSL Behring, Marburg, Germany

Background: Development of neutralizing antibodies remains the most problematic complication in the treatment of patients with congenital haemophilia. Therapy with the bypassing agent rFVIIa is limited by the short half-life of the commercially available product. Here, we report on pharmacokinetics and safety of a novel, recombinant fusion

protein linking coagulation factor VIIa with albumin (rVIIa-FP) in a placebo controlled, first-in-man study in healthy male subjects that have been anti-coagulated with an oral vitamin K antagonist (OVKA).

Aims: To investigate safety andpharmacokinetics of rVIIa-FP in healthy volunteers.

Methods: A total of 40 healthy male volunteers between 18 and 35 years of age were included in the study and were dosed in five consecutive cohorts of eight subjects each. In each cohort, six subjects were randomized to a single dose of rVIIa-FP (140, 300, 500, 750 and 1000 μg/kg) and 2 to placebo. All subjects received anticoagulation with OVKA to reach a stable INR between 2 and 3 prior to dosing with rVIIa-FP/placebo. Dosing with OVKA was continued at a fixed dose for 5 days after injection of rVIIa-FP and then antagonized with Vitamin K.

Results: Tolerance of rVIIa-FP was excellent at all dose levels. No serious adverse events were observed. None of the subjects developed anti-drug antibodies or inhibitors. FVIIa baseline-corrected mean (SD) C_{max} plasma activity increased in a dose-proportional manner, from 9240 (515) mU/mL for the 140 μg/kg dose to 63520 (13515) mU/mL for the 1000 μg/kg dose. Across the dose range, the median half-life (t1/2) was consistent, ranging from 6.1 h to 9.7 h. At the highest dose of 1000 μg/kg, the median FVIIa activity-based was 8.5 h. Clearance (CL) was consistent across the dose levels, ranging from 7.62 to 12.74 [mL/h/kg].

Conclusions: Compared to the commercially available rFVIIa product, the t1/2 of rVIIa-FP is increased and clearance reduced by approximately 3–4 fold. Tolerance and safety in this first-in-man study were excellent. The study has been registered on clinicialtrials.gov (Registration No: NCT01542619).

PB 3.37-6

Adherence to hemophilia treatment in the Dutch pediatric population; reliability and validity of the VERITAS-Pro questionnaire

Lock J[1], Raat H[2], Duncan NA[3], Shapiro AD[3], Peters M[4], Tamminga YJ[5], Leebeek FWG[2], Moll HA[1] and Cnossen MH[1]

[1]Erasmus Medical Center – Sophia Children's Hospital; [2]Erasmus Medical Center, Rotterdam, The Netherlands; [3]Indiana Hemophilia and Thrombosis Center, Indianapolis, USA; [4]Academic Medical Center – Emma Children's Hospital, Amsterdam; [5]University Medical Center Groningen, Groningen, The Netherlands

Background: Patients' adherence is strongly associated with the cost-benefit of hemophilia treatment. It is therefore important to be able to quantify adherence and to formulate interventions aiming to modify patient adherence.

Aims: To assess the reliability and validity of the cross-culturally adapted Dutch version of the Validated Haemophilia Regimen Treatment Adherence scale (VERITAS-Pro) designed to quantify adherence in patients with hemophilia on prophylactic clotting factor replacement therapy. This first evaluation focuses on the test equivalence of the psychometric properties of the original and the adapted VERITAS-Pro.

Patients and Methods: In this study, children from three Dutch Hemophilia Treatment Centers with severe and moderate hemophilia on prophylactic treatment were included. Exclusion criteria were: prophylactic treatment <1 year, presence of inhibitors, language difficulties. Written informed consent and ethical approval was obtained. Parents and adolescents aged 10–18 years filled out the study questionnaire.

The original VERITAS-Pro is a validated adherence scale of prophylactic clotting factor replacement therapy, applied in the USA. The scale consists of 24 items on six (four item) subscales (Time, Dose, Plan, Remember, Skip, Communicate). Lower scale scores reflect higher adherence. The VERITAS-Pro was translated into Dutch according to a predefined protocol with two forward and two backward translations. Psychometric properties (construct validity including Cronbach's alpha and item correlations per subscale, discriminative validity according to the infusion logbooks, test-retest reliability) were empirically assessed.

Results: A total of 60 parents and 30 adolescents filled out the questionnaire with a response rate of 87%. Median age of children was 11 years (IQR 8–14). Test-retest reliability was measured in a subgroup ($n = 58$). Construct validity: mean Cronbach's alphas were adequate (>0.70) for the total score, and the subscales 'skip' and 'communicate', but not for subscales 'time' (0.42), 'dose' (0.34), 'plan' (0.62), and 'remember' (0.50). Two scales had floor effects (>50%), not previously reported. The item-own subscale correlations within all scales were considerably higher than most of the item-other subscale correlations. Test-retest correlations were statistically significant for all scales, except for the subscale 'time'. Discriminative validity: overall total scores were significantly higher for non-adherent respondents according to the infusions logbooks ($n = 48$, $P < 0.05$).

Conclusions: This suggests that the total score of the VERITAS-Pro is useful to quantify adherence to treatment in the Dutch population; subscales are however less applicable. Equivalence of psychometric properties of the adapted VERITAS-Pro was reached on most items.

PB3.38 – Haemophilia A: Clinical – XII

PB 3.38-1

Clinical features and management of hemophilic pseudotumors: a single US center experience

Lim MY[1], Nielsen B[2], Ma A[1] and Key NS[1]

[1]University of North Carolina; [2]UNC Hemophilia and Thrombosis Center, Chapel Hill, USA

Background: Hemophilic pseudotumor is an uncommon but potentially life-threatening complication occurring in 1–2% of hemophilia patients. It is thought to occur more frequently in developing countries that have limited access to factor replacement therapy, and is rarely seen in developed countries. Given the rarity of this condition, consensus on the management of pseudotumors in hemophilia patients is lacking and largely confined to case reports or small series.

Aims: We describe the clinical features and management of hemophilic pseudotumors in a single US institution.

Methods: We retrospectively reviewed the medical records of hemophilia patients with a diagnosis of pseudotumor seen at the UNC Hemophilia Center from 1981 to 2011. We recorded the following data: type and severity of hemophilia, documented etiological antecedent, localization of the pseudotumor, presenting symptoms, management and outcome.

Results: We identified 12 pseudotumors in 11 hemophilia patients in the age range of 23–69 years (median: 47 years) at the time of diagnosis. Ten patients had hemophilia A (severe, $n = 5$; moderate, $n = 4$; mild, $n = 1$) and one patient had moderate hemophilia B. Six patients had known inhibitors or a history of inhibitor.

An etiological antecedent leading to the development of pseudotumor was reported in nine cases (75%): prior trauma to the affected area in six cases and prior spontaneous bleed in the affected area in three cases. Localization of the pseudotumor was confined to soft tissue in three cases (25%), and affected the bones in eight cases (66.7%). The remaining case was a right lung pseudotumor.

Localized pain from the pseudotumor was present in seven cases, of which additional neurological compromise (paresthesia) and vascular compromise (arterial ulcers) occurred in one case each. Two patients presented with a pathological fracture while the patient with right lung pseudotumor presented with hemoptysis. One patient presented with obstructive renal symptoms from his retroperitoneal pseudotumor, subsequently progressing to end stage renal disease, requiring hemodi-

alysis. Six of the 12 pseudotumors (50%) were not diagnosed at the time of initial presentation, with the delay in time to diagnosis ranging from 6 weeks to 6 years.

In eight cases, surgical intervention (incision and drainage [I&D], $n = 2$; excision, $n = 4$; amputation, $n = 2$) was the initial treatment choice, with complete resolution obtained in six cases. Both I&Ds were unsuccessful, with one case subsequently undergoing successful surgical excision, while the other case was followed by an unsuccessful arterial embolization; the patient declined further intervention.

Conservative management with close monitoring occurred in three cases, with one case subsequently requiring surgical resection. The patient with a right lung pseudotumor was treated with multiple arterial embolizations without resolution. He was subsequently placed on biweekly factor replacement therapy to reduce the frequency of hemoptysis.

Conclusion: This is the largest single-US institution case series of hemophilic pseudotumors. Our series demonstrates that hemophilic pseudotumors still occur sporadically, and the diagnosis is frequently delayed. Surgical intervention seems to be a safe and effective treatment, although conservative management may be appropriate in selected cases.

PB 3.38-2

The relationship between specific annual bleed rates and health outcomes among children with severe hemophilia A

Valentino LA[1], Giangrande P[2], Epstein JD[3], Xiong Y[3], Ito L[3] and Li-McLeod J[3]

[1]Rush University Medical Center, Chicago, IL, USA; [2]Oxford Haemophilia & Thrombosis Centre, Oxford, UK; [3]Baxter Healthcare, Westlake Village, USA

Background: Recurrent bleeding suffered by children with severe hemophilia A has been shown to lead to chronic pain, disability, arthropathy and lower health-related quality of life (HRQOL). Little has been published to understand what level of bleeding can be tolerated before patients report an impact on their health outcomes.

Aims: The objective of this analysis was to assess the health outcomes of pediatric patients reporting a zero annual bleed rate (ABR) and identify the incremental impact of higher ABRs on these outcomes.

Methods: A multi-national, cross-sectional survey of severe hemophilia A patients was administered in collaboration with hemophilia associations or hemophilia treatment centers across 10 countries. A centralized ethics review board approved the study. Eligible, consenting caregivers of hemophilia patients under 18 years of age completed a detailed questionnaire during one of two phases: from October-November 2009 (Argentina, China, Russia, US) and January-August 2011 (Chile, Colombia, Malaysia, Mexico, Philippines, Singapore). HRQOL was measured using the Pediatric Quality of Life Inventory (PedsQL) and the EQ-5D. Treatment regimen, ABR, number of target joints and days missed from school were also assessed. Median results of those who reported a zero ABR were compared to those reporting ABR categories of 1–2, 3–4, 5–10, 11–20, 21–30, 31–50 and >51 using Wilcoxon Rank-Sum Test.

Results: 470 parents/caregivers of severe hemophilia A children completed the survey. The mean age of pediatric patients was 9.7 years. 48% of the pediatric patients were on an on-demand treatment regimen while another 48% were on prophylaxis (defined as regular infusions to prevent bleeds from occurring), and the remainder did not specify. A pattern emerged between an increase in ABR and significant worsening of HRQOL scores. Compared to patients with a 0 ABR who reported a median PedsQL Total score of 82.6, patients with ABR categories of: 3–4, 5–10, 11–20, 21–30, 31–50, 51 or more showed significantly worse median PedsQL Total scores of: 71.2, 65.3, 68.7, 67.4, 64.0 and 56.5, respectively (all $P < 0.05$). This statistically significant pattern held for all PedsQL summary scores (physical, psychosocial, school) as well as the EQ-5D Index and EQ-5D VAS scores (all $P < 0.05$). Additionally, differences in number of target joints and missed days from school all showed the same statistically significant trend of progressively worse scores when comparing 0 ABR to ABR categories of 3–4 and beyond. There were no significant differences between patients with zero compared to 1–2 ABR on these health outcomes.

Summary/Conclusions: This analysis suggests that even 3–4 bleeds per year may have a negative impact on a patient's joint health, days missed from school and HRQOL. Efforts to maintain a 0 ABR among pediatric patients with severe hemophilia A may help ensure optimal outcomes.

PB 3.38-3

Comparison of factor VIII half-lives in severe haemophilia A following switch to Refacto AF

Needham J[1], Lewis H[1], Rangarajan K[2], Phillott A[1] and Rangarajan S[1]

[1]Hampshire Hospitals NHS Foundation Trust, Basingstoke; [2]Imperial College School of Medicine, London, UK

Background: Haemophilia A patients on prophylaxis therapy have pharmacokinetic studies performed as part of routine clinical management to confirm that their circulating factor VIII level is being maintained between doses at an appropriate level to reduce the risk of spontaneous bleeding. Concerns have been raised regarding pharmacokinetic performance of B-domain-deleted recombinant factor VIII (BDD rFVIII) compared to full-length factor VIII (FL FVIII) replacement therapy. This is retrospective analysis of laboratory data collected from patients treated with recombinant full length Factor VIII concentrate under a prophylactic regime and switched to B-domain deleted Refacto AF on an equivalent dosage regime and frequency as part of national procurement.

Aims: To compare factor VIII half-life measurements and thrombin generation in patients with severe haemophilia A since switching to BDD rFVIII from full-length factor VIII (FL FVIII) replacement therapy.

Methods: Factor VIIIC levels were measured on the Destiny Max analyser (Stago) using TriniCLOT aPTT HS, reference plasma (Stago) for FL FVIII replacement therapy and Refacto laboratory standard for BDD rFVIII, FVIII deficient plasma (Technoclone) for 1-stage assay and chromogenic FVIII (Technoclone). Thrombin generation was measured using CAT analyser and reagents (Thrombinoscope). Citrated plasma samples from patients ($n = 9$) were collected during pharmacokinetic studies pre and post FL FVIII or BDDrFVIII replacement therapy at four time points over 32 h.

Results: There was no significant difference detected in the levels of FVIII measured by 1-stage or chromogenic assay for FL FVIII or BDD rFVIII ($P = 0.0.94$ and $P = 0.65$ respectively. There was no significant difference in half-lives between treatment with FL FVIII or BDD rFVIII $P = 0.94$. There was no significant difference in thrombin generation between FL FVIII or BDD rFVIII as measured by endogenous thrombin potential (ETPnM*r), $P = 0.60$

Summary/Conclusions: Laboratory data has not identified any difference in the half-life of circulating levels of factor VIII or thrombin generation in haemophilia A patients treated with either FL FVIII or BDD rFVIII replacement therapy. Pharmacokinetic studies in these patients have not identified any difference in laboratory performance between FL FVIII or BDD rFVIII.

PB 3.38-4

Differential patterns of dynamic whole blood platelet aggregation in haemophilia A following *in vitro* addition of rFVIII and by-passing agents

Jensen MS[1], Sørensen B[2], Fenger-Eriksen C[1], Ingerslev J[1] and Larsen OH[1]

[1]*Aarhus University Hospital, Aarhus, Denmark;* [2]*Guy's and St Thomas' NHS Foundation Trust and King's College London, London, UK*

Background: Haemostatic interventions in haemophilia A vary in mode of action and this may be reflected on platelet aggregation (PA).
Aims: This study examined the PA patterns after *in vitro* addition of recombinant factor VIII (rFVIII) or bypassing agents.
Methods: The study was approved by the appropriate medical ethics committee. Following informed consent citrated whole blood with corn trypsin inhibitor (100 μg/mL) was obtained from 10 patients with severe haemophilia A. Dynamic whole blood PA was evaluated applying a novel not standardized assay using endogeneously generated thrombin as agonist. PA was recorded by impedance aggregometry after addition of tissue factor. Fibrin polymerization was inhibited and WB was spiked with buffer, rFVIII, plasma-derived activated prothrombin complex concentrate (pd-aPCC), recombinant factor VIIa (rFVIIa), or rFVIIa analogue (vatreptacog alfa).
Results: Baseline total PA was reduced in haemophilia A (980 ± 332 AUxmin, [mean]) with the absence of a second wave. All *in vitro* additions induced a healthy PA pattern introducing a second wave of PA. Total PA was increased following pd-aPCC (3124 AUxmin) and particularly rFVIIa analogue (3678 AUxmin) compared to rFVIII (2099 AUxmin) and rFVIIa (2224 AUxmin). Earlier onset of thrombin induced PA was provided by rFVIIa (7.1 min), rFVIIa analogue (2.2 min), and pd-aPCC (5.3 min) compared to rFVIII (11.5 min). Recombinant FVIIa analogue (0.125–2 μg/mL) showed significant dose-response, whereas rFVIIa (1–4 μg/mL) did not.
Conclusion: The haemostatic interventions showed varying potential to support platelet aggregation *in vitro*. This may have implications optimizing patient treatment, however, the potential clinical impact of these observations needs to be addressed in future studies.

PB 3.38-5

Qualitative findings contributing to the development of a hemophilia-specific caregiver burden instrument: caregiver and health care professional insights

Von Mackensen S[1], Wisniewski T[2] and Valentino LA[3]

[1]*University Medical Centre Hamburg-Eppendorf (UKE), Hamburg, Germany;* [2]*Novo Nordisk Inc., Princeton, NJ;* [3]*Rush University Medical Center, Chicago, IL, USA*

Background: The majority of children who have congenital hemophilia with and without inhibitors are treated at home, mainly by their parents; older children treat themselves. Data describing the caregiver experience among this population are limited. There are no disease-specific instruments that have been developed and validated for this population.
Aims: The purpose of this study was to develop an instrument to measure the burden of caring for pediatric patients with hemophilia based on qualitative findings among caregivers and health care professionals (HCPs).
Methods: Item generation was based on two approaches (focus groups, questionnaire evaluation). Two focus groups with caregivers of children with hemophilia were held at RUSH HTC by an experienced psychologist. A semi-structured interview guide was developed for discussions. Notes from discussions were transcribed by an independent note-taker. Qualitative findings were assessed by the psychologist to determine concepts that emerged during focus groups for inclusion in the draft instrument. Statements were thematically categorized and items formulated based on caregivers' statements. A literature review was undertaken to identify existing validated caregiver burden instruments for the general population or chronic/acute diseases. Seven instruments covered aspects suitable for hemophilia caregivers. Approval to use these questions were obtained from the developers or paraphrased when developers did not respond. HCPs were asked to rate each identified question for its importance to hemophilia caregivers on a 5-point Likert scale ranging from '*not important at all'* to *'very important'*. Questions were included in the draft instrument if more than 73% of all HCPs agreed they were '*very important'*. In addition HCPs were asked what the main burden of hemophilia in their opinion is for children, caregivers and HCPs. IRB approval was obtained for both focus groups and HCP assessments.
Results: 11 caregivers participated in focus group discussions. All were caring for children with hemophilia A; three (27%) were caring for children with inhibitors. Caregivers reported patients ranged in age from 2 to 26 years. Discussions with caregivers generated a total of 92 questions organized into eight domains: emotional stress ($N = 21$), medical management ($N = 10$), financial ($N = 6$), personal sacrifice ($N = 6$), work ($N = 11$), interactions with others ($N = 10$), perception of child ($N = 11$), coping with hemophilia ($N = 17$). A total of 16 HCPs completed the HCP evaluation; of these were seven physicians (43.8%), six nurses (37.5%), one social worker (6.3%) and two were employed in 'other' functions (pharmacy, dental hygienist). A total of nine questions were ranked as '*very important'* by HCPs (VI) and eight additional aspects emerged (E) based on HCPs opinions about caregivers' burden: emotional stress: VI = 2, medical management: E = 5, financial: VI = 4, personal sacrifice: VI = 2 and E = 2, interactions with others: VI = 1, coping: E = 1. The draft instrument for pilot-testing contains 109 questions.
Summary: Qualitative findings among hemophilia caregivers and HCPs contributed to the development of a draft instrument to assess caregiver burden specific to hemophilia. Next steps in the process include a pilot test to inform formal psychometric testing, item reduction, and comprehensibility assessments via interviews among a subgroup of pilot test participants.

PB 3.38-6

Findings from a conjoint analysis with hemophilia A patients: clinical characteristics and patient preferences for treatment

Rentz A[1], Pocoski J[2], Gries KS[1], Thompson C[1], Mathew P[2] and Sasané R[2]

[1]*Outcomes Research, United Biosource Corporation, Bethesda;* [2]*Bayer HealthCare Pharmaceuticals, Montville, USA*

Background: We conducted a multi-country, cross-sectional survey of patients with severe hemophilia A to assess their preferences for different treatment attributes.
Aims: To present clinical characteristics of patients participating in a discrete choice experiment (DCE) about differences in preferences for treatment by current treatment regimen
Methods: An international, cross-sectional, web-based DCE was conducted in 2012 with patients with hemophilia A. Participants completed a series of clinical questions about their hemophilia and treatment regimen. The DCE examined eight attributes of factor VIII (FVIII) treatment (dosing frequency, treatment administration time, duration of protection, time required to stop a breakthrough bleed, number of infusions required to stop a breakthrough bleed, physical activity level, infusion volume, and joint protection and preservation). Participants were presented with two hypothetical FVIII profiles described by different levels of the eight attributes. Preference weights for the attributes were estimated using random effects multinomial models. Relative importance (RI) values, which represent the total

proportion of the variance that is accounted for by an attribute relative to the other included attributes, were calculated.
Results: A total of 117 male hemophilia A patients with a mean (SD) age of 35.6 (16.3) completed the survey. Respondents were from the United States, UK, France, Germany, Italy, Spain, and Sweden. The majority were on a prophylaxis treatment regimen (62%) using a recombinant factor product (92%). Of the few respondents with an on-demand regimen, the most frequently cited reason for using on-demand treatment was an acceptable bleeding frequency without prophylaxis. Respondents reported experiencing no breakthrough bleeds per month (40%), one per month (36%), two (11%), three (9%), or four (3%). Thirty-seven percent of patients used one infusion to stop breakthrough bleeds, 14% needed two, and 6% needed three infusions. Sixty percent of respondents reported at least one joint bleed per month. We compared the preferences of prophylaxis and on-demand participants. The most important attribute identified by both groups was joint protection and preservation, with an RI of 25.2 (prophylaxis) and 22.8 (on demand), meaning that on average, prophylaxis and on-demand patients based approximately 25% and 23% of their decision, respectively, on the joint preservation attribute. Prophylaxis patients rated physical activity level as the second most important attribute (RI 19.1), and on-demand patients rated it only fifth (RI 9.5). On-demand patients rated time required to stop a breakthrough bleed as the second most important attribute (RI 20.9), whereas prophylaxis patients rated it as third most important (RI 15.0).
Summary/Conclusions: Patients with severe hemophilia A use treatment regimens that allow them to participate more fully in life through sports and other physical activities. Both prophylaxis and on-demand patients prefer treatments that are effective in protecting joints. Ranking of the remaining treatment attributes illustrates the trade-offs patients are willing to make for a treatment that is effective in preserving joints and maintaining activity levels. These results demonstrate a continued need to develop better factor treatments that provide sustained protective levels of FVIII.

PB3.39 – Heparin and heparinoids – I

PB 3.39-1

Anticoagulant profile studied by thromboelastography of multiple batches of branded enoxaparin and a US generic version of enoxaparin

Walenga JM, Jeske W, Escalante V, Hoppensteadt D, Chaudhry T and Bakhos M
Loyola University Medical Center, Maywood, USA

Introduction: Enoxaparin is the most widely used low molecular weight heparin (LMWH) in the US and has been approved for clinical use in multiple indications. Enoxaparin is a complex biological product with multiple known activities relevant to its antithrombotic effects, and variations in different forms of enoxaparin may have important clinical implications. This study aimed to compare the physiological anticoagulant activity of branded and a generic enoxaparin, using thromboelastography (TEG) to evaluate their effect on the dynamic formation of blood clots as quantitated by interactions between coagulation factors and inhibitors, fibrinogen, platelets and the fibrinolytic system.
Methods: Blood was obtained from 12 healthy volunteers after giving written informed consent. Five batches each of branded (Sanofi-aventis; Bridgewater, NJ) and generic (Sandoz US; Princeton, NJ) enoxaparin were studied. Drugs were purchased through hospital pharmacies as pre-filled syringes containing 40 mg drug. Immediately after venipuncture whole native (no preservative) blood was mixed with various concentrations of branded or generic enoxaparin and TEG (Haemoscope; Niles, IL) was performed without addition of exogenous activators.
Results: Initial TEG analysis of one concentration of all LMWH batches to all 12 donors revealed greater inter-individual variation of the anticoagulant response for the generic product. Investigations revealed a greater batch-to-batch variation for the generic enoxaparin within individual donors and among individual donors. Across all donors both the branded and generic enoxaparin produced a concentration-dependent anticoagulant effect in the TEG; however, the greater degree of variability for the generic LMWH resulted in a less predictable linear response as drug concentration increased. Of note was that some individuals responded with a higher than expected anticoagulant response to given concentrations of the generic enoxaparin. When the increase in TEG R-time was plotted vs. concentration for all donors, a lower overall anticoagulant effect ($P = 0.05$; no overlap of 95% confidence intervals) with a wider inter-individual variation for generic enoxaparin in comparison with branded enoxaparin was demonstrated.
Conclusion: By using only human blood in its native state and evaluating the full dynamic hemostatic process of coagulation, this study was able to demonstrate differences in the anticoagulation response of branded and generic enoxaparins, clinically used LMWHs that have similar anti-FXa, anti-FIIa and average molecular weight. The test system used here more closely mimics the innate *in vivo* anticoagulant action of LMWH than what can be demonstrated by pure buffer system anti-FXa and anti-FIIa singular activities or other single endpoint assay systems commonly used to determine an anticoagulant response. The findings of this study suggest that other pre-clinical and clinical investigations should be performed to validate the clinical interchangeability between branded and generic LMWHs.

PB 3.39-2

Tissue culture based approach to discriminate branded and generic low molecular weight heparins

Goodwin C, Scully MF and Kakkar A
Thrombosis Research Institute, London, UK

Background: Pharmaceutical preparations of heparin and its congeners consist of a heterogeneous mixture of long polyanionic molecules. In addition to their anticoagulant properties, heparins are pleiotropic through a variety of mechanisms of action including modulation of the action of cytokines, chemokines and proteases. With the introduction of generic forms of established pharmaceutical LMWHs, there is increasing need for assays that take into account the often subtle differences in structure of LMWHs, which arise according to the method of manufacture. Simple assays of anticoagulant activity are unlikely to be adequate in this respect.
Aim: It was the aim of the present study to investigate if the ability of heparin to modulate the protein expression by cultured cells could be used to generate a proteomic signature that was unique and discriminatory.
Method: Cultures of HUVECs were treated with 400 nM thrombin in medium containing 2% serum for 3 h at 37 °C (24 well plate). Cells were washed in medium containing 10% FCS and medium containing heparin was then added together with VEGF (20 ng/mL). After 24 h, medium was removed and cells lysed in U9 buffer (9M urea, 2% CHAPS, 10 mM Tris, pH 7.0). 50 μL of the mixture was added to 450 μL of 50 mM Na acetate pH 5.0 and centrifuged at 10,000 ***g*** for 2 min. 150 μL of supernatant was added to CM-10 SELDI chips equilibrated with 50 mM NaAc pH 5.0. After incubation for an hour, the chip was washed and dried before the addition of matrix (SPA). Analysis was carried out in a Ciphergen Biomarker analyser and the data collated and analysed using Biomarker Wizard.
Results: Two series of experiments were carried out in sextuplet; in the first series, we compared the activity of Lovenox with two generic copies (L1 and L2) and in the second series two different batches of Lovenox (A v B), in both sets testing against untreated cells.
Series 1, Lovenox, L1 and L2: Each of the heparins was tested at a final concentration of 0.001, 0.01, 0.1 and 1.0 mg/mL. A dose related

effect was observed with each of the heparins and the results of the analysis showed a difference in intensity of 13 peaks (selecting those according to a $P < 0.05$) was found between Lovenox and L1 and nine peaks comparing Lovenox and L2. There was only one peak different between L1 and L2. Series 2, Lovenox batches A and B: There were no significant differences in peaks when batches A and B of Lovenox were compared at 1 mg/mL suggesting that this approach is unable to detect differences between batches of the same heparin.

Conclusion: These results suggest that the effect of individual forms of LMWH on protein expression by cultured cells is unique and can be used to develop a 'fingerprint' to discriminate each heparin from generic forms using statistical approaches such as decision tree analysis or neural networks as are currently used in the diagnostic field.

PB 3.39-3

Pharmacodynamic response to unfractionated heparin used for initial treatment of acute deep vein thrombosis in elderly patients with renal impairment. A substudy of the IRIS clinical trial

Siguret V[1], Deudon C[1], Golmard J-L[2], Leizorovicz A[3], Pautas E[2] and Gouin-Thibault I[1]

[1]Sorbonne Paris Cité – Université Paris Descartes; [2]Groupe Hospitalier Pitié-Salpêtrière (AP-HP), Paris; [3]Université de Lyon 1, Faculté de Médecine, Lyon, France

Background: The 'Innohep® in Renal Insufficiency Study' (IRIS) was an international, open, randomized, clinical trial comparing the safety of tinzaparin and activated partial thromboplastin time (aPTT)-adjusted unfractionated heparin (UFH) in terms of clinically relevant bleeding (CRB) in elderly patients with moderate to severe renal impairment, treated for initial treatment of acute deep vein thrombosis (Leizorovicz *et al*., 2011). While UFH is usually preferred in these frail patients, little data exists on UFH dose management in very elderly with venous thromboembolism (VTE) in controlled trials.

Aims: In the IRIS patients receiving UFH, we conducted a substudy in order to: i/analyse the characteristics of UFH treatment; ii/identify individual factors determining the UFH dose; iii/evaluate quality of anticoagulation during UFH treatment and its relationships with VTE recurrence and CRB.

Methods: Patients received an IV bolus UFH 50 IU/kg followed by an initial dose (Day1) of 400–600 IU/kg/day given subcutaneously (SC) twice daily; UFH doses were further adjusted by aPTT ratio according to local practice (scheduled at least once daily in the midinterval). Patients received UFH for at least 5 days. Vitamin K antagonist was initiated between Day1 and Day3. Clinical, laboratory (aPTT ratios) and UFH doses were prospectively collected. We classified patients as being in a subtherapeutic, therapeutic or supra-therapeutic range according to each therapeutic range center.

Results: Of the IRIS study population who received UFH ($n = 270$), 259 patients with complete data were analysed: mean age was 83 ± 6 years (70–98 years), mean creatinine clearance (CrCl) (Cockcroft-Gault) 39.7 mL/min (SD 11.9, range 11–59); 25% had severe renal impairment. The mean daily UFH dose was 372 IU/kg (SD 88) over the SC treatment period (mean 6.8 – SD 2.7 days) and decreased from 447 IU/kg (SD 80) on Day1 to 308 IU/kg (SD 152) on Day5. Body-weight ($P < 0.001$), age ($P = 0.013$), sex ($P = 0.03$), and CrCl ($P = 0.049$) were independent predictors of the daily dose (IU), explaining 50% of the dose variability. Over the five first days, 163 patients (63%) had at least three dose adjustments; 104 (40%) had at least one 12 h-interruption of treatment (range 1–8) due to overdosage. The lower limit of the therapeutic aPTT range was reached in 55% of patients within the first 48 h and maintained for four consecutive days in only 17% of patients. The proportion of patients with an overdosage varied from 10% to 42%, between Day1 and Day5, with underdosage from 70% to 42%. High body-weight was associated with overdosage ($P = 0.009$). During SC treatment, 15 patients presented with CRB: six had aPTT ratios above 5.0, among whom five had major bleeding.

Conclusions: Our results confirm the low UFH dose requirements in the elderly with renal impairment with important individual variability. Body-weight, age, sex, and CrCl were the main predictors of the UFH dose in these patients. While the initial dose of 500 IU/kg/day was found adequate to reach the therapeutic range within the first 48 h, this study highlights the difficulties in maintaining the aPTT in the therapeutic range in this population.

PB 3.39-4

High risk of nadroparin to induce cutaneous delayed-type IV hypersensitivity reactions (DTH)

Schindewolf M[1], Recke A[2], Zillikens D[2], Lindhoff-Last E[1] and Ludwig RJ[2]

[1]Goethe University Hospital Frankfurt/M., Frankfurt am Main; [2]University of Luebeck, Luebeck, Germany

Background: Heparin is widely used for prophylaxis and treatment of thromboembolic events. Recently attention has been drawn to heparin-induced skin lesions, as those are observed more frequently than initially reported; e.g. 7.5% of all medical patients and 19–39% of pregnant patients develop heparin-induced skin lesions. These may be the only clinical manifestation of immune-mediated heparin-induced thrombocytopenia, but are commonly caused by a delayed-type hypersensitivity response. Several risk factors, such as molecular weight of heparins, sex, obesity, age, duration and previous heparin therapy have been implied as risk factors for development of heparin-induced delayed-type hypersensitivity.

Aim: To identify possible risk factors of delayed-type IV hypersensitivity reactions (DTH) by a meta-analysis of three prospective studies.

Methods: We have recently performed three independent clinical trials to determine the incidence and causes of heparin-induced skin lesions. Here, data from all trials were used for multivariate logistic regression analysis to determine possible risk factors.

Results: Regression analysis confirmed obesity and prolonged anticoagulant therapy as independent risk factors for development of heparin-induced hypersensitivity. Interestingly, the choice of anticoagulant preparation had the greatest influence. Comparing dalteparin, enoxaparin, the pentasaccharide fondaparinux and nadroparin, the latter was associated with a significantly increased risk to elicit heparin-induced hypersensitivity (log OR 2.2; 95% CI [0.5–4.3], $P = 1.44e^{-5}$).

Summary/Conclusion: As determination of risk factors had not been an endpoint of the initial studies, and investigators did not influence the choice of anticoagulant, a possible selection bias cannot be excluded. Given, the high risk of nadroparin is validated in necessary controlled trials, this would underscore the uniqueness of individual heparin preparations, and should thus be considered for an individualized anticoagulant treatment.

PB 3.39-5

Low incidence of heparin-induced skin lesions in orthopedic surgery patients

Schindewolf M[1], Paulik M[1], Kroll H[2], Wolter M[1], Kaufmann R[1], Boehncke W-H[3], Ludwig RJ[4] and Lindhoff-Last E[1]

[1]Goethe University Hospital Frankfurt/M., Frankfurt am Main; [2]Red Cross Blood Transfusion Service NSTOB, Dessau, Germany; [3]Hôpitaux Universitaires de Genève, Geneva, Switzerland; [4]University of Luebeck, Luebeck, Germany

Background: Heparin-induced skin lesions occur with an incidence of 7.5% in medical and up to 19.8% in pregnant patients during s.c. hep-

arin treatment. Mostly they are due to allergic delayed-type hypersensitivity reactions (DTH), rarely due to HIT.
Aim: The aim was to determine the incidence and causes of heparin-induced skin lesions in orthopedic surgery patients. Secondary outcome measures were: rate of cross-allergies, frequency of thromboembolic and bleeding complications and HIT.
Methods: Patients were prospectively screened for cutaneous adverse effects during prophylactic or therapeutic s.c. heparin treatment for ≥7 days. Further procedures (skin biopsy, subcutaneous provocation, clinical assessment for thrombosis, bleedings and HIT, laboratory HIT-diagnostics) were initiated if a heparin-induced skin reaction was suspected.
Results: 316 patients were recruited between May 2010 – September 2011. The median duration of heparin treatment was 10 days (range 7–331). We observed heparin-induced skin reactions in 6 (1.9%) patients. All lesions could be identified histologically and/or allergologically as DTH reactions. HIT-diagnostics were negative in all six patients. The lesions in 5 of 6 patients occurred in combination with the use of the low-molecular weight heparin nadroparin. Cross-allergies with other heparins were noted in 1 of 6 (16.7%) patients. Three thromboembolic events and four major bleeding events occurred.
Summary/Conclusion: Heparin-induced skin lesions in surgical patients are less frequent compared to medical and pregnant patients. The incidence is 1.9%. They were all due to allergic DTH reactions. Thus, different patient populations seem to carry distinct allergy risk profiles. It is tempting to speculate that in the current cohort of surgical patients postoperative inflammatory states or steroid hormone levels might contribute to the lower incidence of skin lesions. Furthermore, our data support findings from previous studies that different heparin preparations, i.e. nadroparin, show distinct differences in their sensitisation potential.
Investigations and procedures were approved by the local ethics committee of the J. W. Goethe University(16/07). The study was registered at clinicaltrials.gov (NCT00510432) and performed in accordance with theDeclaration of Helsinki.

PB 3.39-6
Incidence of heparin-induced skin lesions in postmenopause

Schindewolf M[1], Borgnis K[1], Kroll H[2], Wolter M[1], Kaufmann R[1], Boehncke W-H[3], Ludwig RJ[4] and Lindhoff-Last E[1]
[1]Goethe University Hospital Frankfurt/M., Frankfurt am Main; [2]Red Cross Blood Transfusion Service NSTOB, Dessau, Germany; [3]Hôpitaux Universitaires de Genève, Geneva, Switzerland; [4]University of Luebeck, Luebeck, Germany

Background: Heparin-induced skin lesions occur with an incidence of up to 19.8% in pregnant patients during s.c. heparin treatment, and occur 7–9 times more frequently in women than in men. Because this suggests a hormonal impact on allergy development.
Aims: The aim of our study was to determine the incidence and causes of heparin-induced skin lesions in postmenopausal women. Secondary outcome measures were: rate of cross-allergies, frequency of thromboembolic and bleeding complications and HIT.
Methods: Patients were prospectively screened for cutaneous adverse effects during prophylactic or therapeutic s.c. heparin treatment for ≥7 days. Further procedures (skin biopsy, subcutaneous provocation, clinical assessment for thrombosis, bleedings and HIT, laboratory HIT-diagnostics) were initiated if a heparin-induced skin reaction was suspected.
Results: 193 patients were recruited between January 2011 – January 2012. The median duration of treatment with low-molecular weight heparins was 11 days (range 7–52). Enoxaparin was used in 92.8%, nadroparin in 6.2%, and dalteparin in 0.5% of patients. We observed heparin-induced skin reactions in 4 (2.1%) patients, and all occurred during anticoagulation with enoxparin. All lesions could be identified histologically and/or allergologically as DTH reactions. None of the lesions was associated with HIT. No thromboembolic events and no major bleeding events occurred.
Summary/Conclusion: Heparin-induced skin lesions in postmenopausal women are less frequent compared to pregnant or medical female patients. The incidence is 2.1%. They were all due to allergic DTH reactions. Our study results indicate that the risk of sensitization after menopause is lower, possibly due to decreasing estrogen or progesterone levels. Future studies might investigate the role of selective estrogen receptor blockers on the modulation of type IV allergies.
Investigations and procedures were approved by the local ethics committee of the J. W. Goethe University(16/07). The study was registered at clinicaltrials.gov (NCT00510432) and performed in accordance with theDeclaration of Helsinki.

PB3.40 – Massive Blood Loss

PB 3.40-1
Contribution of the plasminogen activation system during hyperfibrinolysis in trauma-induced coagulopathy

Cardenas J, Matijevic N, Cotton B, Holcomb JB and Wade C
The University of Texas Health Science Center at Houston, Houston, TX, USA

Background: Traumatic injury is the third leading cause of death in the US. One quarter of all severe trauma patients experience some degree of prolonged hemorrhage due to impaired blood clotting, a phenomenon known as coagulopathy. The etiology behind trauma-induced coagulopathy (TIC) remains unknown. Hyperfibrinolysis, or the inappropriate and rapid breakdown of hemostatic clots, contributes to TIC and is associated with increased fluid resuscitation, hemorrhagic shock, and mortality. Under physiologic conditions, fibrinolysis is primarily regulated by the plasminogen activation system. We hypothesize that clot stability is weakened by excessive plasminogen activation caused by dysregulation of the plasminogen activation pathway during TIC.
Aims: The aims of this study were to (i) determine the relationship between fibrinolysis measured by thrombelastography (TEG) and mortality following trauma, and (ii) characterize changes in proteins of the plasminogen activation system in hyperfibrinolytic vs. non-hyperfibrinolytic trauma patients.
Methods: Whole blood was collected from severely injured trauma patients upon admission to the emergency department. This study was performed with patient informed consent and Institutional Review Board approval. Patient demographics were collected at the time of presentation and from hospital records. Fibrinolysis was determined by TEG (LY30%). Plasma was analyzed for circulating levels of fibrinogen, antithrombin, in addition to active and total tPA, uPA, and PAI-1 by ELISA.
Results: Data was collected on 381 consenting trauma patients. The population contained 69% blunt, 24% penetrating, and 6% burn injuries. Ly30% values ranged from a minimum of 0 to maximum of 92.9 (median 1.6, IQR 0.3–3). Mortality was positively associated with LY30% ($R^2 = 0.91$, $n = 381$). Hyperfibrinolysis for this study was defined as LY30% ≥5 ($n = 19$) where we observed a doubling of the morality rate in this population. These patients were compared to those with an LY30% = 0 ($n = 19$) to dichotomize the experimental population. While plasma levels of fibrinogen, antithrombin, tPA, and uPA are similar between the two groups, hyperfibrinolytic patients display a reduced ability to upregulate plasma levels of PAI-1 from healthy baseline (4 ng/mL total, 10 U/mL active) in response to injury compared to non-hyperfibrinolytic trauma patients (active PAI-1 median 10.0, IQR 18.8–171.1 ng/mL vs. 30.3, IQR 3.2–29.6 ng/mL; $P < 0.05$) (total PAI-1 median 2.4, IQR 1.8–5.4 U/mL vs. 4.5, IQR 3.5–20.1 U/mL; $P = 0.06$).

Conclusions: Excessive plasminogen activation due to inhibition or insufficient expression of antifibrinolytic PAI-1 is a potential contributing mechanism behind hyperfibrinolysis during TIC and offers a point for therapeutic intervention.

PB 3.40-2

Principal roles of platelets and fibrinogen in whole-blood fibrin clot formation in dilutional coagulopathy determined by thromboelastometry

Ninivaggi M[1], Feijge MAH[2], Kuiper GTW[2], Baaten C[2], Marcus MAE[2], Ten Cate H[2], Lancé MD[2], Heemskerk JWM[2] and Van Der Meijden PEJ[2]

[1]CARIM, Maastricht University; [2]CARIM, Maastricht University Medical Center, Maastricht, The Netherlands

Background: Patients undergoing cardiothoracic surgery are massively infused with crystalloids and colloids, resulting in blood dilution and hemostatic insufficiency. A major consequence is diminished elastic fibrin clot formation, which can be measured by rotational thromboelastometry (TEM) in whole blood. Upon dilution, the plasma fibrinogen level is a key limiting factor for clot formation, and this can be readily detected by the TEM assay. How other blood components determine this process, as measured with TEM, is largely unknown.
Aims: To investigate the contribution of blood cells (platelets or red cells) and plasma coagulation factors to fibrin clot formation with TEM under conditions of dilution.
Methods: Control blood was diluted *in vitro* by 20–80%, and then supplemented with blood cells, fibrinogen or prothrombin complex concentrate, and assayed for fibrin clot formation. Plasma was diluted, supplemented with platelets or factor concentrates, and used for measurement of fibrin clot formation (TEM) and thrombin generation (Calibrated Automated Thrombogram method). Blood was obtained from 48 patients before and after cardiothoracic surgery. Blood loss and fluid transfusion during surgery resulted in a 43–49% reduction in platelet and coagulation factor levels. Whole blood and plasma samples obtained before and after dilution were assayed for TEM. Experiments were approved by the medical ethics committee.
Results: In control blood or control plasma, diluted *in vitro*, supplementation of platelets reversed the decreased fibrin clot formation (maximal clot firmness and rate of clot formation). Addition of fibrinogen was partly effective, while addition of red cells or prothrombin complex concentrate was without effect. In diluted plasma, addition of platelets or prothrombin complex concentrate, but not fibrinogen concentrate, reversed the decreased thrombin generation (thrombin peak height and endogenous thrombin potential). In whole blood from patients, dilution due to surgery caused a diminished fibrin clot formation by 19% (maximal clot firmness and rate of clot formation), which was explained by reductions in platelet count and fibrinogen level. Correlation analysis indicated that platelet count was an independent predictor of the maximal clot firmness, measured by TEM. In plasma, reduced fibrin clot formation after surgery was most evident in the absence of platelets. Thrombin generation in plasma was also less affected after surgery with platelets present, and it normalized by addition of prothrombin complex concentrate but not by added fibrinogen concentrate.
Conclusions: Under conditions of dilution, whole-blood fibrin clot formation, as measured by TEM, is primarily determined by the platelet and fibrinogen concentrations. The platelet count should be considered as independent variable of whole-blood TEM assays. Levels of coagulation factors controlling thrombin generation are less critical for the extent of fibrin clot formation.

PB 3.40-3

The use of preoperative erythropoiesis-stimulating agents (ESAs) in patients who underwent knee or hip arthroplasty a meta-analysis of randomized clinical trials

Alotaibi G[1], Alsaleh K[2], Almodaimegh H[3], Aamer A[2] and Kouroukis T[4]

[1]University of Alberta, Edmonton, Canada; [2]King Saud University; [3]Kind Saud Bin Abdulaziz University, Riyadh, Saudi Arabia; [4]McMaster University, Ontario, Canada

Introduction: Erythropoiesis-stimulating agents (ESAs) have been used preoperatively in orthopedic patients to reduce the need for allogeneic blood transfusion. However, their use for this indication is still not widely practiced. The purpose of this review is to evaluate the efficacy of preoperative administration of ESAs on hemoglobin level at discharge and frequency of allogeneic blood transfusion in patients undergoing hip or knee surgery.
Methods: This is a systematic review of comparative randomized clinical trials that compared preoperative ESAs to other interventions or placebo in reducing the need for allogeneic transfusions and increase in hemoglobin levels at discharge.
Results: Pooled results of 26 trials with 3560 participants showed that the use of preoperative ESAs significantly reduced the need for allogeneic blood in patients undergoing hip or knee surgery [Relative Risk (RR): 0.48, 95% CI: 0.38–0.60, $P < 0.00001$)]. Hemoglobin mean difference between ESA and control groups was 7.16 (g/L) [95% confidence interval (CI) of 4.73–9.59, $P = 0.00001$]. There was no difference in the risk of developing venous-thromboembolism between ESA group and the control groups [Risk Difference (RD): 0, 95% CI: −1 to −2%, $P = 0.95$; I2 = 0%].
Conclusion: ESAs offer an alternative blood conservation method to avoid allogeneic blood transfusion in patients undergoing hip or knee surgery.

PB 3.40-4

Predictive value of the HAS-BLED score in patients with atrial fibrillation and chronic kidney disease using vitamin K-antagonists

Kooiman J[1], Van Beers CAJ[1], Bank JRJ[1], Spaans B[1], Cannegieter SC[1], Lip GYH[2], Van Der Meer FJM[1], Rabelink TJ[1] and Huisman MV[1]

[1]Leiden University Medical Center, Leiden, The Netherlands; [2]City Hospital, Birmingham, UK

Background: The HAS-BLED score enables a risk estimate of major bleeding in patients with atrial fibrillation (AF) on vitamin K-antagonists (VKA) treatment, but has never been validated in patients with chronic kidney disease (CKD).
Aim: We analyzed the predictive value of the HAS-BLED score in CKD compared with non-CKD patients.
Methods: Medical records of 416 CKD(eGFR0-30 mL/min, 30–60 mL/min) and 300 non-CKD patients starting VKA treatment for AF between 1997 and 2005 were searched for items on the HAS-BLED score (hypertension; renal or liver disease; stroke; major bleeding or anemia; labile INR, (time within therapeutic range <60%), age >65 years; use of NSAIDs, anti-platelet therapy or alcohol) and major bleeding events, according to the ISTH criteria. Areas under the curves (AUC) of the receiver operating characteristic (ROC) were calculated for the total population and CKD patients.
Results: Mean HAS-BLED score in CKD patients was 3.1 vs. 2.6 in non-CKD patients ($P < 0.01$). Major bleeding occurred in 115/716 (16.1%, 95% CI 12.8–19.9%) patients. The AUC of the ROC analysis in the total population was 0.50 (95% CI 0.44–0.56); 0.53 (95% CI 0.43–0.62) in patients with an eGFR 30–60 mL/min, and 0.35 (95%

CI 0.21–0.49) in patients with an eGFR <30 mL/min. In a Cox regression analysis performed in all patients, renal impairment, labile INR and age >65 years were predictive of major bleeding, hazard ratios 2.5 (95% CI 1.2–5.2), 2.2 (95% CI 1.2–3.7) and 5.2 (95% CI 1.6–16.8), respectively.

Conclusion: Performance of the HAS-BLED score was limited in the total population and further reduced in patients with an eGFR <30 mL/min. Further research is needed before the HAS-BLED score can be used in CKD patients.

PB 3.40-5

Development of an electronic identification tool for in-hospital bleeding

Hogg K, Wells P and Forster A

Ottawa Hospital Research Institute, Ottawa, Canada

Background: In recent years hospital medicine has seen a transition towards patient-physician partnership, with emphasis on quality of care and patient safety. Spontaneous bleeding and peri-operative bleeding are potentially preventable events. There has been little research on the epidemiology of such adverse incidents. A real time identification tool would enable further analysis, to identify potentially preventable causes of bleeding.

Aims: To develop an electronic identifying trigger for peri-operative and spontaneous inpatient bleeding events.

Methods: This was a retrospective study. A search of the hospital ICD 10 coding identified 250 patient admissions during 2011–2012 coded for both bleeding and surgery, 250 coded for bleeding and no surgery, and 500 admissions without a bleeding code. The hospital charts were hand searched, blinded to the ICD 10 coding, to establish whether the admitting team had identified the patient as bleeding, and to extract data on potential surrogate markers of bleeding (type of surgery, drop in haemoglobin, number of units blood transfused, return to operating room, readmission, anticoagulant medication, endoscopy and comorbidity). Receiver operating characteristic (ROC) curves were constructed to evaluate the area under the curves (AUC) for continuous variables, and to identify optimal cut-points. Peri-operative bleeding and inpatient hospital bleeding events were combined into a single bleeding outcome. Variables found to be significant predictors of bleeding on univariate logistic regression analysis were included in multivariate analysis.

Results: 156 patients were documented by their inpatient team as having had a peri-operative bleed and 29 patients had a spontaneous bleed during their hospital stay. 28% of the total cohort were taking an antiplatelet medication, 41% received prophylactic anticoagulation and 19% were fully anticoagulated. 70% of the cohort underwent surgery, the most common surgeries being arthroplasties, neurosurgeries, laparotomies, gynaecological, coronary interventions and bypass grafting. 20% had a diagnosis of cancer. The AUC for the measured drop in haemoglobin was 0.69 (95% CI 0.64–0.74) and for number of units blood transfused, 0.73 (95% CI 0.69–0.78). The optimal model for predicting bleeding included number of units blood transfused, endoscopy procedure, return to the operating room following surgery, readmission and concomitant antiplatelet and anticoagulant therapy. The C-staistic for the model was 0.88.

Summary/Conclusions: Identification of in-hospital bleeding is the first step towards implementing improved systems to reduce preventable bleeding. Our analysis has identified five potential surrogate electronic markers for in-hospital bleeding. Our next step is to validate the performance of this electronic trigger real time within the hospital.

PB 3.40-6

Evolution of plasma fibrinogen levels in trauma patients during the first 7 days of hospital stay is not influenced by initial treatment with fibrinogen concentrate

Schlimp CJ[1], Voelckel W[2], Ponschab M[3] and Schöchl H[2]

[1]AUVA Research Centre, Vienna; [2]AUVA Trauma Hospital of Salzburg, Salzburg; [3]AUVA Trauma Hospital of Linz, Linz, Austria

Background: Coagulopathy is present in approximately one third of all trauma patients on admission to the emergency room and is primarily associated with acquired fibrinogen deficit. Due to early and individualized goal-directed therapy for trauma-induced coagulopathy, fibrinogen concentrate (FC) is increasingly used in some trauma centers. It has been questioned whether the use of FC leads to higher plasma fibrinogen levels (FIB), thus possibly carrying a prothrombotic risk.

Aims: We evaluated FIB on seven consecutive days in acute trauma patients with or without FC therapy in an Austrian trauma centre.

Methods: Retrospective study of patients in the hospital trauma database, admitted to the AUVA Trauma Centre of Salzburg, between 2005 and 2011, in whom FIB was documented on admission to the emergency room and 48 h thereafter. For analysis patients were categorized into two groups: Treatment group (TFC) with patients that received at least 1 g FC during the first 24 h after hospital admission; Control group (CTR) with patients that did not receive FC.

Results: 402 patients were enrolled in this study, with a median (interquartile range) age of 42 years (26–56). 327 patients (81%) were male, overall ISS was 26 (18–38) with 357 patients (89%) classified ISS ≥16. 209 patients (52%) were grouped into TFC, 193 patients (48%) into CTR.

ISS was higher in TFC patients with 34 (25–45) than in CTR patients with 21.5 (16–27), $P < 0.0001$. Mortality was 10% in the TFC group vs. 4.1% in the CTR group, $P = 0.03$. Massive transfusion (≥10 red blood cell units in 24 h) was provided in 30.6% of TFC patients vs. 0.5% in CTR patients, $P < 0.0001$.

FIB (mg/dL) on admission was lower in TCF with 148 (108–192) as compared with CTR with 225 (178–271), $P < 0.0001$.

Mean FC administration was 5 g (3.5–9) with a minimum of 1 g and a maximum of 26 g administered in the first 24 h.

FIB (mg/dL) on admission to the ICU and on day 1 (after admission) was still lower in the TFC group as compared with the CTR group: 155 (124–194) vs. 170 (136–224), $P < 0.01$ and 240 (208–294) vs. 262 (214–312), $P < 0.05$, respectively.

FIB values did not differ significantly between groups on all following days 2–7, reaching the highest values on day 6, in TFC with 680 (521–832) and a minimum/maximum of 228/1292 vs. CTR with 664 (527–781) and a minimum/maximum of 266/1392, $P = 0.82$.

Summary/Conclusion: FIB evolution in severe trauma patients does not depend on initial treatment with FC in the acute phase of trauma care.

PB 3.41-1

Founder effect for a novel GPIBB mutation in Bernard-Soulier patients from La Réunion island

Lanza F[1], Baas M-J[2], Dupuis A[2], Randrianaivo-Ranjatoelina H[3], Jacquemont ML[3], Dreyfus M[4], Lavenu-Bombled C[4], Gachet C[2] and Lanza F[2]

[1]UMR_S949 INSERM, Université de Strasbourg, EFS-Alsac, Strasbourg; [2]UMR_S949 INSERM, Université de Strasbourg, EFS-Alsace, Strasbourg; [3]Groupe Hospitalier Sud Réunion, St Pierre, St Pierre; [4]Centre Hospitalier Universitaire Bicêtre, Le Kremlin Bicêtre, France

Background: Bernard-Soulier syndrome (BSS) is a rare hereditary bleeding disorder due to mutations in the genes coding the platelet

GPIb-IX complex. In a recent survey within the consortium led by Savoia et al (Blood, 2011; 118: 707), 64 different mutations have been reported in over 128 families which indifferently affected the GPIBA, GPIBB and GP9 genes. These are mainly sporadic cases with only rare occurrence of founder effects. Two examples of the opposite are the GP9 p.Asn61Ser and GPIBA p.Ala175Val mutations which have been found in several distantly related individuals of European and Italian origins, respectively.

Aims: Our aim was to study at the genetic level several patients from La Réunion island suspected of presenting with a BSS.

Methods: All patients were recruited at the Groupe Hospitalier Sud Réunion site St Pierre with the exception of one case studied at the Centre Hospitalier Universitaire de Bicêtre. Platelet counts were determined in an automated counter and manually, and platelet size by blood smears observation. Platelet expression of the GPIb-IX complex was monitored by FACS analysis. Sequences of the GPIBA, GPIBB and GP9 genes were obtained after PCR amplification of leukocyte DNA and automated sequencing.

Results: We report on 14 patients from eight different families all originating from l'Ile de La Réunion, a French island in the Indian Ocean. BSS was established on the presence of mucocutaneous bleeding, giant platelets, decreased platelet counts (33–70 G/L), absent GPIba and GPIX, and an autosomal recessive inheritance. Despite the fact that these families did not know of any familial relationship, all 14 patients harbored the same novel GPIBB c.265A>G transition leading to a p.Asn89Asp amino acid change in the GPIbbeta subunit (p.Asn64Asp for the mature protein). Interestingly, this well conserved residue has been previously reported to be mutated to Thr in an isolated BSS case leading to impaired GPIbbeta folding, GPIbalpha maturation, GPIX stability and GPIb-IX surface expression (Strassel C et al, Biochemistry 2003;42:4452; McEwan et al, Blood 2011;118:5292). Prevalence of this mutation suggested that it resulted from a founder effect. This hypothesis was supported by the reconstruction of a genealogy tree dating back 10–14 generations which allowed connecting all the affected individuals to a common ancestor born in 1671 and originating from India.

Conclusion: Although founder mutations in genetic isolates have already been reported in another platelet hereditary disorder, Glanzmann's thrombasthenia, this represents the first such case for BSS, an even rarer disorder. It is expected that the number of patients with this same mutation is substantially larger justifying more extensive screening to improve on genetic counseling.

PB 3.41-2

Identification of novel mutations causing congenital factor XIII deficiency in Pakistan

Borhany M[1], Handrkova H[2], Cairo A[3], Schroeder V[2], Amanat S[4], Naz A[1], Shamsi T[1], Peyvandi F[3] and Kohler HP[2]

[1]National Institute of Blood Disease, Karachi, Pakistan; [2]University Hospital & University of Bern, Bern, Switzerland, Bern, Switzerland; [3]A. Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione I.R.C.C.S. Cà Gra, Milan, Italy; [4]Department of Haematology, PAEC Hospital, Islamabad, Pakistan, Islamabad, Pakistan

Background: Rare bleeding disorders (RBDs) represent 3% to 5% of all congenital coagulation deficiencies, factor VII deficiency being the most common. However, in Karachi, Pakistan, we report a high number of congenital factor XIII (FXIII) deficiency in comparison to other RBDs.

Aims: This study aims to give a first insight into *F13* gene mutations in Pakistani population where the ritual of consanguineous marriages is practised.

Methods: The medical histories of congenital FXIII deficiency patients were recorded in a questionnaire and bleeding score was determined according to RBD database. 5M urea clot solubility test served as a first indicator of FXIII deficiency. FXIII A-subunit and B-subunit antigen levels were determined in citrated plasma by ELISA. FXIII activity was measured with an incorporation assay. Direct sequencing of all exons and intron/exon boundaries of *F13A* was performed. Novel splice site defect was confirmed by RT/PCR analysis.

Results: Patients in our cohort belong to six different families. Molecular analysis of 12 homozygous patients and six heterozygous family members revealed five different mutations in *F13A* gene, four of them being reported for the first time. Most common bleeding manifestations were epistaxis, gum bleeds, bruises, circumcision and umbilical cord bleeding; female patients often experienced menorrhagia and repeated abortions. Mean bleeding score (±SD) in homozygous patients was 13.8 ± 9.6, while heterozygous were mainly asymptomatic (2.0 ± 0.6). Majority (80%) of patients have a history of cousin marriages in their parents.

We identified two mutations localized on the exon/intron boundary (c.1460 + 1G>A and c.2045 G>A). Mutation c.1460 + 1G>A, IVS11 + 1G>A is being reported for the first time, and we confirmed that it leads to a splicing defect. It was found in nine related family members, homozygotes presented with severe FXIIIA deficiency, the FXIII antigen levels and activity in heterozygotes were variable. The second splice site mutation, c.2045 G>A in the last nucleotide of exon 14, was identified in five patients from two different families. This mutation has previously been reported in patients of Indian or Pakistani origin. Two novel missense mutations in exons 8 and 9 (c.1126 C>T, p.Trp375Arg and c.1040C>A, p.Ala346Asp) were identified in single cases and both patients were homozygous for the mutation. Both patients presented with severe FXIIIA deficiency with FXIIIA antigen levels below the detection limit, suggesting that the hypothetical protein would be rapidly degraded. A novel nonsense mutation in exon 4, c.567T>A, p.Cys188X, was identified in two related patients, both being homozygous for this allele. Both patients presented with a complete lack of FXIII.

Conclusion: We have reported four novel mutations leading to congenital FXIII deficiency in a cohort of 18 patients. Early diagnosis of FXIII deficiency enables parental counseling and identification of related family members at risk, which is critical for specific treatment of the patients and for prevention of bleeding complications in the future. We plan to continue to characterize other severe affected patients in our centre to verify if these variants could be recurrent mutations in our specific geographic area.

PB 3.41-3

Intracranial hemorrhage in factor XIII deficiency

Naderi M[1], Eshghi P[2], Karimi M[3], Dorgalaleh A[4] and Tabibian S[4]

[1]Research Center For Children Health (RCCAH), Zahedan University of Medical Science, Zahedan; [2]Pediatric Hematology & Oncology Research Director of Mofid Research Center for Co, Tehran; [3]Pediatrics Hematology & Oncology Department, Shiraz University of Medica Science, Shiraz; [4]Hematology Department, Allied Medical School, Tehran University of Medical Scien, Tehran, Iran

Background: Intracranial hemorrhage as a one of clinical manifestations in severe congenital FXIII deficiency is a life-threatening situation and major cause of death in untreated patients .

Aims: The aim of study was to collect data on patients with FXIII deficiency who had an intracranial hemorrhage.

Methods: In this case series, from January to May 2012, 35 patients with severe F XIII deficiency in Southeast of Iran were evaluated. The ICH episodes, family history, general physical examination, detailed neurological complication, incidence of recurrence, management strategies, survival status were noted.

Results: Out of 35 patients, the site of ICH in 32 individuals was intraparenchymal (91.4%). subdural and epidural hemorrhage were observed in 2 (5.7%) and1 (2.9%) patients, respectively.

The anatomic regions in patients with intraparenchymal hemorrhage was as follow: temporal in 10 patients (28.6%), occipital in 9 (25.7%), temporo-occipital in 4 (11.4%), subdural with temporal in 1 (2.9%), subdural with occipital in 1 (2.9%), parietal in 1 (2.9%), and diffused intraparenchymal hemorrhage in 6 (17.1%). Neurologic complications was also observed in 20 patients (57.1%) including behavioral disorders (28.6%), developmental disorders (11.4%), aphasia (8.6%), ophthalmic complications (5.7%), and hemiplegia (2.9%). Age at diagnosis of FXIII deficiency was significantly correlated with age of CNS bleeding ($r = 0$ .542, $P = 0.001$). Thirty four patients (97.2%) response to treatment response except one patient who had experienced one episode of recurrent. Prophylaxis was started with a dose of 10 IU/kg every 4–6 weeks for all patients. No episode of recurrence was observed in patients after that. Death was recorded in in 44 first degree family members of patients. The causes of death was in 10 cases FXIII deficiency, 17 suspicious death primarily associated with FXIII deficiency disease and eight unknown causes.

Summary/Conclusions: It seems that optimal management of ICH in patients with FXIII deficiency could be depend on immediate recognition and prophylactic treatment. Due to higher risk of such a catastrophic bleeding episode in younger Patients, therefore these patients should be more considered.

PB 3.41-4

Severe FVII-deficiency- a study of geno-phenotype relationship using thromboelastography and thrombin generation assay

Tran HTT[1], Bjørnsen S[1], Tjønnfjord G[2] and Holme PA[2]

[1]Oslo University Hospital; [2]Institute of Clinical Medicine, Oslo, Norway

Background: FVII deficiency is a rare autosomal recessive inherited bleeding disorder characterized by a wide heterogenicity in the bleeding phenotype. The correlation between a bleeding tendency and the plasma FVII activity level is weak. Currently, there exist no laboratory test that can predict the bleeding risk accurately.

Aims: We aimed to study whether thromboelastography (TEG) and thrombin generation assay (TGA) are suitable.

Methods: To predict the bleeding risk and to investigate whether there is any association between the plasma level of free tissue factor pathway inhibitor (TFPI), platelet aggregation capacity or other relevant coagulation parameters and the bleeding phenotype in persons with severe FVII deficiency.

Materials and methods: Twelve patients ($n = 12$) with severe FVII deficiency (FVII: activity level <1%), aged between 19 and 69, were included. Eleven of those were homozygous for Q100R mutation, whereas one was compound heterozygous. Clinically, 10 had increased haemorrhagic diathesis whereas two were asymptomatic. Blood sampling was performed at baseline for TEG and TGA analysis. TEG was performed using ROTEM, Coagulation Analyzer (Pentapharm®, Munich, Germany) while TGA by calibrated automated thrombin generation method (CAT) (Thrombinoscope BV® Maastricht, The Netherlands) on platelet poor plasma (PPP) and platelet rich plasma (PRP). Furhermore, platelet aggregation was performed, TFPI and haemostatic parameters were measured.

Results: We found no difference in TEG and TGA results between FVII deficient persons with an increased bleeding tendency and persons without. Compared with healthy normals clotting time (CT) and time to peak (ttpeak) was twofold increased (2394 vs. 1095 s for CT and 2966 vs. 1407 s for ttpeak) whereas Maximum Velocity (MaxV) was reduced (5 vs. 3). The TGA data showed that there was a minimal coagulation activation and thrombin generation in all FVII deficient subjects compared with normal (186 vs. 1308 nM thrombin in PRP and 209 vs. 658 in PPP). The level of free TFPI was similar in symptomatic as well as in asymptomatic persons and was within normal range, 8.3 ± 2.6 ng/mL (±SD). None of the participants were tested positive for FV Leiden mutation, prothrombin genmutaion or had abnormal level of anticoagulant inhibitors. A normal platelet aggregation was also found in the asymptomatic persons.

Conclusion: TEG and TGA, when tested in severe FVII deficiency, show results corresponding to the severity of factor deficiency but do not correlate with the bleeding phenotype. Either plasma TFPI level or other known anticoagulant inhibitors are associated with the clinical phenotype. We postulate that an unidentified biologic factor with procoagulant function is responsible for initiating and maintaining haemostasis in the asymptomatic patients and that this factor is probably located in the vessel wall, therefore not measurable with either TEG or TGA. Identifying such a factor will extend our knowledge concerning the coagulation system and the haemorrhagic/thrombotic tendency, providing novel diagnostic and therapeutic opportunities.

PB 3.41-5

Overcoming barriers to diagnosis of bleeding disorders including Acquired Hemophilia (AH) by healthcare practitioners (HCP): The Coags Uncomplicated iPhone/Android/Web application

Cooper D[1], Kessler C[2], Peerschke E[3], Chitlur M[4], Kulkarni R[5], Eberhart G[6] and Gut R[1]

[1]Novo Nordisk Inc., Princeton, NJ; [2]Georgetown University Medical Center, Washington, DC; [3]Memorial Sloan Kettering Cancer Center, New York, NY; [4]Childrens Hospital of Michigan, Detroit, MI; [5]Michigan State University, East Lansing, MI; [6]Cline Davis Mann, Princeton, NJ, USA

Background: Characterized by a prolonged aPTT that does not correct with mixing, Acquired Hemophilia is a rare and often fatal acquired bleeding disorder caused by autoantibodies to factor VIII. Multi-specialty case-based research around an actual case of delayed AH diagnosis (Reding et al 2012) suggested diagnostic delays can result from lack of recognition of the significance/etiology of an abnormal aPTT and focus on site of bleeding by emergency medicine, critical care and other non-hematologists. The Coags Uncomplicated app was initially designed as a collaboration between the hematology community and industry to assist healthcare practitioners (HCPs) in the diagnosis of these cases. Since its introduction, however, the scope has broadened considerably to encompass all congenital and acquired bleeding disorders.

Methods: Based upon gaps around interpretation of PT/aPTT abnormalities and bleeding disorders with normal PT/aPTT, an updated iPhone/android/web application (www.coagsuncomplicated.com) was expanded to include 60+ bleeding disorders. The *Lab Value Analyzer* first screens for medication-related abnormalities, pattern matches lab values entered with disease profiles, and lists potentially matching diagnoses. The *Diagnostic Algorithm* guides HCPs in obtaining additional lab tests. Published algorithms for isolated abnormalities of PT and aPTT were reorganized to include also an algorithm for common pathway (abnormal PT/aPTT) and disorders with a normal PT/aPTT. The *Neonatal* module compares entered lab values with age-adjusted normal values and provides a tailored algorithmic approach including reference age-adjusted normal values. Educational components provide.

Background: On all assays, diseases and medications. Third party analysis of de-identified utilization data are monitored to assess diagnoses reached and educational needs.

Results: Since January 2011, 5259 downloads resulted in 3744 registrations (Heme/Heme-Onc 1620, ER 702, Internal Medicine 244, Critical Care 217, Pediatrics 111, Surgery and obstetrics/gynecology 111). Common lab value analyzer matches were disseminated intravascular coagulopathy (6%), dysfibrinogenemia (5%), lupus anticoagulant (5%) and monoclonal gammopathy (5%). Common diagnostic algorithm endpoints were DIC (23%), liver disease effect (17%), vitamin

K deficiency (15%), lupus anticoagulant (5%), and warfarin/heparin effects (4%/4%). AH diagnoses were reached 73 times (2%) in diagnostic algorithm and 143 times (2%) in lab value analyzer.
Conclusions: Diagnosis of bleeding disorders first and foremost requires HCP recognition of abnormal laboratory values (including awareness of age-related normal values) that can prompt inquiry into the cause of the bleeding, not just its location. Monitoring demonstrated medication effects (lab value analyzer) and common disorders (lab value analyzer and diagnostic algorithm) were most accessed. This innovative approach helps to bridge the knowledge gap for non-hematologists and to facilitate initiation of prompt appropriate referrals to hematology.

PB 3.41-6

A literature review on the burden of illness and management of congenital FXIII deficiency

De Jager T[1], Pericleous L[2], Le Lay A[2] and Kokot-Kierepa M[3]
[1]*Pharmerit, Rotterdam, The Netherlands;* [2]*Novo Nordisk A/S, Bagsværd, Denmark;* [3]*Novo Nordisk Health Care AG, Zurich, Switzerland*

Background and Aims: Factor XIII congenital deficiency (FXIII CD) is a serious bleeding disorder caused by a lack of clotting factor XIII. This disease results in lifelong bleeding diathesis, defective wound healing, and spontaneous abortions. The aim of this study was to review available literature on the burden and management of FXIII CD in order to provide insight into how it affects the lives of patients and their families, and to evaluate the current treatment paradigm.
Methods: A broad literature search was conducted in PubMed, Embase and Cochrane databases using disease specific search terms for FXIII CD. All studies reporting data on the humanistic and economic burden of FXIII CD and available treatments were included in the final selection. No language or time restrictions were applied.
Results: Out of 551 records, 13 studies met the inclusion criteria. Three of the studies reported the occurrence of bleeds and intracranial hemorrhage (ICH) in patients with FXIII CD; the remaining 10 publications reported efficacy and safety outcomes of treatment with FXIII concentrates. No reports on the economic consequences of FXIII CD were identified. In selected literature, FXIII CD is described as one of the most severe forms of a congenital coagulation disorder, primarily due to severe bleeding events and a high risk of ICH. Current literature suggests over 50% of untreated FXIII CD patients experience severe bleeding symptoms, with ICH reported in 20–60% of patients and regarded as a major cause of death and morbidity. Data on health-related quality of life (HRQoL) pertaining to the impact of such complications in patients with FXIII CD is sparse. Only one prospective questionnaire-based study including five FXIII deficient patients was found, demonstrating that the severity of bleeds is a factor which influences HRQoL. However, from other rare coagulation disorders, like Von Willebrand disease, it is known that severe bleeds have a detrimental impact on HRQoL. Therefore, very severe complications, such as ICH should be prevented where possible. It is widely accepted practice to prophylactically treat patients with FXIII CD, as early as possible in their lives, to prevent the occurrence of bleeds, including potentially life-threatening ICHs.
Summary and Conclusions: Limited data is available on the humanistic and economic burden related specifically to FXIII CD. However, the high risk of severe bleeds, including ICH, is widely accepted to result in a high level of burden in patients with bleeding disorders. Therefore, potential bleeds should be prevented with a safe and effective prophylaxis treatment. Until recently the treatment of FXIII CD was limited to plasma or plasma-derived products, bearing the risk of pathogen contamination, as well as time consuming, high volume infusions. Recently, a recombinant FXIII has been developed enabling an efficient and safe prophylaxis in patients with FXIII A-subunit CD with no risk of contamination with viral agents, prions and other infectious agents. Further research is required to gain insight in how specifically FXIII CD affects HRQoL and to fully understand associated economic consequences.

PB3.42 – Von Willebrand disease: CLINICAL – IV

PB 3.42-1

Analysis of sequence variation reported within the von Willebrand factor gene locus

Hampshire DJ and Goodeve AC
University of Sheffield, Sheffield, UK

Background: The von Willebrand factor (*VWF*) gene consists of 52 exons; exons 2–52 encoding the VWF protein. Mutation of *VWF* results in von Willebrand disease (VWD), the most common inherited bleeding disorder. VWD is divided into three distinct types; types 1 (VWD1) and 3 (VWD3) caused by mild-moderate or severe reduction in circulating plasma VWF respectively, and type 2 (VWD2A, VWD2B, VWD2M, VWD2N) caused by specific defects influencing normal VWF function. The ISTH-SSC on VWF online database (VWFdb) provides access to VWF/VWD information for diagnostic and research laboratories. This information includes a searchable registry of *VWF* sequence variation (derived from investigator submissions and literature reports), recently moved to the Leiden Open (source) Variation Database (LOVD) system (http://www.LOVD.nl/VWF), including new fields (VWF:Ag, VWF:RCo, FVIII:C, bleeding score, multimer profile) providing access to substantial phenotypic information for each variant. VWFdb also lists variants by patient highlighting additional information, for example homozygosity/heterozygosity for recessive mutations. Unlike VWFdb, the Human Genome Mutation Database (HGMD) only catalogues *VWF* variation reported in the literature, with no additional phenotypic information.
Aims: (i) To evaluate the extent of *VWF* sequence variation currently reported. (ii) To investigate any patterns in sequence variation based on VWD type.
Methods: The VWFdb registry and HGMD (accessed January 2013) were examined for unique sequence variants and these were classified as either mutations or polymorphisms. Mutations were further grouped by VWD type. Variant location vs. VWD type was mapped according to VWF protein domains.
Results: VWFdb contains information on 585 unique *VWF* variants; 424 mutations and 161 polymorphisms. Analysis of HGMD data highlighted an additional 173 variants, the majority of which resulted in missense/nonsense mutations (n = 120, 69%). Mutations represented all VWD types, the majority associated with VWD1 (n = 135, 23%), VWD2A (n = 107, 18%) and VWD3 (n = 176, 29%) with VWD2B (n = 30), VWD2M (n = 32) and VWD2N (n = 30) mutations each accounting for 5%. VWD1 and VWD3 mutations occurred throughout VWF (30% and 23% D3-A2 domains respectively; 15% and 14% C1-CK domains respectively). VWD1 mutations also clustered around A3-D4 (22%), whereas VWD3 mutations clustered around D1-D2 (35%). VWD2 mutations predominantly occurred in specific domains (VWD2B/2M: A1; VWD2N: D'/D3). VWD2A mutations were located throughout VWF, however hotspots (D2, D3-A2 and CK) demonstrated subtype specificity, for example VWD2A(IIE) in the D3 domain. Interestingly, the combined data contained 87 (15%) mutations either associated with multiple VWD types or unclassified, many of which (47%) were located in exons 25–28.
Conclusions: There are currently 758 unique variants reported in *VWF* (585 in VWFdb; 173 in HGMD), 597 (79%) associated with VWD. Those associated with VWD mostly account for VWD1, VWD2A and VWD3, and occur throughout VWF. VWD mutations located in exons 25–28 (D3/A1 domain NH_2 boundary) may result in a pleiotropic phenotype making them difficult to classify. Reports of *VWF* variation

on HGMD not currently entered on VWFdb highlights the requirement for investigators to submit both their published and unpublished data.

PB 3.42-2

Phenotypic and genotypic characterization of 10 Finnish patients with von Willebrand disease type 3: discovery of two main mutations

Jokela V

Helsinki University Central Hospital, Helsinki, Finland

Background and aims: Severe von Willebrand disease (VWD) type 3 is a rare autosomal-recessively inherited bleeding disorder, showing considerable genotypic heterogeneity. We investigated the phenotype in correlation to the genotype in Finnish type 3 VWD patients.

Methods: Ten patients (40% out of total of 28 patients recorded in Finland) from different families previously diagnosed with VWD type 3 treated at the Coagulation Disorder Unit in Helsinki University Hospital were re-evaluated for bleeding tendency and treatment. Phenotypic characterization included coagulation and platelet function testing confirming the diagnosis. Multimer study was performed for all the patients. Bleeding history was evaluated using a bleeding assessment tool modified from the Tosetto score and also with regard to specific bleeding symptoms. Detailed genealogical information was obtained from patients. The genotype was assessed by initial screening for the common c.2435delC mutation and subsequently if needed, by analyzing all 51 coding exons of the von Willebrand factor (VWF) gene.

Results: The diagnosis of type 3 VWD was confirmed for all patients. The patients presented with surprisingly heterogeneous bleeding phenotype: seven patients with severe spontaneous bleeding tendency required prophylactic treatment with replacement therapy whereas three patients on on-demand treatment presented with relatively mild bleeding phenotype. Clinical symptoms included hemophilia-like hemarthropathy in 8/10 (80%) patients studied. In addition, all patients presented with epistaxis and all female patients with menorrhagia. Two patients (20%) had a history of alloantibody development. In genotype analysis we discovered two common mutations among the patients: nine of the 20 (45%) alleles were found to carry the c.2435delC frameshift mutation, previously described to be frequent in countries surrounding the Baltic Sea. The nonsense mutation c.4975C>T (p.R1659X) was found on 8/20 (40%) of the alleles. Additionally, three novel mutations, a potential splice site mutation (c.874 + 2T>C) and two frameshift mutations (c.1668delC and c.2072delCCinsG) were found. Seven patients were homozygous and three compound heterozygous for the reported mutations.

Conclusion: Our study indicates that mainly two mutations (c.2435delC and p.R1659X) are causing the majority of type 3 VWD in Finland, unlike the reports from most of the previously studied populations. c.2435delC has been commonly reported at high frequency in countries surrounding the Baltic Sea, 50% in Sweden, 20% in Germany, 75% in Poland and, in addition 12% in Hungary. A common origin can be suggested for this mutation and our study supports this theory. Our genotype results in this group of patients set future standards for the genetic testing among the type 3 VWD population in Finland.

PB 3.42-3

Bleeding caused by acquired von willebrand syndrome (AVWS) in adult patients with congenital heart disease (CHD)

Waldow HC[1], Westhoff-Bleck M[2], Templin C[3], Detering C[1] and Von Depka Prondzinski M[1]

[1]Werlhof-Institut, Hannover; [2]Medizinische Hochschule Hannover, Hannover, Germany; [3]Universitätsspital Zürich, Zürich, Switzerland

Background: In acquired heart disease espec. aortic valve stenosis AVWS is typical. However, little is known about the role and prevalence of von Willebrand syndrome in congenital heart disease in adults. We hypothesized that VWS may play a causative role in surgical as well as non-surgical bleeding in different types of CHD.

Aims: We evaluated the prevalence and relevance of AVWS in CHD including various defects.

Methods: AVWS was evaluated in 192 patients in relation to the underlying cardiac defect, operative procedures and presence of Eisenmenger Syndrome. PT, aPTT, PFA-100, VWF:Ag, VWF:RiCof, VWF:CBA, FVIII:C, repeated multimeric analysis and MCMDM bleeding score were performed in addition to tests evaluating heart, liver and kidney function.

Result: The overall prevalence of AVWS in this study was 20.8%. It was found across all cardiac defects, with the highest prevalence in defects of great complexity (38%) in contrast to 9% in patients with CHD of simple/moderate complexity ($P < 0.001$), Eisenmenger Syndrome ($P < 0.001$) and more severe heart failure symptoms (NYHA III/IV vs NYHA I, $P < 0.001$; NYHA III/IV vs. NYHA II, $P = 0.044$). Only 2/11 patients (18%) with aortic stenosis showed AVWS. Among lab results, a combination of multimeric analysis, VWF:Ag/VWF:CBA ratio (sensitivity: 77.5%, specificity: 93.3%) and PFA-100 (Col/Epi sens.: 77%, spec.: 52%; Col/ADP sens.: 75%, spec.: 74.3%) were suitable to detect AVWS. The use of the MCMDM bleeding score does not seem to be appropriate in these patients to objectify the bleeding tendency (sens.: 22.5%, spec.: 92.7%).

Summery/Conclusions: Here we present the largest study on patients with congenital heart disease and acquired von Willebrand syndrome to date. This study demonstrates that AVWS occurs in patients with various congenital cardiac defects, but the highest prevalence is in patients with more complex CHD. We, therefore, suggest preoperative screening for AVWS in all patients with CHD to prevent intra- and postoperative bleeding complications using a panel of specific lab tests.

PB 3.42-4

Type 2N von Willebrand disease in the population of Little Poland

Zdziarska J[1], Iwaniec T[2], Budde U[3], Skotnicki AB[4] and Musial J[2]

[1]Jagiellonian University Medical College, Kraków; [2]Department of Medicine, Jagiellonian University Medical College, Kraków, Poland; [3]Hämostaseologie und Transfusionsmedizin MEDILYS Laborgesellschaft c/o AK Altona, Hamburg, Germany; [4]Department of Hematology, Jagiellonian University Medical College, Kraków, Poland

Background: Won Willebrand disease (VWD) is the most prevalent inherited bleeding disorder. Differential diagnostics of type 1 and type 2 VWD requires access to an experienced coagulation laboratory. Type 2N VWD, first identified in 1989 in Normandy, is characterized by decreased von Willebrand factor (VWF) binding to factor VIII (FVIII), resulting in disproportionally low plasma FVIII levels. VWF activity and antigen level can be decreased or normal, type 2N VWD is therefore often misdiagnosed as mild hemophilia A (HA) or HA car-

rier state. To identify this condition VWF:FVIII binding assay (VWF:FVIIIB) has to be performed.

Aims: We present the process of identification and laboratory diagnosis of type 2N von Willebrand disease in our reference hemophilia treatment center in Little Poland (circa 3,300,000 inhabitants, 165 VWD patients and 111 mild HA patients registered).

Methods: In the years 2009–2012 twenty individuals were selected with clinical or laboratory suspicion of type 2N VWD (all VWD patients with FVIII:VWD ratio lower than 0.7 and all HA patients with strong tendency to mucosal bleeds or unusual mode of inheritance). FVIII and FV activity was measured by the one-stage assay using Siemens reagents (BSC XP, Siemens Germany), VWF activity (VWF:RCo) was measured by turbidymetric method using BCS XP analyzer and VWF antigen level (VWF:Ag) with enzyme linked fluorescent assay (ELFA, BioMerieux, France). VWF:FVIIIB was performed in the MEDILYS Laboratory Hamburg (Germany) with an established inhouse method (Schneppenheim et al. 1996).

Results: Among our 20 patients and their four symptomless relatives VWF:FVIIIB was significantly decreased in five individuals (7–22%, mean 13.4%, normal range 60–180%) and moderately decreased in other five (43–55%, mean 46.6%), all belonging to six families. In one other patient type 2N VWD was diagnosed based on family history, bleeding symptoms and slightly decreased FVIII activity (45%, *n*. 50–150%). In the remaining 13 patients type 2N VWD was excluded. Combined FVIII and FV deficiency was excluded in all patients.

In all six type 2N patients FVIII activity was lowered to 31–45% (mean 36.6%). VWF:RCo was decreased only in one patient (47–132%, mean 82%, *n*. 50–150%) and the FVIII/VWF:Ag ratio was 0.34–0.63 (mean 0.43). Five of them show a history of mucosal, post-surgery and/or postpartum bleeds. In five 2N VWD carriers all parameters were within the normal range. In one carrier with lifelong history of posttraumatic joint/muscle bleeds FVIII activity was 11%, indicating coinheritance of mild HA.

Summary/Conclusions: We identified six cases of type 2N VWD (3.6% of all VWD patients registered in our region). To assess the true prevalence of type 2N VWD in Little Poland all mild HA patients should be screened with the VWF:FVIIIB assay. Implementation of this measurement in at least one reference laboratory in Poland would facilitate this task. Molecular testing should be available to identify the underlying genetic defect in female patients with mild HA and no male HA patients within family.

PB 3.42-5

The usage of pediatric bleeding questionnaire in the diagnosis of von willebrand disease and thrombocyte function defects among Turkish children

Belen FB, Koçak U, Isik M, Keskin Yilmaz E, Öner N, Sal E, Kaya Z, Yenicesu I and Gursel T

Gazi University, Ankara, Turkey

Background: The diagnosis of mild bleeding disorders is not easy in the pediatric population as most of the 'healthy' subjects also report bleeding symptoms. In order to get a precise bleeding history Pediatric Bleeding Questionnaire (PBQ) has been developed previously.

Aim: The aim of the study was to determine the relevance of PBQ in the diagnosis of von Willebrand disease and thrombocyte function tests and to determine a 'clinically significant' bleeding score cut off for our population to differentiate 'hemostatically normal bleeders' and 'children with mild bleeding disorders'.

Methods: In our study, Turkish children previously diagnosed with von Willebrand disease (VWD), thrombocyte function defect (TFD) and healthy children without any symptoms (Control group 1) and healthy children with symptoms but found hemostatically normal (Control group 2) were analysed with PBQ.

Results: Von willebrand disease group consisted of 46 patients (27 VWD Type 1, 5 VWD Type 2, 14 VWD Type 3), TFD group consisted of 65 patients (7 Glanzmann Thrombastenia, 9 Bernard Solier syndrome, 4 Hermansky Pudlak syndrome and 45 thrombocyte secretion defects). Control 1 group had 38 and Control Group 2 had 32 patients. The ages of all groups were between 6 months and 18 years. The median bleeding scores were four in VWD Type 1, seven in VWD Type 2, 16 in VWD Type 3, nine in Glanzmann thrombasthenia, 10 in Bernard Solier Syndrome, 7.5 in Hermansky Pudlak syndrome, four in thrombocyte secretion defect, 0 in Control one group and 1 in Control two group. The patient and control subjects were compared as four major groups (VWD, TFD, Control 1 and 2 groups) with PBQ. The most frequent clinically significant bleeding symptoms that can differentiate VWD/TFD and control groups were found to be epistaxis, oral cavity bleeding, bleeding after tooth extraction, menorrhagia and post circumsicion bleeding. The cut off level for 'clinically significant bleeding score' was found to be ≥3 (AUC: 0.785%95 CI: 0.718–0.852). The sensitivity, specifity, PPV and NPV of PBQ to define VWD vs. Control group 1 was %93.5; %97.4; %97.7; %92.5; VWD vs. Control group 2 was %93.5; %87.5; %91.5; %90.3; TFD vs. Control group 1 was % 89.2; %97.4; %98.3; %84.1 and TFD vs. Control group 2 was %89.2; %87.5; %93.5; %80 respectively.

Conclusion: In conclusion, PBQ was found to be useful in the diagnosis of VWD and TFD in Turkish children, however to reach an exact diagnosis hemostatic laboratory tests are stil warranted.

PB 3.42-6

Characterization of Von Willebrand Disease type 2A mutation G1579R in the Brno-VWD study

Vangenechten I[1], Smejkal P[2], Zapletal O[2], Bouddount F[1], Zavrelova J[2], Blatny J[2], Penka M[2], Michiels JJ[1] and Gadisseur A[1]

[1]Antwerp University Hospital, Edegem, Belgium; [2]University Hospital Brno, Brno, Czech Republic

Von Willebrand Disease (VWD) is an autosomally inherited bleeding disorder caused by a quantitative or qualitative defect of von Willebrand factor (VWF). The Von Willebrand Factor mutation c.G1579R in the A2-domain is known to be responsible for a 'classic' type 2A (group 2) VWD with normal multimerization and secretion, but with increased susceptibility to degradation by ADAMT13.

In the Brno-VWD study blood was collected from 205 patients representing 95 families with suspected VWD. FVIII:c, VWF:Ag, VWF:RCo, VWF:CB, VWFpp, VWF-FVIII binding (if indicated), VWF multimers and molecular analysis were performed in all patients.Within the Brno-VWD study we analyzed 17 patients from five families with the c.G1579R mutation.

As expected, the results show that the c.G1579R mutation is characterized by a very low VWF:RCo/VWF:Ag ratio (mean 0.23, CI_{95} 0.17–0.30), a very low VWF:CB/VWF:Ag ratio (mean 0.31, CI_{95} 0.26–0.36) reflecting decreased platelet binding, and an increased VWFpp/VWF:Ag ratio (mean 1.57, CI_{95} 1.43–1.70) showing increased elimination through proteolysis by ADAMTS13. Multimeric analysis shows a type 2A pattern with loss of high molecular weight multimers and a pronounced first sub-band. Unexpectedly, because classic VWD type 2A is mostly linked with platelet aggregation abnormalities there is also a relatively low FVIII:c/VWF:Ag ratio (mean 0.59, CI_{95} 0.50–0.67) which cannot easily be explained by the mechanism behind this mutation. The difference with the overall mean FVIII:c/VWF:Ag ratio in the full Brno-VWD population of1.13 (CI_{95} 1.04–1.21) is striking.

Although the VWD mutation c.G1579R is conventionally classified as a 'classic' type 2A (group 2) mutation the results of the FVIII:c/VWF:Ag ratio indicate that other mechanisms may be present which may lead to reclassification of this mutation.

PB 3.43-1

Resistance of C2362F von Willebrand factor to ADAMTS13-induced proteolysis

Casonato A[1], Pontara E[2], Morpurgo M[2], Cattini GM[2], Battiston M[2], Barbon G[2], Saga G[2], Daidone V[2] and De Marco L[3]
[1]*University of Padua Medical School, Padova;* [2]*University of Padua, Padova;* [3]*IRCSS, C.R.O. Aviano, Aviano, Italy*

Background: The triplet-organized multimer pattern of circulating von Willebrand factor (VWF) is the result of the proteolytic action of the metalloprotease ADAMTS13. VWF carrying the C2362F mutation (C2362F-VWF) characteristically lacks the normal oligomer structure, which is replaced by a diffuse smear extending to the origin of the separating gel, suggesting the presence of unusually large species. We suggest that this picture might stem from C2362F-VWF being ADAMTS13-resistant.
Aims: We aim to demonstrate that the C2362F mutation alters the susceptibility of VWF to the proteolytic action of ADAMTS13.
Methods: The effects of recombinant ADAMTS13 on C2362F-VWF were explored in patients' plasma VWF and recombinant VWF fragments. Given the very low circulating VWF levels in patients homozygous for the C2362F mutation, blood samples were enriched with VWF by cryoethanol precipitation. Normal and mutated VWF fragments extending from domains A3 to B3 were produced using the pEXP5-NT/TOPO$^{(R)}$ vector and Origami E. coli strain. ADAMTS13-induced proteolysis experiments were performed under static conditions in the presence of urea, with a constant amount of normal and mutated plasma VWF and increasing concentrations of ADAMTS13. Again under static conditions, the binding of recombinant biotinylated ADAMTS13 to VWF was explored in the presence of EDTA by means of an ELISA assay, using both plasma and recombinant normal and mutated VWF fragments.
Results: Patient's plasma C2362F-VWF was found completely ADAMTS13-resistant. Whatever the concentration of recombinant ADAMTS13, there was no sign of the abnormally-large VWF multimers of C2362F-VWF disappearing, nor any increase in the representation of triplet multimer bands. At the same ADAMTS13 concentrations, in normal VWF the large VWF multimers disappeared and the satellite bands became more strongly represented, in a pattern resembling type 2A-II von Willebrand disease. Binding experiments were carried out to ascertain whether the ADAMTS13 resistance of C2362F-VWF is due to an abnormal interaction between the two molecules. ADAMTS13 binding to C2362F-VWF was found significantly impaired (around 40% lower than the normal counterpart), and this defective binding was confirmed using the C2362F A3-B3 recombinant VWF fragment.
Conclusions: These findings demonstrate that the loss of cysteine 2362 makes VWF resistant to proteolysis by ADAMTS13. This abnormality seems to be at least partially due to a defective binding of ADAMTS13 to VWF. The C2362F-VWF mutation thus brings to light a new abnormality in the VWF-ADAMTS13 relationship, i.e. the existence of an ADAMTS13-resistant VWF.

PB 3.43-2

Chicken glycoprotein Iba and Ibβ form both GPIb and non-GPIb complexes: implications for the evolution of GPIb-IX

Zhou L[1], Yang W[2], Liang X[1] and Li R[1]
[1]*Emory University, Atlanta, GA;* [2]*University of Texas Health Science Center, Houston, TX, USA*

Background: The association of various subunits in human glycoprotein (GP) Ib-IX-V complex has been characterized extensively in transfected cells, as the surface expression level of GPIb-IX correlates with its proper assembly. The interaction among GPIba, GPIbb and GPIX transmembrane helices, in cooperation with those between GPIbb and GPIX extracellular domains, provides the driving force for GPIb-IX assembly. GPV associates weakly with GPIb-IX. However, it is not clear if the assembly of GPIb-IX from other species is the same as that of human GPIb-IX and how GPIb-IX has evolved into its highly integrated form.
Aim: This study characterizes the assembly of chicken (*G. gallus*) GPIb-IX complex and its difference from human complex.
Methods: Chicken GPIbα, GPIbβ and GPIX genes were cloned from total mRNA extracted from fresh chicken blood and appended with a N-terminal immuno tag. The same tags were also appended to corresponding human paralogs. The plasmids containing human or chicken GPIb-IX genes were transiently transfected, in various combinations, into Chinese hamster ovary (CHO) cells. Surface expression levels of GPIb-IX subunits, and the association among them, were measured by flow cytometry, and immunoprecipitation. Disulfide formation between GPIba and GPIbb was analyzed by SDS-PAGE under non-reducing conditions.
Results: While the sequences of cloned chicken GPIbb and GPIX cDNAs are the same as predicted in the NCBI database, the N-terminal sequence of the cloned chicken GPIbα cDNA differs, due to incorrect prediction of a splicing site. Like human GPIb-IX, efficient expression of chicken GPIb-IX in the plasma membrane of transfected CHO cells required all of its subunits. However, in addition to the GPIb complex (i.e. GPIbb-GPIba-GPIbb), nearly half of chicken GPIba connects with chicken GPIbb to form a non-GPIb complex (i.e. GPIbb-GPIba-GPIba-GPIbb). Domain swapping analysis showed that surface expression of human GPIX could be enhanced by coexpression of human GPIbb, or a human/chicken GPIbb chimera (GPIbb-hTM) that contains the human-derived transmembrane domain, but not chicken GPIbb. Surface expression chicken GPIX could be enhanced by coexpression of chicken GPIbb, but not human GPIbb nor GPIbb-hTM. Coexpression of chicken GPIbα, GPIbb-hTM and human GPIX produced GPIb and very little non-GPIb complex. Further sequence analysis identified residues in the GPIbb transmembrane domain that are critical to specific GPIb formation and conserved across mammalian species, but not in birds, reptiles, amphibians or fishes.
Conclusions: Chicken GPIba, GPIbb and GPIX form human-like GPIb-IX complex but also a non-GPIb complex. The interfaces between GPIbb and GPIX extracellular domains are largely conserved between human and chicken, but differences in the interface between transmembrane domains are observed. That such difference coincides with the division of platelet-bearing and thrombocyte-bearing vertebrates suggests that the non-GPIb complex plays a functional role in thrombocytes.

PB 3.43-3

Characteristics and angiogenic properties of blood outgrowth endothelial cells from a type 3 von Willebrand disease patient

Groeneveld DJ[1], Dirven RJ[1], Wang J[2], Valentijn K[1], Voorberg J[3], Reitsma PH[1] and Eikenboom HCJ[1]
[1]*Leiden University Medical Center, Leiden, The Netherlands;* [2]*National University of Singapore, Singapore, Singapore;* [3]*Sanquin-AMC Landsteiner Laboratory, Amsterdam, The Netherlands*

Background: Blood Outgrowth Endothelial Cells (BOECs) from von Willebrand Disease patients (VWD) have been used as an effective tool for studying von Willebrand factor (VWF) storage and secretion defects. Isolation of these cells from peripheral blood from both type 1 and type 2 VWD patients has proven to be efficacious. However, successful isolation of BOECs from type 3 VWD (complete absence of VWF) patients has not been reported yet. VWF plays a major role in

blood coagulation as it is involved in platelet adhesion and functions as a carrier protein for factor VIII. Besides playing a role in coagulation, it has recently been demonstrated that endothelial VWF regulates angiogenesis and that BOECs from type 1 and 2 VWD patients seem to display increase *in vitro* angiogenic capacity. Whether this also holds for type 3 BOECS is unknown.

Aims: We aimed to isolate BOECs from a type 3 VWD patient in order to investigate whether angiogenesis is also increased in BOECs from patients who have a complete lack of VWF.

Methods: BOECs were derived from peripheral blood of a type 3 VWD patient compound heterozygous for a nonsense mutation p.Arg2535X and an unknown mutation on the other allele. Informed consent and ethical approval was obtained. Endothelial phenotype of the cultured cells was evaluated by fluorescence activated cell sorting (FACS). Angiogenic capacity of these cells was analysed *in vitro* by matrigel assay for the tube formation and migration assay for wound healing capacity. Immunofluorescence staining was performed to visualize VWF.

Results: We successfully isolated BOECs from a type 3 VWD patient. FACS analysis confirmed the presence of endothelial markers including CD31, CD144 (VE-Cadherin) and KDR/VEGFR-2. Cells were negative for the monocyte markers CD45 en CD14. Immunofluorescence staining showed cells express PDI and β-catenin, but do not express VWF or P-selectin. No Weibel-Palade bodies (WPB) were observed. Preliminary data on the angiogenic properties of these cells revealed a higher migration rate for the type 3 VWD BOEC compared to BOECs from three healthy individuals (0.64 μm/min ±0.06) vs. 0.49 μm/min ±0.07). When seeded onto matrigel the patient's BOECs formed more capillary-like structures than healthy BOECs (35,214 μm vs. 32,486 μm) and these structures contained more branching points (138 vs. 115) and loops (54 vs. 45).

Conclusion: We established that it is feasible to obtain BOECs from a type 3 VWD patient. Preliminary results indicate that BOECs obtained from a type 3 VWD patient have enhanced angiogenic potential compared to BOECs from healthy individuals as evidenced by faster migration and enhanced capillary formation. The pro-angiogenic state is possibly caused by constituent release of angiogenic factors normally stored in the WPB like angiopoietin-2 and insulin-like growth factor binding protein 7 (IGFBP7).

PB 3.43-4

Characterisation of observed changes in vWF target disposition following repeated administration of the anti-vWF Nanobody caplacizumab

Callewaert F[1], Ulrichts H[1], Jacobs S[1], Rossenu S[2], Schoolmeester A[1], Verschueren K[1], Baumeister J[1] and Holz JB[1]

[1]Ablynx NV, Zwijnaarde, Belgium; [2]MSD, Oss, The Netherlands

Background: Caplacizumab is a bivalent Nanobody that targets the von Willebrand Factor (vWF) A1 domain and blocks the interaction of any sizes and activation states of vWF with the platelet glycoprotein (Gp)Ib-IX-V receptor. Nonclinical and clinical data revealed manageable and transient reductions in vWF antigen (vWF:Ag) and Factor VIII clotting activity (FVIII:C) levels upon repeated administration of caplacizumab, indicating a reversible effect of the Nanobody on vWF disposition.

Aims: The objective of this study is to characterise and identify the molecular mechanism of vWF:Ag and FVIII:C changes in nonclinical and clinical species.

Methods: vWF:Ag and FVIII:C levels were measured in nonclinical studies (baboon efficacy/safety study and 13-week/26-week toxicity studies in cynomolgus monkey) and Phase I multiple-dose clinical study. Biostatistical analysis compared the vWF disposition in cynomolgus monkey vs. human. A pharmacokinetic/pharmacodynamic (PK/PD) model was developed to characterise the disposition of caplacizumab and to describe the decreases in vWF:Ag levels in humans. vWF biosynthesis was evaluated by studying vWF release by endothelial cells *in vitro*, and by *ex vivo* analysis of vWF propeptide (vWFpp) levels in toxicity studies.

Results: Data from Phase I studies in human and data from the 13-week and 26-week repeated-dose toxicity studies in cynomolgus monkey indicated decreases in vWF:Ag and FVIII:C after repeated administration of caplacizumab. The observed changes are dose-dependent but saturable. Values never reached clinical significant levels: maximal changes in vWF:Ag levels ranged from ±25–40% of baseline in the 26-week toxicity study, and from ±35–40% of baseline in the Phase 1 study (i.e. lowest observed mean levels of 0.36–0.47 U/mL), with proportional decreases in FVIII:C. Statistical analysis demonstrated that the changes in vWF:Ag and FVIII:C levels observed in humans were comparable or slightly less pronounced compared to cynomolgus monkey. vWF:Ag and FVIII:C levels were also reversibly decreased in a baboon model of acquired thrombotic thrombocytopenic purpura (TTP). The effect was not linked with clinical symptoms, even in conditions of severe thrombocytopenia. Values rapidly normalised to predose levels after stopping treatment in all studies.

Experimental evidence points towards an altered clearance of vWF in complex with caplacizumab, rather than a change in vWF biosynthesis: (i) the ratio of vWFpp to processed vWF was changed upon treatment with caplacizumab in toxicity studies. A decrease of vWF:Ag was observed, while vWFpp was unchanged compared to control animals. (ii) *in vitro* data did not show an effect of caplacizumab on the stimulated or constitutive release of vWF by endothelial cells. (iii) PK/PD modelling indicated that the elimination rate of the drug-target complex is decreased compared to free drug in humans.

Summary/Conclusions: Repeated administration of caplacizumab results in mild and transient reductions of vWF:Ag and FVIII:C in the clinic. These changes are mirrored by nonclinical *in vivo* and *in vitro* models. Experimental evidence and PK/PD modelling suggest a change in the elimination rate of the vWF-drug complex due to target binding of the compound. The changes are expected to lead to manageable symptoms in the clinic, even in conditions of TTP. Caplacizumab is currently in Phase II clinical development.

PB 3.43-5

Acquired Von Willebrand Disorder in Pediatric Extracorporeal Membrane Oxygenation

Trung NC[1], Shiu-Ki H[1], Nguyen KT[2], Soundar EP[1], Hundalani SG[1], Cruz MA[3] and Teruya J[1]

[1]Texas Children's Hospital/Baylor College of Medicine; [2]Texas Childrens' Hospital; [3]Baylor College of Medicine, Houston, TX, USA

Extracorporeal membrane oxygenation (ECMO) can provide lifesaving temporary hemodynamic and/or respiratory support in critically ill patients. The use of ECMO has been rapidly increasing worldwide. However, life-threatening bleeding remains a major complication with ECMO. Acquired von Willebrand disease (VWD) while on ECMO has been suggested to occur in small case series. Increased consumption via ADAMTS-13 proteinolysis of von Willebrand factor (VWF) has been proposed as one of the mechanisms of acquired VWD. However, the characteristics of acquired VWD in pediatric patients on ECMO have not been fully studied. The aim of this study was to describe the VWF hemostatic pathway in pediatric patients on ECMO. Plasma samples of pediatric patients on ECMO were collected from a single center. We measured VWF antigen (VWF: Ag), VWF ristocetin cofactor assay (VWF: CoF), VWF collagen binding assay (CBA), VWF multimeric analysis, VWF propeptide (VWF: PP), Factor VIII activity, and ADAMTS-13 activity. We also calculated and normalized the various biomarkers to VWF: Ag such as CBA to VWF: Ag ratio (VWF: CBA/Ag). We also calculated the percent large plasma VWF multimers by using radio optical densitometry on the VWF multimeric gels. We defined the percent large plasma multimers

as the multimeric bands above the three smallest molecular weight bands. We analyzed plasma from 12 patients on days 1 and 5 of ECMO. VWF: Ag were (297%, 112–333) on day 1 and (261%, 198–350) on day 5 (median, interquartile range). VWF: CoF/Ag were (0.6, 0.5–0.7) and (0.5, 0.4–0.5) and VWF: CBA/Ag were (0.43, 0.39–0.69) and (0.44, 0.35–0.60) on day 1 and day 5, respectively. VWF: PP/Ag were significantly higher on day 1 (2.2, 1.67–2.85) then on day 5 (0.94, 0.72–1.37) ($P < 0.05$). FVIII were (153%, 69–180) and (156%, 115–253) and ADAMTS-13 were (52%, 48–60) and (75%, 57–85) on day 1 and day 5, respectively. The percent large plasma VWF multimers were (79%, 73–85) on day 1 and (69%, 19–79) on day 5. VWF multimeric gel analyses revealed loss of large plasma VWF multimers in three patients. Seven patients had life-threatening bleeding events. VWF: CoF/Ag were (0.45, 0.30–0.50) vs.(0.50, 0.50–0.65) and VWF: CBA/Ag were (0.41, 0.38–0.51) vs.(0.60, 0.32–0.66) in patients with life-threatening bleeding compared to no bleeding on day 5, respectively. VWF: PP/Ag were (1.06, 0.72–1.63) vs. (0.94, 0.21–1.37) in patients with life-threatening bleeding compared to no bleeding on day 5. The percent large plasma VWF multimers were (64%, 29–74) vs. (79%, 19–83) in patients with life-threatening bleeding compared to no bleeding on day 5, respectively. In conclusion, pediatric patients on ECMO had evidence of acquired VWD with loss of VWF function as indicated by low ratio (<0.7) of VWF: CBA/Ag and VWF: CoF/Ag. Furthermore, our study is the first to show that the VWF: PP/Ag, a marker for synthesis, was significantly decreased from day 1 to day 5 on ECMO. This decrease in VWF: PP/Ag ratio suggests that decreased synthesis could also play a role in acquired VWD on ECMO. Further studies are warranted to better understand the mechanisms of VWF pathway coagulopathy on ECMO.

PB 3.43-6
Physical fitness determines the von willebrand factor response to exhaustive physical exercise

Sonneveld MAH, Van Loon JE, Praet SFE, De Maat PM and Leebeek FWG
Erasmus University Medical Center, Rotterdam, The Netherlands

Background: Physical stress triggers the endothelium to release von Willebrand Factor (VWF) from the Weibel Palade bodies. Since VWF is a risk factor for arterial thrombosis, it is of great interest to discover the determinants of the VWF response to physical stress. Recently it has been shown that three important genes determine VWF:Ag levels: Syntaxin Binding Protein-5, Syntaxin-2 and the VWF promoter. Since the SNARE proteins may be involved in Weibel Palade body exocytosis, we hypothesize that these genetic variations may be associated with the exercise induced VWF:Ag rise.
Aims: We aimed to investigate the effect of exhaustive physical exercise on VWF levels and to identify its main mediators.
Methods: 105 healthy individuals (18–35 years) free from cardiovascular risk factors were included in this study. Each participant performed an incremental exhaustive exercise test on a cycle ergometer. Respiratory gas exchange measurements were obtained while cardiac function was continuously monitored using ECG. Venous blood was drawn from the forearm at baseline and directly after exhaustion. VWF antigen levels (VWF:Ag) were determined with an in-house ELISA. DNA was isolated for genotyping of common variations in Syntaxin Binding Protein-5 (*STXBP5*, rs1039084 and rs9399599), Syntaxin-2 (*STX2*, rs7978987) and VWF (promoter, rs7965413).
Linear regression analysis was used to analyse the relationship between performance related determinants and VWF levels. Informed consent was obtained and the study was approved by a recognised medical ethics committee.
Results: The median VWF:Ag level at baseline was 0.94 IU/mL [IQR 0.8–1.1] and increased with 47% [IQR 25–73] after exhaustive exercise to a median maximum VWF:Ag of 1.38 IU/mL [IQR 1.1–1.8] ($P < 0.0001$). The strongest determinants are performance related ($P < 0.0001$), namely the peak power output per kg bodyweight ($\beta = 0.6$ [95% CI 0.4;0.7]), the ratio between the power output at the ventilatory threshold and the peak power output in Watt ($\beta = -2.6$ [95% CI −4.00; −1.2]), VO_2 peak per kg ($\beta = 0.05$ [95% CI 0.03;0.06]) and the maximum respiratory exchange ratio at peak power output ($\beta = 3.7$ [95% CI 2.0;5.5]). We observed a gender difference in VWF: Ag response to exercise (females 1.2 IU/mL [1.1;1.6] and males 1.7 IU/mL [1.2;2.1], $P = 0.001$), which was associated by a difference in performance. Genetic variations in *STXBP5*, *STX2* and the VWF promoter were not associated with VWF:Ag levels at baseline nor with the VWF:Ag increase.
Summary/Conclusion: VWF:Ag levels strongly increase upon exhaustive exercise and this increase is strongly determined by physical fitness level and the intensity of the exercise, while there is no clear effect of genetic variation in *STXBP5*, *STX2* and the VWF promoter.

PB3.44 – Von Willebrand factor – V

PB 3.44-1
Defining the molecular basis underlying the physiological interaction between Von Willebrand factor and galectins in normal plasma

Rawley O, O'Sullivan JM, Chion A, O'Regan N, Jenkins VP, Brophy TM and O'Donnell SJ
Trinity College Dublin, Dublin, Ireland

Background: Von Willebrand Factor (VWF) is abundantly glycosylated with 12 N-linked and 10 O-linked glycans, which are heavily sialylated. Importantly, these structures influence VWF functional properties, including plasma clearance and susceptibility to ADAMTS13 proteolysis. Although the molecular mechanisms through which glycans modulate VWF biology remain poorly understood, recent studies have demonstrated that plasma VWF circulates in complex with specific members of the galectin family. Moreover, these galectin-interactions modulate VWF-mediated thrombus formation *in vivo*.
Aims: In this study, we sought to define the molecular basis underlying the interactions between VWF and galectins -1 and -3 respectively.
Methods: VWF was purified from human plasma (pdVWF) by cryoprecipitation and 2BCL gel filtration. VWF glycosylation was then modified using specific exoglycosidases. Blood group specific VWF was purified from pooled group AB, O or Bombay plasmas. Mutated full length VWF and a series of truncated VWF domain fragments were transiently expressed in HEK293T cells. Recombinant galectin-1 and -3 were expressed in *E. coli* and purified via nickel affinity chromatography. Binding interactions were characterized via modified immunosorbent assay.
Results: Both galectin-1 and galectin-3 bound to pdVWF in a dose-dependent manner. Pre-incubation with PNGase F markedly decreased binding to both galectin-1 and galectin-3 ($13 \pm 1\%$ and $57 \pm 2\%$, $P < 0.001$). Moreover, removal of both N- and O-linked glycans (PNGase F and O-glycosidase treatment) further attenuated galectin-3 binding ($21 \pm 1\%$, $P < 0.0001$). ABO blood group antigen expression significantly influenced interaction with both galectins. In particular, group AB VWF bound to both galectin-1 and galectin-3 significantly better compared to group O VWF. In keeping with its lack of AB antigen expression, platelet-derived VWF bound both galectins with significantly reduced affinity compared to pdVWF. Terminal sialic acid and sub-terminal galactose expression on VWF also modulated galectin interaction. For example, enzymatic desialylation of pdVWF with α2-3,6,8,9 neuraminidase markedly enhanced binding to galectin-1 and galectin-3 ($231 \pm 6\%$ and $136 \pm 6\%$, $P < 0.05$). Importantly, both galectins −1 and −3 bound with higher affinity to HMWM VWF multimers compared to LMWM of the same blood group. The relative importance of specific VWF domains in regulating galectin interaction was investigated using a series of recombinant truncated domain fragments. Differential galectin binding was evident across the individual domains. Interestingly, a key role for the VWF A domains was observed. In keeping with these findings, incubation with

ristocetin significantly enhanced pdVWF binding to both galectin-1 and galectin-3 (914 ± 50% and 205 ± 23%, $P < 0.05$). Moreover, both galectins bound to the VWD type 2B mimic R1450E with significantly enhanced affinity (165 ± 10% and 117 ± 4%, $P < 0.05$). Finally, targeted removal of the individual N-linked glycan located at N1515 in the VWF A2 domain via site directed mutagenesis lead to dramatically decreased galectin-3 binding (23.86 ± 3%, $P < 0.0001$).
Conclusions: These novel data define the molecular basis underlying the physiological VWF-galectin interaction. In particular, we have demonstrated that both N- and O-linked glycan determinants modulate VWF-galectin binding through terminal sialic acid and ABO blood group expression, with an additional role for specific N-linked glycans. Furthermore, we have identified a critical role for the VWF A domains in modulating these interactions.

PB 3.44-2
Free thiol groups in von Willebrand factor (VWF) are required for its proper function under physiological flow conditions

Solecka BA[1], Fuchs B[1], Weise C[2] and Kannicht C[1]
[1]Octapharma R&D; [2]Freie Universität Berlin, Berlin, Germany

Background: The multimeric plasma glycoprotein von Willebrand factor (VWF) is exceptionally rich in cysteine, and its structure is largely determined by inter- and intramolecular disulfide bonding. Additionally, VWF was shown to contain unpaired cysteine residues potentially affecting protein function. The significance of free thiols on the surface of plasmatic VWF has been confirmed previously with respect to platelet binding under pathologically high shear stress. Furthermore their potential involvement in functional VWF self-association occurring at elevated shear stress has been suggested.
Aims: Objective of the present study was to investigate whether free thiol groups of plasma VWF contribute to the physiological VWF function under high physiological arterial shear stress conditions. Furthermore, we aimed to elucidate possible underlying mechanisms involved in this regulation.
Methods: Free and accessible thiol groups of plasma-derived VWF were blocked with N-ethylmaleimide (NEM). Derivatization was followed by detailed structural and functional examination including multimer analysis (MMA) and Fourier transform infrared spectroscopy (FTIR). Functional differences between the NEM-derivatized sample and the control sample were detected using an *in vitro* flow chamber system with respect to VWF-mediated platelet adhesion to collagen. Interactions with collagen type III and platelet glycoprotein (GP)Ib receptor were investigated using surface plasmon resonance (SPR). Identification of accessible cysteine residues was accomplished using biotin-linked maleimide (MPB) followed by analysis of multimer and domain incorporation as well as mass spectrometry.
Results: Blocking free thiol groups provoked substantial loss of VWF activity with respect to platelet recruitment to collagen type III under flow. The lowered platelet adhesion to collagen type III was shown to be a combined effect of inhibition of (i) the initial VWF binding to collagen type III as well as (ii) VWF-platelet GPIb interaction. Free thiol groups were accessible for derivatization solely on the surface of coiled multimers. Domain incorporation studies revealed a high level of derivatization in VWF *N*- and *C*-terminus. This was in accordance with the mass spectrometric analysis, where 19 MPB-derivatized peptides, predominantly located at the *N*- and *C*-terminus, could be identified.
Conclusion: Blocking free thiol groups in VWF significantly impaired mediation of platelet adhesion under physiological shear stress conditions. This result suggests an essential functional role of free thiol groups in VWF regarding binding to subendothelial matrix as well as platelet recruitment.

PB 3.44-3
Detecting the inner-interaction sites of VWF A1 domain and A3 domain

Jiang M
Jiangsu Institute of Hematology, Suzhou, China

Background: VWF is a multimeric glycoprotein composed of multiple functional domains and it interacts with the platelet membrane receptor GPIb-IX-V complex through its A1 domain and with collagen fibers through its A3 domain. Several researches indicate that the A1-A2-A3 triple domain has a more complicated secondary structure rather than the three single domains. Recently, we demonstrated that there was interaction between A1 and A3 domain. The interaction generally will be interrupted by conformational change of A1 and A3 each.
Aims: To unravel the mechanism of inner-interaction of VWF A domain and map the interaction binding site in detail.
Methods: We introduced 11 amino-acid mutations of A1 domain and 13 mutations of A3 domain. The mutants were expressed as recombinant VWF A1, VWF A3 as well as full-length VWF. The role of mutation site in A1-A3 interaction was evaulated in a binding assay using snap/clip-tag technology.
Results: The Asp(506), Tyr(508), Lys(549) of A1 domain and Arg (1026), Pro(1027) of A3 domain significantly reduced binding affinity of VWF A1-A3 interaction. Arg(632), Lys(643), Leu(964) and Gln (966) has weak impact on A1-A3 binding affinity. In addition, the reduction of the affinity enhanced the binding of platelet GPIb to VWF A1 domain.
Conclusion: It was predicted using bioinformatics methods that some amino-acid sits on VWF A1 domain or A3 domain were related with interaction of these two domains. Our results confirmed that some sites of them can indeed interfere the affinity of VWF A1-A3 interaction. Interestingly, several sites were in line with VWD mutaion site. These results help us to reveal the function of VWF A domain and the pathogenesis of VWD.

PB 3.44-4
Oxidized von Willebrand factor is associated with thrombotic micro- and macro-angiopaties in diabetes mellitus

De Cristofaro R[1], Oggianu L[2], Lancellotti S[3], Pitocco D[4], Zaccardi F[4], Rizzo P[4], Martini F[4] and Ghirlanda G[4]
[1]Catholic University School of Medicine; [2]Section of Biology Applied to Human Health 'Rome Tre' University; [3]Department of Medical Sciences, Catholic University School of Medicine; [4]Diabetes Care Unit, Department of Medical Sciences, Catholic Univ School of Medicine, Roma, Italy

Background: The thrombogenic activity of Von Willebrand factor (VWF) is proportional to its molecular size and is inversely related to its proteolysis by ADAMTS-13. Oxidation of VWF at Met1606 with formation of sulfoxy-methionine severely impairs its proteolysis by the metalloprotease. Thus, oxidative stress may favor accumulation of high molecular weight VWF multimers, which can have prothrombotic effects. Moreover, diabetes mellitus, especially type 2, is characterized by high production of reactive oxygen and nitrogen species.
Aims: This study was aimed at assessing in patients with type 1 and type 2 diabetes whether protein carbonyls, marker of oxidative stress, are associated with both the level and oxidation status of VWF as well as with micro- and macroangiopathic complications.
Methods: Eighty-three diabetic patients (41 type 1 and 42 type 2 diabetic subjects) and their respective 83 healthy controls were studied after verifying the availability, through institutional databases, of clinical biochemistry records spanning at least 3 years. Plasma proteins and VWF-bound protein carbonyls were measured by immunoassays, whereas VWF multimers were studied by SDS-agarose gel electrophoresis.

Results: Type 2 diabetic subjects had higher levels of VWF antigen (VWF:ag), VWF activity (VWF:act) and plasma proteins' carbonyls in comparison with both their controls and type 1 diabetic subjects. Moreover, high molecular weight VWF multimers and specific VWF-bound carbonyls were significantly increased in subjects with micro- and macro-angiopathic complications. By contrast, in both type 1 and type 2 diabetic subjects, ADAMTS-13 activity was in the normal range. In a multivariable analysis, only VWF-bound carbonyls were significantly associated with any form of thrombotic angiopathy, considering the entire group of T1- and T2 diabetic patients.
Summary/Conclusion: These data provide first evidence that not only high VWF levels but also its oxidation status and the presence of high molecular weight VWF multimers, not observed in SDS-agarose gel electrophoresis of normal subjects are associated with thrombotic angiopathies in diabetes mellitus. These findings may help identify diabetic patients particularly at risk for these complications and elucidate a pathogenetic mechanism, centered on exalted activity of VWF, which contributes to the genesis of thrombotic angiopathies in this clinical setting

PB 3.44-5

A single finger prick for the assessment of Von Willebrand factor binding to platelets

Baaij M[1], Schutgens REG[2], Urbanus RT[2], Vu TDN[2], De Groot PG[2] and Roest M[2]

[1]UMC Utrecht; [2]University Medical Center Utrecht, Utrecht, The Netherlands

Background: It has been shown that blood collection via finger prick can be used for platelet function measurements. Significant correlations have been found between whole blood aggregometry (WBA) in venous blood and platelet reactivity time in capillary blood. However, there have been no publications that report a finger prick method to assess the binding of Von Willebrand factor (VWF) to platelets. We have developed a finger prick assay which requires only 40 μL of blood to measure the ristocetin induced binding of VWF to platelets. This could provide a new simple and less invasive method to assess binding capacity in disease (e.g. Von Willebrand disease VWD) and in response to therapy such as DDAVP or VWF infusion.
Aim: Our aim was to develop a finger prick based method for the assessment of VWF binding to platelets.
Methods: This study was approved by the Medical Ethics Committee of the University Medical Center Utrecht. The procedures followed were in accordance with the Helsinki Declaration. After informed consent, blood samples were obtained from 30 healthy controls. Blood sample collection procedure is slightly altered when compared to the conventional method; the hand is not warmed and a small tourniquet is placed around the base of the finger, total 'ligature time' is <1 min 30 s. An appropriate sized sterile safety lancet is used and capillary blood is collected in a 200 μL EDTA Microvette. The assay consists of a serial dilution of ristocetin (0–0.75 mg/mL) containing a fixed concentration of FITC labelled anti-VWF antibody. 5 μL of citrated blood was added to each well and VWF binding was assessed with fluorescent activated cell sorting. Results were plotted in a dose response graph.
Results: Mean age was 29.7 years, 12 subjects (40.0%) were male. 16 (53.3%) subjects had blood type 0, 11 (36.7%) type A and 3 (10.0%) Type B, none were type AB. We have recently validated this assay in healthy donors and VWD patients using *venous* blood. The inter-donor variability in the finger prick assay is comparable to the venous assay. The intra-donor variability, comparing the dose response curves in one donor on the same day, is low. We observed a strong learning curve in collecting blood, this could be due to the slightly altered finger prick method.
Summary/Conclusion: This is the first report on a finger prick method for the assessment of ristocetin induced VWF binding to platelets. Once experience in the specific finger prick method is gained, it is a simple, minimally invasive and reproducible method. Further research into the effect of disease and therapy on this assay will be performed. If these effects can be quantified, the assay would ideally be further developed into a Point of Care test.

PB 3.44-6

Quality specifications for imprecision, bias and total error to be used for measures of von Willebrand Factor antigen, activity and multimerisation

Harsfalvi J[1], Szekeres-Csiki K[2], Meiring M[3], Sandor A[2], Pataki L[2], Nemeti A[2] and Udvardy ML[2]

[1]University Debrecen, Medical and Health Science Center, Debrecen, Hungary; [2]Medical and Health Science Centre, University Debrecen, Debrecen, Hungary; [3]Faculty of Health Sciences, University of the Free State, Bloemfontein, South Africa

Background: Reduced quantity or quality of von Willebrand Factor (VWF) is responsible for the symptoms of the most frequent hereditary bleeding disorder: von Willebrand disease (VWD). Increased VWF level or activity is linked to thrombotic thrombocytopenic purpura (TTP), various vascular disorders, liver diseases and cancers and also seems to be useful biomarkers of these diseases as indicators of endothelial damage.
Aim: Our aim is to provide quality specifications for imprecision, bias and total error to be used for measures of VWF antigen (VWF:Ag) level, activity (VWF collagen binding, VWF:CB) and multimerisation (MMW25). To analyze function structure relationship, we also aim to relate these VWF parameters to each other. Furthermore, we aim to correlate the quantity measures of functional test results to disease symptoms and genotype to better understand structure-function relationships.
Methods: Polyclonal antibody based VWF:Ag assay, VWF:RCo assay, five commercial and two freshly isolated human collagen type I and type III based VWF:CB assays, SDS-agarose multimer analysis and quantitative densitometry with a software developed by us for numerical expression of the VWF multimerisation, genetic analysis by direct sequencing of exon 28 (primers were designed at the basis of Penas et al 2005). Statistical quality tools (fishbone diagram, check sheet, control chart, histogram, Pareto chart, scatter diagram and stratified sampling).
Results: Specimen handling, storage and processing and all assay conditions were standardized. The limit of detection of the VWF:Ag and VWF:CB assays are 1.5 and 3.1 ng/mL respectively. Using control samples from different sources assessed accuracy and analytical error was 5.2 and 3.5% respectively. Analytical measurement range was 3.1–185 ng/mL (VWF:CB) and 3.1–218 ng/mL (VWF:Ag) at a standardized 200-fold plasma dilution. Clinical reportable range was 5–1653 and 3–1862 ng/mL at different dilutions of samples (50–3200). Total errors of the methods were 7–19%. Bland-Altman plots were used to evaluate agreement between VWF:Ag and VWF:CB assays applied for 1218 samples. Diagnostic sensitivity and specificity evaluated by applying the methods for 45 genotyped VWD patients.
Summary/Conclusion: Specimen handling, storage and processing is one of the critical factors, the other is the dilution buffer in the different assays. Using validated assays, VWF parameters became valuable tools as endothelial damage indicators and promising diagnostic or prognostic markers of many other diseases.

PB 3.45-1

Prothrombin complex concentrate use for the emergency reversal of vitamin K antagonists

Lancashire J[1], Smith N[1] and Crowther M[2]

[1]*Heart of England NHS Foundation Trust, Birmingham;* [2]*Worcestershire Royal Hospital, Worcester, UK*

Introduction: The need for normalisation of coagulation because of major bleeding or the requirement to perform invasive procedures are the primary indications for prothrombin complex concentrate (PCC) in patients receiving vitamin K antagonists (VKA).

Methods: We retrospectively audited the use of PCC over a year in two hospitals in the West Midlands Region of the UK.

Results: One hundred and eleven patients, all receiving warfarin, received PCC (either Beriplex® or Octaplex®). The mean age of the patients was 77 years, with 58.6% men. Ninety four percent of patients were discussed with a haematologist and 91% of patients were felt to have appropriate indications for PCC. The majority of patients had atrial fibrillation (74.8%) with other indications including DVT/PE (15.3%) and heart valve replacement (7.2%). Indications for PCC were major bleeding (73.0%) (gastrointestinal 46.9%, intracranial 42.0%, subcutaneous/intramuscular 6.2%) or an interventional procedure (26.2%) (abdominal surgery 42.3%, hernia repair 11.5%, orthopaedic 15.4%, urology 30.8%, central venous access 11.5%) or sepsis 0.9%.

There was a considerable time delay between it being recognised that the patient required warfarin reversal and requesting PCC (median 1 h 10 min, range 10 min–5 h 14 min) and from issue of the product by the Blood Bank and it being infused (median 1 h 46 min, range 10 min–6 h 55 min). This meant that the median time from the need for warfarin reversal being recognised to infusion of PCC was 3 h 25 min (range 45 min–11 h 14 min). All patients had their warfarin withheld but only 92.8% received vitamin K (with variable dosing).

Sixty seven percent of patients (who had a post-PCC INR available) achieved a normal INR. Mortality and morbidity was significant with 22 patients (19.8%) of patients dying in the first 30 days. Causes of death were bleeding (36.4%), sepsis (36.4%), cardiac events (22.7%) and cancer (4.5%). Time of death ranged from 10 h, due to an intracranial haemorrhage, to 21 days (due to sepsis). Of those surviving the rate of thrombotic events was 12.4% with six cardiac events, three PEs and two ischaemic strokes.

Conclusion: The two factors stand out from this audit. Firstly the excessive time from when it becomes evident that the patient requires warfarin reversal until they receive the PCC. Intravenous vitamin K works within 6–12 h therefore several of the patients could have been managed with vitamin K alone thus reducing the need for PCC and the extra risk associated with this.

The second finding is the high rate of thrombotic events, of which five were deaths, this further reinforces the need to use PCC only in those who either have life, limb or sight threatening bleeding or require emergency surgery that cannot wait for VKA reversal with vitamin K.

PB 3.45-2

Validation of a new questionnaire measuring Satisfaction with Medical Care in Non Valvular Atrial Fibrillation patients (SAFUCA study)

Gónzalez-López TJ[1], Ruiz M[2], Villasante F[3], Gónzalez-Porras JR[4], Franco E[5], Aranguren JL[6], Tuñon J[7], De Salas-Cansado M[8], Pardo A[2] and Soto J[8]

[1]*Universitary Hospital of Burgos, Burgos;* [2]*Autónoma University of Madrid, Madrid;* [3]*Healthcare center José Marvá, Madrid;* [4]*Hospital of Salamanca, Salamanca;* [5]*San Carlos Clinic Hospital, Madrid;* [6]*Madrid Clinic, Fuenlabrada, Madrid, Madrid;* [7]*Jiménez Díaz Foundation Hospital, Madrid;* [8]*Pfizer Spain, Alcobendas, Madrid, Spain*

Background: Treatment satisfaction measurement is a very relevant issue in the clinical follow-up of patients and their adequate handling. Although other generic instruments are already available we intend to develop a specific instrument for those patients treated for non-valvular atrial fibrillation (NVAF).

Aims: To validate a new questionnaire developed to measure satisfaction with medical care (antithrombotic treatment effectiveness and control, daily living interference) in patients with NVAF.

Methods: The 25-items instrument, reduced from a 37-items initial version, was administered to 254 NVAF patients under antithrombotic treatment, along with the Treatment Satisfaction Questionnaire for Medication (TSQM) concurrent questionnaire, and five visual analogic scales (VAS) measuring: Quality of Life (patient), perceived effectiveness (patients and clinician), general satisfaction (patient), and tolerability (clinician). Dimensional structure was assessed through inter-rater agreement and Confirmatory Factor Analysis, and convergent and divergent correlation with other measurements.

Results: An expert panel composed of six specialists rated a high correspondence with the theoretical construct attaining high values on concordance indexes (0.53–0.81) for items on their target dimension. A high goodness-of-fit was obtained (χ^2/df = 1.55, CFI = 0.71, RMSEA = 0.049) for the 7-dimensional structure (item #): 1- Effectiveness (3), 2- Convenience (3), 3- INR interference (4), 4.- Impact on HRQoL (6), 5- Undesired Effects (3), 6- Satisfaction with care (3) y 7- Overall Satisfaction (3). Correlations with TSQM convergent dimensions were moderate/higher (0.328–0.647) than those with divergent dimensions. Correlation pattern with VAS scores was concordant with that expected

Conclusions: The reduced questionnaire presents good construct, structural, convergent and divergent validity properties. The seven proposed dimensions are stable and well defined in the 25-item version.

PB 3.45-3

Reversal of the oral direct thrombin inhibitor dabigatran captured by visco-elastic and thrombo-imaging techniques

Lindahl T[1], Hillarp A[2], Gustafsson KM[1] and Wallstedt M[1]

[1]*Linköping University, Linköping;* [2]*Lund University, Malmö, Sweden*

Background: In the near future large numbers of patients are expected to be on antithrombotic treatment with the direct oral thrombin inhibitor dabigatran. It is also expected that a small percentage of the patients will experience serious bleeding or be in need of urgent surgery. In those instances the clinicians need guidance how to treat the patient in order to arrest or prevent bleeding. At present no specific antidote is available.

Aim: The aim of the project is to provide the medical community with data to support decision-making by testing different *in vitro* procedures for improving the coagulation in blood or plasma spiked with dabigatran

Methods: Whole citrated blood was spiked with dabigatran (Boehringer-Ingelheim), 200 μg/L and 400 μg/L for viscoelastic measurements of clotting (ReoRox instrument from Medirox, Nyköping, Sweden) with coagulation initiated with tissue factor (0.24 nM) or platelet-rich plasma (dabigatran only 200 μg/L) for measurement of clot initiation on a tissue factor coated surface and clot propagation velocity utilizing video-recording (Thrombodynamics Analyzer T-2 instrument from HemaCore LLC, Moscow, Russia). Different candidate drugs; fibrinogen (Riastap®, CSL Behring), activated prothrombin complex concentrate (ACCP; FEIBA®, Baxter AG), prothrombin complex concentrate (PCC; Ocplex®, Octapharma), recombinant factor VII (rVIIa; Novoseven®, Novo Nordisk), with potential to reverse the dabigatran effects on haemostasis, was be added at therapeutic concentrations used in patients for other indications at present and then reanalyzed.
Results: In viscoelastic measurements fibrinogen had small effects, if any, on clotting time but increased clot elasticity. APCC shortened clotting time considerably, for the lower concentration of dabigatran even to shorter times than the control. PCC partially reversed the prolongation caused by dabigatran. rVIIa had no significant effects. A limitation of this study is the relatively high tissue factor concentration used (0.24 nM) which might obscure the effects of platelets on enhancement of coagulation and thus also a potential positive effect of rVIIa. As measured by video-recording dabigatran did not influence the initial rate of coagulation at the surface, but attenuated the propagation of coagulation and decreased clot size (measured at 30 min). APCC not only reversed the dabigatran attenuation of clot propagation but increased above the value for the control for initial rate of coagulation, PCC and rVIIa had only minute effects.
Conclusion: APCC and PCC seem to have some potential for reversal of dabigatran effects on coagulation, but APCC in to high doses might induce too much coagulation and eventually cause thrombotic complications. Clinical studies are needed to evaluate the potential of these drugs for reversal of dabigatran effects on haemostasis in patients.

PB 3.45-4

Simulation of the international normalized ratio during switching therapy from rivaroxaban to warfarin and its potential clinical implications

Siegmund HU[1], Burghaus R[2], Kubitza D[2] and Coboeken K[2]
[1]Bayer Technology Services GmbH, Leverkusen; [2]Bayer Pharma AG, Wuppertal, Germany

Background: The oral anticoagulants warfarin and rivaroxaban are options for the management of several thromboembolic diseases. In patients receiving long-term anticoagulation therapy, switching from rivaroxaban to a vitamin K antagonist (e.g. warfarin) may be required in some patients, which necessitates co-administration of both drugs initially because of the slow onset of action of warfarin. However, both drugs affect prothrombin time and the international normalized ratio (INR), complicating warfarin dosing during the transition (co-administration period).
Aims: The objective of this study was to use a computer model of blood coagulation to evaluate the influence of rivaroxaban 20 mg once daily on INR during the co-administration period of a switch from rivaroxaban to warfarin.
Methods: A model of coagulation that included the formation and clearance of the vitamin K-dependent coagulation factors was used. Factor clearance was implemented as an exponential decay to reflect physiological conditions. To validate the model, warfarin decay simulations were conducted first. To calibrate the model, warfarin concentration fit by best match of modelled and experimental Factor II and Factor VII concentrations was conducted, and prothrombin time and INR values were simulated by use of a phospholipid concentration that matched Neoplastin Plus®. To simulate the combined effects of both anticoagulants on INR during a switch from rivaroxaban to warfarin, warfarin initiation was simulated by adjusting the warfarin effect magnitude to reach desired target INRs in a sufficient time scale (21 days); the warfarin effect values obtained every 6 h from this simulation and the desired rivaroxaban plasma concentrations (derived from pharmacokinetic modelling of phase II dose-ranging studies in patients being treated for deep vein thrombosis) were used in the coagulation model. The increases in the simulated INR caused by rivaroxaban were used to generate nomograms. Simulations were done by emulating Neoplastin Plus and Innovin® reagents.
Results: Warfarin decay simulations showed that the simulator had good prediction quality. Rivaroxaban-induced increases in the total INR from the warfarin-attributed INR were seen in simulations emulating Neoplastin Plus. There was an approximately linear dependence on rivaroxaban plasma concentration. However, the rivaroxaban-induced deviation of INR was also dependent on the magnitude of the warfarin-induced basal INR. Simulations emulating Innovin showed smaller rivaroxaban-induced increases in INR from the warfarin-attributed INR compared with Neoplastin Plus. At median trough rivaroxaban plasma concentrations (38 μg/L), the INR contribution of rivaroxaban was 0.5–1.2 with Neoplastin Plus and 0.3–0.6 with Innovin if the warfarin-only INR was 2.0–3.0. At a high trough concentration of rivaroxaban (160 μg/L), the contribution of rivaroxaban had a maximum increase in INR of approximately 1.0 if the overall INR was 2.0–3.0 when Innovin was used.
Summary/Conclusions: Based on the simulations, the best time to measure the effect of warfarin on INR would be at the time of trough rivaroxaban concentrations (24 h after rivaroxaban dosing) during the co-administration period when switching from rivaroxaban to warfarin. Furthermore, the use of Innovin would be preferred to Neoplastin Plus because of its substantially lower sensitivity to rivaroxaban, thereby reducing the influence of rivaroxaban on measured increases in INR.

Pharmacodynamics and pharmacokinetics during the transition from warfarin to rivaroxaban in healthy subjects: a multicentre, randomized, placebo-controlled study

Kubitza D[1], Becka M[2], Mueck W[2] and Krätzschmar J[2]
[1]Bayer HealthCare AG; [2]Clinical Sciences, Bayer HealthCare Pharmaceuticals, Wuppertal, Germany

Background: In clinical practice, patients receiving long-term anticoagulation therapy for the prevention and treatment of thromboembolic disorders may require switching between anticoagulants, for example, from vitamin K antagonists (e.g. warfarin) to rivaroxaban, or vice versa. Rivaroxaban and warfarin both affect coagulation tests, and information on the pharmacological changes that occur during such transitions would be useful to physicians.
Aims: The primary objective of this study was to investigate the relevant pharmacodynamic parameters during the transition from steady-state warfarin to rivaroxaban 20 mg once daily in healthy volunteers.
Methods: This multicentre, randomized, placebo-controlled, parallel-group study enrolled 96 healthy men, aged 18–45 years. All subjects provided written, informed consent prior to enrolment and the study was registered with EudraCT (2008-005540-16). Subjects were randomized into three treatment groups. In group A, warfarin was administered in varying doses to achieve a steady state with an international normalized ratio (INR) range of 2.0–3.0; rivaroxaban 20 mg once daily was then given for 4 days (days 0–3) starting 24 h after warfarin was stopped. In group B, the same warfarin regimens as treatment group A were used to achieve an INR of 2.0–3.0, followed by placebo once daily for 4 days (days 0–3). In group C, rivaroxaban 20 mg once daily was given for 4 days (days 0–3) without prior warfarin treat-

ment. Blood samples were collected at prespecified time points for pharmacodynamics and pharmacokinetic analyses. The following pharmacodynamic parameters were assessed: anti-Factor Xa activity, inhibition of Factor Xa activity, prothrombin time (PT), activated partial thromboplastin time (aPTT), HepTest, prothrombinase-induced clotting time (PiCT), Factor VIIa activity, Factor IIa activity, and endogenous thrombin potential (ETP).

Results: The pharmacodynamic profiles during the transition from steady-state warfarin (INR 2.0–3.0) to rivaroxaban 20 mg once daily varied and depended on the type of test used. An additive effect was observed on the prolongation of PT/INR during the initial transition period. The mean maximum prolongation of PT (in seconds) was 4.39-fold in warfarin followed by rivaroxaban group (group A) compared with 1.88-fold in warfarin followed by placebo group (group B) and 1.57-fold of baseline value in the rivaroxaban alone group (group C). However, at trough concentrations (i.e. 24 h after rivaroxaban dosing) rivaroxaban had minimal influence on the PT/INR. Inhibition of Factor Xa activity, aPTT and ETP were also enhanced during the transition from warfarin to rivaroxaban, but to a lesser extent compared with the PT. In contrast, the effects of rivaroxaban on anti-Factor Xa activity, HepTest and PiCT were not affected by pretreatment with warfarin. There was no pharmacokinetic interaction between the two drugs during the transition.

Conclusions: Changes in pharmacodynamic parameters during transitioning from warfarin to rivaroxaban vary depending on the tests used. The data suggest that INR monitoring should be stopped once rivaroxaban is initiated during the transition from warfarin to rivaroxaban. Conversely, when switching from rivaroxaban to warfarin, INR monitoring of warfarin therapy should be performed at trough rivaroxaban levels during the co-administration period.

PB 3.46-2

Combination effects of edoxaban, an oral direct factor Xa inhibitor, and P2Y12 receptor antagonists on ADP plus tissue-factor induced thrombin generation in human platelet-rich plasma

Morishima Y and Honda Y

Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: Activated platelets and tissue factor participate in arterial thrombosis by forming platelet aggregates that initiate and propagate blood coagulation. Adenosine diphosphate (ADP) is one of the major agonists for platelet activation. Edoxaban is an oral, once daily, direct, selective and reversible factor Xa (FXa) inhibitor in late-stage clinical development for the prevention of stroke and systemic embolic events in atrial fibrillation and the treatment and prevention of recurrence of venous thromboembolism.

Aims: To determine the effects of (a) edoxaban; and (b) the combination of edoxaban and a P2Y12 receptor antagonist (clopidogrel or ticagrelor) on thrombin generation induced by ADP plus tissue factor in human platelet-rich plasma (PRP).

Methods: Citrated human PRP from healthy subjects was stimulated with 10 μM ADP plus 0.25 pM tissue factor in the absence or presence of edoxaban and/or P2Y12 receptor antagonists. Thrombin generation was measured by means of calibrated automated thrombography with the thrombinoscope software. Lag time, peak, time to peak, endogenous thrombin potential (ETP), and maximum rate parameters were calculated from thrombin generation curves.

Results: Combination of ADP (10 μM) and low concentration tissue factor (0.25 pM) induced reproducible and steady thrombin generation in human PRP. Edoxaban (40 and 80 ng/mL), active metabolite of clopidogrel (AM-Clo, 10 and 20 μg/mL), and ticagrelor (3 μg/mL) alone inhibited ADP plus tissue factor-induced thrombin generation. Edoxaban significantly suppressed all five parameters (lag time, peak, time to peak, ETP, and maximum rate) of thrombin generation. AM-Clo inhibited lag time, peak, time to peak, and maximum rate, but not ETP. Ticagrelor suppressed peak, time to peak, and maximum rate, but not lag time or ETP. Concomitant presence of edoxaban (40 and 80 ng/mL) and AM-Clo (10 and 20 μg/mL) or edoxaban (40 and 80 ng/mL) and ticagrelor (3 μg/mL) produced a significant and additive inhibition of ADP plus tissue factor-induced thrombin generation compared to the single agents.

Conclusions: ADP plus tissue factor induces thrombin generation in human PRP. Both edoxaban, a FXa inhibitor, and P2Y12 receptor antagonists (clopidogrel and ticagrelor) inhibit this effect; however only edoxaban had a significant effect on all five thrombin generation parameters and especially ETP. Moreover, significant additive effects were observed with the concomitant presence of edoxaban and a P2Y12 receptor antagonist. The present results suggest that ADP plus tissue factor-induced thrombin generation assay may be a useful biomarker to quantitate and monitor the effects of combination therapy with FXa inhibitors and P2Y12 receptor antagonists.

PB 3.46-3

Efficacy and safety of weight-adjusted extended duration tinzaparin for prevention of post-operative venous thromboembolism after bariatric surgery

Siegal DM[1], Handa P[2], Crowther M[1], Douketis JD[1], Anvari M[1] and Tiboni M[1]

[1]St. Joseph's Healthcare Hamilton and McMaster University, Hamilton, Canada; [2]Tan Tock Seng Hospital, Novena, Singapore

Background: Bariatric surgery patients are at moderate to high risk for venous thromboembolic events (VTE) with pulmonary embolism representing the most common cause of post-operative death. The majority of VTE occur at a median of 14 days after hospital discharge. The optimal dosing strategy and duration of anticoagulant thromboprophylaxis have not been established.

Aim: To evaluate the efficacy and safety of post-operative thromboprophylaxis using weight-adjusted tinzaparin continued for 7 days following hospital discharge in patients undergoing bariatric surgery.

Methods: We conducted a retrospective chart review of 366 consecutive patients undergoing bariatric surgery from July 2009 to December 2010. Patients received thromboprophylaxis with weight-adjusted tinzaparin 4500–14,000 units daily (75 μ/kg, rounded to the nearest prefilled syringe). The primary efficacy outcome was the frequency of VTE within 30 days of surgery. The primary safety outcome was the frequency of major bleeding (International Society on Thrombosis and Haemostasis definition) within 30 days of surgery. Patients with a baseline indication for therapeutic dose anticoagulation were excluded from analysis. Trough anti-Xa levels were measured in 190 patients at approximately 7 days following surgery.

Results: Mean age was 44.8 years (SD 9.4). Median body mass index was 45.9 (range 30.9–71.0). A total of 351 and 342 patients were included in the efficacy and safety analyses, respectively. Outcome data were unavailable for nine patients (2.4%). VTE occurred in two patients (0.6%; superior mesenteric vein thrombosis, pulmonary embolism). Major bleeding events occurred in eight patients (2.3%) who received at least one dose of tinzaparin. Trough anti-Xa levels were undetectable in 143 patients. In the remaining 47 patients the median trough anti-Xa level was 0.12 (range 0.10–0.41).

Conclusions: Weight-adjusted extended duration tinzaparin appears to be an effective and safe thromboprophylaxis strategy in bariatric surgery patients. We found no evidence of drug accumulation despite use of large doses of tinzaparin.

PB 3.46-4

Effective inhibition of proteases of the coagulation cascade by di-cationic pentamidine-like molecules

Church FC, Rein-Smith C, Whinna H, LeFrapper L, Monroe D and Tidwell R

UNC-CH School of Medicine, Chapel Hill, NC, USA

Background: There has been a recent surge of interest in the replacement of heparin and warfarin with more targeted antithrombotic agents that would reduce thrombosis but also lower the incidence of bleeding found with warfarin. Progress has been made in this arena with the introduction of several new drugs to the market and early reports suggest that these drugs are effective at inhibiting thrombosis. However, the risk of major bleeding with these drugs was greater than existing treatments in some clinical trials, with only a minimal benefit in lowering thrombosis. There has been recent interest in creating small molecule inhibitors against factor IXa and factor VIIa, which may be superior therapeutic targets to thrombin and fXa. Di-cationic, 'pentamidine-like' compounds have been investigated for therapeutic use as anticoagulants, platelet inhibitors, contraceptives, anti-virals, anti-inflammatories, anti-cancer agents, anti-fungals and anti-protozoan agents. While the mechanism of action of these compounds is not known for all of the above listed uses, the anticoagulant effect of these compounds appears to be due to inhibition of serine proteases of the coagulation pathway. Recent work has produced a library of over 2800 mono- and di-cationic molecules and several have shown promise in clinical trials in treating tropical diseases, but the majority of this library has not yet been screened for potential anticoagulant therapies.
Methods: We screened the anticoagulant potential of a subset of 15 compounds from the di-cationic library using prothrombin time (PT), activated partial thromboplastin time (aPTT), calibrated automated thrombography (CAT), coagulation factor inhibition assays, and an *in vivo* ferric chloride model of thrombosis.
Results: We find that 5 of the initial 15 compounds selected for screening (1RRT 063, 279OXD 032, 25DAP 013, 150OXD 230 and 1MCC 182) showed prolonged PT and aPTT, increased time to thrombin generation, and decreased total thrombin generated. Of these five compounds, two were effective fXa inhibitors (279OXD 032 and 1MCC 182) while two were effective thrombin inhibitors (1RRT 063 and 25DAP 013). In an *in vivo* thrombosis model, 150OXD 230 and 1RRT 063 significantly prolonged the time to occlusion while 25DAP 013 had no effect on time to occlusion.
Conclusions: These results suggest that our initial screening strategy for the entire di-cationic library is valid, and that this library may yield novel, targeted anticoagulant molecules that have the potential as therapeutic anticoagulants. Additionally, the *in vivo* results highlight the need to utilize an *in vivo* model in order to verify that compounds which may exhibit anticoagulant properties *in vitro* are also effective *in vivo*.

PB 3.46-5

Adherence to oral anticoagulants in an outpatient setting

Ergül S[1], Erkens PGM[2], Ten Cate-Hoek AJ[1] and Ten Cate H[1]

[1]Maastricht University Medical Centre; [2]Maastricht University, Maastricht, The Netherlands

Background: Patient's compliance to therapy is crucial for good quality treatment. Literature reports that 50% of patients may cease to be adherent for drugs prescribed in chronic conditions that are left unmonitored. The introduction of a new generation of oral anticoagulants (NOACs) with a short half-life and for which no regular laboratory controls are necessary, may therefore harbor an increased risk of treatment failure due to non-adherence. Insight into patient factors that may influence treatment outcomes is lacking.
Aim: To explore the risk factors that may affect treatment compliance in the outpatient setting, and to evaluate the adherence to oral anticoagulants (OAC) and the relation to emotional status
Methods: This is a cross-sectional study of patients visiting the Thrombosis Service of the Maastricht University Medical Center in The Netherlands between December 2012 and January 2013. Patients were invited to complete an anonymous questionnaire including questions on: patient characteristics, indication for anticoagulant treatment, comorbidity, medication adherence and emotional status. Medication adherence was measured by application of a self-assessed Dutch version of the Morisky Medication Adherence Scale (MAMS-8); emotional status was measured with the Dutch self reported depression (CES-D) scale. Completed questionnaires from patients ≥18 years old, treated with OAC therapy for at least 2 months were included in the analysis. Self-reported adherence rates were classified into three categories: low, medium and high adherence. Descriptive statistics were performed with SPSS 19.0.
Results: In this study 316 questionnaires were retrieved, of which 275 were included in the analysis. The mean age of the patients in this cohort was 69.5 years (range 18–89 years), 48.7% of patients was ≥70 years old. 38.2% of the patients were female, 57.1% male. Education level of patients was similar to that of the Dutch population; 22.9% had an elementary education, 65.6% tertiary or higher and 11.5% a university education. The most common clinical indications for OAC use were atrial fibrillation (45.9%), the presence of artificial heart valves (20.4%) and myocardial infarction (19.7%). Most patients reported on comorbidities of which cardiovascular diseases (61.1%), hypertension (60.7%), hypercholesterolemia (46.9%) or diabetes (16.7%) were common. Self-reported adherence rates were categorized as low in 8%, medium in 80% and high in 12% of patients. No correlation was found between depressive symptoms and medication adherence ($r = -0.175$).
Conclusions: In contrast to reported adherence rates in literature, 92% of patients had medium or high adherence. This could be due to the positive effect of structured care with regular visits and treatment monitoring, but this may also be suggestive for reporting bias. The levels of adherence were found not to be significantly associated with any of the patient characteristics. The emotional status as measured by the CES-D scale, did not influence the adherence rate in this sample. Further studies are needed to identify risk factors for non-adherence and further explore the effect of structured care.

PB 3.46-6

Rivaroxaban superior to Nadroparin for thromboprophylaxis in patients receiving hip or knee arthroplasty

Heckmann MB[1], Hillebrand I[2], Silay H[2], Thermann H[3], Siebold R[3], Klonz A[3], Gruber G[3], Scheller G[3] and Heckmann F[2]

[1]Zentrum für Gefäßerkrankungen und Präventivmedizin, Atosklinik; [2]Zentrum für Gefäßerkrankungen und Präventivmedizin, Atos Klinik; [3]Atos Klinik Heidelberg, Heidelberg, Germany

Background: Deep-vein thrombosis (DVT) and subsequent pulmonary embolism (PE) are major complications in total joint arthroplasty of the lower limbs. Low molecular weight (LMW) heparins have been the gold standard for prophylactic treatment. In this regard, however, studies on the usage of new oral anticoagulants and especially rivaroxaban have shown promising results. Nonetheless, very few independent studies have been published and practically no study investigated the usage under normal clinical conditions.
Aims: Aim of this study was to evaluate the efficacy of rivaroxaban vs. nadroparin for thromboprophylaxis in patients receiving either total hip or total knee arthroplasty in an 'every day life' clinical setting.
Methods: In a mono-centric non-randomized controlled study performed from 2007 until 2013, Patients receiving hip or knee arthro-

plasty were administered nadroparin body-weight adapted 5700–7600 I.E. subcutaneously, beginning during surgery, or oral rivaroxaban 10 mg daily, starting 8 h after surgery. Anticoagulation was continued for 35 days. Mobilization was initialized the first day after surgery. All patients were screened for DVT or muscle-vein thrombosis (MVT) using bilateral compression sonography combined with color doppler sonography between days 5 and 9 after surgery.

Results: DVT or MVT occurred in 13 (6.0%) of 218 patients given nadroparin and in 24 (3.0%) of 810 patients given rivaroxaban representing an absolute risk reduction of 3.0% (95% confidence interval 0.1% to 5.8%, $P < 0.035$) while no significant difference in bleeding was reported by the surgeons.

Conclusions: While overall complications were quite low compared to published data, a daily oral dose of 10 mg rivaroxaban was more effective than a daily weight-adapted subcutaneous dose of nadroparin of 5700–7600 I.E. in preventing DVT, MVT or PE after arthroplasty.

PB 3.47-1

A low fixed dose of Prothrombin Complex Concentrate is cost effective in emergency reversal of vitamin K antagonists

Khorsand N[1], Giepmans L[2], Meijer K[2], Van Hest R[3] and Veeger N[2]

[1]UMCG, Den Haag; [2]University Medical Center Groningen, Groningen; [3]Academic Medical Center, Amsterdam, The Netherlands

Background: Prothrombin Complex Concentrates (PCC) are commonly recommended for treatment of major vitamin K antagonist (VKA) associated bleeds. While their efficacy and safety have been well studied, a well defined dosing strategy is still lacking.

Recently, we studied the effectiveness of a low fixed PCC dose regimen of 1040 IU F IX compared to the commonly applied variable PCC dosing strategy based on body weight, baseline INR and target INR in a prospective, two-cohort design. This study showed that the low fixed dose of PCC was non-inferior to the variable dose in terms of clinical outcome. In reaching the target INR, defined as INR <2, the fixed PCC dose was non-inferior in patients with a baseline INR below 7.5. An important question from both a clinical and costing point of view is whether additional interventions were needed in the fixed dose cohort to reach the non-inferior outcome as observed in our study.

Aims: In the present study we assessed the cost-effectiveness of a low fixed PCC dose strategy of 1040 IU IX vs. the variable PCC dosing strategy.

Methods: A decision tree model was used in which target INR and clinical outcome were taken into account. Clinical outcome and resource utilization were obtained from our prospective, non-inferiority study in patients admitted through the emergency room. Only direct medical costs that were made during hospitalization were included. Analyses included Monte Carlo simulations and base-case analysis to assess the mean treatment costs, as well as costs per successfully treated patient (mean costs per patient/probability to obtain a patient with INR decrease below the target INR and a positive clinical outcome).

Results: The mean treatment costs were €5774 (Sd 294) for the fixed dose ($N = 59$) and €7408 (Sd 365) for the variable dose strategy ($N = 78$). PCC costs accounted for 13% and 17% of the treatment costs in the fixed dose and the variable dose cohorts, respectively.

In the majority of patients target INR was reached with a positive clinical outcome (N fixed dose: 50/59, N variable dose: 64/78). Costs per successfully treated patient were €6929 (Sd 352) and €9029 (Sd 445), for the fixed dose and variable PCC dose strategy, respectively ($P < 0.001$). Sensitivity analyses confirmed the robustness of these findings.

Conclusions: Our cost analyses showed that a cost reduction in PCC with a low fixed dose strategy did not coincide with a cost increase due to utilization of other treatment options for VKA associated bleedings. Furthermore, by treatment of these bleeding emergencies with a low fixed PCC dose strategy, on average €1634 per patient to €2100 per successfully treated patient was saved compared to a variable dosing strategy.

Taking into account the effectiveness of the low fixed dose of PCC in our previous study, we conclude that a low fixed dose of 1040 IU IX PCC is more cost-effective in emergency reversal of VKA than a higher variable dosing strategy.

PB 3.47-2

Interaction of metformin with the vitamin K antagonist phenprocoumon

Wijnen J, Van De Riet I, Lijfering WM and Van Der Meer F

LUMC, Leiden, The Netherlands

Background: Anticoagulant therapy with vitamin K antagonists (VKA) like warfarin, phenprocoumon and acenocoumarol is hampered by the interaction of the VKA with a great number of other drugs. Metformin is generally not considered as an interacting drug. We observed however a number of patients using VKA with a decreased INR after starting metformin. Therefore we performed this study to systematically investigate the influence of metformin on phenprocoumon, the VKA mostly used in our anticoagulation clinic.

Aims: In this cohort study we investigated the influence of metformin on the dosage of phenprocoumon in stable anticoagulated patients.

Methods: All patients of the Anticoagulation Clinic Leiden using phenprocoumon and metformin in the period January-March 2009 were screened. Patients starting metformin within this period and continuing metformin for at least 2 months were included. The first delivery date of metformin was checked with the pharmacist. Patients were excluded when they started another drug that is known to interfere with phenprocoumon or when they were having medical interventions requiring adjustment of the anticoagulation treatment during the observation period. We compared the average daily dosage of phenprocoumon in mg and the INR at three specific moments: before, 6 weeks after and 3 months after the start of metformin. In addition the number of patients having an INR below the therapeutic range was compared at these three moments. Statistics were performed using a paired t-test and a McNemar's test.

Results: 369 Patients were using metformin next to phenprocoumon within the observation period. Of these, 27 started metformin within this period and met the inclusion criteria.

The average phenprocoumon dosage increased from 2.13 mg/day before the start of metformin to 2.37 mg/day at 6 weeks (mean increase 0.23 mg, 95% CI: 0.12–0.34) and 2.49 mg/day at 3 months (mean increase 0.36 mg, 95% CI: 0.24–0.48).

The average INR decreased from 2.88 before the start of metformin to 2.26 (mean decrease 0.63, 95% CI 0.41–0.85) at 6 weeks and 2.54 (mean decrease 0.35, 95% CI 0.24–0.48) at 3 months after the start of metformin.

One patient had an INR below the therapeutic range before the start of metformin which increased to 10 patients (OR 10, $P = 0.0004$) at 6 weeks and two patients (OR 2, $P = 1.0$) at 3 months after the start of metformin.

Conclusions: Starting with metformin in patients using phenprocoumon resulted in a significant increase of the mean daily dosage of phenprocoumon. Despite the increased dosage of phenprocoumon, mean INR-values decreased in nearly 40% (10/27) of patients below the therapeutic range.

Therefore, clinicians should be aware that the dosage of phenprocoumon should be increased once metformin is started. Further research is necessary to investigate whether warfarin and acenocoumarol are also influenced by metformin. With the increasing prevalence of diabetes and the increasing popularity of metformin in the treatment of dia-

betes the combination of metformin with VKA will be encountered much more frequently in the future.

PB 3.47-3

Inhibition kinetics of plasma-derived and recombinant activated protein C in human plasma

Müller J, Zimmermann J, Kupper T, Oldenburg J and Pötzsch B
University of Bonn Medical Center, Bonn, Germany

Background: The half-life of plasma activated protein C (APC) and its regulation and functional manipulation are important basic information for both, APC assay development and estimation of APC-mediated *in vivo* effects. To date, however, detailed information on the impact of heparins, APC-targeting ligands, and plasma levels of Protein S on APC half-life are lacking.
Aims: The aim of this study was to assess the impact of heparins of different molecular weights, APC-targeting DNA-aptamers, and protein S (PS) levels on the inhibition kinetics of recombinant (rAPC) and plasma-derived APC (pAPC) in plasma.
Methods: The half-life of plasma APC in the absence or presence of the different agents was determined using exogenously added or previously immobilized APC. Reactions were stopped at different time points using aprotinin that targets the active site of APC. Levels of residual free APC in the samples were measured using a recently described oligonucleotide-based enzyme capture assay (J Thromb Haemost. 2012; 10: 390–8). Inhibition kinetics were monitored by either loss of APC amidolytic activity or formation of APC-PCI-complexes over time.
Results: Recombinant and pAPC showed no significant differences in inhibition patterns or corresponding formation of APC-PCI-complexes. The presence of negatively charged molecules like heparins or DNA-aptamers enhanced the inhibition of APC in a size- and concentration-dependent manner. Interestingly, the pentasaccharide fondaparinux (Arixtra®) showed no influence of APC inhibition patterns, even at highest concentrations. In the presence of molecules that accelerate APC-inhibition, addition of aprotinin still proved to be reliable for the prevention of further inactivation of plasma APC, being an important information with respect to the development of aptamer-based assays for plasma APC measurements. In contrast to heparin or aptamers, plasma concentrations of PS showed no consistent effect on APC inhibition patterns.
Summary/Conclusions: The inhibition of plasma APC was found to be accelerated by negatively charged molecules that target the basic exosite of APC. This effect depends on size and concentration of these molecules. Plasma concentrations of Protein S did not correlate with APC half life times, indicating, if at all, only a minor effect of PS on serpin-mediated inactivation of APC. The results shown here mainly question the implications of low and high-molecular weight heparins on APC functional activity *in vivo*.

PB 3.47-4

The clinically relevant interaction of warfarin and capecitabine

Kessler P, Poul H and Harudova M
Hospital Pelhrimov, Pelhrimov, Czech Republic

Background: Capecitabine is an orally administered prodrug of 5-fluorouracil and is frequently used in patients with metastatic colorectal or breast cancer. The stability of anticoagulation in patients with metastatic cancer undergoing chemotherapy is often poor. The elevation of INR in patients treated simultaneously with warfarin and capecitabine has been repeatedly reported, and inhibition of S-warfarin biodegradation during capecitabine therapy has been described.
Aims of the study: (i) To determine the average daily warfarin dose and the average interval between INRs before, during and after concomitant capecitabine therapy. (ii) To detect the differences in percentage of time in therapeutic INR range (TTR) before, during and after capecitabine therapy. (iii) To detect the differences in percentage of time above therapeutic range.
Patients: Ten consecutive patients (six men and four women) treated with warfarin, in which capecitabine therapy was administered.
Methods: The patients were prospectively followed before, during, and after capecitabine therapy, the dose of warfarin was adjusted according to the INR. The average daily dose of warfarin, average interval between INRs, percentage of TTR and percentage of time above therapeutic range before, during, and after capecitabine therapy was calculated.
Results: The average daily dose of warfarin before, during and after capecitabine therapy was 4.62 (2.63–8.5) mg, 2.56 (1.03–4.31) mg and 3.76 (1.4–7.2) mg, respectively. The average warfarin dose during capecitabine therapy was significantly lower, than before capecitabine ($P = 0.003$), the average warfarin dose after capecitabine therapy was higher, than during capecitabine therapy, the difference was not significant ($P = 0.06$). The average daily warfarin dose was reduced after initiation of capecitabine therapy by 39.7 (15.0–72.3)%. The average interval between INRs before, during, and after capecitabine therapy was 11.10 (5.17–25) days, 8.41 (5.53–10.9) days, and 11.19 (7.3–13.5) days, respectively. The interval after capecitabine therapy was significantly longer, than the interval during capecitabine therapy ($P = 0.024$), the difference of intervals before and during capecitabine therapy was not significant ($P = 0.138$). The percentage of TTR before, during, and after capecitabine therapy was 78.2% (95% CI 69.4–87.1%), 56.6% (95% CI 40.8–72.4%), and 71.4% (95% CI 52.8–90.0%), respectively. The percentage of TTR was significantly higher before capecitabine treatment than during capecitabine therapy ($P = 0.035$), the difference between percentage of TTR during and after capecitabine therapy was not significant ($P = 0.356$). The percentage of time above therapeutic range before, during, and after capecitabine therapy was 11.3% (95% CI 0.3–19.9%), 33.4% (95% CI 16.4–50.3%), and 2.4% (95% CI 0–5.5%), respectively. The percentage of time above therapeutic range was significantly higher during capecitabine therapy, than before capecitabine therapy ($P = 0.038$), and than after capecitabine therapy ($P = 0.018$).
Conclusion: The capecitabine therapy in patients treated with warfarin results in the enhanced effect of warfarin and increased risk of warfarin overdose and bleeding complications. The stability of anticoagulation is poor during the capecitabine therapy and the frequency of INR monitoring should be increased. When the stability of INR is unachievable, an alternative anticoagulant therapy should be considered.

PB 3.47-5

Prothrombinase induced clotting time (PICT) for the monitoring of new oral anticoagulants

Hoppensteadt D, Walenga JM, Cunanan J, Iqbal O and Fareed J
Loyola University Medical Center, Maywood, USA

The new oral anticoagulants such as Rivaroxaban (Bayer Healthcare) (R) Apixaban (BMS/Pfizer) (A) and Dabigatran (Boehringer Ingleheim) (D) have been approved for Several indications in theUS and Europe. Initially it was suggested that these agents did not require monitoring at the approved dosages for specific indications, however there have been reported bleeding complications with some of these agents that warrants the monitoring of these drugs to optimize therapy in some patient populations. A new clot-based assay, the prothrombinase induced clotting time (PICT) (Pentapharm, Basal, Switzerland) has been developed to monitor the anticoagulant effect of these new oral anticoagulants. In the assay plasma is mixed with FXa, phospholipids, calcium and RVV-V from the venom of the Daboia russelli. The prothrombinase complex formed and the Xa and IIa generated is inhibited by the test agent.

Materials: Citrated blood was drawn from five donors and spun at 800 rpm to obtain platelet rich plasma (PRP). The PRP was removed and spun at 3000 rpm to obtain platelet poor plasma (PPP). The PRP was frozen at −80 °C for 24 h and the PPP and PRP were supplemented with A, R and D in a concentration range of 0–2.5 μg/mL. The plasma samples were analyzed using three PT/INR reagents (Innoven, Dade-Behring, Germany; Recombiplastin, Instrumentation Laboratories, Bedford, MA; Neoplastin, Stago, Parsippany, NJ), two APTT reagents (Platelin, TCoag, Ireland; Actin FSL, Instrumentation Laboratories, Bedford, MA), Heptest and the one stage PICT. All assays were performed on the ACL 300 Plus (, Instrumentation Laboratories, Bedford, MA). The PICT was also run on the ST4 (STago, Parsippany, NJ).
Results: In the PPP system, the A, R and D showed assay differences in the clotting times which demonstrated good sensitivity to D and R compared to A. No individual assay except for PICT demonstrated good sensitivity to all three drugs. In the PT/INR assay, all reagents were sensitive to D and the Innovin and recombiplastin were sensitive to R and showed a weaker response to A. Similar responses were observed in the APTT and Heptest assay. In the PICT, all reagents showed a concentration dependent increase in the PICT test. D was strongest followed by R, and A showed the weakest effect. In the PRP supplemented system, all agents showed a weaker effect on the clotting times in all tests, however PICT demonstrated a concentration dependent response for all agents. Comparable results for the PICT were obtained on both instruments used for the PICT.
Conclusions: These results demonstrated that neither the PT/INR, APTT nor heptest can be solely used to monitor the effects of all of the new oral anticoagulants. The one stage PICT is a simple, fast, automated or semi-automated test which can be performed on any mechanical or optical coagulation analyzer to monitor the anticoagulant effects of these agents. In addition, the one stage PICT can also be used to monitor the effects of these agents in other matrices such as PRP. These studies warrant clinical validation of this test in patients treated with the newer oral anticoagulant drugs.

PB 3.47-6
Ex vivo monitoring of Fenprocoumon reversal by prothrombin complex concentrate using thrombography

Brinkman HJA[1], Herpers R[2], Van Beem RT[3], Mertens K[1], Strengers WF[3], Van Rossum AP[2] and Castel A[2]
[1]Sanquin Research, Amsterdam; [2]Bronovo Hospital, The Hague; [3]Sanquin Plasma Products, Amsterdam, The Netherlands

Background: The vitamin K antagonist (VKA) Fenprocoumon is an oral anticoagulant (OAC) used to treat and prevent thromboembolic diseases. The prothrombin complex concentrate (PCC) is used as an emergency treatment to reverse OAC anticoagulation when excessive bleeding occurs or to prevent patients on OAC treatment from excessive bleeding during surgery. PCC dosing strategies are based on body weight and clotting time INR values, but it is not unusual in clinical practice that more PCC is required than initially calculated.
Aim : The aim of the present study was to assess the added value of thrombography in monitoring patients' haemostatic status and subsequent PCC dosing calculations.
Methods: Blood samples were collected from patients on Fenprocoumon anticoagulation before and within 15–30 min after PCC administration. Venous blood samples were collected into siliconized tubes containing trisodium citrate (0.129 M, 1/9 v/v) and platelet poor plasma was prepared and frozen within 2 h after venipuncture. Plasma samples from hospitalized Fenprocoumon treated patients undergoing surgery and plasma samples from Fenprocoumon treated individuals that presented themselves with bleeding complications were included in the study. Plasma samples were subjected to INR measurements and thrombography (CAT method). The present study was conducted with the approval of the ethical committee of the involved medical institution and plasma samples were included in the study after patients had given their informed consent.
Results: In all patients on Fenprocoumon treatment we observed rapid normalization of both INR and thrombin generation lag time upon PCC addition. However, for the bleeding arrest in a subpopulation of patients more PCC was required. Cumulative dosing revealed a linear relationship between PCC dose and the thrombin generation parameters peak thrombin and area under the curve. Normalization of these parameters as well as bleeding arrest in these patients needed at least twice the amount of PCC as needed for INR and lag time normalization.
Conclusion: These data point towards thrombography as a potential beneficial tool in calculating PCC dosing.

PB 3.48-1
Impact of pre-injury warfarin use on hospital mortality in elderly united states residents with torso trauma

Collins CE, Santry PH, Witkowski ER, Flahive JM and Anderson AF Jr
University of Massachusetts Medical School, Worcester, MA, USA

Background: More than 2 million Americans are started on warfarin annually for indications including atrial fibrillation, venous thromboembolism, peripheral vascular disease, and coronary artery disease, resulting in more than 30 million prescriptions per year. As the US population ages, the elderly are becoming an increasingly large proportion of the trauma population, giving rise to concern about the risk of injury-related bleeding complications due to warfarin. Relatively little is known about the impact of anticoagulation on elderly patients suffering from chest, abdominal, and/or pelvic trauma. These extracranial injuries can be severe and potentially fatal. We studied a cohort of elderly Americans with torso injury to determine the effects of warfarin exposure on outcomes in patients with torso trauma.
Aims: To determine the effect of pre-injury warfarin use on the outcomes of US patients admitted with torso trauma.
Methods: A retrospective review of a 5% random sample of Medicare claims data from 2009 to 2010 was performed for enrollees with at least 1 year of Medicare eligibility. Torso trauma cases were identified using ICD-9 codes for abdomen, chest, or pelvic injuries. Using Part D Prescription drug claims, warfarin exposure was defined as two or more warfarin prescriptions filled in the 60 days prior to injury. Characteristics and outcomes (mortality, length of stay, ICU days) between warfarin patients and patients not on warfarin were compared using univariate tests of association. Multivariable models adjusted for age (10-year increments), concomitant head injury, need for ICU care, co-morbidity index, sex, and race were run to measure the independent effect of warfarin exposure on mortality.
Results: We identified 6820 torso trauma patients, of which 5.7% were treated with warfarin. Patients on warfarin were more likely than non-users to be white non-Hispanic (94% vs. 88%, $P = 0.04$), older (15% vs. 22% for 65–74 years, 42% vs. 37% for 75–84 years, and 44% vs. 41% for >84 years, $P = 0.004$), and have more co-morbidities (57% vs. 55% for Elixhauser index 0, 4.4% vs. 5.4% for Elixhauser index 1, 6.5% vs. 8.4% for Elixhauser index 2, and 33% vs. 32% for Elixhauser index 3 $P = 0.53$). In univariate analyses by age group, mortality rates differed between warfarin patients and those not on warfarin in the oldest age group (>84 years) (10.7% vs. 4.7%, $P = 0.001$). There was no statistically significant effect on hospital length of stay or ICU days between the warfarin patients and those not on warfarin. In multivariable models, all co-variates, except race and co-morbidity index, were independent predictors of mortality. Warfarin exposure increased the odds of death nearly two-fold (odds ratio 1.9, 95% confi-

dence interval 1.3, 2.9) after adjusting for potential confounders, including age.

Conclusion: Anticoagulation with warfarin increases risk of mortality after torso trauma in elderly patients, driven largely by the oldest patients on warfarin, suggesting that physicians should exercise caution when giving chronic anticoagulation to the oldest (>85 years) elderly patients. As newer agents are developed for chemical anticoagulation, such added risks must be considered prior to initiating therapy.

PB 3.48-2

Reversal of anticoagulant effects of apixaban with non-specific prohaemostatic agents: an *in vitro* study

Godier A[1], Martin AC[2], Samama CM[1], Fischer AM[2] and Le Bonniec B[2]

[1]*Hopital Cochin;* [2]*Paris Descartes, Sorbonne Paris Cité, Paris, France*

Background: As a potent anticoagulant agent, apixaban an oral factor Xa inhibitor exposes to a risk of haemorrhagic complications. In the absence of specific antidote, bleeding management is challenging.

Aim: To investigate the efficacy of three prohaemostatic agents, recombinant activated factor VII (rFVIIa), prothrombin complex concentrate (PCC) and activated prothrombin complex concentrate (aPCC) to neutralize, *in vitro*, the anticoagulant effects of apixaban on several laboratory assays.

Methods: Blood samples were collected into 0.105 M sodium citrate from healthy volunteers from the local blood bank (Etablissement Français du Sang, Paris, France). Whole blood (WB) was spiked with apixaban at therapeutic (200 ng/mL) and 3-fold higher concentrations and either rFVIIa (equivalent to 90 and 120 µg/kg), PCC (25 and 50 UI/kg), or aPCC (80 and 160 UI/kg). Reversal was assessed on WB with thromboelastography (ROTEM®, TEM innovation), but also on platelet poor plasma (PPP) using standard laboratory assays (PT, aPTT) and thrombin generation test (TGT). Clot turbidity, as a function of time and measured on a spectrophotometer was added to explore the dynamics of fibrin polymerization[1].

Results: Apixaban concentration-dependently lengthened coagulation times (PT, aPTT, ROTEM® Coagulation Time [CT]). It also increased lag time (LT) and decreased endogenous thrombin potential (ETP) and peak height. On turbidity curves, fibrin polymerization was delayed and slower compared to control suggesting a network made of thinner fibers.

rFVIIa had predominant effects on kinetics parameters. It overcorrected coagulation times (PT, aPTT, CT) at apixaban therapeutic concentration and only partly restored them in overdose situation. It also decreased LT. At therapeutic concentration only, it accelerated fibrin polymerization.

PCC increased peak height and ETP, which was up to 50% higher compared to apixaban alone in therapeutic situation. They shortened PT and CT whereas paradoxically lengthened aPTT. Turbidity curves were not modified.

With aPCC, almost all parameters were improved: PT, aPTT, LT were shortened, thrombin peak was higher, ETP was overcorrected and fibrin polymerization started earlier and was faster compared to apixaban alone suggesting improvement of fiber thickness. Surprisingly, on ROTEM®, CT was never modified.

Conclusions: The non-specific prohaemostatic agents tested, partially or completely corrected several laboratory assays. aPCC was the most seducing one as it improved almost all parameters. Several points need to be discussed: reversal effects of aPCC were not confirmed in WB, increasing concentration of prohaemostatic agents had no additive effect and the putative efficacy was strongly dependent on the observed parameter (rFVIIa best option on CT, PCC on ETP). This underlines the need for a more robust endpoint and for clinical trials.

PB 3.48-3

Determination of dabigatran, rivaroxaban and apixaban using UPLC-MS/MS and comparison with coagulation assays for therapy monitoring

Van De Kerkhof D[1], Schmitz E[2], Boonen K[1], Van Den Heuvel D[1] and Brunsveld L[2]

[1]*Catharina Hospital;* [2]*Eindhoven University of Technology, Eindhoven, The Netherlands*

Background: Over the last several years, novel oral anticoagulants (NOACs) have been developed. Monitoring of these new drugs was postulated to be obsolete, because of improved pharmacokinetics and pharmacodynamics. However, it soon became evident that monitoring can be important for patients having deviating posture, diminished renal function or in emergency (bleeding) situations. Since conventional coagulation assays are not suitable for adequate monitoring, many new coagulation assays have been developed. At this moment, there is no agreement about which assays are preferred for the measurement of NOACs. Additionally, peak and trough concentrations in stable situations have not been unequivocally determined.

Aims: Our goal is the development of a reference UPLC-MS/MS technique for the quantification of dabigatran, rivaroxaban and apixaban, comparison with several coagulation tests and determination of target values for peak and trough plasma concentrations.

Methods: Plasma and full blood were spiked with dabigatran, rivaroxaban and apixaban for calibration and quality control. Labeled internal standards of the NOACs were added, followed by protein precipitation. Analysis was done with UPLC-MS/MS using a two-step Multiple Reaction Monitoring (MRM) monitoring mode. Validation of the method was done by determining specificity, matrix effects, precision, LLOQ, LLOD, carry over, recovery and stability. Several coagulation assays (PICT (Pentapharm), ECA-T (Stago) & Hemoclot (Hyphen) for dabigatran and PICT & STA Liquid anti-Xa (Stago) for apixaban and rivaroxaban) were validated with standard protocols. Target values were determined in an in-clinic orthopedic population and out-clinic cardiologic population. Samples were taken 2, 4 and 12 h after taking the drug to establish peak and trough concentrations. Different coagulation assays were be evaluated for their trueness by comparison with UPLC-MS/MS.

Results: All calibration lines were good ($R^2 > 0.99$) and no significant difference could be seen between plasma and full blood calibration lines. Stability tests showed adequate stability during sample storage and freeze-thaw cycles. Specificity was good and LLOD/LLOQ were <1 ng/mL. Matrix effects and carry over were absent. For dabigatran, rivaroxaban and apixaban, the recovery was respectively 73%, 78% and 104%; bias was respectively 4.6%, 4.17% and 4.9%; total precision was respectively 4.7%, 4.8% and 4.10%. The studied coagulation assays showed adequate reproducibility and bias.

Conclusion: An adequate UPLC-MS/MS method for the measurement of dabigatran, rivaroxaban and apixaban was developed and validated. Target values were determined and compared to different coagulation assays in an in-clinic orthopedic and out-clinic cardiologic patient population.

PB 3.48-4

Measurement of anti-Xa activity of apixaban in plasma

Samama MM[1], Guinet C[1], Le Flem L[1] and Amiral J[2]

[1]*Biomnis Laboratory, Ivry-Sur-Seine Cedex;* [2]*Hyphen BioMed, Neuville Sur Oise, France*

Background: Apixaban is a new oral anticoagulant, a direct reversible Factor Xa (FXa) inhibitor approved in thromboprophylaxis after major orthopaedic surgery and for stroke prevention in patients with non-valvular atrial fibrillation.

Although no coagulation monitoring is required, measurement of apixaban anticoagulant activity may be required in some special clini-

cal settings: emergency surgery, bleeding, thrombosis, reversal with pro-hemostatic drugs, compliance, and suspect co-medication interference.

Aims: Recently it was reported that anti-FXa measurement was preferable to PT and APTT. We have furthered the investigations of the influence of apixaban on anti-FXa activity using two different techniques in order to measure its concentration in plasma.

Methods: Apixaban, kindly provided by Bristol-Myers Squibb (New York), was dissolved according to manufacturer's recommendations. Pooled human platelet poor normal plasma (Cryocheck) was supplemented with apixaban at concentrations covering the expected clinical therapeutic range, from 10 to >600 ng/mL, then assayed with two anti-FXa methods. Measurements were performed in duplicate, with two series a day, on three consecutive days ($N = 12$). Two controls were analyzed in each series: C1 at 300 ng/mL, C2 at 150 ng/mL.

Samples were analyzed with the Rotachrom® assay (Diagnostica Stago, Asnieres, France) and with the Biophen® DiXaI assay (Hyphen Biomed, Neuville-sur-Oise, France), using the STA-R instrument (Diagnostica Stago, Asnières, France).

The DiXaI assay is a specific method for direct FXa inhibitors insensitive to heparin, low molecular weight heparin (LMWH) or fondaparinux. Plasma is assayed diluted at 1:50. The DiXaI assay shows intra-assay ($N = 10$) and inter-assay ($N = 20$) coefficient of variations from <3% to <10%.

Results: Rotachrom, designed for measuring LMWH anti-FXa activity, is not appropriate for apixaban since concentrations >200 ng/mL cannot be determined. A variant technique, using plasma diluted 1:4 (rather than 1:2) and a plasma sample of 20 µL rather than 50 µL gives a linear dose-response curve from about 5–400 ng/mL.

- The DiXaI method gave an inverse linear dose-response relationship for rivaroxaban concentrations from 5 ng/mL to 500 ng/mL, and the same with apixaban. Therapeutic concentrations of heparin, LMWH or fondaparinux are not measured. On six independent series, performed over 3 days, with two series per day, recoveries for the two controls were of 103% for C1 and of 101% for C2, and inter-assay CVs <5%.

Summary/Conclusions: Clinicians must be aware that PT and APTT can be normal in apixaban treated patients with a significant hypocoagulant activity. Measurement of anti-FXa activity is preferable when clinically indicated. Our results are in agreement with a recent work showing that the anti-FXa measurement is preferable for the measurement of direct FXa inhibitors. Moreover, a specific anti-FXa assay (DiXaI), insensitive to heparins or fondaparinux, is useful in patients switching from heparin therapy to apixaban. Standardization of the anti-FXa measurement of apixaban is in progress by a working group of the ISTH.

PB 3.48-5

Patient outcomes with anticoagulation therapy after hip and knee replacement: comparison of two models of care

Bathija S[1], Walton SM[2], Lau DT[3], Galanter WL[2], Schumock GT[2] and Nutescu E,[2]

[1]United States, Chicago, IL; [2]University of Illinois at Chicago, Chicago, IL; [3]Centers for Disease Control and Prevention, MD, USA

Background: Warfarin is commonly used for venous thromboembolism (VTE) prophylaxis of patients undergoing hip and knee replacement surgery. Management of patients on warfarin therapy has been a challenge, especially in inception phases of therapy. Pharmacist-managed anticoagulation clinics have been reported to attain better anticoagulation control compared to routine medical care (RMC). However, the two models of care have not been compared for patients receiving post-surgery VTE prophylaxis which requires short-term therapy.

Aim: To compare quality of anticoagulation control between specialized care (pharmacist-managed antithrombosis clinic [ATC]) and RMC (orthopedic clinic) in an inception cohort receiving short-term post-surgery VTE prophylaxis with warfarin.

Methods: We conducted a retrospective, observational study of patients who underwent total hip or total knee replacement surgery at University of Illinois Hospital and Health Sciences System between the years 2000 and 2009, and were referred to either the ATC or RMC for post-surgical anticoagulation prophylaxis. Means for continuous variables were compared by using *t*-tests and frequencies for categorical variables were compared by using chi-squared tests. Propensity scores were used to adjust for potential confounding on observable risk factors. Propensity score was defined as the predicted probability of being managed by ATC compared to RMC. The average treatment effect (ATE) and average treatment effect for treated (ATT) for ATC compared to RMC was expressed as the% change in anticoagulation control (expressed as the time in therapeutic international normalized ratio range [TTR]) using inverse probability weighting and regression adjustment.

Results: A total of 873 patients were included in the study cohort, of which 294 were referred to ATC and 579 to RMC. The average age of the study cohort was 60 ± 12.3 years, and 68% were female. The majority of patients was African Americans (53.8%), followed by Caucasians (19.7%), followed by Hispanics (19.6%) and other race (6.9%). Before applying the propensity score method, several covariates were imbalanced between the two groups. For example, the average length of warfarin therapy (46.7 ± 20.3 vs. 31.9 ± 10.7; $P < 0.05$) and inpatient length of stay in days (7.0 ± 4.6 vs. 6.3 ± 3.3; $P < 0.05$) were significantly higher in ATC compared to RMC. After balancing the groups using inverse probability weighting and performing regression adjustment, TTR remained significantly higher in ATC compared to RMC via both ATE (7.1% higher in ATC vs. RMC, $P < 0.001$) and ATT (9.08% higher in ATC vs. RMC, $P < 0.001$).

Summary: Patients managed in the specialized pharmacists-led ATC had better anticoagulation control compared to routine medical care. Our study is among the first to evaluate and show benefit of a specialized systematic anticoagulation management model on quality of anticoagulation in an inception cohort receiving short-term post-surgery thromboprophylaxis.

PB 3.48-6

Psychological influence of the media on patients commencing oral anticoagulation in atrial fibrillation; a qualitative analysis

Borg Xuereb C[1], Shaw RL[1], Lip GYH[2] and Lane DA[2]

[1]School of Life and Health Sciences, Aston University; [2]University of Birmingham Centre for Cardiovascular Sciences, City Hospital, Birmingham, UK

Background: Oral anticoagulation (OAC) reduces stroke risk in patients with atrial fibrillation (AF); however it is still underutilized and sometimes refused by patients. Two inter-related studies were undertaken to understand the experiences and what influences this underutilisation of warfarin treatment in AF patients. These studies explored physician and patient experiences of AF and OAC treatment. The paper focuses on specific sub-themes from the study that explored patients' experiences will be discussed.

Aim: The study in question aimed to explore the experiences which influence patients' decisions to accept, decline or discontinue OAC.

Methods: Semi-structured individual interviews with patients were conducted. Three sub-groups of patients ($n = 11$) diagnosed with AF were interviewed; those who accepted, refused, and who discontinued warfarin. Interpretative phenomenological analysis (IPA) was used to examine the data. IPA is a qualitative method that focuses on how participants make sense of an experiences phenomenon.

Results: Three over-arching themes comprised patients' experiences: (i) the initial consultation, (ii) life after the consultation, and (iii) patients' reflections. In the last theme, patients reflected on their perceptions of aspirin and warfarin. Aspirin was perceived as a natural wonder-drug while warfarin was perceived as a dangerous drug usually given to people at the end of their life. Interestingly they perceive both drugs as 'old'. However, for aspirin it had a positive association, old meaning tried and tested. While for warfarin, old meant 'has been around for too long'.

Conclusion: Media had an important role in how patients' perceptions of these two drugs were influenced. Literature shows that framing techniques, i.e. using certain words or phrases such as 'rat poison', are processes adopted by media to alter medical knowledge into lay person's language. Patients in turn form negative cognitive schemas, between the word 'poison' and warfarin, leading to the negative perception of warfarin which could influence non-adherence to treatment. This qualitative research highlighted the potential influences of the media on AF patient perceptions commencing OAC treatment. The association between media stimuli and patient perceptions on OAC should be further explored. The influential power of lay-media could also be instrumental in disseminating appropriate educational material to the public.

PB 3.49-1

The activity of GlycoPEGylated recombinant FIX (N9-GP) can be measured in two-stage chromogenic and one-stage clotting assays

Holm PK, Sørensen MH, Hermit BM and Ezban M

Novo Nordisk A/S, Maaloev, Denmark

Introduction: N9-GP is a 40K glycoPEGylated recombinant human FIX derivative. The PEG group is selectively attached to an N-linked glycan in the activation peptide of recombinant FIX (N9), which upon activation is released and generates activated FIX (FIXa) similar to native FIXa [1]. In haemophilia B patients the half-life of N9-GP is 93 h which is approximately five-fold prolonged compared to BeneFIX® and MonoNine® [2].

The aim of this study is to evaluate the performance of N9-GP relative to non-PEGylated rFIX in two-stage chromogenic and one-stage clot assays.

Method: Different FIX preparations (N9-GP, N9, MonoNine® and BeneFIX®) were spiked into Haemophilia B plasma and tested in two different two-stage FIX chromogenic assays (Biophen® and Rossix®) using the WHO FIX international standard. The same FIX preparations were analysed in the FIX one stage clotting assay with different aPTT reagents using the WHO FIX international standard and a N9-GP standard. The N9-GP standard was calibrated against the WHO FIX international standard using SynthAFax® as the APTT reagent.

Results: The activity of N9-GP, N9, MonoNine® and BeneFIX® was comparable when spiked into Haemophilia B plasma and measured in the two different two-stage chromogenic assays calibrated against WHOFIX international standard. The PEG group of N9-GP does not appear to interfere with the reagents in the chromogenic assays.

APTT reagents SynthAFax®, Cephascreen® and DAPPTIN® provided full recovery of N9-GP activity (100% ± 25%) in the one-stage clotting assay using the WHO FIX international standard. Some reagents resulted in activity below 75% and other reagents resulted in values above 125% when calibrated against WHO FIX international standard. In general, aPTT reagents containing ellagic acid provided activities within target range (100% ± 25%), whereas reagents containing silica gave values above target, indicating some interaction of the silica based material with the PEG group of N9-GP. Full recovery was achieved for all APTT reagents when using the N9-GP standard.

Conclusion: As for MonoNine® and BeneFIX®, the activity of GlycoPEGylated recombinant FIX (N9-GP) can be reliably measured in two-stage chromogenic and one-stage clotting assays using ellagic acid based APTT reagents against the WHOFIX international standard. Other APTT reagents provided either too low or too high activity, probably because of interaction with the PEG group of N9-GP. The reagent specific variations can be normalised by introduction of an assay specific conversion factor or by using a N9-GP standard. The data illustrate the need for evaluating performance of new FIX products in various activity assays using different reagents.

PB 3.49-2

Comparative field study evaluating the activity of recombinant Factor IX – Fc fusion protein (rFIXFc) in plasma samples at clinical haemostasis laboratories

Sommer J[1], Buyue Y[1], Peters RT[1], Jiang H[1], Gray E[2] and Pierce GF[1]

[1]Biogen Idec Hemophilia, Waltham, MA, USA; [2]NIBSC, South Mimms, Potters Bar, UK

Background: The recombinant coagulation factor IX Fc fusion protein (rFIXFc) consists of a single molecule of human factor IX (FIX) covalently linked to the dimeric Fc domain of human immunoglobulin G1 (IgG_1). rFIXFc utilizes the FcRn receptor-mediated immunoglobulin cycling pathway to extend its plasma half-life. The rFIXFc product was studied in a global, multi-center, Phase 3 clinical study (B-LONG) with prophylactic dosing intervals ranging from 7 to 21 days.

Aims: To evaluate the performance of commercially available one-stage clotting assay reagents used at clinical laboratories for monitoring of rFIXFc activity in patients, we conducted a field study to assess the accuracy and inter-lab variability in measuring rFIXFc activity in spiked plasma samples at 30 clinical haemostasis laboratories.

Methods: Human hemophilic donor plasma was spiked with either rFIXFc or a rFIX comparator product at 80, 20 or 5 IU/dL based on the label potency. Laboratories were blinded with respect to the drug product and concentration in each vial and were asked to test three sets of samples on different occasions using their routine one-stage clotting assay and in-house FIX plasma standard. The results were evaluated for accuracy, intra- and inter-laboratory variation, and possible product-specific assay discrepancies.

Results: The median spike recovery for rFIXFc was 68.7 IU/dL, 19.5 IU/dL, and 5.7 IU/dL at the nominal 80, 20 and 5 IU/dL concentrations, respectively, among the 30 laboratories. For rFIX, the corresponding spike recoveries were 97.8 IU/dL, 27.8 IU/dL and 7.9 IU/dL. Intra-laboratory variation was typically below 15% for both products. Among the three major activators used in clotting assays, ellagic acid ($n = 8$ labs) generally resulted in the highest observed activities, with median spike recoveries and inter-laboratory variation (%CV) of 93.3 IU/dL (13%), 28.3 IU/dL (18%) and 8.2 IU/dL (41%) for rFIXFc and 104.5 IU/dL (13%), 31.7 IU/dL (19%) and 8.7 IU/dL (35%) for rFIX at the 80, 20 and 5 IU/dL concentrations, which were well above the nominal concentrations. In comparison, silica ($n = 18$ labs) and kaolin ($n = 3$ labs) typically resulted in lower observed recoveries, with median results of 63.6 IU/dL (24%), 18.0 IU/dL (32%) and 5.3 IU/dL (35%) for rFIXFc and 97.7 IU/dL (13%), 27.6 IU/dL (19%) and 7.7 IU/dL (28%) for rFIX at 80, 20 and 5 IU/dL samples, respectively.

Summary/Conclusions: Our field study revealed a combination of laboratory- and reagent-specific assay variabilities, with progressively higher variability at lower FIX concentrations and non-linearity against the FIX plasma standard observed with both rFIXFc and the comparator (rFIX) product. This lead to consistent over-estimation of FIX activity at the lower levels and overall higher than expected inter-laboratory variability for both products. The differential reagent-dependent effects on rFIXFc and rFIX observed in the field study were

reproducible in side-by-side comparisons at a central laboratory. For both products, the assay results were generally consistent when compared between laboratories using the same reagents and calibrators. The rFIXFc product can be monitored in patients using existing methods and current plasma standards in the majority of haemostasis laboratories with reasonable accuracy and without the need for a product-specific standard.

PB 3.49-3

The effect of different APTT reagents on the potencies of plasma-derived and recombinant factor IX concentrates in one-stage clotting assays

Wilmot HV, Hogwood J and Gray E
NIBSC, Potters Bar, UK

There are several new Factor IX (FIX) therapeutics in development, including recombinant and modified products. Currently, the one-stage clotting assay is employed for potency labelling of all FIX products. Although the current plasma derived International Standard (IS) has served well as a calibrant for licensed FIX concentrates, it is not clear whether it can provide valid potency estimates for the new generation recombinant products. There are suggestions of assay discrepancy related to Activated Partial Thromboplastin Time (APTT) reagents used when these products are assayed against the plasma derived IS. The aim of this study is therefore to evaluate the effects of choice of APTT reagent on the potencies of both plasma-derived (pdFIX) and recombinant (rFIX) concentrates.

Frozen aliquots of pdFIX and two different rFIX (rFIX1 and rFIX2) products were assayed against either the 4th IS FIX Concentrate (07/182) or an in-house rFIX reference (07/142) by the one-stage clotting assay as described by the European Pharmacopoeia, using incubation times as recommended for each of the APTT reagents tested. Several different APTT reagents covering a range of phospholipid sources and activators were used: Actin FS, APTT-SP, SynthAFax, Siron, CK Prest and Cephascreen. Potencies were determined by parallel line assay. Four assays were performed on each material. Data were calculated using combination of potencies and differences were deemed significant at the 5% level by Tukey's analysis of variance.

All assays were statistically valid. Against the 4th IS (07/182), the pdFIX showed no significant differences in potency estimates between APTT reagents (average potency 89 IU/mL, GCV 7.2%). This was not the case for either rFIX. rFIX1 showed significantly higher potencies with Actin FS and APTT-SP (average 125 IU/mL, GCV 0.55%) than with the other four reagents (average 93 IU/mL, GCV 4.8%). rFIX2 behaved similarly, with Actin FS and APTT-SP producing significantly higher potencies than all other APTT reagents (average 97 (GCV 1.14%) vs. 76 (GCV 6.2%) IU/mL). Against the rFIX reference (07/142), the pdFIX showed reasonable agreement in potency estimates between APTT reagents, with some significant differences, particularly with SynthAFax, which generated significantly higher potency estimates than the others (114 IU/mL compared to 84 IU/mL, GCV 12.9%). In contrast, both rFIX materials showed good agreement in potency estimates relative to the rFIX reference, with rFIX1 showing no significant differences between APTT reagents (average 104 IU/mL, GCV 7.1%), and rFIX2 showing only a small difference between SynthAFax and Actin FS ($P = 0.02$).

Different APTT reagents therefore yielded significantly different potencies when rFIX was assayed relative to a pdFIX standard, and vice versa. These differences were reduced when a 'like for like' standard was used. There are many different commercial APTT reagents and several new recombinant or modified FIX products in development that may assay differently to the current IS. The combination of these two factors could result in discrepant potencies between different laboratories. The data presented here suggest that assaying like against like reduces the discrepancy and highlights the importance of choice of standard.

Population pharmacokinetic model for a novel recombinant fusion protein linking coagulation factor IX with albumin (rIX-FP) in hemophilia B patients

Parasrampuria R[1], Easton R[1], Yao Z[1], Bensen-Kennedy D[1], Voigt C[1], Jacobs I[1] and Massimo M[2]
[1]CSL Behring, King of prussia, USA; [2]Azienda Ospedaliero-Universitaria Careggi, Firenze, Italy

Background: rIX-FP is a recombinant fusion protein linking coagulation FIX with human albumin intended for prophylaxis and on-demand treatment of hemophilia B. Results from the first-in-human dose escalation trial have demonstrated improved pharmacokinetics of this product with prolonged half-life. Thus, there is a great interest in evaluating less frequent administration of this product to prevent bleeding.

Objectives: The objective of this analysis was to evaluate pharmacokinetics of rIX-FP by means of population pharmacokinetic (PK) approach.

Methods: A population pharmacokinetic model was built using FIX activity levels from 37 subjects which were measured using a validated 1-stage clotting method after administration of three dose levels of 25, 50 and 75 IU/kg rIX-FP. The influence of potential covariates such as age, body weight, and baseline value was evaluated. Model robustness was assessed using nonparametric bootstrap and visual predictive check approaches.

Results: A two compartment model appropriately described the rIX-FP pharmacokinetics. A covariate analysis identified baseline as influencing the volume of distributions of rIX-FP. The visual predictive check indicated that the final pharmacokinetic model adequately predicted observed concentrations.

Conclusions: The parameter estimates of the population PK model were similar to the estimates from the traditional non-compartmental approach. The selected pharmacokinetic model accurately characterized rIX-FP pharmacokinetics and integrates information across all dose groups. This model was utilized as a tool to simulate various dosage regimens to instruct future clinical trials.

PB 3.49-4

Efficacy and safety of a novel rFIX (BAX326): phase III study in previously treated patients with severe or moderately severe hemophilia B undergoing surgical or other invasive procedures

Windyga J[1], Lissitchkov T[2], Stasyshyn O[3], Mamonov V[4], Ghandehari H[5], Chapman M[5], Fritsch S[5], Pavlova BG[5], Wong WY[5] and Abbuehl BE[5]
[1]Institute of Hematology and Transfusion Medicine, Warsaw, Poland; [2]Specialized Hematological Hospital 'Joan Pavel', Sofia, Bulgaria; [3]Academy of Medical Sciences of Ukraine, Lviv, Ukraine; [4]Hemophilia Research Center RAMS, Moscow, Russian Federation; [5]Baxter BioScience, Westlake Village, CA, USA

Background: Factor IX (FIX) replacement with regular prophylactic infusions has substantial benefits for patients with hemophilia B, a congenital X-linked bleeding disorder associated with a decrease or lack of circulating FIX. BAX326 is a recombinant FIX manufactured with two viral inactivation steps (solvent/detergent treatment and 15 nm nanofiltration) and without addition of any human or animal materials.

Aims: This first prospective clinical trial was conducted to assess the safety and efficacy of BAX326 in previously-treated patients with hemophilia B, 12 to 65 years of age with severe (FIX level <1%) or moderately severe (FIX level ≤2%), as well as to characterize the PK profile of BAX 326 and determine equivalence with comparator rFIX.

Methods: Safety was evaluated by adverse events, clinical and immunological assessments. PK parameters were compared between BAX326 and a commercial rFIX in a crossover design. Hemostatic efficacy after twice weekly prophylaxis with BAX326 was determined in terms of annualized bleeding rate compared with a historical control group treated on-demand. The study was approved by relevant medical ethics committees and informed consent/assent was obtained from each subject prior to enrollment.
Results: BAX326 was equivalent to the comparator rFIX in terms of AUC $_{0–72\ h}$/dose. BAX326 is safe and well tolerated in hemophilia B, with no signs of immunogenicity or thrombotic events. Compared with the annualized bleeding rate (ABR) in the historical control group, there were significantly fewer bleeds in subjects who received twice weekly prophylaxis with BAX326 over at least 3 months during the present study with a bleed reduction of 79%. Joint bleeds (major joints: wrist, elbow, shoulder, hip, knee, ankle) occurred at a mean ABR of 2.85 (4.25) compared with 1.41 (2.87) in non-joint bleed sites. Of the 32/56 subjects with bleeds, 90.6% (29/32) had arthropathy at screening and only 28.1% (9/21) did not have target joints, as compared to subjects without bleeds, of whom 79.2% (19/24) had arthropathy and 50% (12/24) did not have target joints at screening. The ABRs by bleeding site (i.e., joint vs. non-joint) and cause were further analyzed by subjects with (N = 46) and without arthropathy (N = 8), as well as with target joint (N = 35) and without (N = 21). Higher mean ABRs were observed in subjects with arthropathy vs. without arthropathy (4.54 vs. 2.57 for all bleeds, 3.16 vs. 1.02 for joint bleeds, and 1.97 vs. 0.25 for spontaneous bleeds). A similar pattern was observed for the ABRs of joint bleeds and spontaneous bleeds in subjects with target joints (N = 35) (mean ABR: 2.41 ± 3.79) and those with no target joints (mean ABR: 0.58 ± 1.63). Most bleeds, irrespective of location, cause, or baseline status, were controlled with 1–2 infusions of BAX326 and with an efficacy rating of 'excellent.'
Summary: BAX326 has a positive safety profile and is efficacious in treating bleeds and in routine prophylaxis in PTPs aged ≥12 years with hemophilia B. The results also demonstrate that subjects with target joints and hemophilic arthropathy receiving secondary prophylaxis tend to have higher ABRs as compared to those without these underlying conditions.

PB 3.49.6

Prospective study of a novel recombinant factor IX in previously treated patients with hemophilia B

Windyga J[1], Lissitchkov T[2], Stasyshyn O[3], Mamonov V[4], Oh M-S[5], Chapman M[5], Pavlova BG[5], Wong WY[5] and Abbuehl BE[5]

[1]Institute of Hematology and Transfusion Medicine, Warsaw, Poland; [2]Specialized Hematological Hospital 'Joan Pavel', Sofia, Bulgaria; [3]Academy of Medical Sciences of Ukraine, Lviv, Ukraine; [4]Hemophilia Research Center RAMS, Moscow, Russian Federation; [5]Baxter BioScience, Westlake Village, CA, USA

Background: Factor IX (FIX) replacement with regular prophylactic infusions has substantial benefits for patients with hemophilia B, a congenital X-linked bleeding disorder associated with a decrease or lack of circulating FIX. Summary: BAX326 has a positive safety profile and is efficacious in treating bleeds and in routine prophylaxis in PTPs aged ≥12 years with hemophilia B. The results also demonstrate that subjects with target joints and hemophilic arthropathy receiving secondary prophylaxis tend to have higher ABRs as compared to those without these underlying conditions.

PB 3.50-1

Tyrosine phosphorylation of macrophage factor XIII-A: a potential mechanism for controlling intracellular enzyme activation and localization

Cordell PA, Smith K, Pease RJ and Grant PJ

University of Leeds, Leeds, UK

Background: In addition to the plasma, coagulation factor XIII A-subunit (FXIII-A) is present in hematopoietic cells including macrophages. Both plasma and macrophage pools have been implicated in cardiovascular repair processes but the mode of action of the macrophage enzyme is uncertain. Cross-linking of intracellular proteins by FXIII-A has been reported and it has been proposed that secretion of the enzyme from macrophages could occur to cross-link the extracellular matrix. However the mechanisms mediating intracellular FXIII-A activation and secretion remain unclear. Unlike in plasma, cellular FXIII-A is not activated by proteolysis and the calcium concentration required for activation *in vitro* is supra-physiological. Further, FXIII-A lacks an ER-Golgi leader sequence and little evidence exists for secretion from macrophages.
Aims: To gain insight into the function of macrophage FXIII-A we examined for enzyme secretion and activation under a range of conditions. We also investigated whether post-translational modification of FXIII-A could regulate these processes.
Methods: Human macrophages were generated from $CD14^+$ monocytes by culture for 6d in the presence of M-CSF. Murine macrophages were generated by bone marrow culture with CSF-1 for 7d. FXIII-A was measured in lysates and medium by immunoprecipitation/immunoblotting. Cell-surface proteins were labelled on live unpermeabilized cells at 4 °C and cells were imaged by confocal microscopy.

Transglutaminase activity was assayed by incorporation of dansylcadaverine into cellular proteins. Tyrosine phosphorylated FXIII-A was detected by immunoprecipitation using anti FXIII-A antibody followed by immunoblitting with anti pan-phosphotyrosine antibody. Proximity ligation assays also utilized this antibody combination and were performed using commercially available reagents

Results: No cell-surface or secreted FXIII-A was detected from resting or activated macrophages. However, protein cross-linking was detected upon PMA treatment and cross-linking also occurred in $TG2^{-/-}$ macrophages. Tyrosine phosphorylation of FXIII-A in transformed cells has been reported so we investigated this modification in macrophages. Immunoprecipitation/immunoblotting showed FXIII-A tyrosine phosphorylation in these cells but not in plasma or in platelets. Proximity ligation assays confirmed tyrosine phosphorylation and showed accumulation in the perinuclear region. An increase in phosphorylation was detected upon PMA treatment and both phosphorylation and cross-linking greatly increased when cells were preincubated with orthovanadate.

Summary/Conclusions: We have demonstrated that FXIII-A can be tyrosine phosphorylated in macrophages and that phosphorylation is increased by the protein kinase c activator PMA. We have also shown that PMA induces intracellular protein cross-linking in wild-type and in $TG2^{-/-}$ cells, strongly implicating FXIII-A in this process and suggesting a link between FXIII-A phosphorylation and enzyme activation. Elevation of tyrosine phosphorylation and intracellular cross-linking by orthovanadate treatment provides further evidence for this link. We therefore propose that macrophage FXIII-A could mediate reparative processes by cross-linking of intracellular proteins upon activation by phosphorylation leading to alteration of cell function. Potential substrates include the cytoskeletal proteins actin, vinculin and tubulin and the cell surface receptor AT1. Cross-linking of these or related substrates could modulate macrophage adhesion/migration, phagocytosis and intracellular signalling.

PB 3.50-2

Biochemical and numerical simulation of thrombin decay

Kremers RMW[1], Crépin L[2], Kerdélo S[3], Wagenvoord R[1] and Hemker CH[1]

[1]CARIM, Maastricht University, Maastricht, The Netherlands; [2]European University of Brittany, Brest, France; [3]Diagnostica Stago, Gennevilliers, France

Background: Human plasma contains various thrombin inhibitors such as antithrombin (AT), α2Macroglobulin (α2M) and a group of miscellaneous serpins. Thrombin decay during thrombin generation (TG) is predominantly caused by AT (~65%) and α2M (~25%) with a small role for the other inhibitors. Thrombin decay is slowed down in the presence of fibrin(ogen), because fibrinogen contains thrombin binding sites, which compete with thrombin inhibitors for thrombin binding. Mathematical simulation models of TG at present do not take into account the interaction of thrombin with α2M or fibrin (ogen).

Aims: As a first step in a larger project in which we aim to arrive at congruence between mathematically simulated and experimentally obtained TG curves, we want to obtain a quantitatively correct description of thrombin decay in plasma.

Methods: The AT and α2M concentrations were determined in the control normal pool plasma (NPP) and a biochemical model was prepared, which consisted of purified human AT and α2M in Ringer buffer containing albumin and citrate. Thrombin decay was determined in this model system and in non-recalcified defibrinated NPP by the addition of purified human thrombin and the subsequent measurement of the disappearance of thrombin activity in time. Thrombin decay was measured in absence and the presence of various concentrations of fibrinogen.

The AT dependent decay was described as a bimolecular reaction (k_1) and the α2M and remaining thrombin inhibitor dependent decay as pseudo-monomolecular reactions (k_2 and k_3). Thus, a simple mathematical model for thrombin decay was obtained using ordinary differential equations.

$-dT/dt = k_1*AT_t*T_t + k_2*T_t + k_3*T_t$ and $d(\alpha2MT)/dt = k_2*T_t$

Results: The biochemical model consisting of AT and α2M (1.94 mM and 3.03 mM, respectively, as measured in NPP) could satisfyingly mimic total thrombin decay in plasma (1.122 and 1.168 μM/min, respectively), whereas thrombin decay in a biochemical model consisting of AT alone could not (0.961 μM/min, $P < 0.001$). The rate of thrombin decay by α2M was the same in defibrinated NPP and the biochemical model (0.21 μM/min). For each condition, a satisfying fit could be obtained between the biochemical model, the numerical model and defibrinated NPP.

The addition of fibrinogen (3 mg/mL) reduced the velocity of total thrombin decay in the biochemical model system (16%, $P = 0.004$) as well as in plasma (37%, $P = 0.010$). This was primarily due to its effect on thrombin decay by α2M (53%, $P = 0.004$; 43%, $P = 0.011$, respectively). In the biochemical system, the presence of fibrinogen primarily affects thrombin decay by α2M (fibrinogen reduced k_2 by 70%; $P = 0.004$) more than thrombin decay by AT (k_1 was 10% reduced; $P = 0.065$).

Conclusions: Our results suggest that in addition to AT, both α2M and fibrinogen are of great importance in the biochemical simulation of thrombin decay and are therefore indispensable in any representative model of thrombin generation.

PB 3.50-3

Hemostatic status pre – post intracoronary injection of peripheral blood stem cells in patients with recent myocardial infarction

Cosphiadi I[1], Santoso T[1], Kosasih A[2], Atmakusumah D[1], Lyana S[2], Abdulmuthalib A[1], Harryanto R[1], Auda A[2], Alwi I[1] and Sudoyo AW[1]

[1]RSCM; [2]Darmais National Cancer Center, Jakarta, Indonesia

Background: Cardiovascular disease has increased in the last half century, it is becoming one of the major cause of morbidity in all hospital admission. Myocardial infarction (MI) constitutes half of all coronary heart disease cases. Current guidelines emphasize early coronary reperfusion on acute myocardial infarction (AMI) to alleviates mortality rates. However these conventional therapy sometimes cannot reverse the damage to infarcted myocardium. Even with timely executed rapid reperfusion, there are still patients with AMI surviving with significant LV dysfunction.

On the other hand patients undergoing PCI procedure are at risk for further ischemic events not only because procedure-related platelet activation occurs, but also due to the persistent platelet hyperreactivity and enchanced thrombin generation associated with ACS. This hypercoagulable state, in addition to vascular injury and platelet activation from PCI may lead to abrupt vessel closure, restenosis, and subacute stent thrombosis. It is not known how the acute coronary thrombosis alter the kinetics of the systemic coagulation system.

In the recent researches, Stem cell therapy has been highlighted as new therapy for patient population at risk for heart failure. Meta-analysis showed safety and favorable effects of stem cell transplantation in patients with AMI. In our latest research we successfully demonstrate the effect of injecting Peripheral Blood Stem Cells (PBSCs) in improving cardiac functions in patients with ST-segment elevation AMI. Intercorrelation between arterial and venous thrombosis risk factor 'vice versa' have not been established yet.

Aims: The purpose of this study is to report hemostatic parameter changes, such as *platelet aggregation, blood and plasma viscosity*, prothrombin time, APTT, CRP and fibrinogen, before and after (3 months) intracoronary administration of stem cell therapy.

Methods: A total of 24 patients diagnosed with anterior ST-segment elevation AMI who had successful percutaneous coronary intervention (PCI) with drug-eluting stent implantation within 15 days after onset of symptom were enrolled. PBSCs were harvested and injected into the infarct-related artery after five consecutive days of G-CSF administration. Recombinant human erythropoietin was administered at the time of intracoronary PBSCs injection.
Results: This research produce surprising results. Some of the patients' hemostatic parameter show 'normalization', which is is rarely achieved even by optimal AMI treatment. There were no significant difference between baseline vs. 3 months in spontaneous aggregation ($P = 0.350$), PT ($P = 0.793$), APTT ($P = 0.255$) and TT ($P = 0.254$). There were also no significant difference between baseline vs. 3 months in plasma viscosity ($P = 0.442$) and blood viscosity ($P = 0.843$). Nevertheless the patient who has their blood and plasma viscosity above or below normal laboratory range return to normal point after the treatment. Both PT and APTT also show normalization value, as seen in table 4. Both Fibrinogen and CRP level show significant decrease between baseline and 3 months after treatment ($P = 0.009$) and ($P = 0.04$) respectively.
Conclusion: PBSC mobilization with G-CSF and EPO based-intracoronary injection, showed normalization and improvement of hypercoagulable state beyond optimal conventional treatment post AMI.

PB 3.50-4
Successful use of recombinant activated factor VII for a major surgery in a patient with severe FXI deficiency and severe allergic reaction to fresh frozen plasma

Unuvar A, Hocaoglu E and Devecioglu O
Istanbul University, Istanbul School of Medicine, Istanbul, Turkey

Severe congenital FXI deficiency is the commonest of the rare bleeding disorders. In contrast to hemophilia A or B, bleeding tendency in FXI deficiency do not correlate with FXI level. Therefore, optimal management of the patients with FXI deficiency is difficult. In addition, the bleeding risk for a surgery depends upon the type and the site of surgery and increases in high fibrinolytic areas such as the mouth, and nose. Several therapies such as fresh frozen plasma (FFP), FXI concentrate, fibrin glue, antifibrinolytic drugs are available for these patients. In the last years, the successful off-label use of recombinant activated factor VII (rFVIIa) has been reported in a very limited number of cases, including those with inhibitors. However, the dose and the duration of rFVIIa treatment has varied greatly between these case reports, and the development of thrombosis is a major concern. In this case report, we present our successful experience with the off-label use of rFVIIa for repairing the alveolar cleft and anterior palatal fistula in a 7-year-old boy with severe congenital FXI deficiency and severe allergic reaction to FFP. The patient was born to first degree consanguineous parents with the clefts of lip and palate. He was diagnosed as a severe congenital FXI deficiency (FXI:C level 0.2%) after the bleeding from the cleft lip repair surgery when he was 6 months old. First successful cleft palate surgery was done with FFP concentrates and tranexamic acid, when he was 18 months old baby. He was followed-up in our unit. The repairing surgery of alveolar cleft and anterior palatinal fistula was planned when he was 6.5 years old. However, severe allergic reaction developed during FFP infusion at the dental extraction before surgery. For this reason, we planned to use of rFVIIa for his surgery (FXI concentrate is not available in Turkey). Tranexamic acid was started orally every 8 h the day before surgery, and was given intravenously 2 h before surgery, and rFVIIa was given 40 μg/kg 1 h before surgery. Secondary alveolar bone grafting technique was performed under general anesthesia for the patient who was in his period of mixed dentition. Ilium was chosen as the donor site for obtaining autogenous cancellous bone grafts. The second dose of rFVIIa was given 4 h later after the first dose, and the dose of rFVIIa was reduced to 20 μg/kg, and continued at 6 hourly intervals for the first day, 8 hourly for the second day, 12 hourly for the 3rd and 4th day, and once a day for 5th and 6th day at the same dosage. Tranexamic acid was given until to 10 days after the surgery. No excessive bleeding or thrombosis were observed. In conclusion, low-dose rFVIIa therapy was successfully used for a major surgery in our patient with severe FXI deficiency and severe allergic reaction to FFP. However, treatment safety is a major concern and the best dosing regimen of this off-label drug is still to be defined for the selected patients.

PB 3.50-5
The 78 kDa glucose response protein (GRP78) interacts with ATP to inhibit a modified prothrombin time

Kamel S[1], Sharma A[1], Zhang XM[2], Selan C[1], Samudra A[1], Salavaris E[3], Coia G[4], Adams T[4], Cowan P[3] and Nandurkar H[1]
[1]The University of Melbourne, Melbourne, Australia; [2]Wuhan Third Hospital, Wuhan, China; [3]St Vincent's Hospital, Melbourne, Australia; [4]CSIRO, Melbourne, Australia

Background: We have previously described an interaction between the LLD domain of thrombomodulin (TM), a multi-domain glycoprotein expressed primarily on vascular endothelial cells and GRP78, the 78 kDa glucose regulated protein. GRP78, an ER chaperone, is found on the surface of endothelial and several tumour cells. We generated recombinant GRP78 and analysed its effect on haemostasis *in vitro* and *in vivo*. We previously showed GRP78 has anticoagulant, antithrombotic and antiplatelet properties. GRP78 prolongs TF dependent clotting (in a modified prothrombin time, PT) but not TF independent clotting. GRP78 also inhibits FXa generation (Xa spectrozyme assay) while showing no effect on thrombin time. We also demonstrated for the first time that recombinant GRP78 (8–10 μg/mL) can inhibit platelet aggregation up to 80% (compared to buffer) in response to collagen (1 U/mL), TRAP (1 μM) and ADP (10 μM). Pre administration of GRP78 also prolonged mouse tail bleeding time and GRP78 conferred significant protection in a platelet dependent model of acute venous thrombosis, induced by collagen (1.2 μg/g) into the jugular vein of anaesthetised mice.
Aim: Building on the work performed in our laboratory, we aimed to further explore the anticoagulant effects of GRP78 by investigating interactions of GRP78 with one of its substrates, ATP. GRP78 is known to bind ATP via the ATPase domain (aa 1–391) and exhibits a low level of ATPase activity. The binding of ATP to GRP78 is known to change tertiary confirmation of the latter and enhance the binding avidity of GRP78 to other substrates.
Method/Results: Using a high sensitivity phosphate assay (EasyRad [TRADEMARK] phosphate assay Biochem Kit[TRADEMARK]) we showed that our purified GRP78 had a very low rate of ATPase activity of 0.02 nmole ATP hydolyzed/min/mg.
We performed a modified PT using recombinant thromboplastin as a source of tissue factor and 20 μg/mL of GRP78 with 12 mM $CaCl_2$. We found that preincubation of GRP78 with calcium and ATP (1 mM) for 180 s resulted in a three fold increase in clotting time when compared with GRP78 and calcium alone ($P < 0.05$).
In an attempt to find a point in the pathway where GRP78 may inhibit coagulation, we performed a modified FXa (activated factor X) chromogenic assay (1/12 dilution of liquid Xa in STA™-Rivaroxaban anti FXa assay) to assess FXa inhibition by GRP78. GRP78 at 18 μg/mL did not inhibit FXa activity.
Conclusion: The addition of ATP to GRP78 prolongs a modified prothrombin time and may do so by enhancing the binding of GRP78 to a clotting factor or inhibitor involved in the coagulation cascade. GRP78 does not appear to inhibit FXa but we have shown it reduced FXa generation suggesting the point in the pathway at which it inhibits coagulation is above this level.

PB 3.50-6

Post-operative bridging therapy in a tertiary hospital in Singapore

Pandit N, Boey R, Tan JYL, Choo T and Tay JC
Tan Tock Seng Hospital, Singapore, Singapore

Background: Perioperative management of surgical patients who require temporary discontinuation of Warfarin involves, weighing the risk of thrombosis during the interruption against the risk of bleeding when such therapy is used in close proximity to a surgical procedure. There is a paucity of randomized clinical trials and practice is based on consensus guidelines and narrative expert reviews.
Aims: To look at the risk of thrombosis and bleeding in patients who underwent bridging therapy during their attendance at the Anti Coagulation Clinic (ACC).
Methods: This retrospective study amongst patients who attended ACC for 'perioperative bridging' looked at the risk of bleeding (patients given bridging therapy) and thrombosis (patients whose anticoagulation was interrupted). Data were collected for the reason for anticoagulation, nature of surgery, number of days Warfarin was discontinued and Heparin given, post-operative day on which anticoagulation was restarted and the incidence of thrombosis and bleeding post-operatively upto a period of 3 months.
Results: Fifty-four patients were analyzed, of which nine patients had procedures with a low bleeding risk for whom Warfarin was not interrupted. Amongst the patients with a high bleeding risk for whom Warfarin was interrupted ($N = 45$), all received instructions for post operative bridging with LMWH and Warfarin. Postoperatively the average time to attain therapeutic anticoagulation (INR >2) while on Warfarin was more than 7 days.
Amongst these, only 40% patients complied to low molecular weight heparin while the INR was sub-therapeutic. 20% were not advised anticoagulation due to major bleeding.
However, despite there being no contraindication for full therapeutic anticoagulation only one patient had an episode of Thromboembolism (ischemic CVA in Atrial fibrillation) in the immediate post operative period.
Conclusions: The risk of major bleeding is about 20% in patients undergoing interventions with a high bleeding risk while on bridging therapy. This is independent of the level of anticoagulation at the time of bleeding and more dependent on the nature of the surgical procedure. Delay in achieving therapeutic anticoagulation (initially with LMWH and subsequently with Warfain -therapeutic INR) in the post operative period is due to a combination of factors- smaller loading doses of Warfarin, interaction of Warfarin with diet and medications, reluctance on part of the Surgeon and the Clinic to ensure compliance of the regimen. Delay in achieving therapeutic anticoagulation is not associated with an increase in the risk of Venous Thromboembolism in the post-operative period.

Sensitivity of various aPTT reagent – instrument combinations to dabigatran concentrations

Selby R[1], Black L[2], Kulkarni S[1] and Piraino D[1]
[1]*Sunnybrook Health Sciences Centre;* [2]*University Health Network, Toronto, Canada*

Background: It is known that the activated partial thromboplastin time (aPTT) is sensitive to the oral thrombin inhibitor dabigatran and may be useful in determining the relative intensity of anticoagulation in urgent clinical situations. However, the variation in sensitivity of different aPTT reagent-instrument combinations to dabigatran is not well studied.
Objective: To assess the responsiveness of the common aPTT reagent-instrument combinations in use in Ontario, Canada, to dabigatran concentrations across the therapeutic range.
Methods: Six aPTT reagents and three coagulation analyzers were used in this study. The aPTT reagents were CK Prest and PTT A from Diagnostica Stago, SynthASil and APTT-SP from Instrumentation Laboratories (IL) and ActinFS and ActinFSL from Siemens. The analyzers were Diagnostica Stago – STAR-Evolution, IL – ACL TOP and Siemens – CS 2000i. All aPTT reagents were reconstituted and used as per individual manufacturers' assay protocols. The Dabigatran plasma calibrator kit (HYPHEN BioMed) containing a set of three calibration plasmas at concentrations of 0.04 μg/mL, 0.28 μg/mL and 0.51 μg/mL spanning the therapeutic range of dabigatran was used. Additionally, the 0.28 μg/mL and 0.51 μg/mL calibrators were diluted with pooled normal plasma (Precision Biologic Cryocheck) to make concentrations of 0.10, 0.15, 0.35 and 0.45 μg/mL to provide additional time points. The pooled normal plasma was also run as a zero concentration. An aPTT was performed on each of the dabigatran concentrations as well as the pooled normal plasma (zero concentration) using each aPTT reagent on each coagulation analyzer generating individual aPTT results at the seven different dabigatran concentrations for the reagent-instrument combinations.
Results: All six aPTT reagents resulted in aPTTs ranging from 26 to 35 s with pooled normal plasma (zero dabigatran concentration) across the three different analyzers. For the 0.04 μg/mL concentration (corresponding to the trough dabigatran concentration) the aPTT range for the six aPTT reagents on the IL-ACL TOP analyzer was 41–53 s, on the Stago analyzer was 45–52 s and on the Siemens analyzer was 40–56 s. For the 0.51 μg/mL concentration (corresponding to the upper end of the dabigatran therapeutic range) the aPTT range for the six aPTT reagents on the IL-ACL TOP analyzer was 84–112 s, on the Stago analyzer was 83–111 s and on the Siemens analyzer was 73–120 s. There was overlap between the aPTT results for the 0.28 μg/mL concentration and the 0.51 μg/mL concentration for all reagent-instrument combinations. While all reagents exhibited a curvilinear dose response at high dabigatran concentrations, CK Prest and PTT-A reagents were the most sensitive to dabigatran on all the coagulation analyzers while Actin FSL was the least sensitive across all the analyzers.
Conclusions: This study provides an evaluation of the varying sensitivity (dose-response) of six different aPTT reagents run on three different coagulation analyzers commonly used across Ontario, Canada, to varying concentrations of dabigatran across the therapeutic range. This information may be clinically useful for assessing the relative intensity of coagulation specific to the reagent-instrument combination used to determine the aPTT.

PB 3.51-2

Bleeding disorders in children presenting with different bleeding symptoms or abnormal coagulation tests-First evaluation results in an out-patient clinic

Unuvar A, Yildiz I, Kamer I, Karaman S, Uysalol E, Kilic A, Unuvar E and Oguz F
Istanbul University, Istanbul School of Medicine, Istanbul, Turkey

Mild bleeding symptoms (easy bruising, epistaxis, etc.) are common in the general population, and are reported in up to 25–45% of healthy people. Many of them do not have any identifiable bleeding disorders. In this study, our aim was to determine the clinical and laboratory features of 102 children referred for the first evaluation of a suspected bleeding disorder in an out-patient clinic of a university hospital. The medical records of 26,737 children (between 31-Oct-2011 and 31-October-2012) at the Department of Ambulatory Pediatrics were assessed, and 111 children with suspected bleeding disorders who did not have a known bleeding disorder were identified. Nine children were excluded from the study due to lost to follow-up. The patients with ITP were also excluded. Bleeding symptoms, duration of bleeding symptoms,

any bleeding history at newborn period, family history of bleeding, physical exam findings, and laboratory evaluation (complete blood count, PFA100 test, and coagulation tests) were analyzed, retrospectively. All coagulation tests were studied in the Pediatric Hematology&Oncology Hemostasis Laboratory. The mean age of the 102 patients (52 M, 50 F) was 8.9 ± 4.1 years (range 2–18 years). The most frequent bleeding symptoms were epistaxis in 36, easy bruising in 33, and menorrhagia in seven patients. The range of duration of bleeding symptoms was 2 days–6 years. Nine patients were referred for the evaluation of prolonged PT and/or aPTT levels, and two for pre-op evaluation. After the first evaluation at the Department of Ambulatory Pediatrics, 63 patients (61.8%) did not have a diagnosed coagulopathy, and 39 patients(38.2%) were diagnosed as a congenital bleeding disorder. The diagnoses included vWD type 1 in eight, vWD type 2 in four, vWD and FXI deficiency in three, mild hemophiliaA in four, moderate hemophiliaA in two, hemophiliaA carrier in two, hemophiliaB carrier in one, FXI deficiency in two, FV deficiency in three, FVII deficiency in two, viral infection induced thrombocytopenia in two, FX deficiency, combined FII, VII, IX, X and FXII deficiency, combined FV and FVIII deficiency, combined FVII and FX deficiency, FXII deficiency, platelet function disorder in each patient. Acquired coagulation inhibitor was not detected in any patient. Nine of 39 patients had a family bleeding history. Twenty-eight percent of the patients with epistaxis (10/36; mild hemophilia(3), vWD type 1(3), vWD + FXI deficiency(1), FVII deficiency(1), FV deficiency(1), FII, VII, IX, X + FXII deficiency(3), 30.3% of the patients with easy bruising (10/33; vWD type 1(3), vWD type 2(1), moderate hemophilia(1), hemophiliaA carrier(1), FV deficiency(1), FXI deficiency(1), FVII + X deficiency(1), viral infection induced thrombocytopenia(1), and 57.1% of the patients with menorrhagia (4/7; hemophiliaB carrier(1), vWD + FXI deficiency(1), FX deficiency(1), platelet function disorder (1) were diagnosed as a bleeding disorder after the first clinical and laboratory results. All 39 patients were referred to the Pediatric Hematology&OncologyUnit for the last evaluation and diagnosis.

In conclusion, about 40% of children presenting with bleding symptoms were diagnosed as a bleeding disorder in the out-patient clinic after the first evaluation. Menorrhagia may be the first clinical manifestation for the patients with bleeding disorders, and if a child with menorrhagia is referred, an underlying bleeding disorder should be considered.

PB 3.51-3

Studies on thrombin generation and thrombelastometry in haemophilic plasma show good correlation at low FVIII levels and the feasibility to use frozen samples of PRP

Zetterberg E[1], Knobe K[2] and Berntorp E[2]

[1]Skane University Hospital; [2]Lund University, Malmö, Sweden

Introduction: Replacement therapy in haemophilia A and B is currently based on plasma FVIII or IX activities even though it is known that FVIII and FIX plasma levels not always correlate to bleeding phenotype. In fact, in one study 10% of patients with severe haemophilia had a very mild phenotype with practically no spontaneous joint bleeds (Aledort LM et al 1994, Beeton K et al 2006). Neither genotype nor APTT based assays can identify these patients.

The last decade new methods aiming to evaluate the total capacity of the hemostatic system has been developed, namely thrombin generation (TGA) methods and viscoleastic assays (rotational thrombelastometry, ROTEM and thrombelastography, TEG). TGA measures the total amount of thrombin that is released in platelet poor plasma (PPP) or platelet rich plasma (PRP) over time, after activation with small amounts of tissue factor or kaolin. ROTEM/TEG measures the time to clot formation as well as the viscoelastic properties of the clot.

Correlation between TGA and the bleeding phenotype has been shown in patients with heamophilia (Santagostino et al. 2010, Trossaert et al. 2008), but so far no data have been published on the correlation between ROTEM/TEG parameters and tendency to bleed.

Aim: The aim of this study was to investigate if TGA parameters correlate to ROTEM parameters in patients with severe heamophilia at (i) baseline and (ii) after injection of replacement therapy.

Methods: Blood samples were taken from patients with heamophilia on regular prophylaxis before and after injection of their regular FVIII concentrate. Patients had not taken their prophylaxis later than 72 h before blood sampling. TGA was measured according to the method of Hemker on fresh and frozen citrated PPP and PRP samples after activation with tissue factor at 1 pM. ROTEM was performed on citrated whole blood after activation by diluted kaolin or innovin.

Results: In concordance with previous studies thrombin generation correlated poorly to FVIII levels at low FVIII concentrations (1–5%). However a strong correlation between TGA parameters in PRP and ROTEM parameters was seen in patients before injection of factor concentrate. Surprisingly the same parameters did not correlate after replacement therapy was given. This was explained by TGA being much more sensitive to the effect of FVIII compared to ROTEM parameters. When comparing the effect of freezing PPP and PRP, thrombin generation was significantly lower in frozen PPP than in fresh samples, whereas no significant difference was seen in frozen PRP compared to fresh at low FVIII levels.

Conclusions: Both Thrombin generation and Thrombelastometry have a potential to more accurately reflect the hemostatic potential in patients with haemophilia at low levels of FVIII. Thrombin generation in PRP is more sensitive than ROTEM in measuring the effect of replacement therapy. Thrombin generation can be measured on frozen samples of PRP, facilitating the use of this method in multicenter studies.

PB 3.51-4

Comparison of hemoclot thrombin inhibitor® and activated partial thromboplastin time with a reference UPLC-MS/MS method to monitor patients receiving dabigatran etexilate

Douxfils J[1], Hjemdahl P[2], Malmström RE[2], Ronquist Y[2], Beck O[2], Baudar J[3], Classen J-F[3], Chatelain C[3], Chatelain B[3], Mullier F[3] and Dogné J-M[1]

[1]University of Namur, Namur, Belgium; [2]Karolinska University Hospital/Solna, Stockholm, Sweden; [3]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: The pharmacokinetic properties of dabigatran exetilate (DE) with low bioavailability and a dependence on renal function for its excretion result in considerable variation in plasma drug concentrations. Even if monitoring of dabigatran levels/effects are not needed in the majority of patients, a non-negligible proportion of patients will obtain either insufficient or supra-therapeutic levels of the drug when given a fixed dose. Therefore, possibilities to monitor DE therapy would be useful, e.g., in patients with renal impairment or possible drug interactions, and in cases of severe bleeding or recurrence of thrombosis, in anticoagulation bridging or before urgent or elective surgery. Monitoring may also be useful in infants, pregnant women or in patients with extreme body weights. Assays such as aPTT or the Hemoclot Thrombin Inhibitor® (HTI) have been proposed to evaluate drug concentrations but previous findings are based on *in vitro* analysis and results must be confirmed in clinical samples. The gold standard for therapeutic drug monitoring is mass spectrometry.

Aim: To compare aPTT and HTI measurements with the reference method, Ultra Performance Liquid Chromatography coupled with tandem mass spectrometry (UPLC-MS/MS), in plasma samples from DE treated patients.

Methods: Seventy-one plasma samples were included. aPTT was performed using CKPrest® and Synthasil®. HTI was performed according to instructions from the manufacturer using a STA-R Evolution®.

For the UPLC-MS/MS, after sample preparation, the analytes were separated on an Acquity BEH® column shield RP18 and detected by a Micromass Quattro Premier XE® mass spectrometer operating in positive electrospray ionization mode.

Results: The plasma concentration range was 0–645 ng/mL as measured by UPLC-MS/MS. The HTI and UPLC-MS/MS analyses correlated well with a Pearson correlation coefficient (r^2) of 0.97 (95% CI: 0.95–0.98; $P < 0.0001$). The Bland-Altman analysis showed a mean difference of 9 ng/mL (standard deviation (SD): 21 ng/mL; 95% limits of agreement: −32 to 50 ng/mL). However, the HTI method could not detect low, probably therapeutic levels of DE (<20 ng/mL) whereas the detection limit of UPLC-MS/MS was 2 ng/mL.

The aPTT and UPLC-MS/MS methods were not closely correlated (r^2 values of 0.59 and 0.50 for Synthasil® and CKPrest®, respectively). The Bland-Altman analysis showed a mean difference of −0.8 s between the two reagents (SD: 8.7 s; 95% limits of agreement: −17.9 to 16.3 s).

Conclusions: There is poor sensitivity and an important inter-individual variability with the aPTT and this test cannot be recommended to estimate plasma dabigatran concentrations. A normal aPTT could not exclude therapeutic levels of dabigatran and, conversely, therapeutic levels of dabigatran do not always result in abnormal aPTT. Thus, anticoagulant effects of DE are only detected by aPTT if they are pronounced. The HTI assay, on the other hand, showed little inter-individual variability and good agreement with UPLC-MS/MS measurements in the intermediate – high plasma concentration range for DE. Detection of low levels for, e.g., compliance monitoring or to rule out significant anticoagulant effects in DE treated patients requires the more sensitive UPLC-MS/MS method. HTI measurements and/or drug levels should be studied in relation to clinical outcomes.

PB 3.51-5
Clot waveform analysis in patients with bleeding disorders

Siegemund T[1], Scholz U[2], Schobess R[2] and Siegemund A[2]
[1]*The Scripps Research Institute, La Jolla, CA, USA;* [2]*MVZ Labor Dr. Reising-Ackermann und Partner, Leipzig, Germany*

Background: Clot waveform analysis was introduced several years ago to achieve a better discrimination of factor VIII activity in hemophilia A by an extended interpretation of the clot formation process in an aPTT assay. Considering basic physico-chemical laws like Lambert-Beer law and the Michaelis-Menten kinetics, the method may provide more information than just factor FVIII concentration. By using an optical detection system, alteration of absorbance during clot formation is mathematically processed to obtain data regarding fibrin formation (measured curve), thrombin activity (first derivative), prothrombinase activity (second derivative) and tenase activity (third derivative).

Clotting times in aPTT based assays do not provide information about the complexity of the coagulation process, thrombin generation assays are cost- and labor-intensive. Especially, during bleeding episodes a fast, easy and reliable diagnosis is beneficial.

Aim: Disturbances of the coagulation system that lead to a high bleeding tendency are associated with diminished factor Xa or thrombin generation. This study is aimed to show the feasibility of clot waveform analysis in screening and monitoring of patients with bleeding disorders. The results are compared to methods like thrombin generation, PFA-100 and Von Willebrand Factor (VWF)-related diagnostics in different clinical situations.

Methods: Clot waveform analysis is measured using an ACL TOP (Instrumentation Laboratory, Kirchheim, Germany), using a Synthasil-activated aPTT assay (Instrumentation Laboratory). Measured optical data were processed using the Savitzky-Golay algorithm. Coagulation parameters were measured using standard test systems. Thrombin generation was measured as ETP (Siemens Healthcare Diagnostics, Marburg, Germany) or Technothrombin TGA (Technoclone, Vienna, Austria).

Patients were from our center were included after an informed consent was obtained. For all subjects the underlying bleeding disorder was characterized thoroughly.

Results: Patients with bleeding disorders show a significantly altered clot waveform compared to healthy controls. There is a clear correlation between severity of bleeding disorders and clot waveform analysis parameters. In hemophilia thrombin, prothrombinase and tenase have increasing sensitivity for different levels of factor VIII. Clot waveform analysis, especially the calculated course of the tenase complex, correlates with the extent of factor VIII, IX or recombinant FVIIa substitution. Under this conditions thrombin generation shows significantly less sensitivity.

In patients with Von Willebrand disease under DDAVP administration, clot waveform analysis reflects the procoagulant effect in a similar way like conventional test systems like measuring VWF parameters (activity or PFA 100).

Conclusions: Clot waveform analysis is an inexpensive and fast method to screen and monitor patients with bleeding disorders and can be done without any additional measurements beside an aPTT. In cases of replacement therapy the effects on tenase, prothrombinase, thrombin and fibrin formation can be investigated within a short time frame. The method can be easily adapted to other optical detection systems.

PB 3.51-6
Laboratory monitoring of unfractionated heparin therapy

Polokhov DM[1], Soshitova NP[1], Balandina A[1], Orel E[1], Vasiliev S[1], Gnedova A[1], Ataullakhanov F[1] and Galstian G[1]
Scientific Center for Hematology, Moscow, Russian Federation

Background: Unfractionated heparin (UFH) therapy is commonly monitored by activated partial thromboplastin time (aPTT).

Objective: To compare the sensitivity and specificity of aPTT and global tests of haemostasis – Thrombodynamics and thromboelastography (TEG) by adding UFH to blood samples *in vitro* and by monitoring of UFH therapy in patients.

Methods: *In vitro* analyses were performed on 10 blood samples of healthy donors to which a number of UFH concentrations were added. Ten patients with high risks of thrombosis treated by intravenous UFH infusion were enrolled in the study. Blood samples were taken before the UFH infusion beginning, in 3, 6, 12, 24 h ($n = 2$) or once a day during 5 days ($n = 10$). The parameters of TEG (angle), Thrombodynamics (stationary velocity, Vst) and aPTT were determined. M ± SD are shown as a result.

Results: Vst and angle decrease in 2.8 and 2.6 times (25 ± 3 vs. 9 ± 3 μm/min, 26 ± 5 vs. 10 ± 2 deg, respectively) as 0.08 IU/mL UFH were added *in vitro* to blood and in 7.5 and 5.8 times, respectively, as 0.33 IU/mL UFH were added (angle was not determined in 7/10 samples with this dose). APTT increases in 1.6 times (35 ± 2 vs. 56 ± 18 s) and in 2.8 times, respectively. UFH concentration in blood of patients treated by 1000 IU/h is about 0.15 IU/mL.

Vst reveals hypocoagulation in 3 h after the 1000 IU/h UFH infusion beginning (2.2 times decrease) and reaches the lowest constant value in 12 h. APTT reveals hypocoagulation only in 24 h (2.3 times increase). TEG parameters cannot be determined after 12 h.

Statistical comparison of the assays parameters in the blood samples taken before the UFH infusion beginning (group 1) and from patients receiving UFH 300–650 IU/h (group 2) or 800–1300 IU/h (group 3) revealed that Vst is significantly different ($P < 0.05$) between all groups (29 ± 6, 13 ± 7, 5 ± 2 μm/min, respectively). APTT differs only in patients receiving high UFH doses (29 ± 4 s, 38 ± 12 s, 61 ± 20 s, respectively). Angle differs in all groups (39 ± 16, 20 ± 15, 5 ± 5 deg, respectively), but it was not determined ($R > 120$ min) in 13 of 24 blood samples from patients treated by high UFH doses.

Four cases of thromboses in UFH treated patients were observed. Thrombodynamics revealed hypercoagulation in three of them (excluding 1 catheter-related thrombosis), TEG and aPTT only in 1.
Conclusions: Thrombodynamics can be more effective in monitoring UFH therapy than aPTT and TEG.

PB3.52 – Blood coagulation tests – XII

PB 3.52-1

Platelet aggregometer according to the Born method is not suitable to control biological effectiveness of Minirin in the DDAVP test

Siegmund B, Wördemann S, Siegmund B and Pollmann H
Praxis Dr. med. H. Pollmann, Münster, Germany

Background: Desmopressin (DDAVP, Minirin) is used successfully to normalize hemostasis in patients with thrombocytopathy (TCP), von-Willebrand-Syndrome Type 1 (vWS1) and mild hemophilia A. Unfortunately, not every patient responds adequately to Minirin. To approve the biological effectiveness of Minirin, the PFA-100 is very often used.
Aims: Due to the limitations of the PFA-100 an alternative was wanted and initially seen in the APACT 4004. Suitability for the DDAVP test of both systems was evaluated in the present comparative study.
Methods: Coagulability (platelet aggregation) of the blood from patients with TCP ($n = 7$) or vWS1 ($n = 7$) was tested before and after Minirin infusion (0.3 µg Minirin per kg body weight) in the APACT 4004 and PFA-100. Additionally, thrombocytes were counted and plasma levels of factor VIII activity (FVIII), von-Willebrand factor antigen (vWF) and ristocetin cofactor (Risto) were measured.
Results: Normalization of coagulability by Minirin resulted in the PFA-100 collagen/ADP system in a significant ($P < 0.0001$) reduction of the occlusion time from 131.0 ± 31.1 s before to 54.6 ± 7.9 s after infusion of Minirin in patients with vWS1 and from 95.1 ± 19.1 s to 54.3 ± 9.6 s ($P = 0.0003$) in patients with TCP. FVIII, vWF and Risto normalized from 77.7 ± 25.9%, 60.6 ± 19.7%, and 47.0 ± 26.7% to 141.0 ± 18.7% ($P = 0.0002$), 137.3 ± 33.6% ($P = 0.0002$), and 140.1 ± 26.1% ($P < 0.0001$) by Minirin. Comparable results were obtained with PFA-100 collagen/epinephrine. In contrast, the normalization of coagulation parameters by Minirin could not be demonstrated with the APACT 4004. Maximal aggregation parameters for the initiation of coagulation with ADP, collagen, epinephrine and ristocetin in vWS1 blood were 60.1 ± 9.8%, 50.5 ± 24.9%, 56.4 ± 15.5%, 62.2 ± 10.6% before and 50.1 ± 20.1% ($P = 0.2597$), 37.2 ± 19.8% ($P = 0.2904$), 46.6 ± 21.8% ($P = 0.3515$), 49.8 ± 22.2% ($P = 0.2071$) after Minirin application. Results of patients with TCP were comparable.
Summary/Conclusion: Feasibility of PFA-100 for conformational testing of the effectiveness of Minirin in patients with vWS1 or TCP was verified. However, in contrast the APACT 4004 was not sensitive to the Minirin induced changes of coagulation parameters. Therefore, the APACT 4004 cannot be used to test the biological effectiveness of Minirin.

PB 3.52-2

Effect of eculizumab administrations on the haemostatic changes in patients with paroxysmal nocturnal hemoglobinuria

Seregina E[1], Nikulina O[2], Tsvetaeva N[2], Balandina A[3] and Ataullakhanov F[4]
[1]HemaCore LLC; [2]National Research Center for Hematology; [3]Center of Pediatric Hematology, Oncology and Immunology; [4]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Background: Eculizumab is approved to reduce the intensity of intravascular hemolysis and thrombotic risk in patients with paroxysmal nocturnal hemoglobinuria (PNH)[1].
Aim: The aim of this study was to investigate the coagulation state in PNH patients under eculizumab treatment.
Methods: Three patients with PNH in state of permanent hemolysis, requiring constant red cell transfusions, were enrolled in this study. Eculizumab administration was 1 time per week; the tests were performed 1 day before and 1 day after administration for 4 weeks. Further eculizumab administrations last for 2 months, the tests were performed in the day of administration before the infusion. Thrombodynamics (a new method based on a spatial fibrin clot growth registration), thromboelastography (TEG), activated partial thromboplastin time (aPTT), prothrombin index (PI), D-dimer assay, the concentration of lactate dehydrogenase (LDH), and the concentration of hemoglobin (Hb) were performed. In thrombodynamics assay the initial clot growth velocity (Vi) was determined.
Results: TEG parameters, aPTT and PI were in normal or in hypocoagulation area before treatment. Vi was increased (58 ± 7 µm/min with normal range 36–56 µm/min, $P < 0.001$). Enlarged D-dimer levels in two patients (0.8 mg/L, 2.1 mg/L with normal range 0–0.5 mg/L) confirmed the well-known tendency to hypercoagulability during haemolytic crises. D-dimers were in norm for one patient (0.3 mg/L). Coagulation tests data wasn't significantly ($P > 0.5$) changed the day after eculizumab administration: Vi was 60 ± 8 µm/min, the parameters of the TEG, aPTT, PI were in normal or in hypocoagulation area. D-dimers remained in norm in one patient under eculizumab treatment. Other two patients had the decrease of D-dimer level with some incidents of D-dimer's increase during the treatment. LDH level progressively decreased and Hb level increased in all patients indicating the reduction of hemolysis. Physical health was improved. During further eculizumab administrations for 2 months all tests data was not significantly ($P > 0.5$) changed.
Conclusion: Eculizumab administrations did not reduce hypercoagulability in PNH patients, they are still need the prescription of anticoagulant therapy. Thrombodynamics was sensitive to the state associated with the increased risk of thrombotic events in PNH patients.

PB 3.52-3

Evaluation of assay performance monitoring direct thrombin inhibitors with TECHNOCLOT® DTI in plasma samples contaminated with indirect thrombin inhibitors

Wagner L, Binder NB, Leitner M and Riha M
Technoclone GmbH, Vienna, Austria

Background: The increasing use of the new oral direct thrombin inhibitors (DTI) dabigatran creates the need of the measurement in clinical routine. Plasma samples obtained from blood drawn through heparinized tunneled venous access devices may contain heparin in unknown concentration. Technoclot® DTI is a modified thrombin time based assay which can be used for measurement of DTIs in the presence of indirect thrombin inhibitors.

Aim: The aim of this study was to evaluate the performance of the new TECHNOCLOT® DTI assay with the DTI dabigatran in plasma samples containing indirect thrombin inhibitors.
Method: Technoclot® DTI is a clotting assay based on the inhibition of a constant and defined concentration of thrombin. Clotting times measured are directly related to DTI concentrations.
Calibration of the assay was performed with Technoview dabigatran. Technoview Dabigatran Controls were used for assay control. The assay was performed automated using the Coasys Plus C coagulation analyzer.
Normal plasma with a defined concentration of dabigatran was spiked with different concentrations of unfractionated Heparin and low molecular weight Heparin.
Results: Dabigatran was calibrated in the range of 0–500 ng/mL and assay performance proved by dabigatran control sample measurements.
The recovery of dabigatran value was below ±10% of target value for all samples spiked with different concentrations of UFH up to 1.2 IU/mL and LMWH up to 1.2 IU/mL. Using the diluted thrombin time the overestimation of dabigatran concentration in samples with 0.8 IU/mL UFH or LMWH was 16% and 13% respective, rising to 37% and 21% for samples with 1 IU/mL UFH or LMWH.
Conclusion: Our data demonstrate that TechnocLOT® DTI is suitable for monitoring the direct thrombin inhibitor dabigatran with good precision in samples containing up to 1.2 IU indirect thrombin inhibitors.

PB 3.52-4
Application of an automated genotyping system (Verigene®) in a thromboembolic disease unit

Gallego P[1], Martínez A[2], Cerezo-Manchado J[2], Padilla J[2], Soler G[2], Navarro N[2], Vicente V[2], Roldán V[2] and González-Conejero R[2]
[1]Centro Regional de Hemodonación, Hospital Morales Meseguer; [2]Centro Regional de Hemodonación, Hospital Morales Meseguer, UMU, IMIB, Murcia, Spain

Background: The path to an accurate and personalized medicine goes through a genotyping implementation in daily clinical practice with devices able to obtain a fast and simple result. However, several factors such as an appropriate technical training, the availability of specialized equipments or an expert laboratory and consuming time make it difficult.
Aims: To evaluate an automated genotyping system, using whole blood to measure the polymorphisms most frequently associated with acenocoumarol dose requirements as well as frequent molecular variants of thrombophilia: Factor V Leiden (FVL) and prothrombin 20210A (PT20210A).
Methods: Detections of FVL and PT20210A polymorphisms (inherited thrombophilia markers) as well as *VKORC1* and *CYP2C9* polymorphisms (rs2323991 and CYP2C9*2 and *3, respectively) were performed in parallel using a routinely real time PCR genotyping and an automated genotyping system: – Genotyping technology provided by Verigene ® (Nanosphere, Grifols) consists in a low density matrix which does not require previous PCR amplification of DNA. This system uses whole blood (up to 7 days from extraction) and allows the study of one sample per process, with an average duration of 3 h per sample and requiring EDTA or citrate indistinctly as anticoagulants. – The routine protocol for genotyping these SNPs in our laboratory involves an automatic extraction of DNA (QIAmp DNA Blood Kit) followed by real time PCR genotyping (using Taqman commercially available probes; Applied Biosystem). We analyzed blood samples from 177 consecutive unselected patients: 97 were tested for thrombophilia markers and 80 for VKORC1/CYP2C9 genotypes.
Results: In the thrombophilia study, concordance between both genotyping systems was 100%. However 15 samples (15%) were missed in Verigene® system: 11 because of reading problem and 4 because of sample deterioration. Four discrepancies between the two genotyping systems were found when we tested VKORC1/CYP2C9 genotypes (95% concordance). In this study, 10 samples were missed in Verigene® system (10%): eight because of reading problem and two because of sample deterioration.
Conclusions: The Verigene® system is an automated genotyping system whose main advantages are reliability and rapidity. It uses whole blood and does not require a highly specialized training. By contrast, the mean failure rate of automated system (12.5%) in comparison with the routine genotyping (5% for FVL and 1% for the rest of genotypes) could be a point in favor of routine methods. Finally, the high degree of concordance between both procedures (98%) makes of Verigene® system a procedure to take into account to introduce pharmacogenetic testing in any laboratory.

PB 3.52-5
Evaluation of the Grifols Q analyzer for routine and special hemostasis tests

Montalvao SL, Silva B, Camargo A, De Fatina T, Picoli SK, Pereira E, Annichino-Bizzacchi JM and Vinicius E
Centro de Hematologia e Hemoterapia, Hemocentro, Campinas, Brazil

Background: Robust and standardized validation protocols are needed to assess the performance of new coagulometers. Grifols Q Analyzer is a fully automated coagulometer that analyzes multiple parameters of hemostasis, and can be used for both screening and more specialized coagulation tests, including coagulometric, chromogenic and immunologic assays.
Aim: To evaluate the performance of Q Analyzer (performance characteristics and throughput calculation) and to provide a comparison with an established method in a reference hemostasis laboratory.
Methods: The validation process was established according to the Clinical Laboratory Standard Institute (CLSI Linearity-EP-6-, CLSI full precision-EP-5A, comparison method, CLSI EP-9). We evaluated PT, APTT, FV:C, FVIII:C (three different patient groups: hemophilic, Von Willebrand and thrombotic) and VWF:Ag (three different methods ELISA as reference method and IL and Grifols as two new automated methods), using coagulometric and chromogenic methods. Six parameters were evaluated for each test, by the following strategy: (i) Linearity, by using calibration curves performed consecutively with standard reference material; (ii) preliminary precision (within-run), by repeated testing of a normal and abnormal frozen sample 20 times on the same run; (iii) total precision, by performing 2 runs on 20 separate days, each run consisting of two replicates of the two plasma samples (normal and abnormal); (iv) carryover, by alternating samples spiked with heparin (>1.0 IU/mL UFH) and normal plasma in the APTT determination; (v) throughput, (calculated by subtracting the time to obtain the first completed test panel to that of the last completed panel), by loading the equipment with 30 samples and using different test panels; and (vi) method correlation, for coagulation, chromogenic and immunological assays against the reference method. For the statistical analysis the data was assessed for linear regression r^2, method comparison (Passing & Bablok) and agreement (Bland-Altman).
Results: 140 samples were evaluated for PT and APTT (77/PT and 63/APTT) including 29 patients under warfarin treatment, 15 patients with chronic liver disease, 10 patients treated with unfractionated heparin, 10 patients with hemophilia, and 10 patients with rare coagulation deficiencies. High correlation was obtained between the two methods (r^2 = 0.96 for the PT and r^2 = 0.89 for the APTT). However, differences in reagent performance were observed in selected patient groups when synthetic reagents were compared with reagent obtained from animal sources. The VWF:Ag was evaluated in 30 VWD patients and 33 healthy subjects, with all blood groups equally represented. The automated methods showed high correlation with the classical

ELISA, yielding a linear regression $r^2 = 0.89$. Median results with IL and methods were 46.13 UI/dL (range 0.64–105.5) and 40.70 UI/dL (range 1.3–114.6), respectively, with no statistical significant differences. We also observed satisfactory performance of Q Analyzer for intra, inter and total precision as evidenced by the low coefficient of variations (CV%): 3.6% in normal and abnormal PT, and 4.9% and 3.2% in normal and abnormal levels APTT, respectively. No carryover was detected. The effective throughput was 104 tests per hour for the PT and 64 tests per hour for the APTT.

Conclusion: Using a comprehensive validation protocol, the Q Analyzer showed satisfactory results.

PB 3.52-6

Apixaban: safety, usefulness and practical details of laboratory monitoring

Douxfils J[1], Classen J-F[2], Baudar J[2], Walbrecq S[2], Chatelain C[2], Chatelain B[2], Dogné J-M[1] and Mullier F[2]

[1]University of Namur, Namur; [2]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: Apixaban is direct factor-Xa inhibitor that reached the market for the prevention of venous thromboembolism in patients undergoing major orthopaedic surgery and in stroke prevention in patients with non-valvular atrial fibrillation.

Thanks to its predictable pharmacokinetic profile, biological monitoring is not required. Nevertheless, evaluation of plasma drug concentration may be valuable in specific situations such as recurrent thrombosis, bleedings, before urgent surgery, in case of bridging and in case of at least two risk factors among the following ones: drug interactions with caution, moderate renal impairment and moderate hepatic impairment. Monitoring may also be useful in infants, pregnant women or in extreme body weights, although no relevant data on drug levels associated with approximate therapeutic and harmful ranges are currently available.

Aims: The aim of this study is to assess and provide good laboratory practise for the accurate estimation of apixaban plasma concentration using routine or more specific coagulation assays.

Methods: Apixaban was spiked at increasing concentrations (0–500 ng/mL) in pooled citrated normal human platelet poor plasma (PPP) to measure Prothrombin Time (PT), dilute PT and activated Partial Thromboplastin Time (aPTT) with different reagents, dilute Russell Viper Venom Time (screen and confirm), Thrombin Generation Assay (TGA) with different inducers and different anti-Xa chromogenic assays.

Results and Discussion: As mentioned in previous studies, PT is not sensitive enough to allow accurate quantitative measurement of the plasma drug concentration (concentration needed to double the clotting time [2xCT] from 154 to 1367 ng/mL). Indeed, the 2xCT is 154 ng/mL with the most sensitive reagent while the mean C_{max} obtained in a short PK study after one oral intake of 5 mg apixaban (dose given in atrial fibrillation) is 96 ng/mL. This can lead to major concern when urgent or elective surgery is required and in definitive, a normal PT cannot exclude the presence of apixaban at therapeutic concentration. Activated Partial Thromboplastin Time presents a better sensitivity but shows a plateau after 100 ng/mL reflecting the uselessness of this test to estimate the impact of apixaban on the secondary haemostasis. Dilute Russell Viper Venom time shows a sensitivity of 205 ng/mL (screen), which is not enough sensitive.

On the opposite, chromogenic anti-Xa assays seem to be very sensitive (concentration requires to halve the OD/min: 2–20 ng/mL). Nevertheless, the relation is not always linear and some methodologies need to be adapted to ensure a broader range of application.

TGA may be useful to assess the pharmacodynamics effects of apixaban on the coagulation process. Nevertheless, the turn around time and the lack of standardisation are currently limitations that restrict the use of this method.

Conclusion: Prothrombin time could not be used as screening test to assess the risk of bleedings as it was proposed for rivaroxaban another direct FXa inhibitor. A more specific and sensitive assay such as chromogenic anti-Xa assays using calibrators should be used to correctly estimate the concentration of apixaban. Finally, standardization of the time between the last intake of apixaban and the sampling is mandatory.

PB3.53 – Blood coagulation tests – XIII

PB 3.53-1

Haemostatic abnormalities in patients with Noonan syndrome

Artoni A

Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milan, Italy

Background: Noonan syndrome is a congenital disorder whose main clinical features are short stature, dysmorphic facial features, congenital heart defects and genital defects. Several patients require surgery at a young age. A bleeding diathesis and various coagulation abnormalities have been anedoctically reported.

Patients and methods: A cohort of patients with Noonan syndrome was investigated with coagulation and platelet function tests. If ratios of prothrombin time (PT) and/or activated partial thromboplastin time (aPTT) were prolonged, the activity of clotting factors was measured. Children without history of bleeding admitted for urologic surgery formed the control group. Bleeding score was calculated in all patients and controls.

Results: The study population included 39 patients with Noonan syndrome (median age 10 years, range 1–28) and 28 controls of similar age. PT and aPTT were normal in 21 patients and all controls, while they were prolonged in 18 patients (46%). Clotting factor assays revealed partial deficiency of FVII in 10 (single or combined with deficiency of other vitamin K-dependent factors), of FXII in 3, and of FVIII, FIX or FXI in three other patients. One patient had combined deficiency of FX, FIX and FV and another had lupus anticoagulant. Oral vitamin K was given to three patients with FVII deficiency with normalization of PT. Platelet aggregation and secretion to ADP 4 μM and collagen 2 μg was significantly reduced in patients than in controls. Bleeding score was above 5 in 4 patients, but no correlation with coagulation or platelet abnormalities was observed.

Conclusion: Nearly 50% of patients with Noonan syndrome shows an impairment of platelet function or mild coagulation abnormalities likely related to vitamin K deficiency. This should be considered before performing surgery in these patients.

PB 3.53-2

The impact of blood sampling and major surgery on plasma levels of thrombin and activated protein C

Müller J[1], Friedrich M[1], Rühl H[1], Becher T[1], Kupper T[1], Oldenburg J[1], Mayer G[2] and Pötzsch B[1]

[1]University of Bonn Medical Center; [2]University of Bonn, Bonn, Germany

Background: Due to their high stability, affinity and specific binding-patterns, DNA-based aptamers, in combination with a stabilizing blood sampling strategy, proved to be valuable tools for the measurement of enzymatically active, circulating coagulation factors (Angew Chem Int Ed Engl. 2011; 50: 6075–8; J Thromb Haemost. 2012; 10: 390–8). To date, however, only limited data on preanalytical requirements and the impact of different procoagulant states on plasma enzyme levels are available.

Aims: The aim of this study was to investigate the influence of the blood collection technique on assay results and to assess the impact of major surgeries on circulating enzyme levels.
Methods: Serial blood samples were taken from three healthy donors. An antecubital vein was punctured with 18- or 21-gauge (G) butterfly catheters. In addition, blood samples for determination of reference values were taken from 20 healthy donors (21G). Furthermore, samples were taken during the course of knee- and hip-replacement surgeries from an indwelling venous cannula (18G). All corresponding plasma samples were analyzed for active thrombin, APC, as well as indirect markers of coagulation.
Results: Serial blood sampling showed that slow downed blood flow leads to an artificial increase of direct and indirect markers of thrombin activity. In contrast to thrombin, APC-levels were not influenced by sluggish blood flow. In 19 of 20 tested healthy individuals, plasma levels of both, active thrombin and APC were found to be below the LLOQ of the corresponding assays (1 and 2 pM, resp.). For one donor, blood sampling was difficult, leading to a massive increase of all thrombin markers. During the course of hip- and knee replacement surgery, plasma levels of both, active thrombin and APC increased to high picomolar levels but returned to baseline only few hours after. As expected, observed kinetics of *in vivo* thrombin and APC generation as well as corresponding peak levels were different between these two types of surgery.
Summary/Conclusions: Plasma levels of free thrombin and APC are novel markers that reflect the current state activity of blood coagulation and its regulation. The blood sampling technique used may lead to an artificial increase of plasma thrombin levels. Overall, the found results pave the way for future studies that will lead to a deeper understanding of the *in vivo* kinetics of the plasmatic coagulation cascade.

PB 3.53-3
Von Willebrand Factor and factor VIII inhibitor testing

Siegemund T[1], Scholz U[2] and Siegemund A[2]
[1]The Scripps Research Institute, La Jolla, CA, USA; [2]MVZ Labor Dr. Reising-Ackermann und Partner, Leipzig, Germany

Background: The development of inhibitors is a major side effect of hemophilia A treatment. Moreover autoantibodies against factor VIII (FVIII) may emerge in healthy patients. In both cases treatment is focused on the prevention of bleedings and the eradication of the inhibitors by means of excessive administration of FVIII (immune tolerance induction, ITI).
Several assays were designed to monitor inhibitor development or eradication in patients with inherited or acquired hemophilia. Most assays base on the reduction of FVIII activity by mixing a FVIII source with dilutions of an inhibitor-containing sample. Inhibitor assays show a large inter-laboratory variability, varying sensitivity and specificity. In ITI discrepancies between inhibitor strengths, FVIII half-life and recovery are observed regularly; usually the inhibitor assays show no FVIII inhibition despite shortened and diminished FVIII recovery.
However, several publications suggest the usability of inhibitor assays to show a superiority of von Willebrand factor (VWF) containing preparations in prevention and therapy of FVIII inhibitors, based on the competition between VWF and some inhibitors for binding FVIII.
Aim: This study is aimed to reveal the influence of VWF on the results from inhibitor assays. Using basic laws of molecule interaction, it is intended to demonstrate how design and execution influence the assay result.
Method: Effect of VWF on inhibitor assays was simulated by applying the Law of Mass Action and reaction kinetics in computer models. The simulations were compared to inhibitor measurements using classical inhibitor assays or various designs of ELISA-based assays.
Result: If VWF competes with an inhibitor for FVIII binding, VWF influences inhibitor assays in a dose-dependent manner. VWF presence suggests an apparent lower concentration of antibodies. As VWF is found in the patient's sample, in the FVIII source and possibly in dilution media, assay design, sample dilution and reagents interfere with the determination of the true inhibitor concentration. Furthermore, FVIII concentration alters the determined antibody concentration.
The binding kinetics of inhibitors to FVIII is slowed by VWF; therefore, incubation times may alter the result.
Conclusion: As present-day inhibitor assay design distorts the balance between VWF, FVIII and inhibitor compared to the in-vivo situation, the beneficial effect of VWF is overestimated. If an antibody competes with VWF for FVIII binding, its concentration might be underestimated up to factor 30. Inhibitors with low concentration or affinity are easily overlooked; high responders might be classified as low responders. This explains discrepancies between inhibitor strengths, FVIII half-life and recovery in ITI or discrepancies between FVIII activity and ELISA-based assays. An influence of VWF on inhibitor development and inhibitor strength can not be derived from FVIII activity-based assays. Nevertheless, preformed FVIII-VWF-complex might be beneficial in prevention or therapy of acute bleedings in patients with a certain antibody profile.
Based on Law of Mass Action and reaction kinetics, the source of high inter-laboratory variability is more a side effect of the inhibitor assay design than the assay execution itself.
Interestingly, the simulations revealed that FVIII inhibitors that compete with VWF for FVIII show type II-like kinetics.

PB 3.53-4
Application of turbidity monitoring by combined activated partial thromboplastin time and waveform analysis to characterize heterogeneity of hemophilia plasma response to recombinant factor VIII

Leong L, Ramsey Ph, Sim D, Patel C, Murphy JE and Laux V
Bayer HealthCare Pharmaceuticals, US Innovation Center, San Francisco, CA, USA

Background: Heterogeneity of hemophilia A (HemA) response to therapy is well documented. Response to therapy is often monitored by the one-stage activated partial thromboplastin time (aPTT), which detects clot formation as increased turbidity or viscoelasticity upon fibrin polymerization. Recently, we have applied turbidity monitoring via combined aPTT and waveform analysis to facilitate coagulation testing of HemA plasma (Leong et al., www.multiwebcast.com/isth/2012/ssc/20995/).
Aims: In this study, we determined whether turbidity monitoring can describe clot characteristics and whether differences in clot characteristics might account for the heterogeneity of hemophilia response to recombinant factor VIII (rFVIII).
Methods: Individual HemA plasma samples ($N = 17$) were spiked with 1%, 5%, or 25% rFVIII, and aPTT was performed. Once clot time (CT) values were obtained, raw turbidity data were exported and further analyzed to obtain turbidity parameters.
Results: Turbidity characteristics were correlated with individual plasma aPTT CT values. The HemA plasma samples tested were roughly categorized into two groups following correlation of their maximal turbidity values attained using a 25% rFVIII spike with their CT values. Group 1 (10 of 17) plasma samples showed a linear correlation between turbidity maxima and CT, with the turbidity maxima exceeding that of normal plasma (>297 arbitrary units). The high turbidity maxima of group 1 plasma samples suggests that FVIII deficiency and consequent low thrombin generation would give rise to the thick, porous fibrin meshwork described in the presence of low thrombin (Weisel and Nagaswami, *Biophys. J.* [1992];63:111–128). In the group 2 plasma samples, the CT values did not correlate with the turbidity maxima values obtained, as the turbidity maxima were lower than expected. Correlation of plasma fibrinogen levels with turbidity maxima or maximal rate of turbidity development indicated a direct linear relationship between these parameters, suggesting that the

reduced turbidity maxima of group 2 plasma is a consequence of reduced (but within normal range) fibrinogen levels (<256 mg/dL for normal). This reduced fibrinogen level can potentially impact clot properties, because fibrinogen concentration is a determinant of fibrin structure and viscoelasticity *in vitro* (Ryan et al. *Biophys. J.* [1999];77:111–128)

Conclusions: The application of combined aPTT and waveform analysis indicated that part of the heterogeneity of hemophilia plasma response to therapy may be attributable to subtly reduced (but still within normal range) plasma fibrinogen levels, which can impact clot structure. Future studies correlating clot characteristics (eg, turbidity) with clinical endpoints could elucidate whether differences in clot physical properties can account for the heterogeneity of patient response in hemophilia.

PB 3.53-5

Six SIGMA metric seems not to be applicable as a good quality tool for most laboratory tests of haemostasis

Martinuzzo ME, Barrera HL, Cheluja MG, D'Adamo MA, Otaso JC, Gimenez IM and Oyhamburu J

Hospital Italiano de Buenos Aires-Grupo Bioquímico, Buenos Aires, Argentina

Six Sigma Metric analyses have been greatly expanded as a tool for clinical laboratories, to measure their procedures performance as a whole. For the calculation of SIGMA the BIAS%, CV%, and allowed Total Error (TEA) of the test are used. In Haemostasis different TEA, according to different requirements are used: CLIA, CAP and biological Variation. The aim of the present study was to calculate Sigma for several tests of the Haemostasis Laboratory, using CLIA, CAP and BV TEA requirements, and comparing the performance obtained. We calculate the BIAS as the mean BIAS obtained in the last four EQC surveys in which our laboratory participated. In all of these surveys the performance of our laboratory was successful. We calculated the cv% from the Internal Quality Control at two levels normal and low of Prothrombin time (PT), activated partial thromboplastin time (APTT) and fibrinogen (FIB), and we also calculated SIGMA for every level of results using CLIA, CAP or BV requirements as TEA. When using BV, none of the tests in any level of control reach an acceptable level of SIGMA (>3). For PT using CLIA requirement as TEA (15%) only 17% of month an acceptable SIGMA was obtained for normal control level, and 25% for low abnormal control. When using CAP requirement of 20% as TEA in 58% of months the SIGMA were acceptable (between 3 and 4), in 25%were good (between 4 and 5) and 8% were excellent (>5) for normal level of control, and in 25% of months the SIGMA were acceptable (between 3 and 4), in 33%were good (between 4 and 5) and 17% were excellent (>5) for low abnormal level of control.

Considering APTT, when CLIA or CAP requirements (both consider 15% as TEA) were used, 8% of months SIGMA calculated were good (4–5), and 92% were excellent for normal level of control, and 8% acceptable, 50% good and 42% excellent for low abnormal control.

Finally, analysing fibrinogen when CLIA or CAP requirements (both consider 20% as TEA) were used only in 33% of months SIGMA reached acceptable values (3–4) and 8% good value for normal control level, and 75% acceptable SIGMA for low abnormal control level.

For factor VII, VIII, Antithrombin (AT) and von Willebrand factor (vWFAg) only BV TEA are published and any SIGMA calculated reached an acceptable value.

For free Protein S and Protein C, although BV requirements were used, results obtained were better. The 83% and 75% of SIGMA calculated were >3.0 for normal and low abnormal control levels of Protein C, respectively. Additionally, 58% of SIGMA calculated were >3.0 in the two levels of control in free protein S.

In conclusion, SIGMA metric seems not to be applicable for most of the tests in the haemostasis laboratory. It is particularly true when the BV is used as TEA, because only free protein S and Protein C reached some acceptable SIGMA values, but no coagulation test, nor chromogenic AT or immunoturbidemetric vWF Ag did with these requirements.

PB 3.53-6

Whole blood thromboelatometry and aggregometry in obese patients

Campello E[1], Eva Z[2], Luca S[1], Paolo P[1], Roberto V[2] and Paolo S[1]

[1]Department of Cardiologic, Throcacic and Vascular Science, University of Padua; [2]Department of Medical and Surgical Sciences, University of Padua, Padova, Italy

Background: It was found that obesity is associated with a hypercoagulable state due to either an increased level of clotting factors and/or the inhibition of the fibrinolytic pathway. Furthermore, several authors reported that platelets from obese individuals seem to be more reactive both at baseline and after aspirin, suggesting an innate hyperaggregable state. Traditional coagulation tests cannot evaluate the whole coagulation system. The thromboelastogram record the viscoelastic changes that occur during coagulation, providing a graphical representation of the fibrin polymerization process. Thus, thromboelatogram enables a complete evaluation of the process of clot initiation, formation and stability, using whole blood. The Multiplate® analyzer is a semi-automated point-of-care device that performs multiple electrode impedance aggregometry in whole blood with five different activators.

Aim: We hypothesized that the point-of-care parameters might serve as early biomarkers to identify the prothrombotic state observed in patients with obesity.

Methods: Eighty patients consecutive referred to our Department, of whom 20 were overweight [BMI = 25–29.9 kg/m^2], 20 with I degree obesity [BMI = 30–34.9 kg/m^2], 20 with II degree obesity [BMI = 35–39.9 kg/m^2] and 20 with III degree [BMI>40 kg/m^2]) were enrolled. Eighty age (±3 years) and gender-matched normal weight healthy individuals acted as controls. Viscoelastic clotting measure was performed by thromboelastogram test. The recorded parameters were both in EXTEM and in INTEM tests: clotting time (CT, sec), clot formation time (CFT, sec), maximal clot firmness (MCF, mm), maximum velocity (MaxVel, mm/min), and the area under curve (AUC, mm x100). In FIBTEM test: MCF was considered. Aggregometric impedance measure in whole blood was performed on the Multiplate® function analyser. Platelets were stimulated in different ways: (i) via arachidonic acid pathway (ASPI test) (ii) via the ADP receptor (ADP test) and finally (iii) via the thrombin receptor (TRAP test).

Results: INTEM-test CFT was significantly prolonged ($P = 0.014$) and MCF ($P < 0.001$), VelMax ($P = 0.013$) and AUC ($P < 0.001$) were significantly increased in 3rd degree obese compared with controls. In EXTEM-test MCF ($P < 0.001$), VelMax ($P = 0.034$) and AUC ($P < 0.001$) were significantly increased in patients suffering from 3rd degree obesity compared with controls. MCF in FIBTEM was significantly higher in 1st, 2nd and 3rd degree obesity than controls ($P = 0.027$, 0.002 and <0.001, respectively). A significant difference in platelet aggregation was found between 3rd degree obese subjects and normal controls in each of the tests considered (TRAPtest, $P = 0.011$; ADPtest, $P = 0.005$; ASPItest, $P = 0.02$). A significant correlation between FIBTEM-MCF with BMI (r 0.24, P 0.019) and waist circumference (r 0.21, P 0.04) was observed. Moreover, a correlation between a) BMI with ADP and ASPI test (r 0.49, $P < 0.0001$ and r 0.50, $P < 0.0001$, respectively); b) waist circumference with ADP and ASPI (r 0.62, $P < 0.0001$ and r 0.57, $P < 0.0001$, respectively) was found.

Conclusions: The use of points-of-care is a quick and efficient method for measuring the degree of hypercoagulability and hyperaggregability in whole blood from obese patients, confirming an increase in the prothrombotic state with the increase in fat mass. The possible role of point-of-care devices in leading the anticoagulant prophilaxis/therapy in subjects with obesity is under evaluation.

Des-gamma-carboxyprothrombin (PIVKA-II) in fetus and newborns

Nishiguchi T[1], Kawamura T[1], Kamo A[1], Sugiyama M[1], Kanayama N[2], Kobayashi T[3] and Ibara S[4]

[1]Shizuoka Children's Hospital, Shizuoka; [2]Hamamatsu University School of Medicine, Hamamatsu; [3]Hamamatsu Medical Center, Hamamatsu; [4]Kagoshima City Hospital, Kagoshima, Japan

Background: Vitamin K deficiency bleeding (VKDB) is rare and life-threatening condition. In Japan, thrice oral administration of vitamin K (VK2: 2 mg) is recommended for prevention of VKDB. But, there is minimal or no data for vitamin K (VK) status in antenatal and postnatal period during the 1st month of age.
Aims: The purpose of present study was to investigate des-gamma-carboxyprothrombin (PIVKA-II: protein induced by VK absence) level in fetus and healthy newborns who received prophylactic VK.
Method: The present study was performed in 1997–1998. Cord blood samples were obtained from 22 preterm and 51 full term infants, and heel-cut blood samples (500 μL) from 83 full term newborns just before VK administration. The latter was performed together with examination of Hepaplastin test. In the present study subjects suffering from any obstetric complications were excluded. PIVKA-II was measured using the highly sensitive method, ECLIA (electro-chemiluminence immunoassay). Before collecting the samples, informed consent was obtained from the parents in accordance with the regulations of our institute.
Results: (1) PIVKA-II level (mAU/mL) during antenatal period was median 33 (range 19–235) during 14 to 28th gestational week (*n*:6), 28 (12–63) during 28 to 36th week (*n*:16), 42 (12–1557) during 37 to 38th week (*n*:18), and 50 (14–2834) after 39th week (*n*:31). There was a significant increase after 37 th week of gestation ($P < 0.01$, Man-Whitney's U test). 2) PIVKA-II in newborns who received prophylactic VK was 292 (20–9325) on 0–1 day of life just before the first administration of VK (*n*:21), 38 (11–1657) on the 4–6 day just before second administration of VK (*n*:16) with significant decrease ($P < 0.01$), and 27 (8–76) on 1 month of life just before third administration of VK (*n*:46) with significant decrease ($P < 0.1$). All of 83 newborns had no occurrence of VKDB.
Summary: Present transectional study shows physiological changes of vitamin K status in antenatal period. Namely, PIVKA-II level is low during preterm period and remarkably increases in term period. And present study shows a dramatic increase of PIVKA II on 0–1 day of life, reaching to near 10,000 mAU/mL and a remarkable decrease after VK administration. This suggests an effectiveness of thrice VK administration for prophylaxis of VKDB.

PB 3.54-2

The effect of the variant F2C20209T on the detection of the mutation F2G20210A

Coll I, Tirado I, Martínez-Sanchez E, Souto JC and Fontcuberta J

Hospital Sant Pau, Barcelona, Spain

Background: Genotyping of the *F2G20210A* mutation in the *F2* gene is performed routinely for diagnosis in thrombophilic disorders. We have developed two automate methods using Real Time PCR to analyze this mutation. It has been reported that the variant *F2C20209T* in the F2 gene may complicate the ability to accurately to analyze the mutation *F2G20210A*. Here we present an example of such a complication that we encountered while screening for this mutation in a patient sent to our center.
Methods: DNA was isolated from peripheral blood leukocytes by Autopure (Qiagen, Izasa). The analysis of *F2G20210A* was performed using two methods: that discriminate various alleles. One method is based on the use of allele-specific fluorescent hybridization probes with the *LightCycler LC480* system (Roche). The other method involved the use of the *TaqMan* system with the *ABI7500PCR* system (Applied Biosystem). Direct sequencing was performed with *Analyzer Genetic* 3500 (*Applied Biosystems*).
Results: The patient was referred to our center for the analysis of the *F2G20120A* mutation. Using the *LightCycler* system for a routine analysis the patient showed atypical values for the melting curves: melting temperatures (Tm) 64 °C (vs. 65 °C) for allele *G* and 55 °C (vs. 58 °C) for allele *A*. In contrast, using the *ABI7500 PCR* system with a specific probe for the *G* allele (probe labelled with FAM) the patient showed an atypical pattern. The direct sequencing data revealed that the patient was heterozygous for the *F2C20209T* variant. During the last 4 years, we have analyzed 6000 samples for the *F2G20210A* mutation using the *Light Cycler* system. Also during the last 6 months, we have analysed 400 samples for the *F2G20210A* mutation using the *ABI7500PCR* system. We have detected six homozygotes for *F2G20210A* and in all cases the result have been confirmed by direct sequencing to rule out the presence of heterozygosity for both *F2G20210A* and *F2C20209T*. So far, we have identified a single patient with the *F2C20209T*, which confirm that this variant is rare in the Spanish population.
Conclusions: The prevalence of the *F2C20209T* variant is very low in the Caucasian population and its position adjacent to the *F2G20210A* mutation makes its identification very difficult. Automated methods using Real Time PCR can detect heterozygous *F2C20209T* variant. With the homozygous for *F2G20210A*, direct sequencing is required to distinguish between individuals who are homozygous for the *F2G20210A* mutation and individuals who are heterozygous for *F2G20210A* and *F2C20209T*.

PB 3.54-3

Differentiation of newer oral anti-Xa and Anti-IIa agents with a reference to the regulatory function of thrombin

Fareed J, Hoppensteadt D, Walenga JM, Jeske W, Iqbal O, Gray A and Lewis B

Loyola University Medical Center, Maywood, IL, USA

Introduction: The newer anticoagualnts represent a group of synthetic antithrombin (Dabigatran: Boehringer Ingelheim) and anti-Xa agents (Abixaban;Bistol Meyer Squib/Pfizer; Rivaroxaban: Bayer/Jenssen; E-doxaban; Diachi Sankyo; Bietrixaban: Portola). All agents are low molecular weiht synthetic organomimetic drugs (MW <500 Da) with targeted antithrombin and anti-Xa activities. Their biochemical and pharmacologic properties differ. Although effective in their specific dosage for given indications these agents differ in their safety profiles, bleeding, risk of myocardial infarction and gastrointestinal disturbances have been reported. The purpose of this study is to differentiate these agents in various biochemical and pharmacologic systems to explain the observed differences in their safety and efficacy profiles.
Methods: Dabigatran and rivaroxaban were obtained from commercial sources and apixaban was of a synthetic origin. Each of these agents were profiled in clot based whole blood and plasma assays. Thrombin generation studies were performed using a flourogenic and chromogenic substrate assay. In addition the effect of these agents on clot stability was also measured. The effect of these agents on platelet aggregation was measured using the aggregometry and flow cyotmetry assays.
Results: All agents produced a concentration dependent anticoagulant effect in the global clotting assays in both the whole blood and plasma samples. Assay based variations were observed. The rank order was Dabigatran>Rivaroxaban>Apixaban. In comparison to the anti-Xa inhibitors, dabigatran was found to be relatively weaker inhibition of thrombin and Xa generation in various systems. Dabigatran also pro-

duced a strong inhibition of thrombin-thrombomodulin mediated activation of protein C, thrombin activatible fibrinolysis inhibitor (TAFI) and factor XIII.
Conclusions: While each of the newer oral anticoagulants are potent inhibitors of thrombin and Xa, the anti-Xa agents are relatively potent inhibitors of thrombin generation, however, do not compromise its regulatory function. In contrast, Dabigatran and related antithrombin agents may compromise thrombin's regulatory functions such as activation of protein C, TAFI and Factor XIII.

PB 3.54-4

Protein-peptide docking of human thrombin: towards improved imaging in cardiovascular disease

Zarzycka BA[1], Nabuurs S[2], Van Den Vijver P[1], Vriend G[2], Hackeng TM[1] and Nicolaes GAF[3]

[1]Maastricht University, Maastricht; [2]CMBI, Radboud University Medical Centre, Nijmegen; [3]Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, The Netherlands

Background: Thrombin plays a central role in thrombosis and haemostasis which is why it remains an important target for anticoagulant therapy. Likewise non-invasive *in vivo* thrombus imaging, detection of thrombin provides important information on thrombus size, location and state of progression. Radioactively labeled peptides, that mimic the natural thrombin (peptidic) substrates could be applied in the thrombus imaging e.g. by Positron Emission Tomography (PET). However, we chose to evaluate the potential use of cyclic peptides, which are known to stay in the blood circulation significantly longer than linear peptides which would give the clinician more time and precision for PET imaging.
Objective: Our aim was to rationally design new cyclic peptides leads for thrombin detection, which could be applied in PET imaging.
Methods/Results: Investigation of new cyclic peptides was based on the structure activity relationship (SAR) and structure based virtual screening (SBVLS) which involved protein-peptide docking. We used information from known peptidic thrombin inhibitors in order to probe the S1–S3 subpockets of the thrombin for cyclic pentapeptides. Rationally designed cyclic pentapeptides were synthesized via solid phase peptide synthesis using Fmoc chemistry. The activity of the cyclic pentapeptides was quantitated by *in vitro* kinetic assay through competition with chromogenic or fluorogenic substrates. We evaluated the activity of the best two cyclic pentapeptides in clotting-based assays. The best cyclic pentapeptide exhibits activity characterized by IC50 = 100 μM and it prolonged the APTT-based clotting time by 30% at concentration 100 μM.
Conclusion: We have characterized and synthetized cyclic pentapetides targeted at thrombin using structure activity relationships. Best peptides so far showed inhibitory activities in range of IC50 = 100 μM. Further optimization of the cyclic peptides for *in vivo* experiments is required.
Disclosure of Interest: The author declares no conflict of interest.

PB 3.54-5

Thrombin generation assay in a patient with acquired factor V deficiency

Radu C[1], Gavasso S[2], Bulato C[2], Campello E[2], Castoldi E[3] and Simioni P[2]

[1]University of Padua, Padua, Italy; [2]Department of Cardiologic, Thoracic and Vascular Sciences, University of Padua, Padua, Italy; [3]Department of Biochemistry, Maastricht University, Maastricht, The Netherlands

Background: Development of acquired inhibitors against factor V (FV) is a rare coagulation disorder. The clinical manifestations range from asymptomatic to severe bleeding episodes. FV inhibitors are associated with various diseases and conditions, most commonly major surgery, exposure to bovine thrombin or transfusion of blood components. The inhibitor titer does not correlate with the level of FV deficiency or with the bleeding risk. Since about 20% of circulating FV is stored in platelets, it has been suggested that platelet FV might be inaccessible to inhibitors and be responsible for the usually benign clinical course seen in these patients.
Materials and Methods: An 18-year-old patient suffering from nephrotic syndrome presented a prolongation of the PT and aPTT, but no bleeding complications. Plasma and platelet FV antigen (FV:Ag) and activity (FV:C) were measured by ELISA and a clotting assay, respectively. Thrombin generation (TG) triggered with 5 pM tissue factor was measured in platelet-poor plasma (PPP) and in platelet-rich plasma (PRP) before and after treatment with intravenous IgG (IVIG) and corticosteroid therapy.
Results: The patient had prolonged PT and aPTT. In mixing studies his plasma prolonged the PT and aPTT of a normal plasma. FV:Ag was low (42%) and FV:C was undetectable (<1%). Platelet FV:Ag was normal (110%). Accordingly, virtually no TG could be detected in the patient's PPP, whereas PRP showed a normal TG. After therapy plasma levels of FV:Ag and FV:C increased (60–106%), whereas platelet FV:Ag decreased (20–50%). TG in PPP progressively increased during the follow-up and eventually normalized.
Conclusions: The TG assay could be an alternative approach for the diagnosis and monitoring of haemostatic changes in patients with FV deficiency due to a coagulation inhibitor. Platelet FV rather than plasma FV plays a significant role in preventing bleeding. FV stored inside platelets is protected from the inhibitor and is probably sufficient to overwhelm the inhibitor when released at the site of injury.

PB 3.54-6

Effects of camel milk on platelet function and coagulation parameters in streptozotocin diabetic rats

Abdelgadir A, AidaA Korisha AA and Alhaider A

Colllege of Medicine and King Khalid Uiversity Hospital, Riyadh, Saudi Arabia

Background: Diabetes mellitus remains a major cause of atherothrombotic disorders, due in part to the associated prothrombotic abnormalities. Other than the conventional anti-diabetic management strategies of diet, hypoglycemic drugs and exercise, camel milk was shown to be effective in the control of the hyperglycemia, shows hypoglycemia and also decreases insulin requirements, in both human diabetics diabetic patients and experimental animals.
Aim: The current study aimed to investigate the effect of camel milk on the blood coagulation and platelet function in streptozotocin (STZ) diabetic rats.
Material and Methods: The study was undertaken in three groups of Wister rats,. Group I: controls (n = 20). Experimental diabetes was induced by single intraperitoneal (i.p) injection of STZ (65 mg/kg) in 40 rats: 20 rats (diabetic camel milk-treated, Group II) received camel milk (50 mL/day/rat) orally; the rest were (n = 20; Diabetic untreated, Group III). After 8 weeks of camel milk treatment blood was collected from retro-orbital venous plexus of anesthetized rats the following tests were undertaken: Coagulation tests: PT, APTT, TT and plasma fibrinogen. Platelets aggregation was undertaken tested in platelet rich plasma (PRP) in response to ADP and arachidonic acid (AA). In addition, plasma activities of aspartate aminotranferase (AST) and alanine aminotransferase (ALT), total bilirubin and protein levels, fasting insulin and glucose levels were also measured.
Results: The untreated diabetic animals showed significant weight loss, marked hyperglycemia, decreased insulin level and increased liver transaminases and bilirubin levels. Additionally, there was significant inhibition of the platelet aggregation response to ADP and AA, decreased plasma fibrinogen (>50%) and shortening of APTT while the PT and TT showed less remarkable changes. Treatment with camel

milk decreased the extent of the weight loss and improved the hyperglycemia, reversed fibrinogen consumption and restored platelet aggregation responses.
Conclusion: Other than its hypoglycemic (anti-diabetic) action, camel milk has reversed the haemostatic activation and the consumption coagulopathy induced by STZ, indicating an anticoagulant/antithrombtic action of camel milk. This would also offer yet additional beneficial action of camel milk as anti-thrombotic agent, in addition further to its already well documented anti-diabetic action.

PB 3.55-1

Elevated plasma factor VIII enhances venous thrombus formation and propagation in rabbits: Contribution of thrombin, factor XI, von Willebrand factor and tissue factor

Sugita C[1], Yamashita A[1], Matsuura Y[1], Iwakiri T[1], Matsumoto T[2], Inoue O[3], Kitazawa T[4], Hattori K[4], Shima M[2] and Asada Y[1]
[1]University of Miyazaki, Miyazaki; [2]Nara Medical University, Nara; [3]University of Yamanashi, Yamanashi; [4]Chugai Pharmaceutical Co., Ltd., Shizuoka, Japan

Background: Elevated plasma levels of factor VIII (FVIII) are associated with increased risk of deep venous thrombosis.
Aims: To elucidate how elevated FVIII levels affect venous thrombus formation and propagation *in vivo*.
Methods: We examined rabbit plasma FVIII activity, plasma thrombin generation, whole blood coagulation, platelet aggregation and venous wall thrombogenicity before and 1 h after an intravenous infusion of recombinant human FVIII (rFVIII). Venous thrombus induced by the endothelial denudation of rabbit jugular veins was histologically assessed. Thrombus propagation was evaluated as indocyanine green fluorescence intensity. Argatroban, a thrombin inhibitor, and neutralized antibodies for tissue factor (TF), factor XI (FXI), and von Willebrand factor (VWF) were infused before or after thrombus induction to investigate their effects on venous thrombus formation or propagation.
Results: The rFVIII (100 IU/kg) increased rabbit plasma FVIII activity two-fold and significantly enhanced whole blood coagulation and total plasma thrombin generation, but did not affect initial thrombin generation time, platelet aggregation and venous wall thrombogenicity. The rFVIII infusion also increased the size of venous thrombus 1 h after thrombus induction. Argatroban and the antibodies for TF, FXI or VWF obviously inhibited such enhanced thrombus formation and all except TF suppressed thrombus propagation.
Conclusions: Elevated plasma FVIII levels enhance venous thrombus formation and propagation. Excess thrombin generation by FXI and VWF-mediated FVIII recruitment appear to contribute to the growth of FVIII-driven venous thrombus.

PB 3.55-2

Risk of venous thrombosis associated with coagulation factor VIII levels and the interrelation of other procoagulant and environmental risk factors

Rietveld IM, Lijfering WM, Bos MHA, Rosendaal FR, Reitsma PH and Cannegieter SC
Leiden University Medical Center, Leiden, The Netherlands

Background: High levels of various procoagulant factors affect risk of venous thrombosis (VT). However, levels often vary together while the effect of high levels of some factors on the risk of VT is more pronounced than that of others, particularly at the extremes of the distribution (very high levels).
Aim: We aimed to determine (i) the relation between very high coagulation factor levels and thrombotic risk (>99th percentile); (ii) the magnitude of the effect of high levels of various coagulation factors on the risk of venous thrombosis; (iii) if coagulation factor levels have predictive ability in *a priori* high-risk groups.
Methods: To study the relation between VT and high coagulation levels we used data of 2377 patients and 2940 controls from a population-based case-control study (MEGA study) into risk factors for thrombosis. We measured fibrinogen, FII, FVII, FVII, FIX, FX, FXI and VWF. Odds ratios (ORs) were calculated using logistic regression and adjusted for age and sex, unless stated otherwise. We contrasted the levels >99th percentile to the lowest quartile (reference group). Consent and ethical approval were obtained for this study.
Results: The ORs for the various coagulation factor levels (P99 vs.)
We used the factors of which high levels had an effect on risk in multivariable analysis (i.e. FVIII, FXI and FIX) to study their ability to predict thrombosis in groups with *a priori* high-risk (surgery, trauma, plaster cast, hospitalized, bedridden, cancer, oral contraceptive use, pregnancy and obesity). Since the groups were reduced in size a lower cut-off was chosen to classify high levels (P90). In each of the separate high-risk groups factor FXI and FIX levels had lower predictive ability than FVIII levels, which had predictive value in all high-risk groups, up to a most pronounced OR of 16.7 (95% CI 8.6–32.6) for obesity.
Conclusion/summary: Very high levels of procoagulant factors increase the risk of venous thrombosis. In multivariable models, only high levels of FVIII/VWF, FIX and FXI remain associated with risk. This effect was most pronounced for high FVIII and VWF levels, of which at least FVIII levels also had predictive ability in *a priori* high-risk groups.

PB 3.55-3

Characterization of a panel of anti-FVIII antibodies by domain specificity assignment, pairwise epitope overlap analysis, and determination of affinities for FVIII and rFVIIIFc

Liu ZL, Goodman A, Peters RT and Kulman J
Biogen Idec, Waltham, MA, USA

Background: Prophylactic therapy for Hemophilia A requires frequent intravenous administration of factor VIII (FVIII) due to the relatively short half-life of FVIII. A recombinant FVIIIFc fusion protein (rFVIIIFc) has been generated to increase the half-life of FVIII. Anti-FVIII monoclonal antibodies are valuable reagents for immunoassay development and for cellular uptake, immunogenicity, and structural studies, as well as for use as probes to assess conformational comparability between FVIII and modified variants such as rFVIIIFc. The utility of these antibodies, however, is often limited by a lack of information regarding their epitope specificities and affinities for FVIII.
Aims: This study was undertaken to characterize members of a panel of both commercially available and internally generated anti-FVIII antibodies with respect to chain and domain specificity, epitope overlap, competition with von Willebrand factor (VWF) for FVIII binding, and affinity for FVIII and rFVIIIFc.
Methods: We first characterized 38 anti-FVIII antibodies to either confirm or determine *ab initio* their chain and domain specificity by using biolayer interferometry (ForteBio Octet). The assay format comprised three sequential steps: (i) binding of a first test antibody to a biosensor probe, (ii) FVIII capture, and (iii) exposure of the FVIII-bound probe to a second test antibody. An increase in the spectral interference signal upon exposure of the probe to the second antibody indicates non-competition between the two antibodies, whereas a lack of change in the signal indicates competition. For determination of chain specificity, B domain-deleted FVIII that had been dissociated into separate heavy and light chains was used. For assignment of domain specificity,

a thrombin exposure step was included after step 2 to enable discrimination between the A domains in the heavy chain, as well as between the a3 acidic peptide and the remainder of the light chain. In a further variation of this approach, overlap between antibody epitopes and the VWF binding site on FVIII was evaluated by substituting a VWF for the test antibody in step 1. The affinities of each antibody for FVIII and rFVIIIc (expressed as K_D), were determined on a surface plasmon resonance (SPR) array instrument (ProteOn XPR36).

Results: Thirty eight anti-FVIII antibodies were characterized with respect to their chain and domain specificity, and antibodies that mapped to the same domain were subjected to pairwise epitope overlap analysis. Collectively, this information was used to generate a FVIII interaction map that included K_D values reflecting affinities for both FVIII and rFVIIIFc. Each antibody exhibited similar affinity for both FVIII and rFVIIIFc, with K_D values spanning the picomolar to nanomolar range. In addition, seven antibodies that mapped to the FVIII C domains competed with VWF for binding to FVIII.

Conclusions: The FVIII antibody interaction map is a valuable resource for assay development and investigation of the function and structure of FVIII. Notably, the observation that members of this panel of antibodies exhibit the similar affinities for both FVIII and rFVIIIFc supports the conclusion that fusion of the Fc domain does not distort the structure of the FVIII molecule.

PB 3.55-4

Preclinical safety of a longer acting recombinant factor VIII (BAX 855)

Dietrich B, Horling F, Spatzenegger M, Piskernik C, Wolfsegger M, Ehrlich HJ, Scheiflinger F, Schwarz HP, Reipert BM and Muchitsch EM

Baxter Innovations GmbH, Vienna, Austria

Baxter and Nektar have developed BAX 855, a PEGylated form of Baxter's licensed recombinant (r) FVIII based on the same manufacturing process. BAX 855 is derived from a CHO cell line using a plasma-protein-free method and a virus inactivation step. The preclinical program evaluated the safety and immunogenicity of BAX 855 in different species. Two lots of BAX 855 were used to test batch consistency; the licensed rFVIII served as reference item.

Systemic toxicity was tested in rats and macaques. Rats received BAX 855 intravenously at 350 or 700 U/kg every other day for 28 days: macaques were administered 150, 350 or 700 U/kg every 5 days for 28 days. Toxicokinetics and formation of anti-product antibodies were assessed. The thrombogenic potential was assessed in Wessler's rabbit stasis model; general safety pharmacology was evaluated in telemetered macaques. Comparative immunogenicity assessment of BAX 855 and the licensed rFVIII included their potential modulation of both the innate (human cytokine release assay; human complement activation assay) and adaptive immune system (macaques; three different hemophilic mouse models).

No thrombogenicity was observed in rabbits treated intravenously with BAX 855 at 900 U/kg. BAX 855 also did not cause any adverse clinical, respiratory or cardiovascular effects in macaques and was well tolerated at all dose levels tested.

No drug-related changes were observed in rats. Lower levels of FVIII activity and BAX 855 (measured through its bound PEG) in plasma correlated with the presence of neutralising antibodies at study end. No signs of toxicity were observed at any dose level in macaques. Minor findings, such as prolonged APTT in all animals, were noted in the last week of dosing, probably due to development of cross-reactive neutralising anti-FVIII antibodies against endogenous FVIII. The formation of binding and neutralising antibodies was also reflected in a statistically significant decrease in exposure during toxicokinetic analysis at study end. Antibody formation is an expected immune reaction after repeated application of heterologous human proteins to animals, and has been observed with non-PEGylated FVIII products.

BAX 855 and the licensed rFVIII induced similar low levels of cytokine release and complement activation *in vitro* that were not different from the buffer control group. BAX 855 and the licensed rFVIII induced similar levels and incidences of antibodies against human FVIII in all animal models. Importantly, immune tolerance to human FVIII was maintained by both BAX 855 and the licensed rFVIII in hemophilic mice that are immune tolerant to human FVIII.

In conclusion, BAX 855 was well tolerated in rabbits and macaques at all dose levels; no thrombogenic events and no adverse clinical, respiratory or cardiovascular effects occurred. In addition, no adverse systemic effects were observed in either species after intravenous administration of BAX 855 for 1 month. Thus, 700 U/kg was considered the no observed adverse effect level (NOAEL) in these studies. Results obtained in comparative immunogenicity studies demonstrate that BAX 855 and the licensed rFVIII have a similar immunogenicity profile. The favorable preclinical safety profile of BAX 855 provides the basis for proceeding with human trials.

PB 3.55-5

Comparing projected prophylactic consumption and effects of recombinant factor VIII Fc Fusion (rFVIIIFc) and shorter half-life FVIII products in haemophilia

Krishnan S[1] and Miners A[2]

[1]*Biogen Idec, Weston, MA, USA;* [2]*London School of Hygiene and Tropical Medicine, London, UK*

Background: The mainstay of treatment for individuals with severe haemophilia A is replacement therapy with FVIII. While the treatment of choice is (primary) prophylaxis, the limitation is that it requires people to inject a considerable amount of FVIII. FVIIIs with a longer half-life, such as rFVIIIFc, are currently being studied. Their proposed advantage is less clotting factor utilization and less frequent injections required to receive similar haemostatic effects compared with traditional shorter half-life factor FVIII products. Alternatively, higher trough clotting factor levels could be achieved using identical amounts of rFVIIIFc.

Aims: To develop a decision-analytic model to compare projected prophylactic FVIII consumption and effects (in terms of breakthrough bleeding episodes) of longer-lasting products, such as rFVIIIFc and short-acting FVIII products.

Methods: Factor VIII consumption and bleeding frequency were estimated by adapting PK models of short-acting FVIII developed by Collins et al (2009 and 2010). The first study demonstrated the relationship between clotting factor dose, frequency of infusion, FVIII half-life, and the time individuals are predicted to be below a 1 IU/dL (<1%) FVIII level during the course of a week. The second study estimated the relationship between time under this trough level and bleeding frequency. The developed decision-analytic model links the results from these two studies and also predicts breakthrough bleeding and factor consumption adjusted accordingly for assumptions related to real-world adherence. Half-life data was based on information from the A-LONG phase three clinical trial data (19 h for rFVIIIFc compared with 12.4 for short-acting FVIII). In the base case analysis, results were projected over 1 year for a 30 year old, assuming that adherence was 70% of scheduled prophylactic doses but that missed doses still represented an incurred cost. It was also assumed that individuals receiving short-acting FVIII were infused three times per week with 37.5 IU/kg whereas individuals receiving rFVIIIFc were infused with 37.5 IU/kg twice a week.

Results: The model-generated base case results over 1 year suggest that rFVIIIFc resulted in a similar number of bleeds per year compared with short-acting FVIII (2.03 vs. 2.08 bleeds, respectively) but required 0.16 million fewer IU's of clotting factor (0.31 vs. 0.47 million IU's) compared with a shorter half-life rFVIII. The difference in clotting factor use was considerably higher when a longer time horizon was used: approximately 6.1 million fewer IUs of longer-acting factor were predicted to be used over a 40-year time horizon.

Summary/Conclusions: This decision-analytic model demonstrates the use of a FVIII with a longer half-life such as rFVIIIFc has the potential to reduce the number of injections individuals require and overall factor consumption, without compromising haemostatic efficacy. Indeed, these results suggest that rFVIIIFc, could reduce time under <1 IU/dL and therefore reduce bleeding if similar or improved levels of adherence can be achieved.

PB 3.55-6

PEGylated biopharmaceuticals and safety evaluation of polyethylene glycol (PEG) with focus on PEG-rFVIII

Stidl R[1], Dietrich B[1], Horling F[1], Spatzenegger M[1], Muchitsch EM[1], Bossard M[2], Scheiflinger F[1], Ehrlich HJ[1] and Turecek PL[1]

[1]Baxter Innovations GmbH, Vienna, Austria; [2]Nektar Therapeutics, Huntsville, AL, USA

Biopharmaceuticals are an emerging branch of therapeutic agents. The applicability of such drugs, however, may be impaired by their short half-life, rapid elimination and ability to induce a specific immune response. These disadvantages may be overcome by chemical modification with polyethylene glycol (PEG), which has been shown to enhance the PK and safety profile of several marketed proteins over the last decades.

Baxter and Nektar are currently developing BAX 855, a PEGylated full-length rFVIII based on the FVIII molecule used for Baxter's licensed rFVIII. PEGylation of BAX 855 uses a metabolically stable PEG polymer of 20 kDa and was optimized to retain functionality of the FVIII molecule and improve its pharmacokinetic properties. The protein portion of the PEG- FVIII conjugate is degraded by proteolysis over time, leaving a PEG portion which is rapidly eliminated. An ADME study in rats with radiolabeled BAX 855 showed that the PEG is quantitatively cleared mainly via the kidneys and excreted into urine or via the liver and excreted into feces even at high doses of 2088 and 4176 U/kg. Like other non-degradable entities, physiological clearance mechanisms of PEG may include liver macrophage uptake. Clearance by macrophages in mammals has been reported to cause vacuolization at high cumulative doses of PEG. Generally, vacuoles were shown to consistently resolve over time, with no cellular damage, inflammation at the vacuolation site or functional deficits of affected tissues, and are therefore regarded as non-adverse. Due to the high potency of FVIII, the absolute amount of conjugated PEG applied with PEG-FVIII is within the range of μg per kg body weight and week, which is considerable below the observed threshold for vacuolation in animal studies. As expected for such low PEG doses, no PEG related vacuolations occurred in the preclinical repeated dose toxicity studies conducted where rats received an intravenous dose of 350 or 700 U/kg BAX 855 every other day, and macaques were administered 150, 350 or 700 U/kg every 5 days both within approximately a month. The No Observed Adverse Effect Level (NOAEL) was 700 U/kg for both species.

In summary, no adverse effects were observed in the preclinical studies with BAX 855 and the PEG load was well below the threshold for vacuolation. This favorable safety profile provides the basis for proceeding with human trials.

PB3.56 – Tissue factor – III

PB 3.56-1

The retention and release of tissue factor by endothelial cells results in the differential activation of p38-MAPK and influences the fate of the cells

Ettelaie C, ElKeeb AM, Maraveyas A and Collier MEW

University of Hull, Hull, UK

Background: We have previously shown that the release of tissue factor (TF) into cell-derived microparticles is mediated by the phosphorylation of serine-253. Moreover, activation of protease-activated receptor 2 (PAR2) in endothelial cells results in the prolonged activation of p38-MAPK in cells expressing TF but only a short-term activation in the absence of TF. The prolonged activation of p38-MAPK is often associated with cellular responses including apoptosis.

Aims: In this study we have explored the mechanisms involved in the activation of p38-MAPK in the presence and absence of TF, and examined the outcome on the mediators of cell apoptosis.

Methods: Endothelial cells were transfected to overexpress wild-type TF and activated by incubation with PAR2-agonist peptide or factor Xa. Furthermore, to mutant forms of TF with alanine (TFAla253) or aspartate (TFAsp253) substitutions at serine-253 were used to suppress or promote the release of TF and treated similarly. The activation of p38-MAPK, Rac1 and Src1 was monitored over 180 min by western blot analysis. In addition, the outcome on the mediators of cellular proliferation and apoptosis (cyclin D, p53 and bax) was examined over 24 h by RT-PCR and western blot analysis. Finally, the outcome on cell proliferation and apoptosis was recorded by cell count and TUNEL assay respectively.

Results: In agreement with our previous work, the activation of PAR2 resulted in two separate peaks of p38-MAPK phosphorylation at 40 and 120 min, in cells overexpressing wild-type TF and was augmented in cells overexpressing the TFAla253-mutant form. In contrast, only the initial peak was present in cells without TF, or those expressing TFAsp253. Rac1 phosphorylation was observed at 40 min in cells expressing wild-type TF and the untransfected cells and at 40 and 120 min in cells expressing TFAla253 mutant. In contrast, Src1 phosphorylation was only observed at 120 min post-activation of PAR2 in the cells expressing the wild-type TF and was significantly enhanced in the cells expressing TFAla253. In all cell samples, the level of cyclin D rose at 8 h following the activation of PAR2 and was higher in cells expressing TFAsp253 and wild-type TF than the untransfected cells. Moreover, the levels of cellular p53 and bax were higher in cells expressing TFAla253 than those in the wild-type TF, which were in turn higher than those in TFAsp253 or the untransfected cells. Finally, an increase in the rate of cell apoptosis was observed at 24 h, in the cells expressing TFAla253.

Conclusions: Our data suggest that the retention of TF following the activation of endothelial cells can induce TF-mediated signalling mechanisms that prolong p38-MAPK activation, culminating in the up-regulation of pro-apoptotic mediators and leading to cell death. Endothelial cells do not normally express TF but may do so in response to pro-inflammatory cytokines. In addition, endothelial cells accumulate TF released as microparticles, from the circulation in particular, during disease conditions. Therefore overwhelming amounts of cellular TF, or the disruption of the release of TF upon activation, may result in cellular apoptosis which can lead to endothelial dysfunction in disease conditions.

PB 3.56-2

Human neutrophils express tissue factor in peritonitis

Nguyen P[1], Lakbakbi S[1], Debrumetz A[2], Rieu Ph[2] and Nguyen P[1]
[1]University of Reims; [2]CHU de Reims, Reims, France

Background: The expression of Tissue factor (TF) by human polymorphonuclear neutrophils (PMN) remains controversial. In animal models, PMN recruitment and TF-expressed PMNs have been shown to initiate thrombus formation at the site of injured endothelial wall. Direct evidence of a TF expression by human PMNs is limited. Septic peritonitis is a good model to study chemotaxis, migration and activation of PMNs.
Aims: To study TF expression by human PMNs obtained from patients presenting with peritonitis. To develop an *in vitro* model to mimic inflammation in human PMNs and examine TF expression.
Methods: PMNs were obtained from patients with peritonitis secondary to peritoneal dialysis. PMNs were isolated by immunomagnetic sorting. TF expression was examined by RT-PCR, Western Blot, immunoprecipitation. TF was visualized by indirect immunofluorescence. TF activity was measured by a Xa generation assay and calibrated automated thrombinography. For the *in vitro* study, PMNs from healthy volunteers were purified by density gradient and stimulated by TNF-α and IL-8. The influence of adhesion was studied by the effect of a potent inhibitor of CD11/CD18 (MAb IB4, Calbiochem). We investigated the role of MAPK kinase (MEK) signaling pathway using U0126 (Sigma).
Results: PMNs obtained *ex vivo* from peritonitis strongly express TF (mRNA and protein). Functional assays (Xa generation, thrombinography) indicate that TF is strongly procoagulant. *In vitro*, PMNs expressed TF mRNA in response to TNF. This TF mRNA expression in response to TNF was increased when PMNs were primed with IL-8. On the contrary IL-8 alone weakly induced TF mRNA expression. In contrast, IL-8 alone induced a strong TF protein expression indicating that this chemokine up regulates TF at the translation level. TNF-α induced TF mRNA expression was inhibited by U0126 indicating the involvement of MAPK kinase pathway. When PMN adhesion was inhibited by MAb IB4, we observed a decrease of TNF-α TF expression.
Summary/Conclusions: PMNs from peritonitis allow to study TF expression in inflammatory conditions. Ours results brings direct evidence of a strong TF expression by PMNs in a septic extravascular situation. It iindicates a *de novo* TF synthesis by PMNs. The *in vitro* study suggests that TF expression by PMNs is the result of chemotaxis, adhesion and inflammatory condition.

PB 3.56-3

Plasma levels of bone morphogenetic proteins and circulating monocyte tissue factor in individuals with echolucent and echogenic carotid atherosclerosis

Sovershaev M[1], Sovershaev T[2], Egorina E[1], Bogdanov VY[3], Hansen JB[1] and Sovershaev M[1]
[1]University of Tromsø, Tromsø; [2]University Hospital of North Norway, Tromsø, Norway; [3]University of Cincinnati School of Medicine, Cincinnati, OH, USA

Background: Tissue factor (TF) potently activates blood clotting via interaction with factor VII (FVII) and FX. Circulating monocytes is a major source of blood borne TF and are sensitive to changes in pro- and anti-inflammatory milieu in blood and vasculature. Lipid-rich and calcified atherosclerotic plaques present as echolucent and echogenic ultrasonic lesions, respectively, bare different risk for thrombus formation on their surface. Bone morphogenetic proteins (BMP)-2 and -7 are potent regulators of vascular calcification and could also modulate TF expression in monocytes. So far no studies have investigated the relationship between plasma levels of BMPs and TF expression on circulating monocytes.
Aims: To assess plasma levels of BMP-2 and BMP-7 and expression of TF on circulating monocyte in individuals with echogenic and echolucent carotid atherosclerosis.
Methods: The study has been approved by the institutional committee on the research ethics. We enrolled subjects with echolucent ($n = 20$) or echogenic ($n = 20$) carotid plaques, as well as controls without carotid atherosclerosis ($n = 20$), judged by ultrasonographic examination. Levels of TF and mRNA expression as well as plasma levels of BMP-2 and BMP-7 were measured using flow cytometry, qPCR, and ELISA (R&D Systems, USA), respectively. Effects of BMPs on TF expression in monocytes were tested *in vitro*. Regression analysis and *t*-test has been chosen to test relationships between variables and differences in mean group values. Two-sided $P < 0.05$ was considered significant.
Results: Plasma from individuals with echolucent carotid atherosclerosis contained significantly higher concentrations of BMP-7 than plasma from individuals with echogenic atherosclerotic plaques ($P > 0.05$) and similar to BMP-7 levels in plasma from healthy individuals. Levels of BMP-2 did not statistically differ between the groups. Relative to echogenic group, higher concentrations of BMP-7 in individuals with echolucent atherosclerosis coincided with stronger TF presentation and higher TF mRNA expression in monocytes. *In vitro*, BMP-7 increased the expression TF mRNA and protein at low μmolar concentrations, whereas BMP-2 had no effect on TF expression in resting monocytes.
Conclusions: Plasma levels of BMP-7 are higher in individuals with echolucent atherosclerotic plaques than in individuals with echogenic lesions. This could lead to increased prothrombotic properties of blood of individuals with soft lipid-rich plaques through BMP-7-mediated stimulation of TF synthesis and presentation in circulating monocytes.

PB 3.56-4

Tissue Factor is expressed by osteosarcoma and regulates IL-8 expression

Tieken C and Versteeg HH
LUMC, Leiden, The Netherlands

Background: Osteosarcoma (OS) is a primary bone tumor mostly affecting adolescents. In spite of aggressive treatment, 30–40% of OS patients develop metastatic disease within 5 years and die. Expression of Tissue Factor (TF), the primary initiator of the coagulation cascade, has been observed in various types of cancer, and expression associates with poor clinical outcome. Apart from its role in coagulation, TF/FVIIa-dependent signaling via PAR2 promotes angiogenesis and tumor progression in various cancer types, through enhanced expression of genes such as IL-8 and CXCL-1. Whether TF is expressed in OS and influences OS cell behaviour has never been documented.
Aims: To investigate whether TF is detected in OS specimens, associates with tumor progression and contributes to OS cellular signaling.
Methods: TF protein expression in 19 high-grade conventional OS biopsies and 14 lung metastases was determined by standard IHC using a specific TF antibody. Scoring was performed semi-quantitatively according to staining intensity on a scale as follows: 0 = total negative slide, 1 = weak, 2 = moderate, and 3 = strong intensity. Semi-quantitative TF mRNA expression in the SAOS-2, U2OS, MNNG-HOS and 143B cell lines was determined by PCR using specific TF primers. TF was downregulated in 143B using an shRNA approach. TF, IL-8 and CXCL-1 levels were determined using qPCR.
Results: All OS biopsies and metastases showed immunoreactivity for TF, but intensity varied between specimens. TF-positivity was significantly increased in metastases compared to primary tumors (Chi-square: $P = 0.019$). The OS cell lines SAOS-2, U2OS, MNNG-HOS and 143B were shown to express TF by semi-quantitative PCR. 143B cells were selected because of its pro-angiogenic and metastatic behaviour in murine xenograft models and 143B cells transduced with TF-specific shRNA showed a 0.6 fold decrease in TF levels by qPCR

($P = 0.02$). IL-8 mRNA expression in TF shRNA transduced cells was reduced by 0.48 fold ($P = 0.013$), while CXCL-1 levels were not significantly reduced.

Summary/Conclusion: Here we show that flTF is widely expressed in clinical OS specimens as well as established OS cells lines. We conclude that targeting TF might be a viable option to inhibit osteosarcoma progression in patients, potentially by inhibiting angiogenesis.

PB 3.56-5

Detection of tissue factor bearing microparticles and the study of the clinical significance in the haemostatic dysfunction of acute myeloid leukemia

Yang L, Bai S, Guo Z and Zhang Y

The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Tissue factor bearing microparticles(MP-TF)has recently been shown to play a critical role in the cancer-associated thrombus formation. The latest research has found that its role can not be ignored in hematologic malignancies. Acute myeloid leukemia (AML) especially acute promyelocytic leukemia(APL) often exists hemostatic dysfunction such as disseminated intravascular coagulation (DIC) and threaten the lives of patients seriously. The study of the MP-TF in the haemostatic dysfunction of AML is very limited.

Aims: To analyze the clinical significance of the MP-TF in the haemostatic dysfunctionin of AML patients.

Methods: MP-TF and TF were detected by FCM (antibody: TF-PE and Annexin-V-FITC) and ELISA respsctively in 64 newly diagnosed AML patients including 22 cases of APL.

Results: MP-TF and TF of AML and APL patients are both higher than those in the healthy adults($P < 0.05$), MP-TF especially presents high expression($P < 0.001$). The MP-TF in the patients whose prothrombin time (PT) is prolonged more than 3s is higher than those with normal PT value($P < 0.05$). MP-TF increases along with prolonged PT, TF is not different between the two groups. The MP-TF of APL patients and TF in AML patients with DIC before chemotherapy are both higher than after chemotherapy($P < 0.05$, $P < 0.001$). The level of TF in the patients with abnormal FDP value is increased ($P < 0.05$), but there is no relation between MP-TF and FDP. There was no statistically significant difference of MP-TF and TF between the AML and APL($P > 0.05$), AML with DIC and without DIC ($P > 0.05$)

Conclusions: MP-TF and TF associated with the extrinsic coagulation pathway participate in the haemostatic dysfunction in the AML.

PB 3.56.6

Oral anti-factor Xa and factor IIa agent mediated inhibition of tissue-factor mediated generation of thrombin in prothrombin complex concentrates

Syed D[1], Hoppensteadt D[1], Kahn D[1], Harenberg J[2] and Fareed J[1]

[1]*Loyola University Medical Center, Maywood, IL, USA;* [2]*University of Heidelberg, Mannhein, Germany*

Introduction: Several oral anti-factor IIa and factor Xa agents have recently been developed. These include the thrombin inhibitors Ximelagatran/Melagatran (M) and Dabigatran Etexilate/Dabigatran (D), which require endogenous conversion to the active agents D and M. The factor Xa inhibitors, Rivaroxaban (R) and Apixaban (A), are anti-Xa agents that do not require any endogenous activation. Ximelagatran was withdrawn from the market due to adverse reactions. Dabigatran, Rivaroxaban, and Apixaban are approved for various clinical indications. Antagonism of the anticoagulant effect may be required in bleeding complications. Contradictory results were reported for the efficacy of various prothrombin complex concentrates (PCCs) with these new oral anticoagulants (NOACs). The purpose of this study was to determine the differences in the thrombin generation inhibitory profiles of the newer oral anticoagulant agents.

Methods: Commercially available PCCs namely Octaplex and Beriplex, were used as a source of Factors II, VII, IX and X. To investigate the effect of each of these agents, a working solution of 1 U/mL of both PCCs were supplemented in a graded concentration of 0–1250 ng/mL with M, D, R and A. Thrombin generation studies were carried out using a thromboplastin activator (RC High, Technoclone Vienna, Austria). Total thrombin generated was measured in terms of nM's. The IC-50 for each agent was calculated individually. The time course of thrombin generation was also measured following the kinetic profiles and AUC.

Results: Dabigatran and Melagatran produced relatively weaker inhibition of thrombin generation with the IC-50 values ranging from 410 to 110 ng/mL in Beriplex and 350–1120 ng/mL in Octaplex. Both Rivaroxaban and Apixaban produced strong inhibition of thrombin generation, with the IC-50 ranging from 58 to 62 ng/mL in Octaplex; whereas, in Beriplex these values ranged from 48 to 50 ng/mL. The onset time for thrombin generation and total thrombin formation was concentration dependent. The kinetics of thrombin generation with A and R were distinct from D and M. At concentrations below 310 ng/mL the total amount of thrombin generated was comparable to the control; however, its formation was delayed. In both systems, D exhibited the weakest thrombin generation inhibitory potential. While the onset time of thrombin generation was delayed at concentrations below 310 ng/mL the levels were comparable to or higher than the control.

Discussion: This data suggests that PCC's such as Octaplex and Beriplex can be used to generate thrombin and it's inhibition by new oral anticoagulant drugs. Octaplex generates much higher amount of thrombin than Beriplex at equivalent units. These results also show that in comparison to the oral anti-Xa agents, the oral anti-IIa agents are relatively weaker inhibitors of thrombin generation. These studies also suggest that the differential inhibition of the generation of thrombin through tissue factor by the anti-Xa and IIa agents may contribute to the potential neutralization profile of PCC's for these drugs.

Fibrinogen Geisinger?W335C: impaired self-assembly, diminished clot stiffness, accelerated clot lysis, and association with thrombophilia

Galanakis DK[1], Neerman-Arbez M[2], Sheiner T[3], Quiery A[4], Liu Y[1], Zhang L[1], Manco-johnson M[5], Rafailovich M[1] and Weisel J[4]

[1]*Stony Brook University, Stony Brook, NY, USA;* [2]*University Medical Center, Geneva, Switzerland;* [3]*University of Pennsylvania, Philadelphia, PA;* [4]*Geisinger Med. Center, Danville, PA;* [5]*University of Colorado, Denver, CO, USA*

The poorly understood association of thrombosis with many congenital dysfibrinogens led to the present investigations. A 58 year old woman experienced numerous venous thromboembolic events since age 20 years, as did her father since age 60. A nephew incurred venous sinus thrombosis at age 15. Except for past use of contraceptives and one episode occurring during her only full term pregnancy, exhaustive hypercoagulability testing disclosed no other risks. Fibrinogen levels were 111 mg/dL and 123 mg/dL by functional and antigen assays, respectively. Similarly decreased by both assays were corresponding levels of her father and nephew. PCR and DNA sequencing disclosed a heterozygous missense mutation encoding for fibrinogen γW335C. Her isolated fibrinogen was >96% coagulable and its thrombin time (1 mg/mL, 2 mM $CaCl_2$, pH 7.4) was 28.1 s, control 19.2 s ($n = 2$). Unreduced and reduced SDS-PAGE bands, including those of clots cross-linked by Factor XIIIa, were identical to those of normal controls. Turbidity maxima (350 nm) of single batroxobin- and throm-

bin-induced clots were 41% and 34% of respective controls, and its thrombin-induced polymerization rate (absorbance units/minute $\times 10^{-3}$) was 33, control 108. By thromboelastography (TEG), duplicate clots formed in the presence of gel-sieved platelets (190×10^3/μL, 4 mM $CaCl_2$, pH 7.4, 15% afibrinogenemic plasma, fibrinogen 2 μM, thrombin 0.5 U/mL) yielded maximum signal amplitude (reflecting shear modulus and clot stiffness) 13% and 15% of controls. Thrombin (0.2 U/mL) induced duplicate clots of 3 μM fibrinogen, containing 125 nM recombinant tissue plasminogen activator (rtPA) and 15% afibrinogenemic plasma, yielded lysis times of 91 and 93 min, controls >300 min. In chromogenic measurements, the fibrin (50 μM) enhanced glu-plasminogen activation rate by rtPA (absorbance, 405 nm, increments in units $\times 10^{-3}$/min) was similar to that of controls, $n = 3$. Scanning electron microscopy revealed that 19% of fibrin fibers displayed one or more unevenly spaced bead-like dense bulges, an occasional fiber end, and mean fiber width 81% ($n = 72$) that of controls. The known proximity of γ335 to the 'a'pocket (γ337–379) led to examination of fibrinogen networks, known to consist of fibers whose periodicity and stiffness are virtually identical to those of fibrin counterparts (Koo et al, J Thromb Haemost, 2010; 8: 2727). Fibrinogen, depleted of its soluble fibrin, was incubated (4 mg/mL, 50 U/mL aprotinin, 20 U/mL hirudin, 0.5 mM EDTA, pH 7.4, 4 h) on polystyrene-coated (1 × 1 cm, 100 μm thick) silica plates. Light microscopy disclosed randomly distributed insoluble patches, which by atomic force microscopy (topographic scanning) consisted of three-dimensional fiber networks (≤1 μm height). Fibers were typically fine (diameter 100 ± 40 nm, control 154 ± 27 nm, $n = 7$), short, and branched. Most fibers displayed multiple bead-like bulges, and many were laterally coalesced into loosely packed coarser fibers (diameter 405 ± 100 nm, control 349 ± 63 nm, $n = 7$). Control network fibers were long, smooth, with occasional overlaps and branching. Abnormal fibrinogen and fibrin networks suggest impaired polymerization contact(s) at site(s) other than that enabling 'A knob': 'a'pocket interaction. Accelerated clot lysis is attributable to decreased plasmin resistance, and its co-presence with hypofibrinogenemia suggests a possible decrease of thrombin sequestration by fibrin, enabling pathologic thrombus extension.

PB 3.57-2

The spectrum of mutations associated with hereditary fibrinogen disorders in the UK

Hill M[1], Seth R[1], Gordon B[1], Patel N[1], Nicholson E[2], Campbell TR[2] and Dolan G[1]

[1]Nottingham University Hospitals NHS Trust, Nottingham; [2]Glasgow Royal Infirmary, Glasgow, UK

Hereditary fibrinogen disorders may be quantitative (afibrinogenemia/hypofibrinogenemia) and/or qualitative (dysfibrinogenemia). The clinical significance of fibrinogen disorders are variable and difficult to predict, particularly with dysfibrinogenemia, which although frequently asymptomatic, may also be associated with an increased risk of bleeding and/or thrombosis

The aims of this study were to investigate the spectrum of mutations associated with fibrinogen disorders in the UK and evaluate the role of genetic analysis in assisting clinical decisions.

Inherited fibrinogen disorders are associated with a range of different mutations found throughout the three genes that encode fibrinogen (FGA, FGB and FGG). Genetic analysis was carried out by nucleotide sequencing of the coding regions of these genes. 161 patients from 120 families originating from throughout theUKwere studied, and this approach identified a causative mutation in 154 patients.

123 patients (84 families) had dysfibrinogenemia as defined by discrepant fibrinogen antigen and Clauss activity. All cases were found to be associated with heterozygous missense mutations.

74 patients (61%) from 56 families were heterozygous for FGA c.104G>A (Aα p.Arg35His). Patients with this variant consistently had a clear antigen:activity discrepancy (mean FibAg 3.14 g/L, Fib Clauss 0.6 g/L). This variant was associated with a small increased risk of bleeding but no increased risk in thrombotic or pregnancy complications. Other recurrent mutations included FGG c.901C>T (γ p.Arg301Cys) which was seen in 17 patients (14%) from 13 families. Eleven other missense mutations were detected including three novel variants; Bβ p.Val169Asp and Aα Pro222Thr, in association with hypodysfibrinogenemia and Bβ p.Ile235Thr in association with dysfibrinogenemia.

Genetic variants were detected in 35 patients with quantitative disorders (27 families). Most cases were heterozygous, while severe deficiency was associated with homozygosity/compound heterozygosity. The nonsense mutation Bβ Arg47* was detected in 10 patients (28%) from six families. Seventeen other genetic variants were detected, none recurrently. These included four splice site variants, four small insertion or deletions, one nonsense mutation and eight missense changes. Novel variants include heterozygosity for Aα p.Ser294 fs, FGG c.124-1G>C, γ p.Lys222Asn and γ p.Ala353Asp in association with hypofibrinogenemia, and homozygosity for splicing variant Bβ Gly320Ser in a patient with afibrinogenemia.

This study has given insight into the spectrum of mutations associated with fibrinogen disorders in theUK, which differs from previously reported incidences, and targeted analysis for recurrent variants may offer a more cost-effective strategy for genetic testing.

Although it is important to consider additional genetic and environmental factors, the increasing availability and critical analysis of clinical data in relation to recurrent mutations – particularly Aα p.Arg35His, may support more confident predictions of bleeding/thrombotic risk in dysfibrinogenemia. This study has also allowed the identification and characterisation of novel variants which may further our understanding of fibrinogen structure and function.

PB 3.57-3

Progression in D-Dimer and biomarkers of fibrin formation correlate with outcome in sepsis

Toh JMH[1], Ken-Dror G[2], Downey C[3] and Abrams ST[2]

[1]Liverpool College; [2]University of Liverpool; [3]Royal Liverpool & Broadgreen University Hospitals NHS Trust, Liverpool, UK

Background: Sepsis is associated with an increase in intravascular fibrin formation and its detection is though fibrin-related biomarkers (FRM). Although D-Dimer (DDI) is the most commonly used, fibrin degradation products (FDP) and fibrin monomer (FM) may also have clinical utility in meeting the unmet challenges of early diagnosis and prognosis of sepsis.

Aim: To examine the hypothesis that increased FRM levels are useful in the diagnosis and prognosis of sepsis.

Methods: FDP, DDI & FM assays were measured on 130 plasma samples from patients on the intensive care unit (ICU) with and without sepsis and healthy individuals. Levels were correlated with each other (Pearson correlation coefficient) and also with fibrinogen (FIB), prothrombin time (PT) and platelets (PLT) as global indicators of clot activation as well as antithrombin (AT). Clinical correlation was also determined for outcome (survival/death) from FRM levels on admission and from serial time-dependent changes (ANOVA).

Results: There was strong correlation between all three FRM ($r = 0.38$–0.93, $P < 0.0001$) but only FM correlated significantly with PT, FIB, PLT and AT. However, FDP & DDI levels could significantly discriminate between patients with sepsis, non-sepsis & healthy individuals [Mean FDP: 28.74, 7.27, 1.42 (μg/mL) respectively] [Mean DDI: 7.17, 2.23, 0.29 (μg/mL) respectively] ($P < 0.05$). A single admission level did not predict outcome in all three FRM but longitudinal time-dependent analyses showed serial trends in FDP & DDI levels correlating to outcome at day 28. Statistical significance was only achieved by serial FDP levels [Mean FDP (μg/mL) from 35.36 (first day) to 21.37 (last day), $P < 0.005$].

Conclusion: For early identification of sepsis via identification of coagulation activation, FM is the most clinically useful. For monitoring the patient with sepsis, FDP and DDI levels can identify sepsis on ICU admission with FDP preferable for monitoring due to its statistically significant time-dependent changes in predicting outcome.

PB 3.57-4

Impairment of fibrin properties resulting from coagulopathy at haemodilution and its reverse by a fibrinogen concentrate Haemocomplettan® (Riastap®)

He S[1], Johnsson H[1], Zabczyk M[2], Hultenby K[1], Wallen H[1] and Blomback M[1]

[1]Karolinska Institute, Stockholm, Sweden; [2]Jagiellonian University, Krakow, Poland

Background: Resuscitation of intravascular volume with crystalloid infusion post trauma leads to plasma dilution and a coagulopathy. In haemodilution, fibrinogen is the first factor to become critically low, giving rise to increase of bleeding risk. Although the plasma levels of other coagulants decline in parallel, usually no decrease of thrombin generation (TG) is found in such patients. This may be explained by greater response of TG for dilution of coagulant inhibitors than for dilution of coagulants (De Smedt, 2009).

Aim: To assess whether at haemodilution, i) the decrease in amounts of formed fibrin is more profound than that in TG, ii) the decrease of fibrin quantity is more important than of the network porosity for down-regulating clot stability against fibrinolysis, a natural sequel to haemostasis, and ii) Haemocomplettan® (a fibrinogen concentrate) can restore the impairment of proteolytic resistance of fibrin.

Methods: *In vitro*, a haemodilution model was examined by determining Calibrated Automated Thrombogram, quantity of clotted fibrinogen i.e., fibrin (He, 2013), fibrin network permeability, images of Scanning Electron Microscope (SEM) and Rotational Thrombelastogram (ROTEM). This model was created with a normal plasma pool (NPP) diluted from 100 to 75, 50 and 25%, and then spiked with Haemocomplettan®. Coagulation and fibrinolysis were triggered by tissue factor and t-PA respectively.

Results: At haemodilution, the global marker of TG i.e., Endogenous Thrombin Potential was not changed due to delay of thrombin inactivation. In parallel with dilution, less fibrin was generated and a network with lower permeability (Ks) was formed. Haemocomplettan® added to NPP25% made the fibrin amounts rise but the Ks further decline. According to SEM images, the addition of Haemocomplettan® giving total fibrinogen 2 g/L tightened the network significantly. Noteworthy, an additional network was formed between the major fibrin fibres, comprising thinner fibres and smaller pores than those in the major network. Haemocomplettan® at a higher concentration (total fibrinogen 4 g/L) further modified the appearance of clot: the additional network still existed but the major fibres tended to lateral association forming thick 'fibrin fibre bundles'. In ROTEM assays, haemodilution did reduce the maximum visco-elasticity i.e., Maximum Clot Firmness (MCF) and did shorten the fibrinolysis rate i.e., Clot Lysis time (CLT). When the total fibrinogen rose to 2 g/L after addition of Haemocomplettan®, normalized levels were found in these ROTEM parameters. Greater concentrations of Haemocomplettan® added (total fibrinogen 4–6 g/L) brought parallel enhancements in MCF, but no further prolongation of CLT was induced by the enhancement of fibrin amounts.

Summary: Due to the unequal effect of haemodilution on TG and fibrin formation, clots derived from diluted plasma with insufficiency of fibrinogen are less stable to plasmic digestion, notwithstanding the tightened network structure. This study *in vitro* suggested that normalization of clot strength against fibrinolysis which may have a positive influence on haemostasis needs fibrinogen concentrations no less 2 g/L (after administration of Haemocomplettan®); there may be no more advantage at using higher doses of this concentrate, since 'fibrin fibre bundles' probably formed as seen *in vitro* favor fibrinolysis by exposing more binding-sites to plasminogen (Veklich, 1998)

PB 3.57-5

Global development plan for a double virus inactivated fibrinogen concentrate for the treatment of congenital fibrinogen deficiency

Hegener O[1], Schwartz BA[2] and Knaub S[1]

[1]Octapharma AG, Lachen, Switzerland; [2]Octapharma, Hoboken, USA

Introduction: Congenital afibrinogenaemia and hypofibrinogenaemia are rare inherited disorders occurring in homozygotic patients with an estimated incidence of 1 in 10^6. Patients present with frequent severe bleeding episodes since birth or early childhood. Bleeding may occur after a minor trauma or a small surgical intervention, into the skin, mucosa, muscles, gastrointestinal tract, or the brain. Therapeutic substitution with human fibrinogen concentrate can correct the haemostatic defect and arrest the bleeding in patients with these fibrinogen deficiencies. Octafibrin is a highly purified, lyophilized, human plasma fibrinogen concentrate, without added albumin. Octafibrin is double virus inactivated using two dedicated virus inactivation/removal steps, solvent/detergent treatment, and nanofiltration.

Aim: This poster presents a plan for the global development of Octafibrin, taking into account discussions with European Regulators and the FDA. This plan also involves discussions with the European pediatric committee (PDCO) which oversees the inclusion of pediatric subjects into drug development under the new EMA guidelines.

Methods: The development plan calls for a prospective, randomized, open label, multinational, pivotal PK comparison of Octafibrin to an existing marketed product in 18 adult and adolescent patients, including comparison of a surrogate efficacy endpoint measured by TEG. In a second study the efficacy and safety of the product in bleeding and invasive procedures will be assessed in 24 adult and adolescent patients. Finally a pediatric PK, efficacy and safety study in patients below 6 years will be performed but because of the rarity of these patients this study will not need to be completed before review and approval by the regulatory agencies. Clinical studies are planned to be started end of 2012.

Results: A double virus inactivated, plasma derived fibrinogen concentrate (Octafibrin) will be globally developed in an ultra rare congenital disease after harmonized discussions with EU and US regulators. Pivotal comparative PK data and interim efficacy and safety data will be available at time of regulatory submissions while the finalization of the pediatric study is deferred.

PB 3.57-6

Acquired hypofibrinogenemia assessed by whole blood thromboelastometry profiles in children with acute lymphoblastic leukemia treated with l-asparaginase

Spiezia L, Putti MC, Sartori MT, Campello E, Bon M, Maggiolo S, Varotto S, Geranio G, Basso G and Simioni P

University of Padova, Padova, Italy

Background: Treatment with L-Asparaginase (L-Asp) or PEG-L-Asparaginase (PEG-L-Asp) in patients with acute lymphoblastic leukemia (ALL) is associated with coagulation disturbances, being deep venous thrombosis the most common clinical consequence. Coagulation alterations most frequently reported were hypofibrinogenemia, low plasminogen and antithrombin (AT) plasma levels, protein C and S deficiencies. Whole blood rotation thromboelastometry (ROTEM®),

using FIBTEM test, has been reported to be a good tool to identify hypofibrinogenemia.
Aim: To evaluate whole blood rotation thromboelastometry profiles in children with ALL treated with PEG-L-Asp in order to identify strategies for monitoring and treating complications in LLA children.
Methods: Children treated with PEG-L-Asp for ALL consecutively referred to the Pediatric Hemato-Oncology Clinic of the Padua University Hospital, from June to December 2012, were enrolled. After informed consent, samples were obtained at predefined time points during the induction and reinduction phases of chemotherapy. Maximum Clot Firmness (MCF, normal value 9–25 mm), i.e. the maximum amplitude in millimeters reached in FIBTEM thromboelastogram, which is used to assess the specific role of fibrinogen in whole blood clot formation following inhibition of the platelets by Cytocalasin D, was performed. Moreover, AT and fibrinogen plasma levels were measured on the same samples.
Results: One hundred seventy two sets of thromboelastometry measurements were collected from 26 ALL patients (age range 20 months–17 years; M/F 13/13). Seventy-five MCF measurements (40%) resulted below the lower limit of MCF normal value. A significant linear correlation was found between MCF values in FIBTEM and fibrinogen plasma levels measured with Clauss method ($P < 0.001$). No influence of reduced AT plasma levels on thromboelastometry determination was observed. Replacement with i.v. fibrinogen concentrates was suggested for MCF values <2 mm. No hemorrhagic complication was reported in our cohort. One 6-year old boy presented cerebral venous thrombosis not related to supportive (i.e. fibrinogen, plasma and/or platelets) therapy.
Conclusions: The MCF value in FIBTEM may be used as an alternative test to determine the clotting efficacy of fibrinogen respect to the Clauss assay. The determination of fibrinogen function by means of ROTEM® can be considered a complementary test to the conventional clotting profile used for the management of asparaginase-induced coagulopathy in children with ALL. Larger studies are needed to evaluate the role of thromboelastometry to guide fibrinogen replacement therapy in acquired hypofibrinogenemia due to asparaginase treatment.

PB3.58 – Other coagulation factors – III

PB 3.58-1

Platelet uptake of recombinant factor VIIa takes place *in vivo* but does not prolong its circulating half-life

Hyseni A[1], Schut AM[2], Roest M[1], Lisman T[1] and De Groot PG[1]
[1]*University Medical Center Utrecht, Utrecht;* [2]*University Medical Center Groningen, Groningen, The Netherlands*

Background: The half-life of Factor VIIa (FVIIa) in the circulation in humans is around 2–3 h. However, a once-daily administration of recombinant Factor VIIa (rFVIIa) has been reported to prevent bleeding in patients with hemophilia A, suggesting that the product has a longer therapeutic effect than suggested by its half-life. Previously, we and others have shown that platelets internalize rFVIIa *in vitro*.
Aims: The aim of this study was to investigate if uptake of rFVIIa by platelets also takes place *in vivo* and to evaluate whether this process influences the half-life in the circulation.
Methods: We administered a single bolus dose of 90 μg/kg rFVIIa to six pigs, and collected blood samples before and 12 time-points after administration. The concentration of FVIIa within platelets was assessed in lysates of isolated, washed platelet preparations. We determined VIIa concentrations in these lysates by a functional assay in which we determined the prothrombin time (PT) in Factor VII deficient plasma to which lysates were added. In addition, we assessed FVIIa antigen levels in platelet lysates using a novel ELISA that recognizes activated but not zymogen factor VII.
Results: We detected FVIIa in platelet lysates using both the functional assay and the ELISA. The highest amount of FVIIa detected in platelet lysates was present in the sample taken 1 h after administration of rFVIIa. Platelet FVIIa levels remained elevated up to 12–16 h after infusion. The half-life of platelet FVIIa was similar to that of the half-life of FVIIa in plasma as shown by an unchanged ratio of FVIIa in plasma over FVIIa in platelets in samples taken 1 h or more after injection.
Conclusions: Here we have demonstrated that rFVIIa is taken up by platelets *in vivo* using a model of non-bleeding pigs. The half-life of rFVIIa in platelets is similar to the half-life in plasma, suggesting a continuous exchange of rFVIIa between platelets and plasma. Our hypothesis that platelet uptake protects rFVIIa against clearance is thus not supported by the present experiments.

PB 3.58-2

A fusion of thrombin-activatable FVII and soluble tissue factor displays improved activity and pharmacokinetic properties compared to activated FVII

Salas J, Tan S, Kistanova E, Ashworth T, Chen K, Acosta M, Pape R, Pierce GF, Jiang H, Peters RT, Johnson B and Light D
Biogen Idec Hemophilia, Waltham, MA, USA

Background: Improvements in the pharmacokinetics of recombinant activated factor VII (rFVIIa) are limited by its susceptibility to inactivation by protease inhibitors such as antithrombin III (ATIII), αII-macroglobulin, and tissue factor pathway inhibitor. Furthermore, this susceptibility can be enhanced by mutations aimed at improving the enzymatic activity of rFVIIa. We have previously shown that a thrombin-activatable rFVIIFc variant is resistant to ATIII inhibition, resulting in enhanced pharmacokinetic properties relative to rFVIIa and rFVIIaFc. However, such variant showed poor activity in *in vitro* coagulation assays. We have generated a thrombin-activatable rFVII recombinantly fused to the soluble form of tissue factor (sTF, residues 1–219). We reasoned that such variant would remain in the zymogen form in circulation and resistant to protease inhibitors, but activated at the site of an injury by thrombin. Upon activation, the sTF protein would act as a cofactor to enhance the activity of thrombin-activatable rFVIIa significantly.
Aims: To develop a FVII variant with improved efficacy and pharmacokinetic properties relative to rFVIIa.
Methods: We have generated a thrombin-activatable rFVII variant as an Fc fusion heterodimer, where one Fc moiety is recombinantly fused to the C-terminus of thrombin-activatable rFVII, while the second Fc moiety is fused to the C-terminus of a soluble form of tissue factor. To assess potential unintended effects of the sTF protein on endogenous FVIIa, we generated a negative control heterodimer variant where an arginine essential for thrombin cleavage was mutated to an alanine. The clotting activity of rFVIIa variants was measured by the soluble tissue factor dependent prothrombin time assays (sTF-PT) and rotational thromboelastometry assays (ROTEM). The Factor Xa (FXa) generation activity was determined by monitoring FX activation using a chromogenic substrate specific for FXa. The pharmacokinetics of rFVII variants were determined in hemophilia B mice by ELISA, and ATIII inhibition was assessed by SDS PAGE electrophoresis, sTF-PT and ELISA of the rFVII-ATIII complex.
Results: Both the thrombin-activatable FVII and negative control heterodimers displayed no activity in sTF-PT assays and, consequently, were not susceptible to ATIII inhibition. Furthermore, the thrombin-activatable heterodimer showed enhanced FXa generation activity *in vitro* vs. equal molar levels of rFVIIa following activation by thrombin. When we evaluated activity by ROTEM using blood from hemophilia A donors, the thrombin activatable variant showed an enhancement of activity >10-fold relative to rFVIIa. In contrast, the activity of the negative control variant by ROTEM was negligible, demonstrating that the activity associated with the thrombin-activatable heterodimer is mediated by the FVIIa/sTF complex, not sTF alone. Furthermore, the thrombin-activatable heterodimer displayed

improved pharmacokinetics and prolonged efficacy in HemB mice compared to rFVIIa as determined by ELISA and ex vivo ROTEM.
Summary/Conclusions: The thrombin-activatable rFVII/sTF heterodimer shows high activity following thrombin activation and displays a longer half-life not impacted by ATIII, resulting in a prolonged efficacy relative to rFVIIa. Taken together, these results set the basis for a potential long-lasting recombinant bypass treatment option for hemophilia patients with inhibitors.

PB 3.58-3
Hemostatic effect of an anti-TFPI peptide in a murine model of hemophilic joint bleeding

Hakobyan N[1], Cong L[1], Hartmann R[2], Scheiflinger F[2], Dockal M[2] and Valentino LA[1]
[1]Rush University Medical Center, Chicago, IL, USA; [2]Baxter Innovations GmbH, Vienna, Austria

Background: Tissue factor (TF) is part of the extrinsic pathway of the coagulation system, triggering the coagulation cascade after tissue damage. Tissue factor pathway inhibitor (TFPI) inhibits factor X activation by TF/factor VIIa and thus down regulates coagulation. Anti-TFPI is hypothesized to amplify the effect of TF and therefore boost blood coagulation. Anti-TFPI could therefore be used as a therapeutic agent in hemophilia patients.
Attachment of polyethylene glycol (PEGylation) is known to prolong circulation time of therapeutic agents. A PEGylated, linear anti-TFPI peptide (JBTA8) was developed with improved pharmacokinetic (PK) characteristics. JBTA8 interacts with murine TFPI and is therefore suitable for testing in a murine model of hemophilia.
Aims: The goal of this study was to evaluate the effect of a PEGylated anti-TFPI peptide on puncture induced hemarthrosis in a murine model of hemophilia A and compare its effect with recombinant factor (F) VIII (Advate).
Methods: Mice deficient in FVIII activity (E16 FVIII B6;129S4-F8^{tm1kaz}/J) with severe hemophilia A were treated with JBTA8 (1 mg/kg) or various doses Advate (10, 50 and 100 IU/kg) by intravenous tail vein injection. At specified times after each product administration, the right knee joint capsule was punctured with a 30 gauge needle to induce a onetime hemorrhage. Animals were sacrificed 3 days following joint injury and assessed for the presence of bleeding using gross and histological methods. Total bleeding scores (TBS), which includes gross and histological bleeding scores, were assigned to each joint. The data show that JBTA8 prior to injury significantly reduced joint bleeding. The protective effect of 1 mg/kg JBTA8 on puncture induced hemarthrosis was significantly greater than the effect of 10 IU/kg but <100 IU/kg of Advate assessed by TBS. There was no statistically significant difference in TBS after pretreatment with 1 mg/kg JBTA8 compared to 50 IU/kg Advate.
Summary: These preliminary results suggest that anti-TFPI peptide may provide a protective effect against experimental joint bleeding. The effect of investigated anti-TFPI peptide dose on hemarthrosis was comparable to that of Advate and can contribute to blood coagulation in hemophilia.

PB 3.58-4
Structure and function of chicken protein C inhibitor

Hayashi T[1], Akita N[2], Okamoto T[3], Nishioka J[4] and Suzuki K[4]
[1]Mie Prefectural College of Nursing, Tsu-city; [2]Clinical Engineering Suzuka University of Medical Science, Suzuka; [3]Mie University School of Medicine, Tsu; [4]Faculty of Phamaceutical Sciences, Suzuka University of Medical Science, Suzuka, Japan

Background: Protein C inhibitor (PCI), a member of the plasma serine protease inhibitor (SERPIN) family, is a physiological inhibitor of activated protein C (APC) and thrombin- thrombomodulin complex; they are the main proteases of the anticoagulant protein C pathway. Human PCI also inhibits other serine proteases of the hemostatic system, such as thrombin, factor Xa, factor XIa, factor VIIa (complexed with tissue factor), plasma kallikrein, and urokinase-type plasminogen activator, as well as proteases of the reproductive system such as prostate-specific antigen and acrosin of the sperm. We showed that PCI is expressed in many organs including liver, kidneys, lungs, and the reproductive organs, such as testes, seminal vesicles and ovary in primates, but only in the reproductive organs in rodents. However, it is still unknown whether PCI is present in birds.
Aim: In this study, we cloned a full-length chicken PCI cDNA, and determined its mRNA distribution in chicken tissues, and functional characteristics using recombinant chicken PCI.
Methods: Full-length chicken PCI cDNA was isolated by screening of the Lambda ZAP chicken liver cDNA library using chicken partial PCI cDNA fragment as a probe. DNA sequence determination and Northern blot analysis were performed using standard methods. Recombinant chicken PCI was prepared using Baculovirus expression system. Inhibitory activity of the recombinant chicken PCI for APC prepared from chicken plasma was determined in the presence or absence of heparin.
Results: Chicken PCI cDNA encoded a putative 19-residue signal peptide and a 413-residue mature protein; this showed 46.2%, 46.3%, 42.3%, 45.3% and 44.7% amino acid sequence homology with the human, rhesus monkey, bovine, rat and mouse PCIs, respectively. Chicken PCI had a putative reactive site peptide bond, Arg-Ser, that is the same as the reactive site sequence (Arg-Ser) of other species' PCI, except for bovine PCI. Chicken PCI mRNA (2.1 kb in size) was expressed strongly only in the liver. Recombinant chicken PCI inhibited chicken APC, and this inhibition was dependent on the heparin concentration. The three dimensional structure of chicken PCI, estimated on the basis of the amino acid sequence of chicken PCI, was similar to that of human PCI, which inhibits human APC dependent on heparin.
Conclusion: The data suggest that chicken may have the anticoagulant protein C pathway in plasma, in which PCI regulates APC in heparin-dependent fashion, as in human plasma.

PB 3.58-5
Fibrinogen protects activated factor XIII from early inactivation in human plasma

Müller J, Krammer R, Rühl H, Oldenburg J and Pötzsch B
University of Bonn Medical Center, Bonn, Germany

Background: Activated factor XIII (FXIIIa) is a transglutamase that plays a central role in the regulation of thrombus stability, thrombus regulation, cell-matrix interactions and wound healing. While activation kinetics of FXIII have been extensively analyzed, little is known about the mechanisms involved in the regulation of the catalytic activity of FXIIIa.
Aims: To study the catalytic half-life of FXIIIa in human plasma and to study if fibrinogen plasma levels interfere with the catalytic half-life of FXIIIa.
Methods: To measure time-related changes in FXIIIa activity, recombinant human FXIIIa was added to human plasma and incubated at 37 °C. The loss of FXIIIa activity was measured using a fluorometric FXIIIa assay. This assay was sensitive to a lower limit of quantification of 0.01 IU/mL. To test the interindividual variability, FXIIIa inactivation kinetics were measured in plasma samples obtained from five healthy blood donors. All blood donors gave written informed consent.
Results: In pooled normal plasma the catalytic activity of FXIIIa declined to 74%, 45% and 33% of initial after 5, 30, and 60 min of incubation. The half-life of FXIIIa was approximately 20 min showing a low interindividual variability (CV <10%). In fibrinogen-deficient plasma, the half-life was reduced to 5 min with residual FXIIIa-activi-

ties of 24% and 20% measured after 30 and 60 min of incubation. The catalytic half-life returned to normal after normalization of the fibrinogen level by addition of purified fibrinogen.
Summary/Conclusion: Our data indicate that fibrinogen protects FXIIIa from early inactivation.

PB 3.58-6

Novel mutation of factor XII gene in five Taiwanese families of congenital factor XII deficiency

Shen MC, Lin CY, Lin SY, Chang CS, Wang CC, Lin BD and Hsieh HN

Changhua Christian Hospital, Changhua, Taiwan

Background: Factor XII deficiency was first described by Ratnoff and Colopy in 1955, it was not associated with abnormal bleeding despite causing a marked prolongation of aPTT. Most patients are diagnosed by incidentally found prolonged PTT and normal PT. Factor XII gene is 12 Kb long with 14 exons and is located on chromosome 5q33-qter. More than 200 cases, with more than 20 mutations in the factor XII gene have been reported previously. However, there were no cases reported fromTaiwan.
Aim: We have seen five unrelated families of congenital factor XII deficiency since 1995. Their clinical, laboratory and genetic studies will be presented.
Methods: Factor XII coagulant activity (FXII:C) was measured by one-stage method. All exons and their junctions of factor XII gene were amplified and sequenced. Informed consent was obtained from patients and family members.
Results: Age (year)/sex of the five index patients were 55/Female, 71/Male, 44/F, 59/F and 48/M, respectively, all had no personal or family history of abnormal bleeding. There were no consanguinity in all families. PT/PTT (sec) were 12/257, 11.4/150.7, 10.7/81.6, 10.7/>240 and 10/108, respectively (reference ranges: PT 9.9–12.0, PTT: 28.6–38.6). These were detected during preoperative screens in all index patients, except patient I who was also found to have prolonged PTT and normal PT before she received liver biopsy for evaluation of HBV hepatitis. FXII:C levels (%) were 0.2, 2.2, 2.6, 1.2 and 1.3, respectively (reference range:39–154). Direct DNA sequencing in index patient I identified a homozygous 11908 Gto A transversion resulting in FXII Glu502Lys substitution in exon 13 of the FXII gene. A similar heterozygous mutation was detected in both her parents, sister and daughter. In index patients III, IV and V, a homozygous single nucleotide transversion at 12118 Gto A in exon 14, resulting in FXII Gly542Ser substitution was identified. Two daughters (patient III) and one son each (patients IV and V) had similar heterozygous mutations. In index patient II, a heterozygous 11903 T to A transversion in exon 13 resulting in Leu500Gln substitution and a heterozygous Gly542Ser mutation were identified. The patient's son had similar heterozygous mutation of Leu500Gln. All families showed 46CC at residue 46 of FXII gene. Glu502Lys and Gly542Ser mutations of FXII gene have been reported fromChina. Leu500Gln is a novel mutation which is located within the catalytic domain of FXII gene, and the hydrophobic Leucine substituted to hydrophilic Glutamine may suggest to cause unstable structure of the catalytic triad His393-Asp442-Ser544, resulting in impaired secretion or decrease of the enzymatic activity.
Conclusion: One novel mutation of Leu500Gln in FXII gene was identified among five Taiwanese families of congenital factor XII deficiency. This mutation may suggest to cause reduced secretion of factor XII protein or decrease of the functional activity.

PB3.59 – Regulation of coagulation and fibrinolysis – III

PB 3.59-1

An additional pathway for hypofibrinolysis in diabetes: the role of complement C3

Hess K[1], Alzahrani S[2], Price J[3], Strachan M[4], Baxter P[5], Gamlen T[5], Marx N[1], Schroeder V[6], King R[5] and Ajjan R[5]

[1]University hospital Aachen, Aachen, Germany; [2]Specialized Diabetes and Endocrine Centre, King Fahad Medical City, Riaydh, Saudi Arabia; [3]Centre for Population Health Sciences, University of Edinburgh, Edinburgh, UK; [4]Metabolic Unit, Western General Hospital, Edinburgh, UK; [5]University of Leeds, Leeds, UK; [6]University Clinic of Hematology and Central Hematology Laboratory, Bern, Switzerland

Background: Plasminogen activator inhibitor (PAI)-1 has been regarded as the main antifibrinolytic protein in diabetes but recent work indicates that complement C3, an inflammatory protein, compromises fibrinolysis in individuals with type 1 diabetes (T1DM). However, it is currently unknown whether this holds true in patients with type 2 diabetes.
Aim: To investigate the association between plasma complement C3 levels and fibrinolysis in individuals with T2DM.
Methods: Fibrin clot lysis was determined in 838 patients enrolled on the Edinburgh type 2 diabetes study using a turbidimetric assay. Plasma levels of complement C3, C-reactive protein (CRP), PAI-1 and fibrinogen were analyzed by ELISA. Correlations were analysed using Pearson's test after log transforming non-normally distributed data. The R environment for statistical computing was employed to fit regression models and determine independent predictors of clot lysis time and complement C3 levels.
Results: Clot lysis time showed a highly significant correlation with C3 and PAI-1 plasma levels ($r = 0.25$, $P < 0.0001$ and $r = 0.15$, $P < 0.0001$; respectively). In contrast, a relatively weak correlation was detected with CRP ($r = 0.08$, $P = 0.02$) and fibrinogen ($r = 0.08$, $P = 0.01$). In a regression model involving PAI-1, C3, CRP and fibrinogen, C3 was a predictor of lysis time (predictive value for 0.1 mg/mL change in plasma levels 14.4 [95% CI 7.9, 21.0] $P < 0.001$), as was PAI-1 (predictive value for 0.1 ng/mL change in plasma levels 8.2 [4.2, 12.1; $P < 0.001$]) with a smaller effect shown for 0.1 mg/mL change in fibrinogen levels (5.3 [0.01, 10.5]; $P = 0.049$) and none detected for CRP (−2.5 [−9.7, 4.8]; $P = 0.50$). No correlation was demonstrated between C3 and PAI-1 plasma levels, consistent with previous observations of the two proteins affecting different pathways in fibrin clot lysis ($r = 0.04$, $P = 0.37$). Although women showed higher plasma levels of CRP compared with men (4.49 ± 0.33 and 2.95 ± 0.22 mg/L, respectively; $P < 0.01$) no such difference was found in complement C3 plasma levels (1.336 ± 0.02 and 1.344 ± 0.03 mg/mL, respectively; $P = 0.83$). Plasma levels of C3, CRP, fibrinogen and PAI-1 did not differ in the presence of previous history of myocardial infarction or cerebrovascular disease. Plasma levels of all four proteins correlated with body mass index, but only fibrinogen showed an interaction with age and duration of diabetes. To investigate interactions between treatment and plasma levels of proteins studied, a regression model including all various therapies was constructed. CRP plasma levels were positively predicted by long lasting insulin and nitrate therapy (1.78 [0.86, 2.07] and 1.68 [0.66, 2.53]; $P < 0.05$ for both). In contrast, none of the medication predicted complement C3 plasma levels although a trend was observed in men towards a positive and a negative association with sulphonylurea and antiplatelet therapy, respectively (0.08 [0.05, 1.17] $P = 0.08$ and −0.09 [0.04, −1.83] $P = 0.06$).
Conclusions: C3 is at least as strong as PAI-1 at predicting fibrin clot lysis in subjects with T2DM. Gender and medications are not associated with changes in C3 plasma levels in the population studied. Therefore, future studies investigating fibrinolysis potential should

also analyze C3 plasma levels as a surrogate marker of fibrin clot lysis in individuals with T2DM.

PB 3.59-2
Specific detection of polyphosphate in cells, tissues, and thrombi

Travers RJ, Choi SH and Morrissey JH
University of Illinois at Urbana Champaign, Urbana, USA

Background: Inorganic polyphosphate (polyP) is widely present in biology. The recent discoveries that polyP is secreted from activated human platelets and that it potently modulates coagulation and inflammation have led to a burst of interest in this ancient molecule regarding its roles in human pathophysiology.
Aims: Our goal was to localize polyP in animal thrombosis models, using the isolated polyP-binding domain of *E. coli* exopolyphosphatase (PPXbd) as the candidate detection agent. PPXbd binds polyP with high affinity and has been used to detect polyP in cells, but we felt it essential to determine if PPXbd also binds to anionic glycosaminoglycans like heparin. If PPXbd is specific for polyP, it could be used to reliably detect polyP *in vitro* and *in vivo*, and could function as a novel antithrombotic agent, akin to a blocking antibody.
Methods: We evaluated the ability of PPXbd to specifically identify polyP in the mast-cell like cell line, RBL-2H3, known to have distinct classes of secretory granules containing polyP and/or heparin. PolyP was detected in fixed, permeabilized cells using recombinant PPXbd fused to maltose-binding protein (MBP), followed by rabbit anti-MBP and fluorescent donkey anti-rabbit IgG. To visualize heparin, permeabilized RBL-2H3 cells were treated with human antithrombin, followed by a rabbit antibody to antithrombin and fluorescent donkey anti-rabbit IgG. Control cells were pretreated with exopolyphosphatase or heparinase to destroy endogenous polyP or heparin, respectively. To visualize polyP in thrombi formed *in vivo*, clotted sections of mouse common carotid arteries treated with 5% $FeCl_3$ were removed, formalin-fixed, and paraffin-embedded. Serial 5 μm sections were stained with purified PPXbd-MPB fusion protein followed by peroxidase-conjugated mouse anti-MBP and detection with peroxidase substrate (DAB).
Results: Binding of PPXbd and antithrombin to permeabilized RBL-2H3 cells was readily detectable by immunohistochemistry, displaying punctate staining typical of mast cell secretory granules. Pretreating cells with exopolyphosphatase significantly ($P < 0.001$) reduced the fluorescent signal from PPXbd but not from antithrombin. Conversely, pretreating cells with heparinase significantly decreased the fluorescent signal from antithrombin but not from PPXbd. PolyP was readily detectable in sections of RBL-2H3 cells after formalin fixation and paraffin embedding. We are currently employing this method to detect polyP in sections of thrombi from mouse models of carotid artery thrombosis.
Summary/Conclusion: Immunodetection of polyP via PPXbd binding is robust, even in paraffin sections of cells and tissues, and appears to be highly specific for polyP. This approach can therefore provide important information about the localization of polyP in thrombi and tissues. Our findings also suggest that PPXbd can specifically inhibit the procoagulant activity of polyP *in vivo*, allowing us to test the concept of polyP as a novel antithrombotic target.

PB 3.59-3
Serpins interfering with procoagulant activity and pressure regulation in a basal vertebrate

Ragg H and Wang Y
Bielefeld University, Bielefeld, Germany

Background: Blood coagulation of gnathostomes evolved from a simple cascade of procoagulant proteases at the dawn of vertebrates. Previous analyses showed that lampreys, an extant group of primordial vertebrates, encode many genes pivotal for coagulation, including those coding for prothrombin, factor X, and fibrinogen. However, how control of procoagulant enzymes emerged is largely unknown.
Aims and Methods: In order to reconstruct the ancestry of anticoagulant proteins, we have isolated lamprey cDNAs coding for serpins and characterized the activities of the recombinant proteins towards clotting proteases.
Results: Three serpins were identified that exhibit protease-inhibiting activity directed against central coagulation-promoting enzymes. The lamprey heparin cofactor II (HCII) gene, clearly identified by its syntenic position conserved in all vertebrate genomes, appears to fulfil a role comparable to its counterpart in gnathostomes. Uniquely in vertebrates, lamprey angiotensinogen serves as protease inhibitor that is not only a potent, but also a highly selective thrombin inactivator, as all other serine proteases investigated did not interact with the angiotensin precursor protein. Moreover, heparan sulphate, a widely occurring glycosaminoglycan, strongly stimulates thrombin inhibition, similar to heparin. We also isolated a lamprey serpin depicting inhibitory activity towards human factor Xa, though the serpin was proteolytically cleaved to some extent.
Summary: Together, these three serpins appear to be major regulators of the coagulation cascade in lampreys that are believed to mirror many essential aspects of the early coagulation system. Antithrombin, seemingly not present in lampreys, may have adopted some of physiological roles of these ancestral inhibitors during the advent of 'crown' vertebrates. A scenario now emerges that provides insight into major aspects of the basal interaction network enabling and controlling fibrin formation.

PB 3.59-4
Glycan associated functional changes of desialylated, deglycosylated and recombinant acutobins

Tsai IH, Wang YM, Khoo KH and Chen J-M
Institute Biol. Chem., Academia Sinica, Taipei, Taiwan

Acutobin is a specific α-fibrinogenase isolated from the venom of *Deinagkistrodon acutus* (hundred- pace pitviper), and this serine protease has been used on patients to treat or prevent strokes via intravenous injection. We previously showed that acutobin (40 kDa) contains unique disialyl-rich complex type glycans at four Asn positions. However, whether the glycan's structural variations would affect the enzymatic properties and the pharmacokinetics of acutobin remain to be clarified. Sialidase treated (DS-acutobin) and PNGase treated acutobin (PNG-acutobin) retained the kinetic specificity for fibrinogen Aα and released fibrinopeptide A as effectively as the native acutobin, as shown by SDS-PAGE and HPLC analyses. The sugar-modified acutobins showed slightly increased fibrinogenolytic activity, but induced plasma coagulation as fast as the native acutobin *in vitro*. Moreover, although similar amounts of fibrinogen/fibrin degradation products (FDP) were generated after intravenous injection of either native acutobin or the sugar-modified acutobin in mice, the generation of FDP after intraperitoneal injection of the sugar-modified acutobin was significantly less than that after native acutobin injection. These results suggest the contribution of acutobin's sugars for vascular localization of the protease. Recombinant acutobins (rATBs) were expressed and purified from HEK293T and SW1353 cells, and their N-glycans were profiled by mass spectrometry. The glycans of rATB from HEK293T were found to be smaller than that of native acutobin, while the glycans of rATB from SW1353 were found to be larger. Both rATBs, PNG-acutobin and DS-acutobin showed similar reactivities and kinetic specificities toward the chromogenic substrate N-Tosyl-Gly-Pro-Arg-*p*-nitroanilide. Compared with acutobin, SW1353-rATB showed lower α-fibrinogenase activity, and HEK293T-rATB was no longer specific for the Aα chain. We also found that the N-glycans could protect the stability of acutobin and rATBs at 55 °C but were less protective at higher temperature (≥65 °C). Taken together, our

data suggest that the glycans of acutobin are not necessarily required for substrate binding and catalysis, but are essential for increasing the stability, specificity and pharmacokinetics of the enzyme. The different glycans found in various pitviper thrombin like proteases are probably resulted from co-evolution of the protein sequences and the venom gland N-glycosylation machinery. (The mouse experiments were carried out under the guideline of the regulation of Academia Sinica, Taiwan; grant support was from the National Science Council and Academia Sinica, Taiwan)

PB 3.59-5

An ex vivo evaluation of the hemostatic effects of plasma-derived C1 inhibitor

Levy JH[1], Szlam F[2] and Gelone S[3]

[1]Duke University School of Medicine, Durham, USA; [2]Emory University School of Medicine, Atlanta, USA; [3]ViroPharma Incorporated, Exton, USA

Background: C1 inhibitor (C1-INH) is used to treat or prevent angioedema attacks in patients with hereditary angioedema. Because C1-INH inhibits bradykinin and has the potential to interact with the coagulation system, we evaluated the hemostatic effects of increasing concentrations of C1-INH on human blood using thromboelastometry and thrombin generation.

Methods: Following institutional approval, blood was collected from 10 healthy volunteers who provided informed consent. Samples were processed immediately for thromboelastometry or were centrifuged to obtain platelet poor plasma that was subsequently used to assess thrombin generation. Samples were supplemented with C1-INH (ViroPharma Biologics, Inc., Exton, United States) at concentrations of 0.14, 0.7, 1.4, 2.8, and 7.0 IU/mL. Controls included samples without C1-INH supplementation, samples with the procoagulant recombinant factor VIIa (rFVIIa) (1.5 μg/mL) or prothrombin complex concentrate (PCC) (0.6 U/mL) added, and samples with the anticoagulants antithrombin III (AT-III) (1.2 IU/mL) or desirudin (10 nM/0.5 μg/mL) added. The viscoelastic effects of C1-INH were assessed using the ROTEM® device, while thrombin generation was evaluated using a calibrated automated thrombin generation system. Data are expressed as mean ± SD. Kolmogorov-Smirnov statistics were used to test for normal distributions. Increasing C1-INH concentrations, as well as pro-and anticoagulants vs. control were evaluated by ANOVA for repeated measurements, followed by post hoc analysis using Bonferroni correction. $P < 0.05$ was considered significant.

Results: In the studies testing viscoelastic effects, increasing concentrations of C1-INH did not have a procoagulant effect based on ROTEM measurements when compared to the control data regardless of the activator ($P > 0.05$). At concentrations of 2.8 and 7.0 IU/mL, C1-INH had a mild but statistically significant anticoagulant effect based on maximum clot firmness ($P < 0.05$). rFVIIa significantly decreased clotting time, and desirudin increased clotting time from 59 ± 11 to 103 ± 44 s when the EXTEM reagent was used as an activator ($P < 0.001$) and from 163 ± 8 to 269 ± 42 s with the INTEM reagent ($P < 0.001$). In the thrombin generation studies, there was no difference in the lag time of thrombin generation between C1-INH-supplemented samples vs. control samples regardless of the activator used ($P > 0.05$). Addition of 30 nM rFVIIa shortened tissue factor-activated thrombin generation lag time by ~48%, and by ~ 30% with dilute Actin. Desirudin, a direct thrombin inhibitor, significantly delayed the thrombin generation lag time. Increasing concentrations of C1-INH had no effect on peak thrombin generation as compared with control samples. AT-III decreased peak thrombin generation by >40%, while PCC increased peak thrombin generation by >60%.

Summary/Conclusions: Increasing C1-INH concentrations up to 7.0 IU/mL did not have a procoagulant effect based on viscoelastometry parameters or thrombin generation in blood obtained from healthy volunteers. C1-INH demonstrated a weak anticoagulant effect based on maximum clot firmness at the two highest concentrations studied. There was no evidence of an *ex vivo* procoagulant effect of plasma-derived C1-INH when studied at concentrations up to 10-fold higher than those achieved with clinical dosing in patients with hereditary angioedema.

PB 3.59-6

How aspirin inhibits human cyclooxygenase-1? Hybrid quantum mechanical/molecular mechanical (QM/MM) calculations on the mechanism

Komaromi I, Tóth L and Muszbek L

University of Debrecen, Medical & Health Science Center, Debrecen, Hungary

Background: Aspirin (acetylsalicylic acid; ASA) suppresses the generation of prostaglandin H2, the precursor of thromboxane A2. Aspirin acts as an acetylating agent; its acetyl group is covalently attached to a serine residue (S529) of the substrate-binding cavity of the cyclooxygenase-1 (COX-1) enzyme. The exact reaction mechanism has not been revealed by experimental methods.

Aim: The goal of this study was to characterize the reaction mechanism of the irreversible inhibition of COX-1 by aspirin using static ONIOM (Our N-layer Integrated molecular Orbital molecular Mechanics) type hybrid QM/MM methods. We intended to decide whether the above methods predicted a single-step elementary reaction or multiple-step one(s), leading from the reversible ASA-COX-1 complex to the salicylic acid and acetylated COX-1 products. A further aim was to determine the 'exact' transition state(s) and local minima on the potential energy surface and prove their existence by vibration analyses.

Methods: We used 'high level' *ab initio* and density functional theory (DFT) calculations on a model system; the steric and electrostatic effect of the neighboring amino acids, in a relatively large surrounding region, was also taken into account. The latter was achieved by using the electronic embedding method in ONIOM, which allows polarizing the wave function by the surrounding partial charges. Series of calculations were carried out to assess the dependency of the results on the level of theories applied in quantum chemical calculations.

Results: As there was no available X-ray structure for human COX-1, we derived a model for the respective human protein by homology modeling, using the known structure of sheep COX-1 as a template. Calculations were carried out on this model. ASA was docked into the substrate-binding cavity of the enzyme. The most stable and most populated (~70%) pose obtained by docking resulted in a complex suitable for the next step of the reaction. The potential energy surfaces as a function of the S529 Oγ – C (ASA acetyl carbonyl) and the S529 Hγ – S529 Oγ distances suggested only a single saddle point (i.e. one elementary reaction step) for all the ONIOM QM/MM calculations. The 'exact' transition states can be featured by an almost completed proton transfer, i.e. the reaction has asynchronous character. All our failed efforts to find the 'tetrahedral intermediate' and also the normal mode corresponding to the imaginary frequency in the transition states confirmed a single elementary reaction step for the ASA-COX-1 trans-esterification.

Conclusion: A model for the human COX-1 was constructed by homology modeling. ONIOM type QM/MM methods suggested a plausible single elementary step mechanism for the aspirin – human COX-1 trans-esterification reaction.

PB 3.60-1

Coagulation factors V and X gene polymorphisms are associated with breast cancer risk and correlate with phenotype

Tinholt M[1], Viken MK[2], Consortium OBC[3], Sahlberg KK[4], Nyberg S[4], Skretting G[5], Dahm AEA[5], Lie BA[2], Sandset PM[5] and Iversen N[2]

[1]Oslo university hospital, Oslo, Norway; [2]Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway; [3]OSBREAC, Oslo, Norway; [4]Institute for cancer research, Oslo university hospital, Oslo, Norway; [5]Research Institute of Internal Medicine, Oslo University Hospital, Oslo, Norway

Background: The bidirectional relationship between cancer and thrombosis is now recognized. Tumor cells express procoagulants and may stimulate cancer progression by both coagulation independent and dependent signaling. Tissue factor (TF), FXa and thrombin have been shown to promote migration, angiogenesis, adhesion and invasion. Blood clots may provide a structural platform for settlement and growth of cancer cells.

Aim: We aimed to yield a better understanding of the molecular mechanisms underlying the link between cancer and the hemostatic system. To address this, levels of hemostatic markers in blood of breast cancer patients were compared to controls, and association to single nucleotide polymorphisms (SNPs) in hemostatic marker genes were explored. Genotype-phenotype correlations were conducted between SNPs and mRNA- and protein expression.

Methods: Blood from 390 breast cancer patients* and 350 controls*, and tumor tissue from 150 of the patients have been analyzed. Blood samples were taken immediately before surgery (no prior treatment).

Plasma levels of TF, FVIII, FIX, FX, fibrinogen, VWF, D-dimer, TF pathway inhibitor (TFPI), antithrombin, protein C (PC), protein S, endogenous thrombin potential (ETP) and activated PC resistance (APCR) were determined.

Selected SNPs in hemostatic genes, including F5 rs6025 (factor V Leiden) and F2 rs1799963 (prothrombin G20120A variant) were genotyped by multiplexing (Sequenom). mRNA expression in tumor was measured by Agilent microarray (G4851A).

*All attendants signed a written consent. The study was approved by the Regional Ethics Committee.

Results: A procoagulant state in breast cancer patients was observed as demonstrated by increased APCR and D-dimer levels, as well as higher maximum thrombin generation. The increase in global coagulation may result from elevated levels of FVIII, FIX, VWF and decreased levels of antithrombin detected in patients.

Genotyping of the two most common genetic thrombotic risk factors revealed that F5 rs6025 was equally distributed among patients and controls, whilst the appearance of F2 rs1799963 was twice as common in patients. However, this was not significant due to the low minor allele frequency.

Preliminary results demonstrate novel associations of F10 and F5 SNPs to breast cancer risk. The rare allele of F10 rs3093261 was more frequent among patients (OR = 1.60, [95% CI, 1.17–2.17], $P = 0.003$). The rare allele of F5 rs12120605 was also more frequent in the patients (OR = 1.52, [95% CI, 1.07–2.17], $P = 0.02$), and showed association with increased TF mRNA levels in tumor, implying a possible indirect regulation of pro-coagulant expression in the tumor. In contrast, the rare allele of F5 rs6427199 was more frequent in controls (OR = 0.71, [95% CI, 0.52–0.96], $P = 0.03$), and correlated with antithrombin. This might explain the higher antithrombin levels observed in controls. Furthermore, the same SNP also correlated with lowered APCR, explaining parts of the variation in APCR observed between cases and controls, which could not be explained by FV Leiden.

Conclusion: This study displays activated coagulation in breast cancer patients, and demonstrates new genetic polymorphisms in the F5 and F10 genes that associate to breast cancer risk, and correlate with phenotype. The study provides novel findings, which extend the knowledge on the molecular mechanisms underlying how the hemostatic system relates to breast cancer.

PB 3.60-2

Biomarkers predictive of venous thromboembolism in patients with high grade gliomas

Thaler J, Ay C, Kaider A, Reitter E-M, Haselböck J, Marosi C, Zielinski C and Pabinger I

Medical Univeristy of Vienna, Vienna, Austria

Background: High grade gliomas (HGG) are among the most prothrombotic malignancies. Thromboprophylaxis in patients with HGG is challenging because of the high risk of intracranial hemorrhage. Biomarkers predictive of venous thromboembolism (VTE) might help to identify HGG patients who are likely to benefit from primary thromboprophylaxis.

Aims: To investigate the predictive role of blood biomarkers for occurrence of VTE in patients with HGG. We also examined, whether the development of a specific risk assessment model (RAM) for patients with HGG further improves risk stratification for VTE in these patients.

Methods: We investigated 11 potential biomarkers of future VTE in HGG patients who were included in the Vienna Cancer and Thrombosis Study, which is a prospective and observational cohort study approved by the institutional ethics committee. At study inclusion detailed data on patients' characteristics and information on the tumour histology were recorded.

A blood sample was drawn at study inclusion and each patient was followed for a period of 2 years, until occurrence of VTE and/or death or loss of follow-up.

Results: We included 169 patients with HGG in this study. Hundredtwelve patients had glioblastomas, 37 anaplastic astrocytomas, 11 anaplastic oligoastrocytomas and nine anaplastic oligodendrogliomas. Twenty-six (15.7%) patients developed VTE during follow-up. In multivariable analysis (including age and type of HGG) a significant association ($P < 0.05$) was found between risk of future VTE and the following parameters: leukocyte count (hazard ratio [HR] per doubling: 1.88 [95% CI: 1.02–3.39]), thrombocyte count (HR per 50 increase: 0.71 [95% CI: 0.53–0.92]), sP-selectin (HR per doubling: 2.73 [95% CI: 1.36–6.70]), prothrombin fragment 1 + 2 (HR per doubling: 1.55 [95% CI:1.00–2.34]), FVIII activity (HR per 20% increase: 1.13 [95% CI: 1.03–1.23]) and D-dimer (HR per doubling: 1.50 95% CI: 1.15–1.94]). No association was found with hemoglobin-, C-reactive protein- and fibrinogen levels or peak-thrombin generation.

Using a stepwise forward selection process three dichotomized biomarkers were chosen for an exploratory VTE RAM. This RAM comprised platelet count (cut-off: £25th percentile), FVIII activity (cut-off: ³75th percentile) and sP-selectin (cut-off: ³75th percentile). One point was assigned for each parameter according to the respective cut-off. The cumulative probability of developing VTE after 12 months was 5.9% (2.2–14.9%) in patients with score 0 ($n = 75$), 18.6% (10.4–32.0%) in patients with score 1 ($n = 60$) and 32.3% (17.3–55.1%) in patients with score 2 ($n = 28$). Only three patients had a score of 3 and two of them developed VTE.

Summary/Conclusions: : We identified six biomarkers that indicated an increased risk of developing VTE in HGG patients. Surprisingly, in contrast to previous results obtained in solid tumours, we detected an inverse association between platelet count and risk of VTE, indicating that HGG patients with low platelet count are at particularly high risk of developing VTE. We also developed an exploratory RAM for

prediction of VTE that is able to reliably stratify patients according to their risk of VTE.
The present study provides data for assessing the risk of VTE in HGG patients and identifying those patients at particularly high risk of developing VTE who might benefit from primary thromboprophylaxis.

PB 3.60-3
Pre-existing pulmonary thrombi in cancer patients diagnosed with an unsuspected pulmonary embolism

Bozas G[1], Bradley RL[2], Avery G[2], Stephens A[2] and Maraveyas A[3]
[1]Queen's Centre for Oncology and Haematology, Castle Hill Hospital, Cottingham, UK; [2]Radiology Department, Castle Hill Hospital, Cottingham, UK; [3]Queen's Centre for Oncology and Haematology, Castle Hill Hospital, Cottingham, UK

Background: Pulmonary embolism (PE) is increasingly identified in cancer patients who undergo CT imaging in the absence of clinical suspicion. The morbidity potential of such findings is significant, hence prompt identification and treatment with anticoagulants is warranted. Nevertheless some pulmonary thrombi may remain inconsequential or just clinically unsuspected, at least for a period of time.
Aims: To investigate the prevalence and duration of persistence of pre-existing thrombi in the pulmonary vasculature in patients diagnosed with a clinically unsuspected pulmonary embolism (UPE).
Methods: From March 2010 all cancer patients with a PE as incidental finding are identified and managed under a specialized pathway which involves specifically trained radiographers, radiologists and clinical nurse specialists (previously published). We retrospectively reviewed previous CT imaging of patients with UPE managed under this pathway for pre-existing thrombi in the pulmonary vasculature. All reference CT scans were performed with IV contrast and slice thickness of 1 mm as per institutional standards, but not with pulmonary angiography (CTPA) protocols. Digital films were reviewed by two of the authors (GA and RB) independently. Differences between their assessments were reconciled by mutual consent.
Results: Between March 2010 and March 2012, 108 patients with UPE were included in the pathway. Ninety-one of these patients had assessable previous CT imaging (median time since last imaging: 105 days, range: 47–707). Post reconciliation, the prevalence of pre-existing pulmonary thrombi was 13% ($n = 12$). In two (17%) of these patients pre-existing thrombi were located in the lobar arteries and in 10 (83%) in segmental and sub-segmental branches. In one of the patients, thrombosis was suspected but findings were attributed to tumour infiltration in previous imaging and no further action was taken at the time. Median interval between a current and a previous positive CT chest was 105 days (range: 51–547). Comparison of the distribution of PE in baseline and previous imaging showed that in six (50%) cases it had remained similar for a median of 92 days (range: 63–253), in three (25%) there was progressive extent of thrombosis (scan intervals: 84, 174, 193 days respectively) and in three (25%) distributions of thrombi were different (scan intervals: 51,232, 547 days respectively).
Conclusions: Clinically unsuspected pulmonary thrombi are often missed in non CTPA imaging but in some cases they may not progress for a period of time even without anticoagulation. The sequence of imaging appearances in our cohort of UPE patients might also support the notion that for some patients pulmonary thrombosis may be a local phenomenon rather than a thromboembolic event from a distant site of DVT.

PB 3.60-4
Different patterns of death among cancer patients and venous thromboembolism

Garcia-Garcia JA, Parra- Esquivel P and Lopez-Alonso RJ
University Hospital of Valme, SEVILLE, Spain

Background: Venous thromboembolism (VTE) is a significant cause of morbidity and mortality in patients with cancer. VTE is also associated with early death in subjects with hidden cancer. The timing and evolution to death could be different according to the time of VTE and cancer diagnosis.
Objective: To determine the mortality among patients with cancer according to the time of diagnosis of VTE.
Methods: In a retrospective study, the survival of cancer patients who developed a VTE during 2011 was analyzed. All patients were followed until death or the date of the end of study on 31st December 2012. Subjects were categorized into three groups according the time of VTE diagnosis: (i) Before Cancer, (ii) At the time of cancer diagnosis, (iii) After cancer. The survival time was calculated. The cause of death was also included.
Results: Seventy-two patients were included in the study. Of them, 43 (60%) were male and median (Q1-Q3) was 72 (58–79) years. Median time (Q1-Q3) was 4.4 (1.4–11.2) months. At the time of VTE diagnosis, 34 (47%) and 32 (44%) were under oncology treatment and presence of metastasis. Forty-three (60%) died during the follow-up. The causes of death were: 8 (19%) due to VTE and 35 (81%) secondary to advanced cancer. Most frequent primary cancer included lung, gastrointestinal and pancreas in 14%, 24%, 14%, respectively. According to the time of VTE and cancer diagnosis, 5 (71%), 12 (75%), 26 (53%) subjects died in groups 1, 2 and 3, respectively ($P = 0.07$). Survival time al 1, 3 and 6 months were: i) 76%, 47% and 29% in VTE patients with hidden cancer or at the time of cancer, and, ii) 84%, 64% and 38% in patients who developed VTE after cancer ($P = 0.08$).
Conclusions: VTE patients with hidden cancer or diagnosis at the time of cancer have a worse prognosis than those diagnosed after cancer.

PB 3.60-5
TF, TFPI and TAT complexes in myeloproliferative neoplasms

Gadomska G, Stankowska K, Boinska J, Swistek W, Drela E, Zekanowska E and Rosc D
Nicolaus Copernicus University in Torun, Collegium Medicum in Bydgoszcz, Poland, Bydgoszcz, Poland

Background: Myeloproliferative neoplasms (MPNs) are caused by the neoplastic transformation of multipotent stem cell. In patients with MPNs are observed frequent hemostatic disturbances such as thrombotic disease and bleeding disorder. It is known that the most clinically important coagulation pathway is the tissue factor (TF) -mediated coagulation pathway. In the literature there are no data on the role of TF in the pathogenesis of thrombotic complications in MPNs.
Aims: The aim of this study was to evaluate the blood coagulation mediated by TF in patients with MPNs.
Methods: The study was carried out in a group of 32 patients with MPNs aged 21–86 (mean age 57), treated in the Clinic of Haematology, Dr Jan Biziel University Hospital No. 2 in Bydgoszcz, Poland. These patients were enrolled in the study at the time of the diagnosis of MPNs and prior to the implementation of appropriate treatment. The study group included: 16 patients with essential thrombocythemia (ET), eight with polycythemia vera (PV), five with chronic myelogenous leukemia (CML) and three patients with primary myelofibrosis (PMF). The control group consisted of 30 healthy volunteers, age and sex matched. In blood samples were determined TF, tisssue factor pathway inhibitor (TFPI) and thrombin-antithrombin complexes (TAT) concentration using ELISA tests (Imubind ELISA kits,

American Diagnostica Inc.). The study was approved by the Bioethics Committee of Collegium Medicum in Bydgoszcz, the Nicolaus Copernicus University in Torun, Poland (no. KB/396/2010).
Results: The study showed that patients with ET (Me = 378.36 pg/mL), PV (Me = 319.70 pg/mL), CML (Me = 466.08 pg/mL) and PMF (Me = 378.25 pg/mL) had significantly higher TF concentration than the control group (Me = 130.13 pg/mL). Moreover, patients with ET (Me = 47.98 ng/mL) and PV (Me = 41.98 ng/mL) had also significantly lower concentration of TFPI than controls (Me = 72.50 ng/mL) ($P = 0.010820$ and $P = 0.030290$, respectively). Furthermore, it was observed that in patients with CML was significantly higher level of TAT complexes in comparison to the control group (19.14 ng/mL vs. 2.24 ng/mL, $P = 0.006710$).
Conclusions: TF-dependent activation of coagulation process is reported in the blood of patients with MPNs. In patients with ET and PV is increased tendency to hypercoagulability due to the significantly lower concentration of TFPI.

PB 3.60-6
Prolonged LMWH treatment of venous thromboembolism in patients with cancer-A restrospective observational study

Cortiula F, Fasola G and Barillari G
University Hospital of Udine, Udine, Italy

Background: Patients with cancer have an increased risk of venous thromboembolism (VTE) compared with patients without cancer. The treatment of choice for acute episodes of VTE is 200 UI/kg B.W. of low molecular weight heparin(LMWH) for the first month and 150 UI/kg B.W. for the following 5 months.
Aims: In this retrospective observational study we evaluated if patients with cancer and VTE had been treated according to the current guidelines. We also evaluated the efficacy and safety of the prolonged treatment.
Methods: We considered adherent to the recommended therapy patients who received LMWH at a dose of 200 IU/kg BW ±20% for the first month and 150 IU/kg BW ±20% for the following 5–11 months. LMWH' s dosages were adjusted to fulfill the therapeutic intent, according to renal function and transient chemotherapy induced thrombocytopenia. New VTE episodes were confirmed by objectives tests. The main safety outcome was a clinically relevant bleeding.
Results: We enrolled 204 patients with cancer-related VTE. Mean age of the patients was 66.3 years (36–89). We lost on follow up 55 and therefore 149 remained eligible for data analysis: 70 had pulmonary embolism (PE), 27 had PE and Deep Vein Thrombosis (DVT) of the legs, 52 had lower limbs DVT only.
During the first month of antithrombotic approach,125 of 149 (84%) patients were treated with LMWH, 61% of which with recommended LMWH dosages and 14 patients received from the onset vitamin K antagonist(VKA) therapy through an initial LMWH bridging. Mean LMWH dose during the first month of treatment was 164 IU/kg (46–230).
From the 2nd to the 6th month, 102/149 (68%) patients received LMWH, 50% of which at the recommended dosage. Seventeen switched to oral anticoagulant therapy (OAT) with vit k antagonists (VKA) at variable times .
Forty-four patients received LMWH for 12 months, 27 of them (61%) at 150 IU/Kg BW.
The incidence of a recurrent VTE event while on LMWH at recommended dosages, LMWH at lower dosages and VKA treatment resulted respectively of 0.014, 0.016 and 0.016 event/patient-month. The incidence of major bleeding on LMWH at recommended dosages, LMWH at lower dosages and VKA treatment were respectively 0.0042, 0.0033 and 0.015 event/patient-month with a relative risk of 0.28 for recommended LMWH dosages compared to VKA therapy.
Ten patients were treated with fondaparinux from the onset. From the 2nd to the 6th month 6 switched from LMWH to Fondaparinux. Seven received Fondaparinux continuatively for 6 months. Four patients received fondaparinux for 12 months. In Fondaparinux group we registered two bleeding episodes(0.013 event/patient-month) and one VTE recurrence(0.006 event/patient-month)
Conclusions: LMWH treatment is well tolerated and well accepted in patients with cancer and VTE, in a significant part of which up to the 12th month. Our study seems to confirm that patients on LMWH are submitted to a similar rate of thromboembolic complications as compared with those on OAT, while they seem to be exposed to a lower rate of bleeding complications.

PB 3.61-1
Cerebral venous thrombosis and myeloproliferative neoplasms: results from a combined analysis of 706 patients with cerebral vein thrombosis and 2267 patients with myeloproliferative neoplasms

Dentali F[1], Ageno W[2], Rumi E[3], Poli D[4], Scoditti U[5], Di Minno MND[6], Cassetti I[3], Cazzola M[3] and Passamonti F[2]
[1]University of Insubria, Varese, Italy; [2]Insubria University, Varese, Italy; [3]University of Pavia, Pavia, Italy; [4]AOU-Careggi, Firenze, Italy; [5]University of Parma, Parma, Italy; [6]Federico II University, Napoli, Italy

Background: Philadelphia-negative (Ph−) myeloproliferative neoplasms (MPNs) include polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) with about 70% of patients carrying *JAK2*(V617F) mutation. In MPNs venous and arterial thrombosis are the most common clinical manifestations accounting for a prevalence that ranges from 6 to 12%. In the past, we conducted a meta-analysis finding that the mean prevalence of *JAK2* (V617F) mutation was 32.7% in patients with splanchnic vein thromboses (SVTs) and very low (range, 0.88–2.57%) in other venous thromboembolic events indicating that MPN should be investigated in patients with SVT. Concerning cerebral venous thrombosis (CVT), the scenario of prevalence in MPNs is still unknown.
Aim of the study: To asses if an association between CVT and MPN exists to finally justify a deeper MPN-oriented evaluation in patients with CVT or viceversa.
Methods: We conducted a retrospective study including two large cohorts of patients. The CErebral VEin Thrombosis International (CEVETIS) database was used to collect MPN history and MPN evolution in 706 patients with a well-defined diagnosis of CVT. The Pavia-MPN-database was used to collect CVT history and CVT occurrence after MPN diagnosis in 2267 patients with a well-defined MPN diagnosis.
Results: The CEVETIS database includes 304 patients (43.0%) with idiopathic CVT and 402 patients (57.0%) with secondary CVT (at least one risk factor identified) followed for a median time of 40 months (range 6–297 months). Mean age at CVT diagnosis was 40 years (standard deviation + 16.3 years) and 73.7% were females. In nine patients (1.3%) MPN was diagnosed before CVT, in four patients (0.57%) CVT and MPN were synchronous and in 14 patients (1.98%) MPN occurred after CVT in a median time of 21 months (range 11–120 months). Among these, seven (50%) had idiopathic CVT. Overall, demographics did not reveal any statistically significant differences between patients who had MPN or did not. The Pavia-MPN-database includes 735 patients with PV, 964 with ET and 444 with PMF. Median age was 55.3 years (range 13–91 years) and 51% were females. Nine CVTs were collected: three occurred before MPN diagnosis (at 9, 5.4 and 5 years before MPN), three at MPN diagnosis

and three during MPN follow up (at 0.7, 2.5, and at 3.5 years). To note that seven out of nine CVTs occurred in female and the median age was slightly younger (48.6 years) than the overall MPN population (55.3 years)

Conclusions: This study demonstrates that CVT is not strongly associated to MPN phenotype, indicating that a deep MPN-screening is not needed at least in asymptomatic patients with CVT.

PB 3.61-2

Low molecular weight heparin in hospitalized cancer patients: a systematic review and pooled analysis of placebo-controlled randomized trials

Carrier M[1], Moretto P[1], Khorana A[2], Le Gal G[1] and Zwicker J[3]
[1]*Ottawa Hospital Research Institute, Ottawa, Canada;* [2]*James P. Wilmot Cancer Center and Department of Medicine, University of Rocheste, Rochester, USA;* [3]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA*

Background: Cancer patients are at high risk of venous thromboembolism (VTE). Current Clinical Practice guidelines (ASCO, ACCP and ESMO) recommend the use of pharmacological parenteral thromboprophylaxis for cancer patients requiring hospitalization. These recommendations are based on extrapolation from large placebo-controlled trials assessing the efficacy and safety of thromboprophylaxis in medically-ill hospitalized patients. However, the risk benefit ratio of thromboprophylaxis in hospitalized cancer patients has never been formally assessed.

Aim: To summarize the rates of VTE and major bleeding episodes among medically-ill cancer patients receiving low molecular weight heparins (LMWH) or placebo.

Method: A systematic literature search strategy was conducted using MEDLINE, EMBASE, the Cochrane Register of Controlled Trials and all EBM Reviews to identify all randomized controlled trials comparing a LMWH to placebo in hospitalized medically ill patients. Two reviewers independently extracted data onto standardized forms. The primary endpoint was VTE. Venous thromboembolism was defined as a composite outcome of: (i) deep vein thrombosis (DVT) by protocol scheduled screening studies; (ii) symptomatic DVT (distal or proximal) or pulmonary embolism (PE); (iii) fatal PE; or (iv) sudden death without another plausible cause. Secondary endpoints included major bleeding episodes and symptomatic VTE (lower limb DVT and PE). Corresponding author of manuscript were contacted if primary or secondary outcomes could not be extracted from the original manuscript. Relative risk (RR) using a random effect model was used as the primary measurement with 95% confidence intervals (CIs).

Results: The search strategy identified 242 potentially eligible papers. Four placebo-controlled randomized trials reported the primary outcome measure. Data could be extracted for 96% of cancer patients enrolled into these trials. The three major trials ($n = 278$ cancer patients) compared thromboprophylaxis (enoxaparin 40 mg, dalteparin 5000 IU or fondaparinux 2.5 mg daily) to placebo and were included within the pooled analysis. The pooled RR of VTE was 0.91 (95% CI: 0.21 to 4.0; I^2: 68%) among hospitalized cancer patients receiving thromboprophylaxis compared to placebo. Extreme case modeling of the remaining 4% of the missing data assuming an event rate of 40% in the placebo group did not significantly alter the results (RR: 0.80 (95% CI: 0.23–2.7). An additional three placebo-controlled randomized trial reported ($n = 720$ cancer patients) symptomatic VTE as a secondary endpoint. However, none of the trials reported the symptomatic VTE rates according to cancer status and corresponding authors have yet to provide requested data. Similarly, none of the trials have reported major bleeding rates among cancer patients.

Summary/Conclusion: We observed no significant benefit for LMWH primary thromboprophylaxis in hospitalized patients with cancer. However, only a limited number of cancer patients were enrolled in the three major thromboprophylaxis clinical trials from which current practice guidelines are based. We hope additional data from published trials will become available for analysis to address this important clinical question.

PB 3.61-3

The impact of combined radiation and hormon therapy on the microparticles and tissue factor generation in patients with prostate cancer

Zekanowska E[1], Drela E[1], Rystok D[1], Wisniewski T[2], Ziólkowska E[2], Giemza-Kucharska P[1] and Rosc D[1]
[1]*Nicolaus Copernicus University in Torun, Collegium Medicum in Bydgoszcz, Poland, Bydgoszcz, Poland;* [2]*Oncology Center in Bydgoszcz, Bydgoszcz, Poland*

Background: Tissue factor (TF) plays a critical role in tumour growth and metastasis, and its enhanced release into plasma in association with cellular microparticles (MPs) has been recently associated with cancer progression. Accumulating evidence indicates that combining radiotherapy and hormone therapy in patients with prostate cancer has significantly improved men's survival as compared to hormone therapy treatment alone.

Aim: The purpose of the study was to evaluate the influence of combined hormone therapy and radiation on plasma levels of TF, TFPI and MP generation in patients with prostate cancer.

Methods: 40 patients with prostate cancer (mean age of patients was 67.7 years) were divided according to their cancer status and line of management into: group 1- androgen deprivation therapy combined with radiotherapy (22 patients) and group 2- radiotherapy alone (18 patients). For control, plasma samples were collected from 30 age – matched healthy males with no evidence of cancer. In cancer groups blood samples were collected before, during and 30 days after radiation therapy. Procoagulant activity of circulating MPs, concentrations of TF and TFPI antigens were measured by immunoenzymatic method (ELISA, American Diagnostica).

Results: Before radiation the plasma levels of MP, TF and TFPI were similar in group 1 (respectively: Me 9.94 (Q1- 6.14; Q3–13.44 nM), Me 59.42 (Q1- 35.24; Q3- 97.22 pg/mL), Me 117.26 (Q1- 83.08; Q3–138.26 ng/mL) and group 2 of patients with prostate cancer (respectively: Me 9.75 (Q1- 8.74; Q3–14.44 nM), Me 77.46 (Q1- 53.52; Q3-116.01 pg/mL), Me 105.40 (Q1- 83.64; Q3–147.76 ng/mL). However MP were significantly higher as compared to the control group ($P < 0.01$).

Radiotherapy caused a transient increase in MPs generation in group 1 of patients as compared to group 2 (Me 10.36 (Q1- 7.32; Q3- 15.22) vs. Me 15.83 (Q1- 10.83; Q3- 22.70) nM, $P < 0.02$)

Conclusion: Our data suggests a role of circulating MPs in intravascular coagulation activation in patient with prostate cancer, especially those with radiation therapy treatment alone.

PB 3.61-4

The impact of prophylactic heparin on survival in cancer patients: a meta-analysis

Sanford D, Naidu A, Alizadeh N and Lazo-Langner A
Western University, London, Canada

Background: Cancer is associated with alterations in clotting and fibrinolytic systems and increased risk of venous thromboembolism. Previous research suggests that tumors may exploit the coagulation system allowing for immune evasion and angiogenesis, resulting in survival and dissemination of tumor cells. Several studies suggest that heparin and low molecular weight heparin (LMWH) may have an anti-tumor effect in experimental *in vivo* and *in vitro* models. The clinical implica-

tion of this is unclear. Earlier clinical trials have reported conflicting findings and our previous meta-analysis (Lazo-Langner et al 2007) suggested a beneficial albeit modest effect of LMWH on survival in cancer patients.

Aims: We aimed to evaluate the effect of LMWH compared with placebo or no-anticoagulant intervention on the overall survival of patients with cancer.

Methods: We conducted a systematic review and meta-analysis of randomized trials evaluating use of LMWH compared with placebo in cancer patients without acute venous thrombosis. Data sources included: MEDLINE, HealthSTAR, EMBASE, the Cochrane library, thrombosis and hematology conference abstracts and cross-referencing from reference lists. Data was extracted by one reviewer and verified independently by a second reviewer. The meta-analysis was conducted using the random-effects model and data was analyzed using odds-ratio (OR) and relative risk (RR) calculated for 1 year overall survival.

Results: We identified 301 trials involving use of low molecular weight heparin in cancer patients using our search strategy. Sixteen of these studies met our inclusion criteria, although only seven of these reported data on overall survival or number of deaths at 1 year and these were included in the meta-analysis. Five of the seven studies included only patients with locally advanced or metastatic disease; one study included patients with both limited and advanced solid tumors and one study included only patients with malignant glioma. The pooled odds-ratio for death was 0.96 [95% CI 0.86–1.07, $P = 0.5$] in favor of the LMWH group. The pooled relative-risk for death was 0.98 [95% CI 0.93–1.04, $P = 0.51$] in favor of the LMWH group.

Conclusions: In contrast with our previous findings, the results of this updated meta-analysis suggest that the use of LMWH does not appear to improve overall survival in cancer patients. The trials meta-analyzed included primarily patients with advanced and metastatic disease with a low likelihood of long-term survival or cure. The effect of LMWH on overall survival in patients with limited stage disease still is unknown.

PB 3.61-5

Pro-coagulant activity of malignant ascites

Altayeb T[1], Madden LA[1], Hartley JE[2] and Maraveyas A[3]

[1]*University of Hull, Hull, UK;* [2]*Castle Hill Hospital, Hull, UK;* [3]*Queen's Centre for Oncology, Hull, UK*

Background: Malignancy accounts for approximately 10% of all ascites cases. Ovarian, pancreatic, stomach and colon cancers being the most common primary malignant sites. Tumour-cell infiltration within the peritoneal cavity presents the opportunity to use malignant ascitic fluid to study therapeutic effects of agents directly on the cancer cell. As a first stage in a study planned to investigate the direct and indirect effects of anticoagulants in cancer patients with ascites, we have compared the cancer related procoagulant activity (PCA) and it's driving factors in ascites and plasma.

Aim: The aim of this study was to analyse tissue factor microparticles (TF + MP) and the related PCA of malignant ascites and compare it with the PCA of patient plasma.

Methods: This study was conducted *in accordance with* the *Helsinki Declaration and ethical approval from the regional medical ethics committee was obtained prior to commence (R1220 - 11/YH/0370). Informed written consent was obtained prior to sample collection.*

We included ovarian ($n = 9$), pancreatic ($n = 3$) and colonic ($n = 3$) cancer patients with clinical and radiological evidence of malignant ascites. Those with a known concurrent coagulopathy or receiving anticoagulant therapy were excluded. One litre of ascites and 5 mL of citrated blood were simultaneously obtained. Ascites samples and platelet poor plasma were assessed for PCA using a pro-thrombin time assay and TF + MP, annexin + MP and TF+/annexin + MP were enumerated by flow cytometry. Ascites was analysed for PCA before and after centrifugation (to remove cells) and filtration through a 0.1 μm filter (to remove large microparticles).

Results: Ascites was found to contain TF + MP in all cases. A logarithmic relationship was observed between TF + MP and PCA of ascites, whereby higher concentrations of TF + MP were associated with lower prothrombin time and hence PCA. No relationship was observed between plasma PCA and MP concentration. Centrifugation of ascites resulted in a consistent, proportional reduction in PCA and filtration through a 0. 1 μm filter removed almost all PCA. No relationship was observed between PCA of plasma and ascites.

Conclusions: PCA of ascites was observed to be TF + MP and cell dependent. A reduction in PCA through centrifugation suggests a proportion of the PCA was cell associated and furthermore filtration removed most PCA suggesting PCA in ascites was MP associated.

PB 3.61-6

Clinical profiles of DIC patients with bone marrow carcinosis, aiming for earlier diagnosis and treatment to improve their prognosis

Seki Y and Wakaki K

Niigata Prefectural Shibata Hospital, Shibata, Japan

Background: The clinical course of disseminated intravascular coagulation (DIC) in patients with bone marrow carcinosis (BMC) due to solid cancer is thought to be aggressive with no effective treatment.

Aim: The clinical profiles of patients with DIC and BMC were studied in order to improve the possibility of making early diagnosis and establishing treatment to improve their prognosis.

Methods: Seventeen patients with BMC were enrolled and their background, clinical symptoms, hemostatic profiles, presence of DIC, treatment and prognosis, complications and other laboratory examinations were analyzed.

Results: The primary cancers originated in stomach (seven), lung (three), prostate (two), colon, breast (mamma), urinary bladder, and unknown origin (one). Most of the gastric cancers were poorly differentiated. All cases of lung cancer were of the small-cell type. Lumbago was the most frequent symptom of BMC. Nine cases, comprising six gastric cancers, one lung cancer, and one each of urinary bladder cancer and unknown origin cancer, were diagnosed as DIC. The values for platelet count, fibrinogen, FDP, XDP, AT, α2PI and plasminogen at diagnosis of DIC were $3.2 \pm 1.8 \times 10^{*}4$, 155 ± 109 mg/dL, 100 ± 79 μg/mL, 54 ± 43 μg/mL, $93 \pm 36\%$, $61 \pm 21\%$ and $70 \pm 17\%$, respectively. The period from diagnosis of DIC until death was 15.7 ± 16.3 days. Four cases were complicated with thrombotic microangiopathies (TMA); they were all poorly differentiated gastric cancer or mucin-producing gastric cancer. All cases were accompanied by anemia, high serum levels of lactate dehydrogenase (LDH) and alkaline phosphatase (ALP). All cases that originated as pre-BMC had high serum ALP levels. CA19-9 levels in DIC cases were higher in gastric cancer than were CEA levels and were better tumor markers.

[Conclusions] Markedly low platelet counts, decreased levels of fibrinogen and hyperfibrinolysis were revealed in patients with DIC due to BMC. Patients with BMC from mucin-producing poorly differentiated gastric cancer died earlier. It is very important to check for lumbago, progression of anemia, sustained elevation of ALP or LDH levels, leukoerythroblastosis and levels of tumor markers. Early bone marrow aspiration or biopsy helps to establish an early diagnosis of BMC. Aggressive introduction of chemotherapy could help to prolong the survival period in lung or breast cancer patients, especially in breast cancer.

PB3.62 – Antiphospholipid- IV

PB 3.62-1

Antiphospholipid syndrome in children

Sabapathy CA, Lee SJ, Barsalou J, Komwilaisak P, Williams S, Moharir M, Silverman ED, Levy DM and Brandão LR
Hospital for Sick Children, Toronto, Canada

Background: Antiphospholipid Syndrome (APS) is more frequent in adults than in children. Cohort studies estimate up to 7% of children with venous thromboembolism (VTE) may meet criteria for APS; however, pediatric studies are lacking.
Aims: To describe a large cohort of childhood APS, examining laboratory and clinical characteristics.
Methods: A retrospective cohort from the Hospital for Sick Children (Toronto) included patients <18 years of age diagnosed between 1999 and 2011. Patients were identified from the pediatric thrombosis/rheumatology/stroke databases. Only patients meeting revised Sapporo criteria were included. Demographic, laboratory and clinical data were extracted from medical records. Thrombus resolution for multiple initial thrombi was defined as complete resolution of ≥50% of thrombi. Complete thrombophilia evaluation included factor V Leiden (FVL), prothrombin variant, deficiencies in protein C/S and antithrombin testing. Patients with primary vs. secondary APS were compared using descriptive, parametric and nonparametric statistics as appropriate. Study was approved and consent waived by the local research ethics board.
Results: Over the 12-year study period, 53 patients were identified. Seventy-five percent of the cohort had secondary APS (systemic lupus erythematosus [33%], others [67%]). The overall cohort median age was 11 years (IQR: 1–14; M:F 1.94:1.0). There were 57% venous, 34% arterial and 9% mixed thrombi, distributed as follows: central nervous system (CNS) (38%); non-CNS (49%); and both (13%).
APS laboratory criteria consisted of persistent elevation in anticardiolipin IgG antibodies (75%) and persistent positive lupus anticoagulant (55%). Complete thrombophilia evaluation was done in 44/53 (83%) patients, partial in 6/53 (11%), and missing in three patients. Overall, 36/53 (68%) patients had no concomitant thrombophilia, 9% had incomplete evaluation but showed no defects, and 17% had a positive finding, as follows: (FVL [homozygous (1), heterozygous (5)], prothrombin variant [heterozygous (1)], protein S deficiency (1), none with combined defects). Eighty-nine percent of children received some duration of anticoagulation.
On follow-up imaging 64% had no/incomplete radiological resolution, 34% had complete resolution, and 2% had progression. At least one clinical recurrence occurred in 7/53 (13%) patients.
There was no statistically significant difference in sex, thrombus type/location, thrombophilia status, resolution or recurrence in children with primary vs. secondary APS. There was however a significant difference in proportion of children ≤10 vs. >10 years of age in primary vs. secondary APS groups ($P = 0.005$). There was no statistically significant difference in clinical recurrence based on thrombophilia status nor treatment status; 6/7 recurrences occurred in patients with a negative complete thrombophilia evaluation. At the time of recurrence only 1/7 was therapeutic in their anticoagulation.
Summary/Conclusion: Diagnostically proven APS is rare in children, with secondary APS being seen more frequently. Younger children more frequently had secondary APS, while older children had a more even distribution of primary and secondary cases. Clinical recurrence was low in this cohort, particularly considering the concomitant thrombophilia rate described, and recurrence was not associated with thrombophilia status. Interestingly, most children within this cohort received some duration of anticoagulation and recurrence occurred mostly during subtherapeutic anticoagulation levels. Further prospective work is necessary to explore the ideal anticoagulation length in this population.

PB 3.62-2

RAPS: a prospective randomised controlled phase II/III clinical trial of rivaroxaban vs. warfarin in patients with thrombotic antiphospholipid syndrome, with or without SLE

Cohen H[1], Dore C[2], Clawson S[2], Hunt BJ[3], Khamashta M[3], Machin SJ[2] and Muirhead N[2]
[1]University College London Hospitals NHS Foundation Trust, London, UK; [2]University College London, London, UK; [3]Guys and St Thomas' Hospitals NHS Foundation Trust, London, UK

Background: The current mainstay of the treatment of thrombotic antiphospholipid syndrome (APS) is therapeutic anticoagulation with vitamin K antagonists (VKA), such as warfarin. However, the limitations of VKA have driven a search for new agents, which include rivaroxaban (Xarelto®; Bayer HealthCare). These drugs have been approved for several clinical indications at present based on phase III prospective randomised clinical trials, but these trials may not be directly applicable to patients with APS where there remains an unmet need.
Aim: To demonstrate that the intensity of anticoagulation achieved with rivaroxaban is not inferior to that of warfarin, by measurement of the dynamics of ex vivo thrombin generation using the thrombin generation test (TGT) with the endogenous thrombin potential (ETP) as the key parameter, in patients with thrombotic APS, with or without SLE. Secondary aims: to compare rates of bleeding and recurrent thrombosis, and compare quality of life in patients on rivaroxaban with those on warfarin.
Hypothesis: The intensity of anticoagulation, assessed using the ETP, achieved in thrombotic APS patients on rivaroxaban is not inferior to that obtained on warfarin. The TGT, as a global measure of anticoagulation, can assess the anticoagulant effects of both rivaroxaban and warfarin. Clinically, our hypothesis is that in patients with thrombotic APS, rivaroxaban could induce more predictable anticoagulation and, therefore, a greater sustained reduction in thrombin generation than would warfarin, with additional patient benefits because there is no requirement for regular anticoagulation monitoring
Methods: 156 eligible patients with thrombotic APS, with or without SLE, who have had either a single episode of VTE whilst not on anticoagulation or recurrent episode(s) which occurred whilst off anticoagulation or on sub-therapeutic anticoagulant therapy, currently taking warfarin, target INR 2.5 (range 2.0–3.0), will be randomised either to continue warfarin (standard of care) or to stop warfarin and start rivaroxaban 20 mg once daily as standard. Each patient will have a 6 month treatment period and a final visit 30 days after the end of trial treatment. The planned recruitment period is 10 months and overall trial duration is 24 months.
Results: The primary outcome measure is the percentage change in ETP from randomisation to day 42. The differences between the two arms for the quality of life, efficacy (venous thromboembolism and other thrombotic events) and safety (serious adverse events and all bleeding events) secondary outcomes will be presented as estimates and 95% confidence intervals.
Conclusion: If the trial demonstrates: i) that the anticoagulant effect of rivaroxaban is not inferior to that of warfarin using the ETP; and ii) absence of any adverse effects that cause concern with regard to the use of rivaroxaban, we believe that this would provide sufficient supporting information to change practice for our patients, i.e. to make rivaroxaban the standard of care for the treatment of patients with thrombotic APS, with or without SLE.

PB 3.62-3

Contribution of immunoregulatory cytokines in the pathogenesis of primary antiphospholipid syndrome

Iwaniec T[1], Jakiela B[1], Celinska-Lowenhoff M[1], Swadzba J[2], Musial J[1] and Padjas A[1]

[1]*Jagiellonian University Medical College, Cracow, Poland;* [2]*University Hospital, Cracow, Poland*

Background: The primary antiphospholipid syndrome (PAPS) is an autoimmune disease characterized by the presence of antiphospholipid antibodies with associated vascular thrombosis and obstretical complication. Recent studies suggest defective immunoregulatory mechanisms as a potential cause of autoimmunity.
Aims: To investigate the contribution of immunoregulatory and Th17-associated cytokines in the pathogenesis of PAPS.
Methods: We measured serum concentration of TGF-β1, IL-10, IL-23, IL-17A and IL-27 (high sensitivity ELISA kits) in patients with confirmed diagnosis of PAPS ($n = 20$) and matched group of healthy controls ($n = 20$). Additionally, anticardiolipin (aCL) and anti-β2 glycoprotein I (aβ2GPI) antibodies, and CRP were measured in all subjects studied.
Results: Serum levels of both IL-10 and IL-23 were significantly elevated in PAPS patients as compared to controls (median IL-10: 3.7 vs. 1.7 pg/mL, $P < 0.001$; IL-23: 19.9 vs. 11.6 pg/mL, $P < 0.05$). There was a trend ($P = 0.056$) toward lower concentration of TGF-β1 in PAPS group (14.5 vs. 13.3 ng/mL in controls). IL-17A was detected only in one PAPS patient. All other measurements for IL-17A and IL-27 were below the assay threshold. There was a significant negative correlation between concentrations of TGF-β1, and both aCL IgG ($r = -0.65$) and aβ2GPI IgG ($r = -0.61$). We also observed a positive correlation of IL-23 with IgM aCL ($r = 0.7$) and IgM aβ2GPI ($r = 0.6$). PAPS patients with the history of deep venous thrombosis (DVT) were characterized by significantly higher levels of serum IL-10 ($P < 0.001$) and lower concentrations of TGF-β1 ($P < 0.05$). Finally, serum CRP did not differ between the groups, and there was no association between CRP levels and concentration of measured cytokines.
Conclusions: Our data suggest, that PAPS is characterized by low-grade immune activation and imbalance between immunoregulatory and pro-inflammatory cytokines, which may be responsible for production of antiphospholipid antibodies and subsequent thrombotic symptoms.

PB 3.62-4

Pro-inflammatory and pro-thrombotic markers in antiphospholipid antibody positive patients: subgroup analysis from an open-label prospective pilot study

Willis RA[1], Erkan D[2], Murthy V[1], Ba Gsra[1], Vega JA[2], Ruiz-Limon P[1], Carrera-Marin AL[1], Jatwani S[1], Gonzalez E[1] and Pierangeli S[1]

[1]*University of Texas Medical Branch, Galveston, Texas, USA;* [2]*Hospital for Special Surgery, New York, NY, USA*

Background: Antiphospholipid Syndrome (APS) is a multisystemic disease, characterized by recurrent thrombosis and/or pregnancy loss and antiphospholipid (aPL) antibodies. Elevated aPL antibodies can also be found in 'asymptomatic' individuals and in patients with systemic lupus erythematosus (SLE). Pro-inflammatory and pro-thrombotic markers are associated with aPL-mediated pathogenic effects *in vitro* and *in vivo* and are increased in aPL-positive patients.
Aims: We examined whether those markers are differentially upregulated in persistently aPL positive patients with or without autoimmune disease (APS and/or SLE), utilizing data collected from an open-label prospective pilot study.
Methods: Forty-one persistently aPL-positive patients (29F and 12M) and 30 age/sex-matched controls were included. Exclusion criteria included pregnancy, statin use, prednisone <10 mg/day, and immunosuppressive use (except hydroxychloroquine). Interferon (IFN)-α, Interleukin (IL)1β, IL6, IL8, inducible protein (IP)10, tumor necrosis factor (TNF)-α, vascular endothelial growth factor (VEGF), and soluble CD40 ligand (sCD40L) levels were determined by a multiplex assay (Millipore, Billerica, MA) in the sera of patients and controls. Plasma samples were used to detect sTF using a chromogenic assay. aCL (IgG, IgM and IgA), aβ2GPI (IgG, IgM and IgA), soluble intercellular cell adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1, and E-selectin (E-sel) were evaluated by ELISA. For the purpose of this study patients were divided into groups: Primary APS (PAPS), APS with SLE (SAPS), SLE with aPL antibodies (SLE/aPL), and 'asymptomatic aPL' (asympt aPL). Mann-Whitney Rank Sum test was used to analyze the data.
Results: Of the 12 biomarkers assessed, nine biomarkers (IL6, IL1β, TNFα, IP10, sCD40L, sTF, sICAM1, sVCAM1 and sEsel) were significantly elevated in PAPS patients, 7 (IL6, IL1β, TNFα, IP10, sCD40L, sTF and sICAM1) were significantly elevated in SLE/APS patients, 4 (IL6, IP10, sCD40L and sTF) were significantly elevated in SLE/aPL patients and 3 (TNFα, sCD40L and sTF) were significantly elevated in patients with asymptomatic aPL when compared to controls. Soluble TF and sCD40L were elevated in all four subgroups and there was no difference in sTF titers among aPL-positive groups ($P = 0.055$). TNFα was elevated in three subgroups – [PAPS, SLE/APS and asymptomatic aPL patients] – while IL-6 levels were elevated in the three subgroups – [PAPS, SLE/APS and SLE/aPL]. IL-8, TNFα and IP-10 concentrations were significantly higher in PAPS, SLE/APS and SLE/aPL patients when compared to patients with asymptomatic aPL. VEGF, sICAM-1, and sVCAM-1 concentrations were significantly higher in PAPS patients when compared to the all other groups. There was no difference in the titres of aCL or antiβ2GPI (all isotypes compared) among the aPL-positive subgroups.
Conclusion: Pro-inflammatory and prothrombotic markers are differentially upregulated in aPL-positive patients. These findings may have implications in the pathophysiology of APS and underscore the importance of detecting biomarkers to help in the identification of subgroups of aPL-positive patients.

PB 3.62-5

Laboratory evaluation of antiphospholipid antibodies: have the recommended guidelines for diagnosing antiphospholipid syndrome been followed

Margetic S, Tesija Kuna A, Vukasovic I and Vrkic N

Medical School University Hospital, Zagreb, Croatia

Background: In addition to clinical indicators, laboratory evaluation of antiphospholipid antibodies (aPLAs) is an integral part of the diagnostic criteria for antiphospholipid syndrome (APS). Based primarily on the method detection, there are three major subgroups of aPLAs: lupus anticoagulant (LA), anticardiolipin antibodies (ACL) and anti-b_2-glycoprotein-1 antibodies (anti-b_2GPI). According to the International Society of Thrombosis and Haemostasis (ISTH) recommended guidelines, the laboratory investigation of aPLAs should always include determination of all three groups of antibodies.
Aim: The aim of this study was to analyze the results of laboratory evaluation of aPLAs in unselected consecutive patients who referred for testing during 1 year period.
Methods: LA antibodies were identified by a panel of commercial coagulation assays (Siemens, Germany) including screening tests (activated partial thromboplastin time (APTT, Actin FSL), APTT mixing test, dilute Russell¢s viper venom time dRVVT screen and dRVVT confirmation test. The laboratory evaluation of ACL and anti-b_2GPI antibodies was performed using enzyme-linked immunosorbent (ELISA) assays (Orgentec, Germany) for immunoglobulin M (IgM) and immunoglobulin G (IgG) isotypes.
Results: The prevalence of positive results for individual aPLAs were: LA = 33/991, 3.3%; ACL = 67/1253, 5.3% (IgG = 22/67, 33%; IgM = 31/67, 46%; IgG and IgM = 14/67, 21%) and anti-b_2GPI = 7/

177, 4.0% (IgG 4/7; IgM 3/7, IgG and IgM 1/7). Only for 11/86 (13%) of all positive patients, laboratory investigation included all three groups of aPLAs. Anti-b_2GPI were ordered only for 16/86 (18.6%) patients. LA and ACL were simultaneously ordered for 48/86 (56%) of positive patients, while LA alone was ordered for 10/86 (12%) patients and ACL alone for 33/86 (38%) patients. Among 44 positive cases for simultaneously ordered LA and ACL, 15/44 (34%) were positive for both LA and ACL, 9/44 (20%) were LA positive and ACL negative and 20/44 (46%) were ACL positive and LA negative. Of the total 86 positive results, LA was ordered for 58 patients (67%) with positivity of 57% (33/58), while ACL antibodies were ordered for 77 (90%) patients with positivity of 87% (67/77). Only in 4/33 (12%) of LA positives, 8/67 (11.9%) of ACL positives and 1/7 of anti-b_2GPI positives, laboratory evaluation was performed on two separate occasions at least 12 weeks apart.

Conclusions: The laboratory investigation of individual aPLAs among unselected consecutive patients had shown the prevalence of 3.3–5.3% for individual subgroups of antibodies, with the highest prevalence of ACL antibodies. Our results indicated that laboratory investigation has not been completely performed in accordance with the recommended guidelines on testing, since only for a small number of patients testing was performed for all three subgroups of antibodies or at least for two (LA and ACL). Additionally, for a minority of positive patients testing was ordered on two separate occasions at least after 12 weeks. It is obvious that laboratory has to take the more substantial role in the investigation process of APS, than just providing doctors with numbers. The corrective actions should primarily include ongoing education of clinicians pointing the importance of determining all three subgroups of aPLAs, since patients may be negative for one subgroup of aPLAs and positive for others.

PB 3.62-6

Taipan snake venom time coupled with ecarin time testing enhances lupus anticoagulant detection in non-anticoagulated patients

Moore G, Bromidge E, Polgrean R, Archer R and Squires I

Guy's & St. Thomas' NHS Foundation Trust/GSTS Pathology, London, UK

Background: Accurate and timely detection of LAs is crucial to diagnosis and management of antiphospholipid syndrome (APS). It is hampered by the lack of a gold standard assay or reference preparation, exacerbated by antibody heterogeneity, reagent variability and inconsistencies in raw data interpretation. Limiting analysis to just dRVVT and APTT assays has been proposed, at least in part to foster standardisation, yet even this combination of stalwart tests is by no means infallible and will not detect all clinically significant LAs. Numerous alternative assays have been described but few have been subjected to the same degree of scrutiny as the dRVVT/APTT pairing, although this does not necessarily invalidate them as useful diagnostic adjuncts. Taipan snake venom time (TSVT) screening with an ecarin time (ET) confirmatory assay has been shown to be useful for detecting LAs in patients receiving warfarin or rivaroxaban that compromise dRVVT and APTT assays.

Aims: To assess the diagnostic impact of incorporating TSVT/ET analysis into an existing dRVVT and LA-responsive APTT repertoire when testing non-anticoagulated patients for the presence of LAs.

Methods: dRVVT was performed with Life Diagnostics LA Screen and LA Confirm reagents (Life Therapeutics). APTT was performed using PTT-LA (Diagnostica Stago) in the screen and addition of platelet-derived LA confirmation reagent (Bio/Data Corporation) for the confirmatory test. TSVT was performed using Diagen Taipan venom and diluted Diagen Bell and Alton Platelet Substitute (Diagnostic Reagents) and *E. carinatus* venom (Diagnostic Reagents) for the ET. All LA assays were performed on a CS2000i automated analyser (Sysmex). Screen and confirm clotting times were each converted to normalised ratios via the mean clotting time for each reference interval (RI). Test plasmas were defined as being consistent with the presence of a LA if the screening test ratio was greater than the upper limit of the RI and there was ≥10% correction by the confirm ratio after exclusion of other causes of prolonged clotting times. One hundred and fifty two samples from non-anticoagulated patients being investigated for APS were tested for LA by all three assay systems.

Results: Ninety five of 152 samples (62.5%) were negative for LA by all three assays systems. Twenty two (14.5%) were positive by TSVT/ET and one or both of dRVVT and APTT. Twenty five (16.4%) were positive for LA by one or both of dRVVT and APTT but negative by TSVT. Ten (6.6%) were positive for LA by TSVT/ET but negative with both dRVVT and APTT.

Conclusions: Most of the LAs manifested in dRVVT and/or APTT analysis, as might be anticipated from this reagent pairing. The small number of samples positive by TSVT/ET only, as has been previously demonstrated, emphasise that the many variables that impact on LA testing mean that even a well established dRVVT and APTT pairing cannot deliver diagnostic certainty. In view of low frequency and financial/logistic considerations, TSVT/ET analysis is best placed as a second-line assay where clinical suspicion of APS is high and standard assays are negative, and for use in anticoagulated patients.

PB3.63 – Arterial Vascular Disorders – IV

PB 3.63-1

The ABO, non-O blood groups and their association with hematoma growth in acute intracerebral hemorrhage

Tirado I, Coll I, Mateo J, Martí-Fabregas J, Borrell M, Delgado-Mederos R and Fontcuberta J

Hospital Sant Pau, Barcelona, Spain

Background: ABO blood groups have been associated with various diseases, particulary thrombotic diseases. We tested the hypothesis that the ABO, non-O blood groups are associated with hematoma growth (HG) in patients with acute intracerebral hemorrhage (ICH).

Methods: We studied patients who had a spontaneous ICH within the first 6 h after the onset of symptoms. We included 90 patients (mean age 71 ± 10.8 years), 61% were men and 39% were women. HG was observed in 35 (39%) of the patients. The HG group and the non-HG group were demographically similar. The frequency of intraventricular hemorrhage, and volume of the hematoma at baseline were similar also. HG was defined as an increase of 33% in the volume of hematoma using the computed tomography (CT) data obtained 24–72 h after the onset of symptoms compared to the CT at admission. The volume was calculated using the formula (AxBxC):2. Functional outcome at 3 months was assessed with the Rankin scale score, and it was considered favourable when Rankin score was 0–1 (groups: Rankin 1 0–1; 2nd Rankin ≥2). For genetic analysis, the ABO blood group was determined using the polymerase chain reaction (PCR) with two fragments: one of 252 bp of the exon 6 and other of 843 bp of the exon 7. The fragments were digested with the restriction endonucleases *KpnI* and *MspI*. We used Chi-Square test to compare the frequencies of the two groups: *A2O* and O group (*OO*, *A2O*, *A2A2*) and the non-O group (*A1A1*, *A1B*, *BB*, *A1O*, *BO* and *A2B*).

Results: The frequencies between groups were not significantly different. However, we observed that there was a greater number of patients with HG in the A_2O and O group than in the non-O group (61.3% vs. 38.7%. ns). Also, we observed a higher proportion of non-O group in patients who did not exhibit HG (57.7% vs. 42.3% ns). The Rankin scale at 3 months was not significantly different between the two groups.

Conclusion: Despite the small sample size, we observed that prothrombotic genetic factor, non-O blood group (except *A2*), might play a pro-

tective role in hematoma growth. Further studies with a greater number of subjects need to be done to confirm our results.
Spanish grant RD12/0042/0032. AGAUR 2009 SGR1147.

PB 3.63-2

Pathomechanism of reobstruction after endovascular treatment of the superficial femoral artery: impact of inflammatory cells

Belaj K, Pichler M, Hackl G, Eller Ph, Brodmann M and Gary T
Medical University Graz, Graz, Austria

Background: Pathophysiology of reobstruction after arterial intervention is not well understood so far and seems to differ from typical atherosclerotic plaque lesions. Development of a neointima as a response to injury is induced by different cellular components as platelets, vascular smooth muscle cells and immunity cells. Various laboratory parameters reflect the inflammatory state in atherosclerotic lesions. So far it is unknown whether those parameters influence development of restenosis after endovascular treatment of the superficial femoral artery (SFA) as well.
Methods: We performed a retrospective data analysis of 1064 patients with peripheral arterial occlusive disease treated at our institution between 2005 and 2010 by means of endovascular recanalization (percutaneous transluminal angioplasty (PTA) and stent insertion) of the SFA. We evaluated laboratory parameters reflecting inflammatory state and occurrence of symptomatic reobstruction during a mean follow up of 58 months.
Results: In patients developing symptomatic restenosis after PTA median percentage of monocytes was significantly lower than in patients without reobstruction (median 6.0% vs. 7.0% *P*-value 0.02). Reobstruction rate in stent patients was not associated with monocyte-count. We were not able to find statistically significant differences in levels of lymphocytes, neutrophiles, c- reactive protein and fibrinogen.
Conclusion: Low levels of monocytes are associated with a higher risk of restenosis after PTA but not after stent insertion. We hypothesize that monocytes might have a protective effect in vascular lesions and development of restenosis after PTA as they might harbour properties of endothelial cells.

PB 3.63-3

Presence of organized thrombus in coronary aspirated materials is a predictor of in-hospital mortality in patients with acute myocardial infarction

Nishihira K[1], Hatakeyama K[2], Shibata Y[3] and Asada Y[2]
[1]Miyazaki Prefectural Nichinan Hospital, Nichinan; [2]Faculty of Medicine, University of Miyazaki, Miyazaki; [3]Miyazaki Medical Association Hospital, Miyazaki, Japan

Background: Thrombus propagation on disrupted atherosclerotic plaque leads to acute myocardial infarction (AMI). Recent studies have shown that the histopathology of coronary thrombus is associated with myocardial reperfusion, ST-segment recovery, distal embolization and long-term mortality in patients with AMI.
Aims: We investigated the histopathological characteristics of material aspirated during percutaneous coronary intervention (PCI) in patients with AMI, and assessed whether histological findings are related to in-hospital mortality.
Methods: In this prospective single-center registry, coronary materials were obtained during PCI from 264 AMI patients within 24 h after the onset of anginal symptoms. The presence of organized thrombus, calcification and plaque components in aspirated materials were morphologically assessed.
Results: In-hospital deaths occurred in 17 (6%) patients. Organized thrombi were found in 91 (34%) of 264 patients, calcification was identified in 44 (17%) and plaque components were aspirated from 117 (44%) patients. Rates of in-hospital all-cause mortality were significantly higher among patients with, than without organized thrombus ($P < 0.05$). However, organized thrombus was not associated with peak creatine kinase ($P = 0.94$). Multivariate analysis also identified organized thrombus as an independent predictor of in-hospital death, as well as age, a history of myocardial infarction and the presence of shock ($P < 0.05$). In contrast, calcification and plaque components were not significantly associated with in-hospital mortality.
Conclusions: Our results suggest that the presence of organized thrombus in coronary aspirated thrombus is an independent predictor of in-hospital mortality in AMI patients.

PB 3.63-4

Correlation between burst of thrombin and microvacular obstruction (no reflow) during ST elevation myocardial infarction treated by primary percutaneous coronary intervention

Drouet L[1], Spagnoli V[1], Klein E[1], Sideris G[1], Brumpt C[1], Magkoutis N[1], Berge N[2], Bal dit Sollier C[2] and Henry P[1]
[1]AP-HP; [2]IVS, Paris, France

Background: The principal challenge in primary angioplasty is not to achieve the culprit vessel reopening (which is regularly obtained) but to prevent the myocardial microvascular obstruction: the no-reflow phenomenon which determines initial and long term prognosis of patients. The main factors of the no-reflow are the micro-thrombotic distal embolizations from the main thrombus and the ischemia reperfusion which includes endothelial reactivity induced by numerous cellular reactions. The thrombotic burden at the acute phase of STEMI, is a consequence of platelet and coagulation activation, for which thrombin generation plays a major role due to its multiple molecular and cellular effect in thrombosis, inflammation micro vascular damage
Objective: During the acute phase of STEMI we evaluated the generation of thrombin as assessed by circulating thrombin-anti thrombin complex. In order to study the consequence, we correlated this thrombin generation with other markers of coagulation activation (fibrin D-Dimers, fibrin monomers), markers of cellular activation (microparticles derived from platelets and endothelial cells), microvascular injury and obstruction and infarct size.
Methods: 36 consecutive patients with STEMI admitted for primary PCI were enrolled. Blood samples were collected and analyzed before angioplasty, at the end of angioplasty and 2, 6, 12 and 24 h after angioplasty. Plasma TAT complexes and D-Dimers were evaluated by ELISA methods, fibrin monomers by immunotubidimetric test. Platelets and endothelial microparticles were determined by flow cytometry analysis. Microvascular obstruction was assessed by the myocardial blush at angiography and index of microvascular resistance. Infarct size was assessed by AUC of plasma troponin and CK-MB, angiographic evaluation of myocardium at risk and by MRI.
Results: a burst of thrombin was observed in 33% of the patients and in these patients the peak occurred during primary percutaneous coronary intervention. The same patients increased their circulating platelets microparticles but the kinetics was delayed 2 h after primary PCI and the levels remained high during 24 h. The endothelial microparticles, D-Dimers and fibrin monomers generation remained stable at the acute phase, without burst. Prolonged ischemic time and significant myocardium at risk were correlated with a higher level of thrombin generation ($P < 0.05$). Patients with burst of thrombin had an alteration of myocardial blush ($P < 0.05$), an increased micro-vascular obstruction ($P < 0.05$) and higher troponin I and CK levels ($P < 0.05$)
Conclusion: This study showed a burst of thrombin at the time of primary PCI during STEMI in one third of the patients. When present this burst was associated with more cellular, myocardial and microvascular damage.

PB 3.63-5

Thrombophilic risk factors predisposing to thrombosis in patients sufferd from ocular arterial occlusions

Dropinski J, Kubicka-Trzaska A, Domagala TB, Sanak M and Musial J

Jagiellonian University School of Medicine, Krakow, Poland

Introduction: Retinal vascular occlusion is common causes of blindness and visual morbidity. The role of thrombophilia in the etiology of retinal artery occlusion has not been adequately clarified. Classic risk factors are commonly associated with retinal artery thrombosis, while unclear it is the role of the thrombophilic and coagulation disorders.

Aim: The aim of our study was to establish the prevalence of major and potential inherited and acquired thrombophilic risk factors in 65 patients (39 females, 26 males; age: 56.7 years; range 24–72) with ocular arterial occlusions. The control group consisted of 60 (32 females, 28 males; age: 55.7 years; range 20–72) healthy subjects, without any vascular, eye-related disease.

Methods: In all participants the prevalence of Leiden mutation (FV Leiden), protrombin variant (20210 G/A mutation), Leu 34 polymorphism of the factor (F) XIIIA-subunit, deficiency of protein C, S, antithrombin and antiphospholipid antibodies (aPL) were assessed. Also intima-media thickness (IMT) in carotid arteries were measured using ultrasonography.

Results: Elevated aPL antibody level (IgG>10 GPL; IgM>20MPL) were detected in 15 of 65 patients (23%) and in 4 of 60 controls (6.6%). The incidence of FV Leiden, deficiency of protein C were significantly more common in patients suffered from ocular arterial occlusions ($P < 0.05$) compared to controls. Patients with ocular arterial occlusions had greater IMT than healthy subjects (0.91 mm vs. 0.72 mm; $P < 0.05$). There was no significant difference in the prevalence of deficiency of protein S, 20210 G/A mutation, FXIII Val34Leu polymorphism and antithrombin level between patients and healthy subjects. Among classic risk factors only hypertension, diabetes mellitus, hypercholesterolemia and cigarette smoking were significantly more frequent in patients suffered from ocular arterial occlusions in comparison to controls.

Conclusions: These results show that thrombophilia plays a much important role in the pathogenesis of retinal artery occlusions. According to these data, thrombophilia screening should be consider in preventing and treatment of such events.

PB 3.63-6

TAFI Thr325Ile polymorphism and abdominal aortic aneurysms

Bridge KI, Macrae FL, Johnson A, Scott DJA and Ariëns R

University of Leeds, Leeds, UK

Background: Abdominal Aortic Aneurysm (AAA) is a permanent dilatation of the abdominal aorta, with a natural history of expansion and eventual rupture, accounting for up to 8000 deaths per annum in the UK alone. The presence of intra-luminal thrombus (ILT) is an independent risk factor for expansion and rupture of AAA. Beyond the ILT, the high cardiovascular risk in this group of patients indicates thrombosis may be altered systemically. Recent studies from our laboratory showed that patients with AAA form denser clots with smaller pores, which are more resistant to fibrinolysis.

Thrombin-activatable fibrinolysis inhibitor (TAFI) inhibits fibrinolysis through cleavage of C-terminal lysines from fibrin, impairing the conversion of plasminogen into plasmin and thereby promoting clot stability. A known polymorphism of TAFI, Thr325Ile, has been shown to increase the stability and anti-fibrinolytic activity of TAFI *in vitro*. A recent study indicated a role for TAFI in AAA development, since TAFI deficient mice developed larger AAA upon aortic elastase infusion compared with controls (Schultz G et al, ATVB 2010). Whilst TAFI Thr325Ile has been previously associated with cardiovascular disease, its role in human AAA remains unexplored.

Aim: To investigate the association between the TAFI Thr325Ile polymorphism and AAA, ILT and survival.

Methods: All participants were recruited through the Leeds Aneurysm Development Study (LEADS). A total of 1111 Caucasian subjects ≥55 years (604 patients with AAA ≥3 cm, and 507 age and sex-matched controls, aortic diameter <2.9 cm) were included. DNA was extracted from blood cells, and Thr325Ile genotype was identified using real time PCR, through a commercially available genotyping assay (rs1926447, TaqMan® SNP Genotyping Assay, Life Technologies). Data was analysed using IBM SPSS Statistics version 20.

Results: Genotypes across the study population agreed with the Hardy Weinberg Equilibrium (Controls $x^2 = 0.01$, $P = 0.92$, Aneurysms $x^2 = 0.008$, $P = 0.93$, Total population $x^2 < 0.001$, $P = 0.98$). More patients than controls were both homozygote (9.8% vs. 8.1%) and heterozygote (42.7% vs. 41.0%) for the Ile325 allele; these differences were not statistically significant ($P = 0.429$). The presence of ILT was confirmed on ultrasound scan in 226 of the aneurysm patients (37.4%) but presence or absence ILT was not related to genotype ($P = 0.663$). Although there was a significant difference in survival between aneurysms and controls ($P < 0.001$), survival was not related to TAFI genotype within either group (controls $P = 0.951$, aneurysms $P = 0.549$), or across the population as a whole ($P = 0.234$).

Conclusion: The TAFI Thr325Ile polymorphism did not associate with AAA, presence of ILT, or survival in this group of AAA patients and their controls. These data do not support a major role for this polymorphism in AAA development or intra-luminal thrombus formation.

PB 3.64-1

Hestia criteria with the POMPE-C tool identifies patients with cancer and pulmonary embolism at very low risk for short-term complications

Kline JA[1], Kabrhel C[2] and Beam D[1]

[1]Indiana University, Indianapolis, IN; [2]Harvard School of Medicine, Boston, MA, USA

Background: The Hestia criteria and the Prediction of Mortality from Pulmonary Embolism with Cancer (POMPE-C) are well-suited to risk stratify patients with active cancer and PE. We test the hypothesis that the tandem application of Hestia and a POMPE-C score ≤5% in emergency department (ED) patients with active cancer and PE, would be efficient (>25% categorized as eligible for home treatment) and safe (zero mortality at 30 days).

Methods: Patients with confirmed PE were enrolled from the ED of a large academic hospital. Variables required for Hestia and POMPE-C were collected prospectively and 30 day survival was confirmed by direct observation. Active cancer was defined as under treatment or metastatic.

Results: We enrolled 299 patients with PE, including 107 with any history of cancer and complete data. The 30 day mortality rate was 10/107 (9%, 95% CI: 5–17%). Application of Hestia to all 107 with any cancer excluded 29 patients, leaving 79 evaluable by POMPE-C which was ≤5% in 46 patients (43% 34–52%). None of these 46 (0%, 0–8%) died within 30 days. Fifty-eight patients had active cancer and both the Hestia criteria were negative and POMPE-C were ≤5% in 24/58 (41%, 29–55%). None of these 24 patients died within 30 days (0–13%).

Conclusion: The Hestia criteria negative together with POMPE-C ≤5% identified 41% of outpatients with active cancer and PE at very low risk of short-term mortality. Hestia plus POMPE-C offer an efficient and safe method to risk-stratify patients with cancer and PE.

PB 3.64-2

Prevention of venous thromboembolism after major trauma: efficacy of prophylactic measures and associated bleeding complications

Hitos K, Hsu J and Fletcher JP
University of Sydney/Westmead Hospital, Sydney, Australia

Background: Trauma patients are at a particularly great risk for the development of venous thromboembolism (VTE) due to hypercoagulability, immobilization and venous injury. Without thromboprophylaxis the incidence of deep vein thrombosis (DVT) has been reported to be as high as 63%. The optimal VTE prophylaxis strategy for trauma patients with a contraindication to pharmacological prophylaxis due to the risk of bleeding remains unknown.
Aims: To determine the VTE incidence in major compared to minor trauma patients admitted under a multidisciplinary trauma team as well as assess the efficacy of prophylactic modalities used and associated bleeding complications.
Methods: In total, 1182 patients admitted at Westmead Hospital Level 1 trauma centre were identified from the prospectively maintained Trauma Registry and reviewed (with waiver of consent) over a 6 month period in 2011 and 2012. Patients with an injury severity score (ISS) >12 were categorized as major trauma. Demographic details, mechanism and type of injuries, hospital length of stay (LOS), ISS, prophylactic modalities (mechanical and pharmacological), operative duration, bleeding complications, outcome including in-hospital and 3 month incidence of DVT and pulmonary embolism (PE) were analyzed.
Results: Overall male to female ratio was 2.4:1. 78.4% of patients were minor and 21.6% were major trauma. Mean age was 44.0 years (14.0–100.0) for minor and 46.0 years (16.0–91.0) for major trauma patients with a mean hospital LOS of 4.6 days (1.0–86.0) and 17.2 days (1.0–133.0) respectively ($P < 0.0001$). Mean intensive care LOS was 0.1 days (0.0–7.0) for minor and 2.3 days (0.0–46.0) for major trauma ($P < 0.0001$). No pharmacological prophylaxis was used in 36.6% of minor and 7.7% of major trauma patients. Unfractionated heparin (UH) was used in 56.3% of minor and 88.5% of major trauma patients and low molecular weight heparin (LMWH) in 7.0% and 3.8% respectively. Mechanical prophylaxis was used in 70.4% of minor and 96.2% of major trauma patients. Major bleeding rates for major trauma were 10.7% with no pharmacological prophylaxis and 34.8% with use of UH. For minor trauma patients, the overall in-hospital VTE incidence was 1.0% (0.3% for DVT and 0.7% for PE). For major trauma patients, the overall in-hospital VTE incidence was 7.8% (7.0% for DVT and 0.8% for PE). At 3 months, the VTE incidence for minor trauma patients was 1.2% (0.5% for DVT and 0.7% for PE) and 9.0% (7.4% for DVT and 1.6% for PE) for major trauma patients. Mortality rates were 0.6% for minor and 7.8% for major trauma.
Summary/Conclusion: Our in-hospital incidence of VTE in trauma patients was kept relatively low with use of prophylactic protocols. The 7.8 fold increase in the in-hospital VTE incidence for major trauma together with the two fold rise in PE rates at 3 months reinforces the importance for maximizing optimal thromboprophylaxis relative to risk factors, type and severity of injury, surgical intervention, hospital LOS and bleeding risk. Selective ultrasound screening in patients unable to receive pharmacological prophylaxis due to bleeding risk or inability to use mechanical prophylaxis may be of benefit.

PB 3.64-3

A swine model for pulmonary embolism with autologous clot mimicking sub-massive PE

Beam D, Tune JD, Sturek M and Kline JA
Indiana University School of Medicine, Indianapolis, IN, USA

Background: Safer treatments are needed for severe, submassive pulmonary embolism (PE). Since rodent models are inadequate, a standardized reliable and reproducible large animal model of submassive PE that reproduces physiological abnormalities observed in humans with severe submassive PE would facilitate new drug development.
Aims: Create a swine model of PE with autologous clot, which would resemble severe, submassive PE in humans
Methods: Domestic pigs ($N = 5$ 30–40 kg body weight) were sedated and placed on isoflurane anesthesia. The femoral vein and artery were cannulated to permit blood sampling and pressure measurements, respectively. For autologous clot formation, 2 mL/kg of blood volume was taken and replaced 3:1 with 0.9% NaCl. Whole blood was incubated for 37 °C for 60' in 12 mm diameter glass tubes. Cylindrical clots were removed, washed with warm saline, and loaded into Tygon silastic tubing (ID 6.35 mm, OD 7.94 mm). A 7F Edwards Scientific thermodilution Swan-Ganz catheter was placed via ultrasound guidance in the right external jugular. A cut-down was performed and left external jugular isolated, silastic tubing was introduced into the vein, and clot was gently introduced. Clot was confirmed to be present in the heart with live echocardiography and fluoroscopy. All measurements were taken prior to and 1 h. after delivery of clot.
Summary/Conclusions: Infusion of ~0.5 g/kg clot produced tachycardia (106 ± 6 beats/min), pulmonary hypertension (sPAP 45 ± 4 mm Hg), and mild hypoxemia (95 ± 1%), and a 20 ± 7% decrease in cardiac output. Increasing the clot burden to ~0.7 g/kg showed immediate changes consistent with marginally compensated shock. Heart rate increased to 121 ± 3 beats/min), a marginally decreased systolic arterial blood pressure (101 ± 6 mm Hg), without hypotension, but with severe right ventricular dysfunction, pulmonary hypertension (sPAP 60 ± 2 mm Hg), and hypoxemia (91 ± 1%). At this level a 30 ± 8% decrease in cardiac output was seen. The mean change from basal control values to +60 min post infusion of clot mass of 0.7 g/kg was as follows: mean arterial pressure (MAP) = 80 ± 5 vs. 64 ± 3 mm Hg; heart rate increased from 81 ± 3 to 119 ± 6 beats/min; oxygen saturations dropped from 98 ± 0 to 91 ± 1%; the systolic pulmonary arterial pressure (mPAP) increased from 10 ± 2 vs. 36 ± 2 mm Hg and cardiac output dropped from 2.2 ± 0.1 to 1.6 L/min, PCWP increased from 8 ± 1 to 18 ± 3 mm Hg, and PVR increased from 72 ± 11 to 742 ± 54 dyne*S/cm5. Cardiac arrest occurred as a result of rapidly injecting clot at 0.9 g/kg.
Conclusions: In anesthetized domestic swine, 0.7 g/kg autologous, cylindrical clots instilled via the external jugular vein elicit the pulmonary vascular, hemodynamic and echocardiographic responses of humans with severe submassive PE. This model will be useful for preclinical testing of new fibrinolytic agents in preparation for phase I human studies.

PB 3.64-4

Clinical outcome and prognostic factor of cerebral venous sinus thrombosis in Siriraj hospital

Chinthammitr Y and Bhurihirun T
Siriraj Hospital, Bangkok, Thailand

Background: Cerebral venous sinus thrombosis (CVST) is an uncommon disease with the potentially serious consequences. The clinical outcome of patients with CVST varied from complete recovery to permanent neurological deficits and death.
Aims: To describe the outcome and the prognostic factor.
Methods: Medical records of patients with CVST in Siriraj hospital between year 2001 and 2009 were reviewed retrospectively. Collected data included clinical features, thrombotic risks, imaging result, treatment, and outcome until the second visit after discharge. Patients without data of clinical status at the time of hospital discharge were excluded. Bleeding complication after discharge was also reviewed. The outcome was categorized into two groups with a simple and practical scale: good outcome (able to walk) and poor outcome (need wheelchair, bedridden, and death).

Results: One hundred and fourteen patients (103 women) had a median age of 34.0 years (range 21–65). Most common thrombotic risk was oral contraceptives (30.9%) whereas congenital deficiency of natural anticoagulants was found in 10/110 (9.1%). Mean length of hospital stay was 16.7 + 4.2 days (range 2–25). On discharge date, 29 patients (25.4%) had a poor outcome (five deaths). In the univariate analysis, factors significantly related to the poor outcome were male sex, older age, weakness, cranial nerve palsy, seizure, coma, blurred vision, papilledema, >2 thrombotic risks, number of sinus involvement, involvement of sagittal or transverse sinus, intracerebral hemorrhage, cerebral infarction, and cerebral edema whereas factors associated with the good outcome were Delta's sign, low-molecular-weight heparin use, and warfarin use. In the multivariate analysis, coma and number of sinus involvement were significantly associated with the poor outcome. Poor outcome rate was 90% (9/10) in patients with coma. Among patients without coma, poor outcome was 2.6% (2/77), 60% (12/20), 100% (6/6) for the number of sinus involvement of 1, 2, >3 sinuses, respectively. Among alive patients with poor outcome at discharge, status at follow-up visit (median follow-up time = 7 weeks; range 4–12) was improved in 7/24 and worse to death in 3/24. Major bleeding complication occurred only in the poor-outcome group (2/24 patients; INR = 9.8 and 10.2).
Conclusions: At a 7-week follow-up after discharge, rate of poor outcome was 21.9% whereas mortality rate was 7%. Coma and multiple venous sinus involvement were poor prognostic factors of cerebral venous sinus thrombosis.

PB 3.64-5

Implementation of a venous thromboembolism prophylaxis program in Brazilian hospitals: VTE Safety Zone Brazil

Rocha AT[1], Tandeitinik LS[2], Timi JRR[3], Macedo AG[4], Oigman W[5], Paiva M[6], Pantoja J[7] and Anjos JC[8]

[1]Faculdade de Medicina da Universidade Federal da Bahia, Salvador; [2]Hospital Agamenon Magalhães, Recife; [3]Hospital das Clínicas da UFPR, Curitiba; [4]Santa Casa de Misericórdia de Santos, Santos; [5]Hospital Universitário Pedro Ernesto UERJ, Rio de Janeiro; [6]Hospital Nove de Julho, São Paulo, São Paulo; [7]Hospital Copa D'Or, Rio de Janeiro; [8]Hospital Madre Teresa, Belo Horizonte, Brazil

Background: The ENDORSE study showed that 46% of medical patients in Brazil are at risk for venous thromboembolism (VTE), but only 59% of these were receiving prophylaxis according to the American College of Chest Physicians (ACCP) guidelines. The implementation of hospital prophylaxis programs based on passive distribution of VTE risk-assessment algorithms and continuous medical education are not sufficient to improve the utilization of prophylaxis.
Aims: (i) To evaluate the impact of a hospital prophylaxis program (VTE Safety Zone) implementation based on the standardized distribution of VTE risk-assessment algorithms, lectures and the participation of a hospital VTE prophylaxis committee (VTEPC) on the adequacy of VTE prophylaxis in medical patients; (ii) To compare the evaluation of VTE risk by the ACCP and the Brazilian Guideline for VTE Prophylaxis, and (iii) To evaluate the impact of VTE Safety Zone with and without a formal VTEPC on the utilization of prophylaxis.
Methods: We performed a cross-sectional survey, during a single day, in medical patients admitted to 11 Brazilian hospitals that participated in ENDORSE and that were randomized to be implemented during 12 months with one of two groups of the VTE prophylaxis program. The more intensive (MI) group included a formal VTEPC supported by the hospital director. The rates of adequacy of prophylaxis were compared between the two hospital groups, between the two guidelines recommendations and also with the 649 historical controls evaluated during ENDORSE.
Results: Data of 725 patients were collected: 400 (55%) patients in the MI group and 325 (45%) in the less intensive (LI). The mean age of patients was 65 ± 14 years-old, 50% were men and had a median of 10 ± 8 days of hospitalization. We found that 15% of patients were obese, 57% had reduced mobility, 96% had at least one risk factor (RF) for VTE; mean of 3 RF/patient, but higher in the MI group (3.6 ± 2 vs. 2.4 ± 1, $P < 0.0001$). The more frequent RF were age ≥55 years (75%), intensive care admission (31%), infection (25%), central venous catheter (21%), chronic pulmonary disease (21%), heart failure (19%), pneumonia (19%) and cancer (16%). At least one RF for bleeding was present in 32%. According to ACCP, 54% of the medical patients were at-risk for VTE and 73% had adequate prophylaxis, which was significantly more than the 59% reported in ENDORSE. According to the Brazilian Guideline, 89% were at-risk and 60% had adequate VTE prophylaxis. The adequacy was significantly higher in the MI group as compared with the LI, according to the Brazilian Guideline (73% vs. 50%, $P < 0.0001$).
Conclusions: There were important improvements in the adequacy of prophylaxis in medical patients admitted to Brazilian hospitals between the ENDORSE and the VTE Safety Zone studies. According to the ACCP criteria, after the implementation of the VTE Safety Zone program, more patients at-risk were identified and consequently more patients were receiving adequate VTE prophylaxis. Including a formal VTEPC into a hospital prophylaxis program seems essential to achieve higher goals of adequacy of VTE prophylaxis in medical patients.

PB 3.64-6

The influence of the thrombotic burden on D-dimer plasma levels in acute symptomatic deep vein thrombosis of the lower limbs

Cosmi B, Legnani C, Cini M, Guazzaloca G, Rodorigo G, Valdrè L, Sartori M and Palareti G

S.Orsola-Malpighi University Hospital, Bologna, Italy

Background/Aims: Thrombotic burden might influence the concentration of D-dimer in patients with acute symptomatic deep vein thrombosis (DVT) of the lower limbs. Patients with small thrombi may thus present with relatively low concentrations of D-dimer. To establish whether D-dimer levels reflect the extent of acute deep vein thrombosis (DVT) of the lower limbs. Design: cross-sectional, single centre study.
Patients and Methods: We evaluated consecutive patients with suspected DVT of the lower limbs referring to our vascular emergency department from 2002 to 2009. All patients underwent prestest clinical probability (PCP), compression ultrasonography and D-dimer testing (STA, Stago, cut-off: 500 ng/mL).
Results: We investigated 1187 patients (M:477 – 40%, mean age 65, median 68, range:12–97) among whom 233 proximal DVTs (20%) and 164 distal DVTs (14%) were diagnosed. Prestest clinical probability was likely in 194 (83%) of patients with proximal DVT and in 95 (57%) of subjects with distal DVT. D-dimer levels were higher in patients with proximal DVT (mean: 4.38 μg/mL, median: 3.55 μg/mL; range:0.39–23.65 μg/mL) than in patients with distal DVT (mean: 1.23 μg/mL; median:0.71 μg/mL, range:0.01–12 μg/mL) ($P < 0.0001$) and patients without DVT (mean 0.80 μg/mL, median: 0.46 μg/mL, range:0.01–11 μg/mL) ($P < 0.0001$). D-dimer was below the cut-off in 38% of patients with distal DVT and in 2% of patients with proximal DVT. Among patients with unlikely PCP and D-dimer below the cut-off, distal DVT was diagnosed in 16% and proximal DVT in 0.83%. D-dimer levels were not correlated with the extent of proximal DVT.
Conclusions: D-dimer levels are higher in patients with proximal DVT than in patients with distal DVT. Patients with acute small DVT might present with low concentrations of D-dimer, thus affecting the yield of diagnostic algorithms in suspected acute DVT of the lower limb.

PB3.65 – Hormones, pregnancy, women's issues – III

PB 3.65-1

Does systematic risk assessment in pregnancy identify women at risk for venous thromboembolism and so avoid thrombosis? Experience of an 18 month programme based on national guidance

Creagh MD[1], Dehnel A[2], Rider L[2], McSorley A[1], Carson P[1] and Raja Asri[1]

[1]Royal Cornwall Hospitals NHS Trust, Truro; [2]Peninsula College of Medicine & Dentistry, Plymouth, UK

Background: Pulmonary embolism (PE) remains the leading direct cause of maternal mortality in the UK, whilst pregnancy related DVT may result in significant morbidity. Venous thromboembolism (VTE) has an overall incidence of 1–2/1000 pregnancies. The UK Royal College of Obstetricians and Gynaecologists (RCOG) Green-top guidance 37a (2009) recommends risk assessment (RA) for VTE in early pregnancy and at delivery to guide decisions on thromboprophylaxis. A schema was derived from the RCOG guidance, based on personal and family history of VTE and identified risk factors such as age, multiparity, raised body mass index, thromophilia and the means of delivery. Routine midwife lead RA was introduced at the initial early pregnancy 'booking' visit, with women catagorised as low, intermediate or high risk for VTE by pro-forma. Referral of high risk women to a Joint Haematology Obstetric Clinic enables specialist assessment and consideration for thromboprophylaxis. RA is repeated post delivery, using a hospital prescription chart based schema, or in the event of antenatal admission to hospital.

Aim: To study the effectiveness of a risk assessment schema in identifying at risk women and the prevention of VTE.

Method: Information was collected on patients who developed VTE in pregnancy or the post partum, known to the Joint Haematology Obstetric Clinic. Data from the available pro-forma records was collated for RA catagorisation, or otherwise this was derived from the available clinical and electronic records. Pregnancy outcomes and complications were assessed from the obstetric record.

Results: Over an 18 month period of study, there were a total of 7533 pregnancies at RCHT. Twelve cases of VTE were identified, five PE's and seven DVT's, an incidence of 1.59/1000 pregnancies. Seven cases occurred ante-natally, with five cases in the puerperium. There were no maternal or fetal deaths. Booking RA pro-formas were identified for 10 women and an RA calculated for the two other cases, all subjects being catagorised as low risk. For those five women with VTE in the puerperium, three had a RA recorded post delivery, one assessed as low risk for VTE and two at intermediate risk, while for the two other women their RA. derived from the clinical record, was one at low risk and one at intermediate risk. Only one of three women at intermediate risk for VTE, who by the schema were to be offered heparin thrombophrophylxis, had documentation of this proposed management but she declined therapy.

Conclusion: The observed incidence of 1.59/1000 pregnancies is comparable to the literature. Despite a low RA catagorisation seven women sustained ante-natal VTE, suggesting that this ante-natal schema may not identify risk or avoid VTE. For those post partum VTE cases 60% were classified as intermediate risk, however none received heparin thromboprophylaxis, which may reflect failure to implement new practice and the need for continuing education. Further prospective data should be collected for the schema, with determination of any additional evident risk factors, specifically in antenatal VTE, with comparison to other Units with a similar obstetric practice but with alternative RA schemas.

PB 3.65-2

Incidence of pregnancy outcomes in the conventionally treated purely obstetric antiphospholipid syndrome, pregnancy loss subtype: the NOH-APS observational study

Gris J-C, Bouvier S, Cochery-Nouvellon E, Lissalde-Lavigne G, Mercier E, Mousty E, Balducchi J-P and Marès P

University Hospital, Nimes, France

Background: The incidence of pregnancy outcomes in the purely obstetric form of antiphospholipid syndrome (APS) treated according to guidelines is uncertain.

Aims: We aimed to design a prospective study in women selected on the same clinical criteria, according to the presence of APS, or to the absence of any thrombophilia.

Methods: We performed a 10-year observational study of 1592 non-thrombotic women who had experienced three consecutive spontaneous abortions before the 10th week of gestation or one foetal death at or beyond the 10th week of gestation (*NOH-APS, Blood 2012;119 (11):2624–32*).

We compared the frequencies of pregnancy outcomes among women positive for antiphospholipid antibodies (n = 517; treatment: prophylactic LMWH plus low-dose aspirin LDA), women carrying the *F5* 6025 or *F2* rs1799963 polymorphism (n = 279; recurrent abortions: no treatment; foetal death: prophylactic LMWH), and women with negative thrombophilia screening results (n = 796; no treatment).

We report here the results comparing APS women and thrombophilia negative women.

Results: In control women with negative thrombophilia screening results, initial foetal loss was associated with an increased risk of early spontaneous abortion and of foetal death; of pre-eclampsia (PE), severe PE, PE before 34 weeks and PE with delivery of a small-for gestational age neonate (SGA); of any ischemic placenta disease (IPD); of SGA neonate; of preterm life birth before 37 weeks and before 34 weeks.

In women with recurrent abortions, treated APS women were at increased risk of foetal death; of PE, severePE, PE before 34 weeks and PE with delivery of a SGA neonate; of any IPD; of neonatal death. A trend ($P < 0.15$) for an increased risk of premature birth before 37 weeks and before 34 weeks, for birth of a SGA neonate and for early neonatal mortality was also detected.

In women with foetal death, treated APS women were at lower risk of early abortion and of foetal death. They were at higher risk of PE and of PE before 34 weeks. A trend for an increased risk of premature birth before 37 weeks, of severe PE, of HELLP syndrome, of PE with a SGA neonate and of late neonatal mortality was also detected.

Summary/Conclusions: In women with a purely obstetric APS syndrome attempting a new pregnancy treated according to guidelines, the relative risks of the various pregnancy outcomes depend on the initial clinical presentations, which by themselves impact on the reference prognosis. Treatment does not overcome the risk of pre-eclampsia. Neonatal mortality rates remain increased. New therapeutic options are thus needed.

PB 3.65-3

Prevalence of hereditary thrombophilia is the highest in women who developed pregnancy related thrombosis during first trimester

Bodrozic J[1], Miljic P[1], Gojnic M[2] and Djordjevic V[3]

[1]Clinic of Hematology, Clinical Center of Serbia, Belgrade; [2]Clinic for Gynecology and Obstetrics, Clinical Center of Serbia, Belgrade; [3]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

Background: Venous thrombosis is one of the leading causes of maternal morbidity and mortality. In women of reproductive age, over half

of all venous thrombotic events are related to pregnancy and puerperium.

Aims: We evaluated the presence of hereditary thrombophilia in women with thromboembolic complications during pregnancy and puerperium.

Methods: We conducted a retrospective analysis of 143 consecutive women that developed thromboembolic complications during pregnancy or puerperium (6 weeks after the delivery), and who were referred to our institution for thrombophilia testing from January 2004 to October 2012. Venous thromboembolism was defined as deep vein thrombosis (DVT) of upper or lower extremities, cerebral vein thrombosis and pulmonary embolus (PE). When deep vein thrombosis of lower extremities was present with PE, the event was accounted as PE. Women with thrombosis of superficial veins were excluded from this study. All episodes of venous thromboembolism were confirmed with objective methods (duplex ultrasonography, CT angiography, perfusion scintigraphy, NMR angiography). In all women following causes of hereditary thrombophilia were tested: factor V Leiden and prothrombin G20210A mutations, antithrombin deficiency, protein C deficiency and protein S deficiency. Blood for thrombophilia testing was obtained at least 3 months after cessation of anticoagulant therapy.

Results: Out of 143 women with pregnancy related thrombosis, 54 (38%) developed thromboembolic complications during pregnancy and 89 (62%) during puerperium. The presence of congenital thrombophilia was detected in 29 (54%) women who developed thrombosis during pregnancy and in 23 (46%) women with thromboembolic complications during puerperium.

Out of 54 women who developed thrombosis during pregnancy, 15 (28%) had thromboembolic event in the first trimester of pregnancy, 11 (20%) in the second and 28 (52%) in the third, respectively. Prevalence of hereditary thrombophilia among women with thrombosis in the first, second and third trimester of pregnancy was 72%, 50% and 53%, respectively.

In women who developed thrombosis during pregnancy distribution of thrombosis according localization was as follows: proximal vein thrombosis of lower extremities in 38 (70%), distal veins in 8 (16%), PE in 5 (9%), cerebral vein thrombosis in 2 (4%) and subclavio-axillaris thrombosis in 1(1%). On the other hand, in women with occurrence of thrombosis during puerperium was: proximal vein thrombosis in 42 (47%), distal vein in 21 (23%), PE in 17 (19%), ccerebral vein thrombosis in 8 (10%), subclavio axillar thrombosis in 1(1%).

Summary/Conclusions: We observed the highest prevalence of hereditary thrombophilia in women who developed thrombosis during first trimester of pregnancy compared to advanced stages of pregnancy or puerperium. This finding may indicate the importance of acquired factors in occurrence of thrombosis in second and third trimester of pregnancy and during puerperium. Recognition and elimination of these factors may play an important role in prevention of pregnancy related thrombosis. Two times higher prevalence of PE in puerperium than during pregnancy may be a consequence of underdiagnosing this complication (reluctance to use CT angiography or perfusion scintigraphy) during pregnancy although we cannot exclude the real difference in prevalence of thrombosis during puerperium and during pregnancy.

PB 3.65-4

Protein Z deficiency and Lipoprotein (a) increase are the most frequent abnormalities in women with recurrent miscarriage

Bergmann F, Groening H, Frohne S, Guenther F, Luttkus K and Czwalinna A

Labassociation wagnerstibbe, amedes-group, Hannover, Germany

Introduction: More than 1–2% of women suffer from recurrent miscarriage (RM), vascular complications of pregnancy or implantation failure after assisted reproduction. Guidelines recommend ruling out chromosomal or anatomical abnormalities as well an antiphospholipid syndrome or thyroid dysfunction. In Europa, complete thrombophilia work up is commonly requested. By metaanalysis hereditary thrombophilia (e.g. FV-Leiden-/prothrombinmutation) is questionable in RM. However, low Protein Z (PZ)-levels (<1000 μg/L) (inherited or acquired due to antibodiesare associated with vascular complications in pregnancy (OR 4.17) (Sofi 2010). Lp(a) influences the fibrinolytic system which is important in implantation and placental development and elevated Lp(a) (>30 mg/dL) has been reported in women with vascular complications in pregnancy (e.g. preeclampsia). Elevated FVIII is not associated with poor pregnancy outcome (Middledorp 2004).

Material and Methods: Over 1 year 107 women, median age 32 years, were transferred to our coagulation outpatient clinic to rule out hypercoagulability in women with RM. In all women laboratory work up consists of: TSH, Lp(a), Homocysteine (fasting level), FV- Leiden- and Prothrombinmutation, Antithrombin, Protein C, free Protein S, Protein Z, FXII, Lupusanticoagulant (dRVVT, PTT-LA), Anti-Cardiolipin IgG and IgM, Anti-beta2-GPI IgG, Anti-Prothrombin IgG and Anti-Phosphatidylserine IgG; BMI calculation and medical history, also in complete pregnancy, were documented.

Results: In 32% of our cohort no laboratory abnormality could be detected. 13% had at least two abnormalities. FV-Leiden-/prothrombinmutation were present in 7%, no Antithrombin deficiency; Protein C and S deficiency in 3% and low FXII-levels in 2% and antiphospholipid syndrome in 6%. Hyperhomocysteinemia was detected in 2%. Decreased Protein Z was detected in 20% and Lp(a) >30 mg/dL in 16%. Mean BMI 24.8 (range 17.6–39.1). Abnormal thyroid function was present only in 3%, while some women were already on thyroid medication when investigated.

Discussion: RM is a multifactorial disorder; increased maternal age, BMI, thyroid function as well certain coagulation abnormalities influence pregnancy outcome. The frequency of FV-Leiden-/prothrombinmutation as well as hereditary deficiency of Protein C and S and FXII-deficiency reflects the prevalence found in normal population and therefore cannot be causal in RM, solely. In our cohort low PZ-levels and elevated Lp(a) were the most frequent abnormalities. Such risk factors may have a potent influence on early implantation and placental development. The question remains, which treatment options are feasible: preconceptional ASA and/or LMW Heparin as in women with APS?

PB 3.65-5

Elevated endogenous thrombin potential prior to clinical diagnosis of preeclampsia

Schweintzger S, Weiss EC, Schlagenhauf A, Leschnik B, Bernhard H, Haidl H, Muntean W and Lang U

Medical University of Graz, Graz, Austria

Background: Preeclampsia is a multisystem disorder of unknown cause manifesting in the second half of pregnancy. Endothelial cell dysfunction, enhanced platelet aggregation, activation of coagulation and increased vascular resistance may be involved. Increased thrombin generation was described in patients with preeclampsia and in women with a history of preeclampsia. The measurement of thrombin generation with calibrated automated thrombography is a global function test of the hemostatic system, which allows sensitive detection of prothrombotic states.

Aim: We investigated whether increased thrombin generation is measurable in early pregnancy, before the clinical diagnosis of preeclampsia.

Methods: Blood of 56 pregnant women was drawn repeatedly within the duration of pregnancy. Five women were excluded from the study due to heparin treatment. Eleven women developed a preeclampsia during pregnancy. Blood of six women was drawn before the clinical diagnosis of a preeclampsia. Measurements of thrombin generation were performed in platelet poor plasma using calibrated automated

thrombography. Each sample was measured with PPP reagent (5 pM tissue factor) and MP reagent (no tissue factor). Lag time, time to peak, start tail, peak height and endogenous thrombin potential were calculated from the obtained thrombin generation profiles. In addition prothrombin fragment F1, F2 and thrombin antithrombin complex were measured. All pregnant women were split into groups depending on gestational weeks. Within these groups all parameters were statistically evaluated. Differences between women with an uncomplicated pregnancy and women with a preeclampsia were calculated using *t*-test or Man- Whitney U test.

Results: No differences were found in the dynamic parameters of thrombin generation (lag time, time to peak, start tail) between women with an uncomplicated pregnancy and women with preeclampsia. In the same gestational group, peak height, prothrombin fragment F1, F2 and thrombin antithrombin complex were similar between women prior to diagnosis of preeclampsia and women with a uncomplicated pregnancy. Women who developed preeclampsia exhibited an increased endogenous thrombin potential compared to women with an uncomplicated pregnancy that became statistically significant already at the 16th week of gestation.

Conclusion: Our preliminary results suggest that a high endogenous thrombin potential is associated with the development of preeclampsia. Tthe measurement of thrombin generation with calibrated automated thrombography may have predictive value. A prospective study of larger scale is in preparation.

PB 3.65-6

Effect of prophylaxis with LMWH on implantation in women undergoing assisted reproductive procedures (IVF or ICSI): an interim report of a prospective randomized study

Tormene D, Viganò F, Falcone L, Gava S, Gangemi M and Simioni P

University of Padova, Padova, Italy

Several studies have shown that a pharmacological prophylaxis in women subjected to MPA treatment, lead to an increase of the number of taken oocytes as well as higher rates of implantation and pregnancy.

An experimental strategy employed to improve embryo implantation and possibly positive pregnancy outcome was attributed to the use of heparins, particularly low molecular weight heparin (LMWH).

Aims of the study: The aim of the study is to test whether prophylactic dose of LMWH could improve the implantation rate in women with inherited thrombophilia or a history of two or more than two consecutive implantation failures.

Study population: Women consecutively referred to the Medically Assisted Procreation (MAP) Center of Gynecology Clinic of Padua are considered eligible for the study. All women undergoing intrauterine insemination techniques are excluded because of the inability in this first level technique to ensure fertilization.

Inclusion criteria are: heterozygosity of inherited common thrombophilias (FVL, PTm), hetero/homozygosity of MTHFR, two or more than two previous implantation failures, age >18, informed consent

Exclusion criteria are: deficiency of antitrombin, protein C, protein S, antiphospholipid antibodies, homozygosity or double heterozygosity for FVL/PTm, history of venous thromboembolism.

Women enrolled in the study are randomly divided into two groups. One group receives prophylaxis with LMWH (dalteparin 5000 UI/die) (cases), the other does not (controls).

Cases receive prophylaxis with LMWH from the beginning of MPA procedures to the positive/negative outcome (implantation/implantation failure).

Statistical analysis: The implantation rate in procedures of medical assisted reproduction (whether by IVF or through ICSI technique) is 20–25%. The results of an our previous observation evidenced a risk reduction for implantation failure of 50% [rRR 0.5 (95% IC 0.3–0.8)] in women under prophylaxis. Then, about 257 women in both groups (with and without prophylaxis) need to be enrolled in the study: a power of the study of 90% is needed to demonstrate a reduction of implantation failure of 30% with a statistical significance of 5%, by considering a drop-out of 15%. Statistical analysis is performed by SPSS version 17.0.

Preliminary Results: From September 2012, 50 women have given their consent to participate in the study. At present 20 women have completed a course of procedures: 10 in the group of cases (mean age 39 years, two homozygous for MTHFR C677T, five heterozygous for MTHFR C677T, seven with more than two implant failure) and 10 in the control group (mean age 40 years, one homozygous for MTHFR C677T, four heterozygous for MTHFR C677T, seven with more than two implant failures). Four implants occurred in the group of cases and one occurred in the control group. The odds ratio was 6.0 (95% CI 0.54–68).

Conclusions: The results of this ongoing study are clearly preliminary due to the small number of women evaluated so far. This interim report shows a trend toward a potential advantage of anticoagulant prophylaxis in the improvement of the implantation rate in MAP.

PB3.66 – Inflammation: Clinical – II

PB 3.66-1

New insight on the systemic inflammation response syndrome (SIRS) in STEMI patients undergoing primary percutaneous intervention: clinical features, blood markers, and prognostic significance

Théroux P[1], Luong TM[1], Nicolau JC[2] and Bonnefoy A[3]

[1]Montreal Heart Institute and University of Montreal, Montreal, Canada; [2]Heart Institute, University of São Paulo Medical School, São Paulo, Brazil; [3]CHU Sainte Justine and University of Montreal, Montreal, Canada

Background: Acute myocardial infarction (MI) is recognized as a classical trigger to the development of a systemic inflammation response syndrome (SIRS).

Aims: This study prospectively explored how the traditional SIRS criteria, with or without selected blood markers, could help predict prognosis and orient management in the contemporary era of reperfusion therapy.

Methods: A predictive model for 90-day rates of death and of death or shock was built using clinical variables and blood markers obtained at hospital admission in 337 consecutive patients with ST-segment elevation MI (STEMI) oriented promptly to primary percutaneous intervention.(PPCI).

Results: The traditional SIRS criteria used alone and in combination were found to poorly correlate with clinical outcome and markers. Using ROC curve analyses, a modified SIRS definition that includes ≥3 of 4 of the criteria of age ≥75 years, heart rate >90 beat/min, systolic blood pressure ≤130 mm Hg and white blood cell count of $>10 \times 10^9$/L was strongly predictive of 90-day death (odds ratio, 11.0; 95% CI, 4.2–28.9, $P < 0.001$) and of death/shock (10.8; 4.8–24.0, $P < 0.001$). This model was associated with high levels of blood markers at baseline (IL-6, NT-proBNP and glucose levels $P < 0.001$; C-reactive protein (CRP) $P = 0.004$, and TNFα $P = 0.005$). Incorporating CRP, NTproBNP, and IL-6 in the modified SIRS definition added independent significant prognostic value over SIRS criteria alone (odds for death, 8.0; 95% CI, 2.5–25.9; 9.1, 2.3–35.4; and/or death/shock 5.0, 1.7–15.1).

Summary/Conclusions: A SIRS-like syndrome supported by inflammation markers can be identified at first medical contact and before PPCI in STEMI, and is strongly predictive of death and death or cardiogenic shock during follow-up.

PB 3.66-2

Do therapeutic infliximab concentrations influence TAFI and PAI-1 plasma levels in IBD patients?

Bollen L[1], Vande Casteele N[1], Peeters M[1], Declerck PJ[1], Vermeire S[2] and Gils A[1]
[1]KU Leuven; [2]UZ Leuven, Leuven, Belgium

Background: Inflammatory bowel disease (IBD) patients are three times more prone to develop venous thromboembolism (VTE) compared to controls and reports on the influence of anti-TNF treatment (e.g. infliximab) have been controversial. Hypofibrinolysis is a possible mechanism for this extra-intestinal complication since increased Thrombin Activatable Fibrinolysis Inhibitor (TAFI) and Plasminogen Activator Inhibitor-1 (PAI-1) levels are associated with a risk for VTE.
Aim: To investigate the effect of infliximab induction therapy (week 0 vs. week 14) on TAFI and PAI-1 levels in IBD patients.
Methods: In a prospective study, 78 IBD patients (46 Crohn disease and 32 ulcerative colitis) and 60 healthy controls (HC) participated with informed consent. Trough Levels of Infliximab (TLI) were measured before therapy (w0) and after induction (w14). Levels of total PAI-1, active PAI-1, TAFI antigen (proenzyme) and activation peptide of TAFI (AP, marker for TAFI activation expressed as percentage relative to a normal plasmapool [%PP]) were determined by in-house developed ELISAs. Standard inflammation markers e.g. C-reactive protein, platelets and white blood cells were determined by routine analyses.
Results: Out of the 78 patients, nine were primary non-responders (did not show clinical benefit within 14 weeks) and 14 were secondary non-responders (had good initial response but lost response over time; median TLI of 0.3 μg/mL at w14 [IQR: 0.3–4.6]). These non-responders were excluded in the further analyses. The 55 responders had a median TLI of 4.3 μg/mL at w14 (IQR: 2.5–8.5).
At w0, responders had significantly higher total PAI-1 and active PAI-1 levels compared to HC (36 ng/mL vs. 28 ng/mL, $P = 0.01$ and 9.0 ng/mL vs. 5.6 ng/mL, $P = 0.02$ for total and active PAI-1, respectively). Neither TAFI antigen (16 μg/mL vs. 13 μg/mL) nor AP (117%PP vs. 108%PP) levels were elevated in responders compared to HC. At w0, the total and active PAI-1 levels were significantly higher in responders with a CRP level above 20 mg/L compared to responders with a CRP level below 5 mg/L (53 ng/mL vs. 33 ng/mL, $P < 0.01$ and 11 ng/mL vs. 6.7 ng/mL, $P = 0.03$ for total and active PAI-1, respectively).
During IFX treatment (w0 vs. w14) responders showed a significant decrease in CRP (8.0 mg/L vs. 1.4 mg/L, $P < 0.01$), WBC (7.3×10^9/L vs. 6.2×10^9/L, $P < 0.01$), platelets (336×10^9/L vs. 285×10^9/L, $P < 0.01$) and total PAI-1 levels (36 ng/mL vs. 31 ng/mL, $P < 0.01$). No difference was observed for TAFI, AP and active PAI-1 levels.
Conclusion: Before anti-TNF treatment, total and active PAI-1 levels are increased in IBD patients. Therapeutic levels of infliximab have an impact on total PAI-1 levels but not on TAFI, AP or active PAI-1 levels. The decrease of total PAI-1 after control of inflammation might be partially explained by the significant drop in platelets, containing a high concentration of PAI-1. In addition, none of the responders in this study was diagnosed with thrombosis.

PB 3.66-3

Pulmonary tuberculosis is associated with a systemic but not intrapulmonal procoagulant state

Kager LM[1], Blok D[1], Lede I[1], Bresser P[1], Van der Zee J[1], Meijers JC[2], Ghose A[3], Van 't Veer C[1] and Van der Poll T[1]
[1]Academic Medical Center, Amsterdam; [2]Academic Medical Center Amsterdam, Amsterdam, The Netherlands; [3]Chittagong Medical College & Hospital (CMCH), Chittagong, Bangladesh

Background: Tuberculosis (TB), caused by *Mycobacterium tuberculosis complex*, is a devastating infectious disease with a high mortality. Bangladesh is one of the most affected countries. Knowledge of the contribution of coagulation and fibrinolysis to the host response to TB is highly limited.
Aims: In this observational study performed in Chittagong, Bangladesh, we aimed to obtain insight into systemic and local (at the site of the infection) activation of coagulation during pulmonary TB.
Methods: Parameters of coagulation and fibrinolysis were measured in plasma of 64 patients with primary TB, 11 patients with recurrent TB and 37 healthy local controls. TB was proven by positive Ziehl-Neelsen staining of the sputum and confirmed by PCR. Additionally, nine patients underwent a bronchoscopy with a bilateral bronchoalveolar lavage (BAL) and measurements were performed in BAL fluid from TB-infected lung subsegments and contralateral control subsegments.
Results: Patients with pulmonary TB showed evidence for a systemic procoagulant state as reflected by enhanced coagulation (elevated plasma levels of thrombin-antithrombin complexes and D-dimer; prolonged PT and PTT; dysregulation of individual clotting factors) and impaired anticoagulation (reduced plasma levels of antithrombin and protein C). In addition, plasma tissue-type plasminogen activator, alpha-2-antiplasmin and von Willebrand factor levels were elevated, reflecting a fibrinolytic response and endothelial cell activation respectively. None of these alterations were detected in BAL fluid of TB-infected lung subsegments when compared to control subsegments.
Conclusion: Pulmonary tuberculosis is associated with a systemic but not intrapulmonal procoagulant state.

PB 3.66-4

Blood cell response to a fatty meal in healthy subjects at different degree of cardiovascular risk: effect of orange juice intake

Cerletti C, Tamburrelli C, Gianfagna F, D'Imperio M, De Curtis A, Lorenzet R, Rotilio D, Iacoviello L, De Gaetano G and Donati MB
Catholic University, Campobasso, Italy

Background: A fatty meal has been proposed as a model of acute oxidative stress. Its effect on blood cells needs to be characterized and its possible modulation by polyphenols evaluated.
Methods: The acute effect of a standardized fatty meal on platelets and leukocytes and their interactions was evaluated on 61 apparently healthy subjects (48.6 ± 13.1 years old) at different degree of cardiovascular risk. Subsequently, 18 subjects were randomized, by a cross-over design, to drink during the meal, one liter of either blood or blond orange juice (OJ) (rich or poor, respectively, in anthocyanins), or water (control). Before and 2 h after fatty meal, blood cells were counted and markers of activation measured by flow-cytometry (intra-PMN myeloperoxidase-MPO; leukocyte Mac-1; platelet P-selectin; platelet-leukocyte conjugates).
Results: After the fatty meal, plasma triglycerides-TG (134.6 ± 68.8 vs. 181.5 ± 84.6 mg/dL, before vs after, $P < 0.0001$ by paired t; mean ± SD, $n = 61$) and both leukocyte and platelet counts significantly increased, more markedly in subjects with lower cardiovascular risk. Mac-1 expression too increased (32.2 ± 27.2% vs. 45.6 ± 29.0%, $P = 0.0016$), and MPO decreased (83.1 ± 16.3% vs. 64.5 ± 23.1%, $P < 0.0001$); platelet activation and interaction with leukocytes increase was not significant. Women were more susceptible to the fatty meal changes than men; age did not affect any cell response. BMI influenced platelet count increase, while waist-to-hip ratio affected PMN degranulation; the latter was smaller in subjects at higher risk (all $P < 0.01$). The meal-induced TG increase was reduced by blood OJ ($P < 0.05$); total cholesterol decreased after blood OJ ($P < 0.05$); glucose levels decreased after both OJ ($P < 0.01$). Leukocyte count increase and MPO decrease were significantly attenuated by both OJ. No OJ effect on platelet counts and activation.
Conclusions: Demographic variables and cardiovascular risk degree appear associated with cell response to fatty meal. OJ intake attenuated some of these responses, probably by anthocyanin-dependent and independent mechanisms.

PB 3.66-5

Higher thrombin generation during the luteal phase of a normal menstrual cycle does not depend on inflammatory activity

Chaireti R[1], Larsson A[2], Bremme K[3] and Lindahl T[4]

[1]Linköping University Hospital, Linköping; [2]Uppsala University, Uppsala; [3]Karolinska University Hospital, Stockholm; [4]Linköping University, Linköping, Sweden

Background/Aims: Higher thrombin generation (TG) during the luteal phase of a menstrual cycle cannot be explained by the effect of coagulation factors (submitted manuscript). In this report, we study inflammatory markers as a possible explanatory mechanism, and relate the results to fertility as expressed by the number of pregnancies and deliveries in a cohort of healthy women.
Methods: Our cohort consisted of 102 women not on hormonal medications. Blood samples were collected in the follicular (cycle day, cd 3–5) and the luteal (cd 22–25) phase. The inflammatory markers studied were PTX-3 (pentraxin-3), ICAM-1, VCAM-1, cathepsins L, B, S, hsCRP, e-selectin and p-selectin. Thrombin generation was assessed by the Calibrated Automated Thrombogram®. We used the paired *t*-test to study the differences in the values of the inflammatory markers during the two phases ($P < 0.05$), as well as multiple regression and correlation analysis (Pearson's) for the associations between markers.
Results: All inflammatory markers (except for CATHB and p-selectin) were higher during the follicular phase, however only PTX-3 and hs-CRP reached statistical significance ($P < 0.001$ respectively $P = 0.025$). There were no significant associations between TG and the inflammatory markers as well as the number of pregnancies and deliveries. PTX-3 during the follicular phase was associated with the number of reported pregnancies ($P = 0.014$).
Conclusion: Despite the close interactions between the inflammatory and haemostatic system, our results indicate that, during the menstrual cycle, higher inflammatory activity is associated with lower activation of the coagulation cascade, as expressed by TG. The rise in PTX-3 during the follicular phase was associated with the number of pregnancies for the women in our cohort, and thus indirectly linked with fertility. It is unclear whether our results can be explained by the action of a balancing mechanism that limits the activation of the coagulation cascade during the follicular phase, in order to protect from the higher thrombotic risk associated with inflammation.

PB 3.66-6

Coagulation profile in patients with H1N1 influenza A infection undergoing treatment for haematological malignancies

Rupa-Matysek J, Gil L, Wojtasinska E, Zajdel K, Ciepluch K and Komarnicki M

Poznan University of Medical Sciences, Poznan, Poland

Background: Immunocompromised patients, especially after allogeneic stem cell transplantation (HSCT) are prone to contract influenza A (H1N1) infection. This is a serious complication in patients with haematological malignancies most often resulting in low respiratory tract infection with progression to acute respiratory distress syndrome (ARDS) requiring mechanical ventilation and leading to increased mortality. Hemoptysis or low respiratory tract hemorrhage is frequently reported. Moreover, severe infection and inflammation are associated with activation of coagulation.
Aims: The aim of our study was to evaluate coagulation abnormalities in hemato-oncological patients with A (H1N1) influenza pneumonia by testing conventional coagulation parameters, as well as thromboelastometry and selected thrombophilia markers. The secondary objective was to identify coagulopathy abnormalities predicting a fatal influenza A (H1N1) infection outcome.
Methods: A total of 12 patients (median age 56, range 25–72) treated with conventional chemotherapy ($n = 10$) or allogeneic stem cell transplantation (two patients) were analysed. The underlying diseases included acute myeloid leukaemia ($n = 5$), acute lymphoblastic leukaemia ($n = 1$), myelodysplastic syndrome ($n = 1$), Hodgkin lymphoma ($n = 2$), non-Hodgkin lymphoma ($n = 2$) and chronic lymphocytic leukaemia ($n = 1$). None of the patients received pH1N1 vaccine. Influenza A (H1N1) was confirmed by real-time reverse-transcription polymerase chain reaction for pH1N1 of nasopharyngeal aspirates. All patients received antiviral therapy with oseltamivir in the dose 150 mg b.i.d. Thromboelastometry testing (ROTEM) was performed and selected coagulation parameters were measured at the time of diagnosis. The values of all the coagulation parameters were analyzed in two groups, the patients who survived and the ones who died in the course of the influenza.
Results: Hemoptysis was documented in 75% of the analyzed cases. ARDS developed in five patients. The course of the disease was complicated by Gram negative bloodstream infection in five patients and was fatal in four cases because of ARDS related to influenza. No difference in the mean value of prothrombin time, activated partial thromboplastin time, fibrinogen, fibrin degradation products, factor VIII activity, von Willebrand factor antigen (vWF) and in inhibitors of coagulation activities (free protein S, protein C, antithrombin) were observed between the analysed groups. A significant difference in the mean values of D-Dimer was observed between patients who survived and those who died (3258.1 ± 4187 vs. 7748 ± 7810 ng/mL; $P < 0.05$). Fatal cases had lower leukocyte counts compared with those who survived (0.50 ± 0.87 vs. 2.43 ± 1.51 G/L; $P = 0.0368$). The clot formation time (CFT) in INTEM, EXTEM, APTEM significantly differed between the groups and was longer in the patients who died. Similarly, C-reactive protein (CRP) was significantly higher in patients who developed ARDS and died (68.8 ± 85 vs. 179.12 ± 46.6 mg/L; $P = 0.0336$). In the cluster model, patients with lower leukocyte counts, lower protein C and free protein S activities with higher values of D-Dimer, CRP and vWF were assigned to the poorer outcome group.
Summary: In our cohort, patients with an increased risk of influenza complications and negative outcomes may be characterized by having higher D-Dimer, CRP and vWF and lower inhibitors of coagulation activities and lower leukocyte counts than the patients who survive.

PB3.67 – Inherited risk factors venous thrombosis: Clinical

PB 3.67-1

Molecular analysis of SERPINC1 abnormalities in 19 Japanese patients with hereditary antithrombin deficiency

Kato I[1], Ando Y[1], Takagi Y[1], Suzuki A[1], Okuyama E[1], Murata M[1], Takagi A[1], Matsushita T[2], Nakashima T[3] and Kojima TR[1]

[1]Nagoya University Graduate School of Medicine, Nagoya; [2]Nagoya University Hospital, Nagoya; [3]Yamaguchi University Graduate School of Medicine, Ube, Japan

Background: Hereditary antithrombin (AT) deficiency is susceptible to thromboembolic diseases, particularly deep vein thrombosis of lower limb. To date, more than 200 different mutations responsible for AT deficiency have been identified. It is rare to find large deletions (>100-bp) of this gene (*SERPINC1*), very few cases have been analyzed in detail the deletion region. Traditionally, the direct sequencing analysis of *SERPINC1* is used for genetic survey of AT deficiency, but this method is not capable of detecting heterozygous large gene deletions because of the presence of a second normal allele. MLPA (Multiplex Ligation-dependent Probe Amplification) method came to be used for survey of candidate gene defects in recent years, large deletions came to be relatively easily detected.

Aims: To identify the causative gene abnormalities in patients with hereditary AT deficiency, we analyzed their *SERPINC1* genes.
Methods: The Ethics Committee of the Nagoya University School of Medicine approved this study. We analyzed all genomic sequences for exons and exon-intron junctions of *SERPINC1* gene by direct sequencing method. We also analyzed *SERPINC1* gene by MLPA method as well as real-time PCR to determine relative gene doses. We performed Long-PCR, Nested-PCR and mapping PCR in order to identify breakpoints of the deletion.
Results: We analyzed 19 unrelated Japanese cases with AT deficiency to detect *SERPINC1* abnormalities. We identified causative gene abnormalities in all cases; 8 distinct missense mutations in 11 cases, 1 nonsense mutation, 2 distinct small deletions in 3 cases, 1 small insertion, 1 splicing mutation, and 2 distinct large deletions, respectively. Both of the large deletions seemed to be unique gene abnormalities. One showed a 2094-bp deletion ranging from intron 4 to intron 5, and the other showed a deletion of approximately 130-kb losing the entire *SERPINC1* gene. Interestingly, the latter patient had an autoimmune symptom, and her deleted region of the genomic DNA contained *RC3H1* gene encoding the protein called 'roquin', which involved in repressing self-immune responses. It was reported that the mice with homozygous mutation in this gene developed antinuclear autoantibodies and had the typical features of systemic lupus erythematosus (SLE).
Summary/Conclusion: AT deficiency caused by heterozygous mutation of *SERPINC1* gene is susceptible to thromboembolic diseases, and most *SERPINC1* gene mutations such as the point mutations can be found by direct sequencing analysis. Some *SERPINC1* gene abnormality such as a heterozygous large deletion, however, cannot be detected by this method, because *SERPINC1* gene locates on chromosome 1 autosomally. By MLPA analysis, we identified 2 distinct heterozygous large deletions of *SERPINC1* gene, which showed normal patterns in PCR mediated direct sequencing analysis. MLPA method should be put into practice, when a heterozygous large gene deletion on autosomal chromosome is expected.

PB 3.67-2
Non-O blood group as a risk factor for cerebral venous thrombosis

Tufano A[1], Coppola A[1], Nardo A[1], Bonfanti C[2], Crestani S[2], Frattini F[2], Di Minno MND[1], Cimino E[1], Cerbone AM[1] and Franchini M[2]
[1]"Federico II,, University of Naples, Naples; [2]Carlo Poma Hospital, Mantova, Mantova, Italy

Background: The role of risk factors associated with the development of venous thromboses at unusual sites, including cerebral vein thrombosis (CVT), may be different compared to those of deep vein thrombosis of the lower limbs or pulmonary embolism, the most common manifestations of venous thromboembolism (VTE). In addition to pregnancy/puerperium, oral contraceptives, infection, hematological and autoimmune diseases, thrombophilic conditions are identified as predisposing conditions in patients with CVT. Increasing data recognize the ABO as a susceptibility locus for VTE, non-O blood group carriers sharing a two-fold increased VTE risk than O blood group carriers.
Aims: We addressed the role of ABO blood group as a risk factor of CVT. Methods. Blood groups from a retrospective-prospective cohort of 77 consecutive inpatients (21 men, 56 women, age at the event 39.97 ± 12.73 years, mean ± 1 SD) referred to our Centers from 1997 to 2012 because of a first episode of CVT were compared with data from a large population of asymptomatic Italian blood donors (n = 4272; 2277 males, 1995 females, mean age 34.7 + 10.08 years).
Results: Overall, the CVT episode was clearly associated with an established transient risk condition ('provoked' events) in more than half of patients (40/77, 51.9%). In particular, CVT occurred in 32/56 (57.1%) women while assuming oral contraceptives. Inherited thrombophilia, in the majority of cases due to the prothrombin G20210A polymorphism (n = 19), was detected in 23 subjects (29.9%), with higher rates in patients with apparently 'unprovoked' events (14/37, 37.8%, vs. 9/40, 22.5% in those with 'provoked' CVT). When ABO blood groups were considered, the observed distribution was significantly different from that in blood donors (P = 0.0003). The frequency of O blood group was significantly lower (24.7% vs. 44.5%), and conversely that of non-O blood groups was higher (75.3% vs. 55.5%), in patients with CVT than in blood donors. Therefore, having non-O blood group resulted in a 2.4-fold increase of risk of CVT (crude odds ratio, OR 2.44 95% CI, 1.42–4.26; P = 0.0008). Although the limitation of the sample size hampered reliable comparisons of subgroups, such a difference tended to be higher in CVT patients without thrombophilia (O vs. non-O blood groups: 12/54, 22.2% vs. 42/54, 77.8%; 7/23, 30.4% vs. 16/23, 69.6% in those carrying prothrombin G20210A or Factor V Leiden polymorphisms) and in patients with 'provoked' events (O vs. non-O blood groups: 8/40, 20% vs. 32/40, 80%; 11/37, 29.7% vs. 26/37, 70.3% in those with apparently unprovoked CVT). Indeed, the lowest prevalence of O blood group was seen in non-thrombophilic individuals with provoked CVT (4/26, 15%).
Conclusions: Our results show for the first time in the setting of venous thromboses at unusual sites an increase of risk related to non-O blood group. We were not able to perform a multivariate analysis and gain significant insight concerning the interaction of ABO blood group and other risk factors, including thrombophilia. However, our findings extend the interest in evaluating the ABO blood group in such rare and often challenging VTE through multicenter and prospective studies.

PB 3.67-3
Thrombophilic and systemic risk factors in patients with central retinal vein occlusion

Dropinski J, Sanak M, Kubicka-Trzaska A, Iwaniec T, Domagala TB and Musial J
Jagiellonian University School of Medicine, Krakow, Poland

Introduction: Retinal vascular occlusions are common causes of visual loss. Few and contrasting data are available on the prevalence of risk factors in patients with central retinal vein occlusion (CRVO). Classic risk factors are commonly associated with CRVO, while unclear it is the role of the thrombophilic and coagulation disorders.
Aim: The aim of our study was to establish the prevalence of major and potential inherited and acquired thrombophilic risk factors in 120 patients (64 females, 56 males; age: 57.7 years; range 24–73) with CRVO. The control group consisted of 102 (55 females, 47 males; age: 56.9 years; range 19–72) healthy subjects, without any vascular, eye-related disease.
Methods: In all participants the prevalence of Leiden mutation (FV Leiden), protrombin variant (20210 G/A mutation), Leu 34 polymorphism of the factor (F) XIIIA-subunit, deficiency of protein C, S, antithrombin and antiphospholipid antibodies (aPL) were assessed. Also intima-media thickness (IMT) in carotid arteries were measured using ultrasonography.
Results: Elevated aPL antibody level (IgG>10 GPL; IgM>20MPL) were detected in 25 of 120 patients (20%) and in 8 of 102 controls (7.8%). The incidence of FV Leiden, deficiency of protein C were significantly more common in CRVO patients (P < 0.05) compared to controls. Patients with CRVO had greater IMT than healthy subjects (0.92 mm vs 0.75 mm; P < 0.05). There was no significant difference in the prevalence of deficiency of protein S, 20210 G/A mutation, FXIII Val34Leu polymorphism and antithrombin level between CRVO patients and controls. Among classic risk factors only hypertension, diabetes mellitus, hypercholesterolemia and cigarette smoking were significantly more frequent in CRVO patients than in control subjects.

Conclusions: These data show a potential role of some classic and thrombophilic risk factors in the pathophysiology of CRVO. Measurement of these parameters may be useful in preventing and treatment of such events.

PB 3.67-4

A case of protein S deficiency caused by compound heterozygous mutations in PROS1 gene

Odnoczko E[1], Baran B[1], Vertun-Baranowska B[1], Oldenburg J[2] and Windyga J[1]

[1]Institute of Haematology and Transfusion Medicine, Warsaw, Poland; [2]Institute of Experimental Haematology and Transfusion Medicine, Bonn, Germany

Background: Protein S (PS) is a vitamin K-dependent plasma glycoprotein that plays an important role in the blood anticoagulant system. Inherited PS deficiency caused by *PROS1* mutations is associated with increased risk of venous thromboembolism. One of the most severe thrombotic manifestations (purpura fulminans) is related to the presence of homozygous or compound heterozygous genotypes. Up to date only a few cases with compound heterozygous PS deficiencies have been reported.

Aims: We present here a case of a 25-year-old male who developed massive deep vein thrombosis in the left leg, left and right iliac veins and vena cava inferior complicated by pulmonary embolism at the age of 16. Following the diagnosis of venous thromboembolism the patient was immediately put on indefinite anticoagulation treatment and no thrombo-embolic complications have been observed since.

Results: Laboratory results revealed markedly reduced free protein S antigen level – 15 IU/dL (ref.range 70–130 IU/dL); while other thrombophilic defects were excluded. Direct sequencing of *PROS1* gene indicated two already described causative heterozygous mutations; one in exon 2 (c.233C>T; p.Thr78Met) leading to lower expression of the affected protein and the other in exon 13 (c.1543C>T; p.Arg515Cys) responsible for impaired secretion of the mutant protein. Family studies showed reduced free protein S antigen level in four relatives (parents and two siblings). *PROS1* gene study identified heterozygous mutation p.Thr78Met in the mother (free PS antigen – 50 IU/dL) and sister (free PS antigen – 60 IU/dL), whereas p.Arg515Cys mutation was found in the father (free PS antigen – 19 IU/dL) and brother (free PS antigen – 28 IU/dL). Interestingly, in contrast to the propositus, none of his family members experienced thromboembolic events.

Conclusion: Our results may suggest that thrombosis risk in patient with inherited protein S deficiency is determined rather by the character of genetic defects than by protein S levels in plasma.

PB 3.67-5

Antithrombin-deficiency and pregnancy: report of four cases

Ilonczai P[1], Schlammadinger A[1], Selmeczi A[2], Oláh Z[1], Kerényi A[1], Bereczky Z[1], Póka R[1] and Boda Z[1]

[1]Medical and Health Science Center, University of Debrecen, Hungary, Debrecen; [2]University of Debrecen,Medical and Health Science Center, Debrecen, Hungary

Background: Women with a history of thromboembolism or known thrombophilia have an increased risk for pregnancy-associated recurrent thromboembolism. The risk of fetal complications is also increased in thrombophilia. Antithrombin (AT) deficiency, among inherited thrombophilias, is considered to induce the highest risk of suffering a thromboembolic event during lifetime. The available data concerning relationship between AT deficiency and adverse pregnancy outcomes are conflicting.

Aim: To examine the optimal mode of antithrombotic management in pregnant women with established AT deficiency.

Methods and Results: Four pregnant women with AT deficiency were treated in our center in 2012. Two of them had homozygousBudapest3 mutation, in both cases the AT level was 17% (patients 1 and 2). In two other patients heterozygous mutations in the SERPNC1 gene were found (c.134A>T in patient 3 and a novel mutationdelc.1367–1368 GC, ins c.1367–1371 CTACA in patient 4). Their AT activity was 35–48%, respectively. Patient 1 had a history of recurrent venous thromboembolism and she also had a fetal loss despite heparin prophylaxis 5 years before. In her case the heterozygous form of FV Leiden mutation was also found. All four patients were put on therapeutic dose of enoxaparine upon recognition of pregnancy. The effectiveness of heparin treatment was evaluated by the measurement of anti – FXa activity. Patient 1, 2 and 3 required AT concentrate infusions in a dose of 1500–2000 IU, 2 or 3 times weekly to maintain therapeutic anti – FXa levels. In patients 1, 3 and 4 the pregnancy was uneventful and they had healthy babies born at terminuses. Patient 2 had a fetal loss on week 20.

Conclusion: There is evidence that heparin treatment is required for the prevention of maternal and fetal complications in AT deficient pregnant women. The effect of heparin should be monitored by the measurement of anti-FXa. If the effect is insufficient despite of the therapeutic dose of heparin, the application of AT-concentrate is required. Further data are needed to determine the anti-FXa level which is required to maintain an effective LMWH prophylaxis and to define the time when AT concentrate should be initiated. Furthermore, the dose and administration frequency of AT-concentrate is still an unresolved issue.

PB 3.67-6

Genetic background: analysis of protein C deficiency type I and type II in 26 Portuguese families

Fidalgo T, Martinho P, Salvado R, Silva Pinto C, Oliveira AC, Gonçalves E, Marques D, Sevivas T, Martins N and Ribeiro ML

Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: The inherited deficiency of Protein C (PC) is a well known risk factor for venous thrombosis (VT). Deficiency is classified as type I – both antigen and activity levels are reduced, or type II – antigen levels are normal and the activity is decreased. Plasma PC levels are reliable in moderate to severe deficiencies; however, in mild deficient individuals the levels may overlap with normal. Genetic studies of PROC could be helpful to identify the carriers, even though, the results are often not clear because the majority of the genetic variations are either rare mutations or common polymorphisms. Recently, GWAS shown that ≈50% of the PC deficiency phenotypic variation is caused by the additive effect of mutations in several other loci, namely in the PROCR gene.

Aim: To study the genotype/phenotype correlation of 58 individuals, from 26 unrelated families with a history of thrombosis, who had repeated low or borderline PC plasma levels. Fifty five had type I PC deficiency and three had type II. Clinical data: Among 26 probands, 22 had a personal history of thrombosis: VT (18), arterial thrombosis (2), stillbirths (1) and miscarriages (1) and four only had a family history of thrombosis. The mean age of probands at the time of first thromboembolic episode was 28.86 ± 12.50 years; 17F:9M; Nineteen probands had acquired risk factors – contraceptive drugs, varicose veins, trauma, pregnancy, dyslipidemia and immobilization. Three probands aged 24.33 ± 6.18 all with more than one thrombotic episode, had no identified risk factors and are considered as idiopathic DVT.

Methods: PC activity- amidolytic and coagulant assay; PC antigen/ELISA. Screening of mutations and promoter polymorphism in PROC, and polymorphism Ser219Gly in PROCR by direct sequencing; FVLeiden and FIIG20210A by multiplex ASPCR.

Results: Twelve different PROC mutations were identified: 9 missense: p.Cys105Arg (not previously described); p.Pro210Leu; p.Gly215Glu; p.Arg220Gln; p.Gly239Arg; p.Val339Met; p.Pro369Leu; P.Arg394Trp; p.Trp444Cys; 1 nonsense (p.Arg199X); 1 promoter

(-13A>G); and 1 small deletion (p.Leu212Hisfs*2). The last three mutations, the most frequent, were identified in 15 families, the ones with patients with the higher number of VT episodes. Only one patient was homozygous for a mutation (p.Arg220Gln), all the other were heterozygous. In one family with low PC levels, we could not find any mutation. FVLeiden was identified in six individuals; FII20210A in 3. One patient was double heterozygous for FII20210A and FVLeiden. A statistically significant difference in PC levels was observed between the control group and homozygous for haplotype CGT ($P = 0.0375$) or for polymorphism Ser219Gly ($P = 0.008$); 3/4 individuals with idiopathic DVT were homozygous for haplotype CGT; the presence/absence of Ser219Gly correlates with the different levels of PC in members of the same family.

Conclusion: The molecular studies of PROC and PROCR genes in 51 individuals with low or borderline PC plasma levels allowed the identification of the doubtful carriers. The type and location of the mutations correlates with the severity of the phenotype. Genetic family studies are important to evaluate the need for prophylactic measures, especially in the risk situations, and to offer the prenatal diagnosis in severe cases.

PB3.68 – Paediatric Thrombosis – III

PB 3.68-1

FondaKIDS II: long-term follow-up data of children receiving fondaparinux for treatment of venous thromboembolic events

Young G[1], Michieli C[1], Bernardini L[2] and Ko R[1]

[1]Children's Hospital Los Angeles; [2]University of Southern California, Los Angeles, CA, USA

Background: The incidence of venous thrombotic events (VTE) in children has risen substantially over the past decade, resulting in increasing use of anticoagulation. Fondaparinux has several advantages over low molecular weight hpearins including a longer half-life allowing once daily dosing, no risk for heparin-induced thrombocytopenia and less effect on bone mineral metabolism. Recently, a PK, dose-finding, and safety study of fondaparinux in children was published, however it had only a short period of follow up.

Aims: The purpose of this study was to investigate the long-term safety, dosing, and efficacy of fondaparinux in children.

Methods: The following data were collected from all consecutive children (1–18 years) treated with fondaparinux in a single institution: demographics, location of initial VTE, fondaparinux dosing and fondparinux-based anti-Xa levels, bleeding events, other adverse events, status of VTE and VTE recurrence. Descriptive statistics are used to describe the patients and the outcomes.

Results: Thirty-five patients were included all of whom were included in the safety analysis while 34 were analyzed for dosing (one excluded due to only receiving two doses secondary to an allergic reaction) and 22 for efficacy (six excluded for resolution of DVT on a different anticoagulant, four because fondaparinux given prophylactically, two due to insufficient data, and one due to allergic reaction). There were 18 males (M) and 17 females (F) with a mean age of 9.11 years (median: 9 years; range: 1–17 years). The mean duration of treatment with fondaparinux was 371 days (d) (median: 152 days; range: 2–1566 days). The mean dose of fondaparinux was 0.1 mg/kg/dose (median: 0.1 mg/kg/dose; range: 0.04–0.15 mg/kg/dose). 14 of 22 evaluable patients (63.6%) had complete resolution of their thrombus while 6/22 (27.3%) had partial resolution, and 2/22 (9.1%) had no change. Thus, 20/22 (90.9%) patients had either a complete or partial response while none had progression. The mean time to best outcome from initiation of fondaparinux was 171.5 days (median: 92.5 days; range: 11–839 days). Eleven patients needed a total of 16 dose adjustments to achieve therapeutic levels. Two patients (9.1%) had a recurrent VTE: one was on fondaparinux at the time of recurrence and one was on warfarin. There were three major (intracranial hemorrhage- occurred prior to initiation of fondaparinux subsequently, pulmonary hemorrhage, and subretinal hemorrhage) and six minor (two with blood in stool, one with injection site, one CVC site, one tracheostomy bleed, one epistaxis) bleeding events. Importantly, only one of these events resulted in discontinuation of fondaparinux. One patient had an allergic reaction.

Conclusions: Given the advantages of fondaparinux over other low molecular weight heparins, this study suggests that fondaparinux could be considered a safe and effective alternative for the management of VTE in children.

PB 3.68-2

Safety and efficacy outcomes of home and hospital warfarin management within a paediatric anticoagulation clinic

Jones S[1], McLoughlin S[1], Piovesan D[2], Savoia H[1] and Monagle P[3]

[1]The Royal Children's Hospital; [2]Murdoch Childrens Research Institute; [3]The University of Melbourne, Melbourne, Australia

Background: Improved medical care and new surgical options for paediatric patients with chronic disease has led to an increase in the number of children requiring warfarin therapy. Time in Therapeutic range (TTR) refers to the amount of time a patient's International Normalised Ratio (INR) is within a designated target range. An increase in TTR is correlated with a decreased risk of bleeding or thrombosis. TTR is the most common method of determining the success of warfarin therapy.

Aims: This audit examined the TTR of warfarin patients managed by an anticoagulation clinic (AC) at the Royal Children's Hospital over 12 months. Aims included: determining TTR achievement and incidence of adverse events of all warfarin patients; and comparing TTR achievement between patients self-testing at home and those monitored at hospital.

Methods: INR results for children who currently have their warfarin therapy managed by the AC were analysed. Children were included in the study if warfarin therapy commenced before November 2012. INR results reported between January 1st 2012 and December 31st 2012 were collected. Due to the variation between the numbers of INRs each child required during the audit, cluster analysis of each child's INR results was used to calculate the mean percentage of INR's within TTR. Warfarin-related adverse events included major bleeding and/or thrombotic episodes that occurred during the audit period.

Results: 163 patients were included. 101 children were self-testing their INR and 62 tested their INR at a hospital or pathology service. The median age of patients was 10.6 years (range 0–19 years) and the mean number of days on warfarin for 2012 was 299 (range 80–363 days). The most common indication for warfarin was previous Fontan procedure ($n = 105$). Other indications included prosthetic heart valves ($n = 15$), pulmonary hypertension ($n = 9$), indwelling central venous line ($n = 5$) and deep venous thrombosis/stroke ($n = 8$).

Target range achievement for the cohort was 66.8% (95% CI 64 −69.6). 68.1% of INR tests conducted at home were within the TTR compared with 64.8% of INR tests conducted at a hospital or pathology service. The majority of patients ($n = 137$) achieved a TTR of >50%.

One major bleeding event occurred in a teenage girl with intra-abdominal bleeding and a sublingual haematoma following 3 days of vomiting. The patient's INR at the time of hospitalisation was >10. She required vitamin K, prothrombinex®, transfusion of red blood cells and fresh frozen plasma. There was one thrombotic episode; a non-occlusive thrombus in the Fontan circuit in a 6 year old female. The INR at the time was 1.8. Both patients monitored their INRs at hospital.

Summary: This audit demonstrates equivalence in safety and efficacy outcomes between home self-testing and hospital INR testing in children managed by an AC. Incidence of adverse events and TTR achievement is comparable to international paediatric centres. The size

of this cohort exceeds numbers previously reported when comparing self-testing and hospital monitoring. Routine outcome evaluation of paediatric anticoagulation management within single institutions is warranted due to the difficulties of multi-site studies assessing management strategies.

PB 3.68-3

Pediatric stroke: a single center experience

Sobu E[1], Ozdemir N[2], Tuysuz G[2], Hasiloglu Z[3], Buyru AN[4], Uysal S[5] and Celkan T[2]

[1]Istanbul Univercity Cerrahpasa Medical Faculty, Istanbul; [2]Istanbul University, Cerrahpasa Medical Faculty, Pediatric Hematology Dept., Istanbul; [3]Istanbul University, Cerrahpasa Medical Faculty, Radiology Dept., Istanbul; [4]Istanbul University, Cerrahpasa Medical Faculty, Medical Biology Dept., Istanbul; [5]Istanbul University, Cerrahpasa Medical Faculty, Pediatric Neurology Dept., Istanbul, Turkey

Background: Pediatric stroke, defined as arterial ischemic stroke (AIS), cerebral sinovenous thrombosis (CSVT) and hemorrhagic stroke (HS) is a rare but serious event.

Aims: The aim of this study is to assess the clinical characteristics, risk factors, treatment and outcomes of pediatric stroke cases in a single center.

Methods: We reviewed the records of children who were diagnosed as pediatric stroke at our center between 2000 and 2011. Neonatal cases were excluded. The study was approved by medical ethics committee.

Results: We identified 67 patients with AIS (M/F: 33/34; median age: 2.9 years), 27 patients with CSVT (M/F: 20/7; median age: 8.8 years) and 24 patients with HS (M/F: 21/3), median age: 6.7 years). Main symptoms at presentation were hemiplegia (46%), convulsion (31%), headache (19%), vision defects and strabismus (13%), facial paralysis (11%), aphasia (10%), vomiting (7%), unconsciousness (4%). Hemiplegia was the most frequent symptom for arterial ischemic stroke. Most of the patients with hemorrhagic stroke had an underlying event or disease, 45% had late hemorrhagic disease of newborn (diagnosed >28 days after delivery) and 37% had a history of head trauma. An underlying acute or chronic illness and/or external trigger to thrombosis were present in 20 patients with CSVT and most frequent causes were acute otitis media-mastoiditis, acute leukemia and Behcet disease. Thirty five of 67 patients with AIS had an underlying disease and/or a trigger. The most frequent causes were congenital heart disease and trauma. Thrombophilia work-up was conducted in a group of patients with CSVT (*n*: 15/27), AIS (*n*: 41/67) and none of the patients with HS. At least one prothrombotic risk factor was positive in 78% of patients with CSVT and 37% patients with AIS. MTHFR A1298C heterozygote mutation was the most frequent finding in patients with CSVT. MTHFR C677T mutation was the most frequent finding in patients AIS. In total, 56 of the patients received antithrombotic treatment; no major complications were observed. In AIS, antithrombotic treatment was given to 34 of 67 children; the majority (*n*: 27) received LMWH and acetylsalicylic acid (*n*:20). In CSVT, antithrombotic was given to 22 of 27 children; LMWH treatment was used in 20 and warfarin was used in only 4. Two patients expired due to thrombosis; one of them had AIS and congenital heart disease and the other one had CSVT and macrocephaly telangiectasia syndrome. Neurological sequel was found in 28 of 67 patients (41%) with AIS, 5 of 27 patients (18%) with CSVT, 9 of 24 patients (37%) with HS.

Conclusion: We reviewed our experience of 11 years in diagnosis and treatment of pediatric stroke. Demographic findings in our study were consistent with the literature showing a high percentage of boys. Prothrombotic defects were more in common in children with CSVT compared to patients with AIS. We mainly use LMWH for anticoagulation and in our experience none of our patients had hemorrhage due to the treatment. Our results showed a low mortality rate mainly because only the survivors were referred to our center.

PB 3.68-4

Demonstration of construct validity of the KIDCLOT PAC QL©

Bruce AK[1], Jones S[2], Massicotte P[1] and Bauman M[1]

[1]University of Alberta, Canada, Canada; [2]University of Melbourne, Melbourne, Australia

Background: Quality of life (QOL) as defined by the World Health Organization is 'an individual's perception of their position in life in the context of the culture and value systems in which they live, and in relation to their goals, expectations, standards and concerns'. QOL is an abstract entity which can be measured by a tool developed specific to the patient condition. Vitamin K antagonists (VKA) are known to affect quality of life and the only tool designed to measure its impact on QOL in children and families is the KIDCLOT PAC QL©. Reliability testing, face and content validity, and validation of the scoring system has been reported previously. In absence of a gold standard, further inventory validation can be achieved with construct validity. Construct validity in which the inventory actually measures the construct it is intended to measure can be supported with demonstration of discriminant and convergent validity. Convergent validity measures constructs that are theoretically related to each other to a pre-hypothesized extent. Discriminant validity measures constructs that are theoretically not related to each other. To establish construct validity one must establish both convergent and divergent validity.

Aim: To demonstrate construct validity of the KIDCLOT PAC QL©.

Methods: Convergent validity of the final version of the inventory was examined by measuring the association between the global scales of the KIDCLOT PAC QL ©and the PEDSQL © (an accepted, valid, and reliable inventory for pediatric QOL). The PEDSQL © was used with permission. Discriminant validity was examined by measuring the association between the KIDCLOT PAC QL © and knowledge retention scores (a test taken by parents and children to ascertain their knowledge of VKA) obtained by the same patients. The PEDSQL was selected to examine convergent validity as it is a well-accepted global measure of quality of life in children, has a child and parent-proxy version and takes <10 min to complete. As it is a QOL inventory with no questions specific to VKA the construct should be theoretically medium correlation. The knowledge retention test was selected as it is a test measuring knowledge only and therefore should be theoretically unrelated to the abstract concept of QOL with small correlation. Associations between scorings were tested with Spearman rank correlation because of the ordinal nature of the scales. Informed consent and ethics approval were obtained.

Results: Ninety parents and 42 children completed both the KIDCLOT PACQL and PEDSQL, 40 parents and 19 children completed the knowledge retention test. Convergent validity for the parent-proxy inventory $r = 0.528$ ($P < 0.001$) and for divergent validity $r = -0.213$ ($P = 0.186$). Convergent validity for the child/adolescent inventory convergent validity $r = 0.307$ ($P = 0.48$) and for divergent validity $r = -0.270$ ($P = 0.264$).

Summary: The KIDCLOT PAC QL © demonstrates predicted construct validity with medium correlation with a global QOL measure and small correlation with the knowledge retention test. The tool is now validated and ready for use.

PB 3.68-5

Decreased protein S activity in ulcerative colitis but not Crohn disease in a pediatric Cohort

Szigeti R, Mir S, Reddy S, Nguyen K, Siegele H, Soundar EP, Kostousov V, Kellermayer R and Teruya J

Baylor College of Medicine, Houston, TX, USA

Background: Inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn disease (CD) affect more than 1 million people in theUnited States. Growing evidence recognizes IBD as a chronic

inflammatory condition associated with a hypercoagulable/prothrombotic state, which represents one of the important extraintestinal manifestations, and can lead to increased mortality and morbidity in patients. Thromboembolism (TE) in patients with active IBD is well established with a 6.5% incidence of thrombosis in adults, a 3–4 fold higher risk than in the general population. TE can also occur in the pediatric IBD patients as well. The mechanisms for IBD associated thromboembolic disorders are extensively studied, but not clearly understood.

Aims: The aim of this work was to examine prothrombotic factors in hospitalized pediatric IBD patients.

Methods: Twenty five patients with the diagnosis of UC (n = 10) or CD (n = 15) were recruited between 2009 and 2012 during hospitalization for active disease. The patients were further subclassified based on treatment involving steroids and disease subtype (UC vs. CD). Peripheal blood was evaluated for hemostatic parameters including prothrombotic factors (PT/INR, PTT, fibrinogen, D-dimer, antithrombin, thrombin time, factor VIII, functional protein C, functional protein S, von Willebrand factor antigen and ristocetin co-factor, ADAMTS 13 activity, and lupus anticoagulant) using standard diagnostic procedures. The acquired data were analyzed and compared to an age and gender matched historical control group (n = 25).

Result: The assays for fibrinogen, D-dimer, thrombin time, factor VIII and protein S showed statistically significant ($P < 0.0001$) differences between IBD patients and the control group. Steroid therapy significantly increased fibrinogen ($P = 0.01$), and factor VIII activity ($P = 0.006$). Interestingly, protein S activity was significantly lower in the UC group ($P = 0.001$), while it was comparable to the control group in CD patients ($P = 0.14$).

Conclusions: IBD results in significant prothrombotic factor alterations that are likely a consequence of a complex systemic inflammatory process. Therapeutic interventions, such as steroids, can significantly affect these parameters. Interestingly, while protein C appears to be essentially unaffected in both UC and CD, protein S was significantly decreased only in UC patients within this cohort. Our findings may carry useful information for guiding possible prophylactic measures against thrombotic events in hospitalized pediatric IBD patients.

PB 3.68-6

Antithrombin concentrate in pediatric patients requiring heparin anticoagulation: a retrospective Cohort study

Bauman M[1], Ryerson L[1], Kuhle S[2], Bruce AK[2] and Massicotte P[1]
[1]*Stollery Children's Hospital/University of Alberta, Edmonton;* [2]*Dalhousie University, Halifax, Canada*

Background: Heparins, unfractionated (UFH) and low molecular weight (LMWH), are used in children requiring anticoagulation. *In vivo*, low antithrombin (AT) levels often result in an inadequate anticoagulant effect with UFH. Effective anticoagulation is becoming increasingly important in the pediatric intensive care unit. Critically ill children require heparin anticoagulation for various indications including thrombosis, extracorporeal membrane oxygenation and ventricular assist devices. Developmental hemostasis, in combination with underlying risk factors in ill children, often result in physiologically decreased AT levels. Anticoagulation with UFH requires AT levels >~0.5 U/mL to achieve therapeutic heparin anticoagulation. Administration of antithrombin concentrate (ATC) increases AT levels and heparin effect. Dosing ATC per the manufacturer[1] (ATC dose = [desired level-baseline level] × patient weight in kg/2), results in wastage since ATC is supplied in 1000 Unit quantities.

Aims: The aim of this retrospective cohort study is to determine AT levels pre and post ATC administration, mean ATC dose/kg administered, bleeding, thrombotic or allergic events. During 2008–2011, ATC effect on heparin effect (anti-Xa and PTT) and the change in heparin dose was also collected.

Methods: From 2005 to 2011, the practice at Stollery Children's Hospital was to administer a vial of ATC in patients <20 kg when AT levels are <50% and therapeutic heparin effect is not achieved despite higher than age appropriate heparin doses. When ATC is administered, heparin dose is decreased by 50%, UFH doses, PTT, AT and anti-Xa levels were drawn 30 min post ATC infusion. Ethics approval was obtained.

Results: 121 patients received 246 doses of ATC. Median age (range) and weight (range) were 3.7 months (7 days–10.7 years) and 4.1 kg (2.1–20.0). Mean ATC dose was 222 IU/kg. Mean AT level increased from 0.39 (95% CI 0.37–0.42) to 1.20 U/mL (95% CI 1.10–1.30) post ATC administration. In the 2008–2011 subgroup, UFH doses to achieve a target anti-Xa level pre post ATC were 28 (95% CI 24–32) and 19 (95% CI 16–22) U/kg/h, respectively, for children ≤12 months and 25 (95% CI 19–30) and 19 (95% CI 11–19) U/kg/h, respectively, for children >12 months. The PTT was 110 (95% CI 90–131) and 136 (95% CI 116–156) seconds, pre/post ATC respectively, for children ≤12 months and 66 (95% CI 42–91) and 63 (95% CI 43–84) seconds, pre/post ATC respectively, for children >12 months. There were no hemorrhagic, thrombotic or allergic events.

Conclusions: This is the largest pediatric evaluation of ATC. Administration of high dose ATC appears safe in infants and children. Increasing AT concentration provides additional heparin binding sites as well as increased anti-Xa levels with lower age appropriate heparin doses. Further ATC was minimized due to a sustained effect resulting in more stable anticoagulation. Additional well designed studies are required to further evaluate safety and efficacy of ATC administration and to determine biochemical changes and dosing relationships between ATC and heparin. This data provides the basis for future investigations and the development of pediatric-specific, evidence-based guidelines for ATC use.

Evaluation of a unique mHealth web-based VKA management system

Bauman M[1], Seniuk A[2], Siddons S[3], Bruce AK[4] and Massicotte P[1]
[1]*Stollery Children's Hospital/University of Alberta, Edmonton;* [2]*Independent IT contractor, Edmonton;* [3]*Stollery Children's Hospital, Edmonton;* [4]*Dalhousie University, Halifax, Canada*

Mobile health (mHealth), supported by international health governing bodies, is a growing field that uses web based and mobile communication devices to improve health outcomes, healthcare services and health research, and may be used as a tool for reporting INR results. Patients prescribed long term vitamin K antagonist (VKA) therapy require close monitoring of their INRs. INR results are received by the patient directly from the laboratory or by self-testing using home INR meters and then are reported to the health provider for dose adjustment.

Aim: This study is to evaluate functionality and patient satisfaction with use of the INR reporting website www.kidclot.com.

Methods: The KIDCLOT© website was established as a tool for INR reporting using an SSL address. Two groups of patients prescribed VKA therapy used this website: (i) patients who self-managed (PSM) their VKA therapy and (ii) patients who self tested (PST) INRs with the KIDCLOT© health provider adjusting their VKA dose. Patients entered INR results into the website via computer or smartphone. Each was assigned a secure ID and password to log into the site. Usernames are only identifiable to the KIDCLOT© clinical team with no other patient identifiers stored in the database. Patient and administrative staff have different levels of access; therefore no patient has access to data outside of their own profile. This security is consistent with international health privacy policies.

All patients enter their INR result and VKA dose. PSM patients enter their INR, VKA dose adjustment, next INR testing date and comments. Whereas, PST patients enter their INR which triggers an email

to the KIDCLOT health provider to provide the VKA dose adjustment and next INR testing date. The KIDCLOT© health provider enters the dose plan which alerts the patient. All patients receive an INR test reminder alert the day the INR is due. When reported INRs are outside of the patient's therapeutic range an alert is sent to the KIDCLOT© health provider alerting the provider to review patient decision making, and allow immediate dosing support. Patient satisfaction surveys were completed by patients. Informed consent and ethics approval were obtained.

Results: 33 of 51 website users responded to the satisfaction survey. Results from the patient satisfaction survey found that 100% of respondents 'liked' the website format, found it easy to use, convenient, and preferred the website to any other method of INR reporting. 95% of patients reported that it assisted them to better manage their warfarin through INR alerts and ease of reporting. Patients reported the website to be a 'great improvement' 'the best thing ever' and 'outstanding' for INR reporting. Patients valued the ability to enter personal notes, and resource materials available on the website, and continued to feel supported by the KIDCLOT health care team. The KIDCLOT© health providers found the website to be an effective and efficient method for monitoring VKA therapy and for quality control for patients and health providers.

Conclusion: INR reporting using mHealth is a valued solution for patients and health providers.

PB 3.69-2

Anticoagulation of pulmonary hypertension in children

Monagle KE[1], Jones S[2], King I[3], Weintraub R[2], Monagle P[1] and Newall F[2]

[1]The University of Melbourne; [2]The Royal Children's Hospital; [3]The Murdoch Children's Research Institute, Melbourne, Australia

Background: Pulmonary Artery Hypertension is characterised by increased pulmonary vascular resistance, right ventricular failure, low cardiac output and death. Without treatment, the long term prognosis of children with pulmonary arterial hypertension is poor, with an estimated median survival of <1 year, shorter than that which is seen in adults The reduced pulmonary blood flow leads to an increased risk of thrombosis. Anticoagulation is used in adults with pulmonary artery hypertension, and is recommended by the ACCP for use in children despite the lack of published primary evidence to support its use.

Aim: To determine the safety and efficacy of oral anticoagulant therapy (warfarin) for primary thromboprophylaxis in a cohort of children with Pulmonary Hypertension.

Methods: A retrospective clinical audit of the Royal Children's Hospital, Melbourne, pulmonary hypertension and warfarin INR databases was conducted with relevant outcomes including thrombosis and major haemorrhage, defined *a priori* according to internationally accepted definitions. We also *a priori* determined that a reduction in bone density would be classified as significant if a Z score of less than or equal to −1.0, was reported on a bone mineral density scan.

Results: 18 children (69.94 warfarin years) were examined with each child taking warfarin for an average 3.89 years (range: 0.5–7 years). The primary reasons for the discontinuation of warfarin therapy were death unrelated to warfarin thromboprophylaxis ($n = 4$), and transfer to adult care ($n = 5$), with eight patients remaining on continuous warfarin at the completion of the study. The median age of children starting warfarin was 7.63 years (Range: 0.670–16.4). The most common Target Therapeutic Range for warfarin therapy was 2.0–3.0. Of 1694 INR tests performed, TTR achievement was highly negatively skewed, and was achieved in a median of 48.75% of all tests. However, 89% of patients ($n = 16$) in this study achieved their TTR >30% of the time.

There were no deep vein clots in this cohort. Two patients experienced superficial vein thrombi (three thrombotic events); all at the site of line insertions. Therefore, despite the low TTR achievement numbers, treatment appeared effective. There were several warfarin related adverse events experienced during the study period; with two patients experiencing major bleeds. One was an episode of severe epistaxis, and the other a severe gastro intestinal bleed following a nasogastric tube resite. Of the 10 patients who had had bone mineral density scans, 8 (80%) had significant reductions in bone density in at least one site (hip or lumbar spine).

Summary/Conclusions: The high mortality rate of 22.5% ($n = 4$) in this cohort demonstrates the severity of this condition in children. However there were no clotting related deaths suggesting warfarin therapy can be effective, despite the low rate of TTR achievement in these children. The potential adverse events related to warfarin including bleeding and reduced bone density need to be considered.

PB 3.69-3

Clinical characteristics of pediatric and adolescent index cases with antithrombin deficiency: results of a cohort study

Limperger V[1], Franke A[2], Holzhauer S[3], Manner D[1], Junker R[1] and Nowak-Göttl U[1]

[1]University Hospital of Schleswig-Holstein, Kiel; [2]Christian-Albrechts- University Kiel, Kiel; [3]Charite, Berlin, Germany

Background: Venous thromboembolism [TE] is a multifactorial disease and antithrombin [AT] deficiency [AT] constitutes a major risk factor. In the present study the incidence of AT, the clinical presentation at TE onset and the recurrence rate in a cohort of pediatric index cases are reported.

Methods: In 205 unselected consecutively ascertained pediatric patients (neonate to < 18 years) with TE a comprehensive IT screening was performed along with recording of anamnestic data. Index patients were enrolled between January 1998 and December 2010 and were followed until December 2012 with the study endpoint symptomatic recurrence.

Results: Seventeen of 205 pediatric index patients [8.3%] were carriers of AT deficiency [heterozygous mutations, type 1: point mutation $n = 10$; deletion $n = 2$; stop $n = 2$; type 2: homozygous 'Budapest' $n = 2$; 'Charleville' $n = 1$]. Mean age at first TE onset was 14 years [range 0.1–17]. Thrombotic locations were neonatal renal vein thrombosis [$n = 1$]; cerebral venous thrombosis/stroke [$n = 6$], DVT of the leg [$n = 9$] and pulmonary embolism ($n = 1$]. AT deficiency was combined with FV G1691A mutation in three cases and FII G20210A variant in two. First TE onset was associated with underlying diseases in 70% of patients [use of OAC, smoking, immobilization, surgery]. Spontaneous TE occurred in a neonate with a heterozygous point mutation, a 9-year-old female with a stop mutation and a 14-year-old female homozygous for theBudapest variant. In five of 17 pediatric index patients [29.4%] recurrent TE occurred after withdrawal of oral anticoagulation [performed with LMWH and Warfarin according to CHEST guidelines] at a median follow-up time of 2.5 years [range: 2–8].

Conclusion: In an unselected cohort of pediatric patients with symptomatic TE, the prevalence of AT deficiency was 8.3%, followed by a high recurrence rate of 29.4%. Given its clinical implications thrombophilia testing should be performed in children with a first TE onset not to miss AT deficiency. Long time anticoagulation should be considered in pediatric AT carriers suffering from a first TE.

PB 3.69-4

Clinical experience with recombinant tissue plasminogen activator in the management of intracardiac and arterial thrombosis in children

Buyukavci M, Olgun H, Keskin Yildirim Z, Caner I, Ceviz N and Sahin IO

Atatürk University, Faculty of Medicine, Erzurum, Turkey

Background: Thrombotic events may complicate the clinical course of many neonatal and pediatric pathologic processes. Thrombolytic therapy is generally used for arterial thrombosis in selected patients. Drugs that have been used for therapeutic thrombolysis in children include streptokinase, urokinase and tissue plasminogen activator (t-PA). There are a number of practical advantages of recombinant t-PA (rt-PA) for non-invasive thrombolysis. However, experiences with rt-PA in pediatric age group are less than in adults. Many recommendations for children are based on extrapolation of adult data.
Aims: We aimed to present our experiences with rt-PA in children with intracardiac or peripheral arterial thrombus.
Methods: We conducted a retrospective review of 18 patients who received rt-PA because of thrombus.
Results: We evaluated 18 children (10 boy and 8 girl; age range from 1 day to 17 year) with intracardiac thrombus (n = 5), prosthetic heart valve thrombus (n = 2) and peripheral arterial occlusion (n = 11). Eight of the 18 patients had congenital heart disease and two had rheumatic heart disease. Three patients diagnosed with leukemia and five patients suffered from sepsis, prematurity or meconium aspiration syndrome. Seven of the 11 peripheral arterial thrombosis were observed following an intervention such as angiography. Three of the five intracardiac thrombi were detected in children with leukemia. All children initially received low molecular weight heparin (LMWH). Recombinant t-PA (alteplase) infusion (at a dose of 0.01–0.5 mg/kg/h) was administered in different time periods (3–66 h). Nose bleeding, melena and decreased serum fibrinogen concentration were observed in five patients during the rt-PA infusion. Ten of 11 patients with peripheral arterial occlusion and 3 of 5 patients with intracardiac thrombus showed full recovery. However, there was no response in two patients with intracardiac thrombus and in two children with heart valve thrombus. One patient with prosthetic mitral valve needed re-mitral valve replacement because of the thrombotic event. One newborn patient with aortic thrombus at the level of celiac artery died from sepsis without observing the fibrinolytic response.
Conclusion: Recombinant t-PA infusion seems effective and safe in treatment of peripheral arterial occlusion and intracardiac thrombus in children.

PB 3.69-5

Can we predict poor outcome in neonatal arterial ischemic stroke by testing for the presence of a prothrombotic risk factor (inherited or acquired)?

Labarque V[1], Brandao LR[2], DeVeber G[2], Askalan R[2], MacGregor D[2] and Moharir M[2]

[1]University Hospitals Leuven, Leuven, Belgium; [2]The Hospital for Sick Children, Toronto, Canada

Background: Childhood arterial ischemic stroke (AIS) is increasingly being recognized. A major proportion of childhood AIS occurs in newborns. The relevance of prothrombotic risk factors (thrombophilia) in neonatal AIS (NAIS) is unknown.
Aims: To describe the frequency of thrombophilia in NAIS and to evaluate the potential impact of its presence on recurrence risk and neurologic outcome.
Methods: A retrospective review of NAIS cases from July/1999-August/2009 at our institution was conducted. Thrombophilia testing included protein C (PC), protein S (PS), antithrombin, anticardiolipin antibodies (ACLA), lupus anticoagulant, lipoprotein-a, plasma homocystein, levels of FVIII, FIX, and FXI, and Factor V Leiden, prothrombin (PTG) and MTHFR mutations. Neurologic outcome was assessed by the validated Pediatric Stroke Outcome Measure (PSOM). Measures of association (Fisher's Exact) between thrombophilia and AIS recurrence and outcome were studied.
Results: Eighty-eight neonates with AIS were identified. Seventy-six had prothrombotic testing. Tests were abnormal in 9/76 (11.8%) [2 low PC, 1 elevated ACLA, 1 elevated ACLA plus a high FVIII level, 2 PTG, 1 elevated lipoprotein-a, 1 hyperhomocystinemia with MTHFR variant]. Recurrence was more frequent in neonates with at least one prothrombotic risk factor (OR 6.2 (95%: 1.18–32.56); P = 0.02) and the median time to recurrence was 13 days. Abnormal neurologic outcome (total PSOM $\geq$0.5) was also more frequent in children with than those without a prothrombotic abnormality (P = 0.04).
Conclusions: The presence of a prothrombotic risk factor is not necessarily common in NAIS. Nevertheless thrombophilia may be associated with unfavourable outcomes in neonates. A larger prospective study is needed to verify these findings.

PB 3.69-6

Anticoagulation therapy in pediatric Lemierre's syndrome

Van Herrewegen F[1], Coutinho JM[2], Stam J[2] and Van Ommen HC[2]

[1]Westfries Gasthuis, Hoorn; [2]Academic Medical Center, Amsterdam, The Netherlands

Background: Lemierre's syndrome, most commonly caused by the anaerobic pathogen Fusobacterium necrophorum, is characterized by a recent history of oropharyngeal infection and ipsilateral internal jugular vein thrombosis. As Lemierre's syndrome progresses, complications arise in the form of septic thromboembolism and cerebral venous thrombosis. Although Lemierre's syndrome can affect all ages, demographically there is an incidence peak between the age of 10 and 35. The use of anticoagulation in patients with Lemierre's syndrome is controversial due to concerns regarding hemorrhagic complications.
Aim: To explore the efficacy and safety of therapeutic anticoagulation in pediatric patients diagnosed with Lemierre's syndrome.
Methods: A Pubmed search was performed, sourcing English publications since 2000 on diagnosed Lemierre's syndrome cases, aged 18 years or below. Two literature reviewers independently divided the cases presented in the publications into two groups: patients treated with anticoagulation therapy and patients treated without anticoagulants. For both groups, the development or progression of the jugular vein thrombosis into the cerebral venous sinus and/or development or progression of septic thromboembolism was determinded.
Results: Sixty-four relevant publications were identified, describing a total of 85 pediatric patients. No randomized controlled trials were found. The median age was 15 years (range 0–18) with a male preponderance of 55%. At diagnosis, 27/85 (32%) patients suffered from cerebral venous sinus thrombosis and 48/85 (57%) exhibited septic thromboembolism. Besides antibiotic therapy, 49/85 (58%) patients were treated with anticoagulation. Among anticoagulated patients, 1/49 (2%) demonstrated development or advancement of the thrombus into the cerebral venous sinus compared to 5/36 (14%) of patients not treated with anticoagulation. Development or progression of septic thromboembolism was observed in 10/49 (20%) cases in the group with anticoagulation vs. 12/36 (33%) in the group without anticoagulation. Unfractionated heparin, low molecular weight heparin as well as vitamin K antagonists were used as anticoagulants. The mean duration of anticoagulant therapy was 12 weeks (range 2–48). One patient in the anticoagulation group developed a major bleeding complication: A hemorrhagic pericardial effusion, which required pericardial drainage.
Conclusion: These limited data on anticoagulation in Lemierre's syndrome indicate that anticoagulation may decrease development and/or progression of thromboembolic events, with a low risk of hemorrhagic complications. These results should be confirmed in a prospective, randomized trial.

PB3.70 – Recurrent venous thrombosis – III

PB 3.70-1

The use of the REVERSE study clinical prediction rule for risk stratification after initial anticoagulation results in decreased recurrences in patients with idiopathic venous thromboembolism

Lazo-Langner A, Abdulrehman J, Taylor EJ, Sharma S and Kovacs MJ

Western University, London, Canada

Background: The optimal duration of anticoagulation (AC) in patients with idiopathic venous thromboembolism (VTE) is uncertain but in general at least 6 months are needed. In 2008 our group published the findings of the REVERSE study (Rodger et al., CMAJ 2008), which showed that the group of patients with high risk of recurrence included all males and those females with 2 or more adverse risk factors (age ≥65, body mass index ≥30, VIDAS D-Dimer ≥250 mg/L, and signs of post-thrombotic syndrome). Since 2008 our center modified clinical practice based on such findings. Accordingly, patients in the high risk group have since remained on AC.

Aims: In this study we aimed to evaluate the impact of a practice change using the REVERSE clinical prediction rule on recurrence rates in patients with idiopathic VTE.

Methods: We conducted a single-center, retrospective cohort study of all patients with objectively confirmed VTE who were consecutively referred to our thrombosis clinic from January 1st, 1999 to December 31st 2011. Patients were excluded if the VTE was due to hospital stay, pregnancy, immobility, or surgery. The primary outcome was objectively documented VTE after the initial 6 months of AC. Patients were divided according to the year of diagnosis in two groups (before and after 2008). Groups were compared using χ^2 or Fisher's exact tests, as appropriate. Survival data was analyzed using the Kaplan-Meier method and Cox regression analysis adjusted for thrombophilia and use of AC.

Results: We included 1033 out of 1100 eligible patients. Mean age was 55.59 years (±17.96), the mean length of follow up was 55.5 months (range 0–229), and 48.11% were female. Overall, 569/1033 (55.1%) patients continued AC beyond the initial planned period. Patients continued AC based on REVERSE criteria in 47/371 (12.7%) and 146/198 (73.7%) of cases before and after 2008, respectively. VTE recurrences were observed in 168 (24.5%) patients before 2008 and in 9 (2.6%) after 2008 ($P < 0.001$). The proportion of VTE recurrences in patients continuing vs. stopping AC were 15.% vs. 35.6% ($P < 0.001$, Log-rank $P < 0.001$) before 2008 and 2.0% vs. 3.4% ($P = 0.506$, Log-rank $P = 0.214$) after 2008. Continuation of AC beyond the initial planned period resulted in 75% reduction in VTE recurrence risk (HR 0.25, 95% CI 0.18–0.35; $P < 0.001$) after adjusting for thrombophilia and year of diagnosis.

Summary/Conclusions: Although the present study has limitations mainly arising from its retrospective design, our findings support the use of the REVERSE clinical prediction rule to guide decisions on long term AC duration in patients with idiopathic VTE.

PB 3.70-2

Outcomes after vena cava filter (VCF) placement in patients with acute venous thromboembolism (VTE)

White RH, Li Z, Brunson A, Wun T and Romano PS

UC Davis, Sacramento, CA, USA

Background: Evidence supporting use of VCFs to prevent death or recurrent VTE among patients with acute VTE is limited.

Aims: To determine the effect of VCF placement on the 30-day incidence of death and the incidence of recurrent pulmonary embolism (PE) and recurrent deep-vein thrombosis (DVT) among patients with acute-VTE who did not have cancer.

Methods: Using linked California Patient Discharge records, we performed a retrospective observational study that analyzed outcomes after VCF placement. All cases were hospitalized at one of the 400 non-federal public hospitals in California and had a principal diagnosis of acute VTE. After selecting the first acute-VTE hospitalization between 1/1/2005 and 12/31/2009 in each linked-patient record we excluded cases with, active cancer, prior VCF placement and all cases from hospitals that admitted fewer than 55 acute-VTE patients during the study period. Outcomes were death <30 days, recurrent PE, and recurrent DVT (within 180 days, and at median of 22 months). Three Methods: were used to analyze death <30 days, (i) standard risk-adjusted multivariable analysis, (ii) propensity score-matching (3:1) and (iii) instrumental variable (IV) analysis, using hospital as the instrument. Variables for adjustment included: age, race, sex, PE vs. DVT alone, prior VTE, acute bleeding, surgery, number of comorbidities, risk-of-mortality on admission and insurance status. Cox proportional hazard modeling was used to analyze the risk of post-hospital discharge recurrent VTE.

Results: Among 69,505 acute-VTE cases, the 30-day mortality was 4.3%; 5.4% had recurrent-PE and 6.2% had recurrent-DVT (median follow-up = 22 month). A VCF was placed in 7766 (11.2%) and 505 (6.5%) of these cases died <30 days; using risk-adjusted multivariable analysis of death <30 days, VCF use was associated with an 18% reduction in the odds of death (OR = 0.82, CI :0.74–0.92); but there was no significant difference using inverse-weighting propensity-score analysis (OR = 0.96, CI: 0.91–1.01, $P = 0.11$) or matched propensity-score analysis (OR = 0.91, CI: 0.79–1.05, $P = 0.18$). IV analysis showed no significant difference in the 30-day risk-adjusted mortality rate when the highest tertile VCF-utilizing hospitals (VCF use = 16.6%) and low VCF-utilizing hospitals (VCF use = 4.3%) were compared: Death = 4.3% vs. 4.1%, respectively; difference = 0.2%, $P = 0.31$). Cox modeling to predict recurrent VTE showed that VCF use was associated with a higher risk of recurrent-PE at 180-days (HR = 1.2, CI: 1.0–1.4, $P = 0.046$) but no effect after 22 months (HR = 0.91, CI: 0.81–1.02, $P = 0.09$); VCF use was associated with a 56% higher risk of recurrent DVT at both 180-days and 22 months (HR = 1.56, CI: 1.4–1.7).

Conclusions: Use of different methods: to analyze the effect of VCF use on death <30 days resulted in discrepant findings: simple multivariable regression showed a beneficial effect of VCF use, with an approximate 16–18% relative reduction in the 30-day risk of death (estimate = 0.6% absolute reduction), whereas propensity-score analysis and IV analysis showed no significant difference in the risk of death. For all methods, the effect of VCF use on the absolute risk of death was small, in part because the overall 30-day mortality rate was modest (4.0%). There was no significant effect of VCF use on the ~2-year incidence of post-discharge recurrent-PE, but the risk of post-discharge recurrent-DVT was increased by ~50%.

PB 3.70-3

External validation and updating of the Vienna Prediction Model for recurrent venous thromboembolism using a pooled individual patient data database

Marcucci M[1], Eichinger S[2], Iorio A[1], Douketis JD[1], Tosetto A[3], Baglin TPT[4], Cushman M[5], Palareti G[6], Poli D[7], Campbell TR[8] and Kyrle PA[9]

[1]McMaster University, Hamilton, Canada; [2]Depatment of Internal Medicine I, Wien, Austria; [3]San Bortolo Hospital, Vicenza, Italy; [4]Addenbrookes Hospital, Cambridge, UK; [5]University of Vermont, Colchester, VT, USA; [6]University of Bologna, Bologna, Italy; [7]Azienda Ospedaliero-Universitaria Careggi, Firenze, Italy; [8]Royal Infirmary, Glasgow, UK; [9]Medical University of Vienna, Vienna, Austria

Background: Guidelines recommend consideration of indefinite anticoagulation for patients with an unprovoked episode of venous thromboembolism (VTE) due to their overall high recurrence risk. At the individual level, many patients will never experience recurrence and will be exposed to unnecessary bleeding risk. The Vienna Prediction Model (VPM, Circulation 2010), based on Cox modelling, uses patient sex, VTE site and D-Dimer to stratify patients according to their recurrence risk.
Aims: To externally validate and possibly re-calibrate the VPM, using a large pooled database of individual patient data (IPD) from different prospective studies and validation techniques taking into account the time-to-event.
Methods: Validation cohort (Cohort V): IPD on 904 patients pooled from six prospective studies evaluating the effect of D-dimer on VTE recurrence risk. Both the most common but possibly misleading calibration comparing predictions to the observed raw proportions of events and the comparison of the cumulative recurrence rates predicted by the VPM to those observed in V (estimated by Nelson-Aalen method), at 12 and 60 months within risk strata (Harrell, 1996), were performed. By-study stratified Cox and Weibull regressions, including as covariate the Vienna's linear predictor $X\beta_{Vienna} = x_1\beta_1 + x_2\beta_2 + x_3\beta_3$ (where x_1-x_3 were sex, VTE site and D-Dimer), were also used to check the validity of the Vienna's overall hazard ratio and of the whole VPM (van Houwelingen, 2000). The updating of the VPM was achieved by adjusting the coefficient of each original predictor and including age as new predictor, through a stepwise forward procedure (Steyerberg, 2004). C-statistics, net reclassification improvement and discrimination slopes were used to explore model discrimination.
Results: In Cohort V, 123 (13.6%) patients had recurrent VTE (median follow-up 22 months, 3–71). According to the Cox and Weibull models, the calibrating coefficient for $X\beta_{Vienna}$ was always positive and not significantly different from 1, and the parameters describing the baseline recurrence risk function were similar to those found in the derivation cohort. Conversely, the analysis of goodness-of-fit of the non-recalibrated model showed that the performance of the whole VPM was less satisfying; indeed, the predicted and the observed cumulative rates for five risk strata were both increasing (at 12 months, predicted [95% CI]: 3.0 [1.3–3.7], 4.3 [3.7–4.9], 5.4 [4.9–6.0], 6.6 [6.0–7.5], 9.5 [7.5–18.5]; observed: 5.1 [2.7–9.9], 7.1 [4.0–12.5], 9.0 [5.4–14.9], 13.3 [8.8–20.3], 15.9 [10.9–23.4]), but with the predictions underestimating the observed recurrence rates. In updating the model, coefficients for VTE site and D-dimer, but not for sex, required significant adjustment. When added to this model, age was statistically significant. The c-statistics for the calibrating and the updated model were 0.626 and 0.674, respectively, with a significant higher ability of the updated model compared to the original VPM in reclassifying patients in agreement to their actual outcome.
Conclusions: Using a pooled IPD database as validation cohort we confirmed the validity of overall hazard ratio predicted by the VPM and improved its predictive performance by recalibrating the original coefficients and adding age, thus reinforcing its readiness for clinical application as a risk assessment tool.

PB 3.70-4
Risk factors of recurrent thromboembolism during pregnancy

Galambosi P[1], Ulander VM[2] and Kaaja R[3]
[1]*Helsinki University Central Hospital, Helsinki;* [2]*Helsinki University Central Hospital, Helsinki;* [3]*Turku University and Satakunta Central Hospital, Pori, Finland, Pori, Finland*

Background: Recurrent venous thromboembolism(VTE) is a frequent complication of an initial VTE. There are only few reports on recurrent VTE during pregnancy while on low-molecular-weight heparin (LMWH) prophylaxis.
Aims: To identify risk factors of recurrent antepartum VTE in women with LMWH prophylaxis due to at least one previous VTE episode.
Methods: This observational cohort study was undertaken at the Department of Obstetrics and Gynaecology, Helsinki University Central Hospital. The subgroup of 270 pregnant women with at least a single previous episode of VTE (369 pregnancies) was evaluated closely. All women delivered between 1994 and 2007, and received LMWH-prophylaxis due to prior VTE during pregnancy and postpartum. Antepartum VTE despite the LMWH prophylaxis in this study was defined as a VTE occurred at least 1 week after the initiation of the LMWH-prophylaxis. The risk factors between those women with LMWH-prophylaxis without recurrence were compared to those LMWH-users with recurrence.
Results: Twelve recurrencies (3.3%, $n = 10$ women) during early pregnancy before initiation of the LMWH-were excluded.
The incidence of recurrent VTE despite prophylaxis was 4.3% ($n = 16$ pregnancies in 15 women). Most of these were at high risk for VTE (thrombophilia or ≥2 previous VTE's). The mean gestational week (gw) at time of initiation of LMWH prophylaxis was 15 (range 4–39) in the group without recurrent VTE vs. 7(range 4–18) in the recurrent VTE group ($P < 0.001$). Duration of the medication was 24 (0–37) vs. 30 (range 16–36) gw ($P = 0.009$) respectively. The mean gw at diagnosis of recurrence was 22 (range 7–37) gw. Significant risk factors of recurrence of VTE were ≥2 previous VTE's (5.7% vs. 40.0%, $P < 0.001$) or thrombophilia (26.1% vs. 53.3%, $P = 0.034$). The strongest link existed in antiphospholipid antibodies carriers (2.6% vs. 20.0%, $P = 0.012$). Other risk factors for recurrence were history of VTE related to pregnancy and/or oral contraceptives with RR 8.5 (95% CI 1.1–62.5), but not age >35 years with RR 0.27 (95% CI 0.04–1.82) nor BMI >30 1.49 (95% CI 0.53–4.18).
Summary: Two main risk factors for recurrence of VTE during pregnancy seem to be thrombophilia and history of 2 or more VTE. In those women the LMWH prophylaxis should be initiated in the beginning of pregnancy with at least high prophylactic dose.

PB 3.70-5
Risk factors for recurrence after the first venous thromboembolic event in women

Mitic G[1] and Kovac M[2]
[1]*Clinical Center of Vojvodina, Novi Sad;* [2]*National Blood Transfusion Institute, Belgrade, Serbia*

Background: Despite the anticoagulant treatment substantial percentage (up to 25%) of patients with venous thromboembolic disease experience recurrence. The risk of DVT recurrence is particularly high in patients with unprovoked first thrombotic event. The assessment of the risk of recurrence is important for the decision of the optimal duration of treatment for each individual patient. Whether the risk of recurrence is related to a younger age of onset of VTE is unclear.
Aims: The aim of the study was to compare the recurrence rate of venous thromboembolic events (VTE) in women younger than 45 to women older than 45 years and to assess the predictive value of some laboratory (presence of thrombophilic abnormalities) and clinical thrombosis risk factors (pregnancy, surgery, oral contraceptive use, malignancy, obesity, infection).
Methods: Five hundred and eighty two women after a first objectively confirmed VTE were included in the study, 370 of them younger (mean age 30.2) and 212 older (mean age 58.3) than 45 years. All investigated women were outpatients at Anticoagulation Clinics at Clinical Center Novi Sad and Blood Transfusion Institute Belgrade. The signed informed consent was obtained from all investigated women and the study was approved by the local research ethics committee. All the data regarding the presence of risk factors and thrombophila (antithrombin, protein C, protein S, FV Leiden and FII G20210A mutation) were collected during their regular visits. Each recurrent event was confirmed by compression ultrasound examination, lung scintigraphy, computed tomography/angiography or magnetic resonance imaging.

Results: During a mean follow up of 9.6 years, 123 recurrent VTE events occurred in 100 patients (17.2%). The 1 year incidence of recurrent VTE was 4.3% in young women and 6.1% in older ($P = 0.33$), 5 year incidence of recurrence was 10.8% and 12.7% ($P = 0.51$), and 10 year incidence was 12.9% and 17.1% ($P = 1.0$). Thrombophilia was diagnosed in 163 young women, 56 of them had recurrent VTE, with no difference to the older group, with 10 recurrences out of 29 thrombophilic women ($P = 1.0$). The highest incidence (34 in 103 pts) of recurrences was observed in the group of women with unprovoked VTE as opposed to provoked VTE with 89 recurrences among 479 pts ($P = 0.002$) No significant associations between the recurrence of VTE and presence of risk factors such is pregnancy, surgery, hormone therapy, malignancy, obesity or infection was established in either group. We found no recurrences in the group of young women with oral contraceptive use related first VTE, due to the permanent discontinuation of their use.
Conclusion: The risk of VTE recurrence in women is highest after idiopathic first thrombotic event. According to our results the risk of recurrence is not age dependent. We have found neither laboratory nor clinical factors that could be useful in predicting the risk of VTE recurrence. Our findings could influence the decision on the duration of anticoagulant treatment of women with unprovoked VTE, which should be tailored individualy.

PB 3.70-6

Pulmonary embolism severity index accurately predicts long-term mortality rate in patients hospitalized for acute pulmonary embolism

Dentali F[1], Riva N[2], Turato S[2], Squizzato A[2], Grazioli S[2], Steidl L[2], Guasti L[2], Grandi AM[2] and Ageno W[2]
[1]University of Insubria; [2]Insubria University, Varese, Italy

Background: The Pulmonary Embolism (PE) Severity Index (PESI) is a clinical prognostic rule that accurately classifies PE patients in five risk classes with increasing mortality. PESI score has been validated in studies with a relatively short-term follow-up and its accuracy in predicting long-term prognosis has never been established.
Aim of the study: To asses the accuracy of the original and simplified PESI to predict the 6-month and 1-year mortality rate in PE patients
Methods: Consecutive patients admitted to the tertiaryhospitalofVarese(Italy) with an objectively diagnosed PE between January 2005 and December 2009 were included. Information on clinical presentation, diagnostic work-up, risk factors, treatment, and mortality during a 1-year follow-up was collected.
Results: 538 patients were enrolled in this study. Mean age was 70.6 (±SD 15.2), 44.4% of patients were male, and 27.9% had known cancer. One-year follow up was available for 96.1% of patients. Overall mortality rate was 23.2% at 3 months, 30.2% at 6 months and 37.1% at 12 months. The discriminatory power of the PESI score to predict long-term mortality, expressed as the area under the ROC curve, was 0.77 (95% CI 0.72–0.81) at 3 months, 0.77 (95% CI 0.73–0.81) at 6 months and 0.79 (95% CI 0.75–0.82) at 12 months.
Anticoagulant treatment beyond 3 months did not influence mortality outcome at 6 or 12 months. Simplified PESI had a similar overall accuracy compared to the original PESI at 3 and 6 months, but this was significantly lower at 1 year.
Conclusions: The results of this study suggest that PESI score may also be an accurate tool to define the 6-month and 1-year mortality rates in PE patients.

PB3.71 – Regulation of gene expression in vascular cells

PB 3.71-1

Aspirin influences megakaryocytes gene expression leading to MRP4 up-regulation in human platelets

Massimi I[1], Guerriero R[2], Lotti LV[1], Lulli V[2], Temperilli F[1], Borgognone A[1], Gabbianelli M[2] and Pulcinelli FM[1]
[1]Sapienza – University of Rome; [2]ISS, Rome, Italy

Background: Drugs can trigger changes in the expression of mechanisms susceptible of favouring their elimination. Such mechanisms are related to transient induction of the corresponding gene transcriptional regulation. An important protein involved in drug resistances is Multidrug Resistance Proteins 4 (MRP4), an organic anion cellular detoxifier. We recently demonstrated that its up-regulation has a role for the reduced aspirin action in patients after by-pass surgery.
Aims : As it was demonstrated that aspirin enhances MRP4 mRNA levels in rat and this overexpression is PPARα dependent, the aim of our study is to verify whether aspirin induces MRP4 up-regulation in human platelets through a direct action on megakaryocytic gene expression and whether it is PPARα dependent.
Methodology: We evaluated the changes on MRP4 expression in: human megakacaryoblastic DAMI cells grown in the presence of aspirin or PPARα agonist, WY14643 (WY), in platelets derived from human megakaryocytic progenitor cell cultures and in platelets obtained from healthy volunteers, treated *in vivo* with aspirin for 15 days. MRP4 expression was analysed by Q-RT-PCR, Western blot and immunofluorescence.
Results : In DAMI cells, grown in the presence of aspirin or WY, we found a significant increase in MRP4 mRNA expression (1.5 fold increase for both aspirin and WY). We also revealed an increase in MRP4 proteins expression after treatment with aspirin and WY.
In human megakaryocytic progenitors, grown in the presence of aspirin or WY, MRP4 mRNA expression is higher than in mock culture (1.7 fold increase for aspirin and 2 fold increase for WY). Such treatment shows an MRP4 protein over-expression also in their derived platelets (1.6 fold increase and 1.4 fold increase respectively).
Aspirin induces MRP4 expression after *in vivo* administration, as MRP4 mRNA expression significantly increases in platelets obtained from healthy volunteers treated for 15 days with aspirin (300 mg/die) (approximately 30%, vs. platelets obtained after 1 day's treatment $P = 0.08$). Both Western Blot and immunofluorescence analysis confirm such enhancement.
Conclusion: The megakaryocytes have an adaptive response that leads to cell detoxification of aspirin; in fact, our results show, for the first time, that aspirin treatment induces genomic changes in megakaryocytes leading to MRP4 up-regulation and that PPARα is the nuclear receptor involved in this regulation.

PB 3.71-2

Deleterious effects of a mutant mitochondrial fission protein on calcium and energy homeostasis

Leo V[1], Cahill T[2], Ashrafian H[2], Peers C[3], Boyle J[3] and Dear TN[4]
[1]University of Sheffield, Sheffield; [2]University of Oxford, Oxford; [3]University of Leeds, Leeds; [4]Univeristy of Leeds, Leeds, UK

Background: Cardiovascular disease is the most common cause of morbidity and mortality worldwide, of which cardiomyopathies account for a proportion. One of the hallmarks of progressive heart disease is diminished energy metabolism associated with cardiac mitochondrial dysfunction. A recently identified mouse mutant in the *Dnm1 l* gene, Python, leads to the development of dilated cardiomyopathy. ATP levels were found to be reduced in the heart, but not in other tissues tested.

Aim: This project aimed at clarifying the role of mitochondrial dynamics in the development of heart failure in this model.
Methods: The effect of the mutation on protein function was assessed by measuring mRNA and protein levels, protein-protein interaction levels and direct measurement of mutant protein activity after purification from *E. coli*. The morphological effect of protein dysfunction was investigated by organelle imaging via immunocytochemical staining, while biochemical measurements included cytosolic and mitochondrial calcium levels and the efficiency of mitochondrial oxidative phosphorylation.
Results: Evidence was obtained of alteration in mitochondria, peroxisome and ER morphology in various cell types. There was a suggestion of altered physical interaction between the mitochondria and the ER. Increased cytosolic calcium levels after stimulated release from ER stores and reduced mitochondrial uptake of calcium were observed in Python fibroblasts. Mitochondrial membrane polarization was also altered. These changes were associated with reduced oxidative phosphorylation activity in the hearts of Python mice that increased in severity with age. Ultimately a decrease in cytosolic ATP levels occurred, which was insufficient for normal heart function. Dnm1 l expression was found to increase with age in hearts of wild type mice, but not other tissues. This may be suggestive of an increase in the importance of the Dnm1 l protein in the ageing heart.
Summary: A mutation in the mouse gene, *Dnm1 l*, leads to dilated cardiomyopathy. We hypothesize that the mutation impairs the ability of the mitochondrial fission protein to form stable higher order structures on the mitochondrial membrane, thereby impairing the functional ability of the protein. Mitochondrial fission and ER tethering are subsequently altered. The defect in mitochondrial-ER tethering leads to dysfunctional mitochondrial calcium uptake and altered mitochondrial membrane potential, leading to a progressive decline in oxidative phosphorylation activity and ATP production. The high-energy demanding cardiomyocytes are unable to cope with the decline in ATP levels resulting in cellular dysfunction and a dilative response.

PB 3.71-3

Diet modification in conjunction with regulatory immune response to a combination of ApoB and HSP60 peptides controls progression of atherosclerotic lesions in Apobtm2Sgy Ldlrtm1Her/J mice

Mundkur AL, Mukhopadhyay R, Varma M, Samson S, Chen D, Lu X and Kakkar V

Thrombosis research Institute, Bangalore, India

Background: The pathogenesis of atherosclerosis involves inflammation and immune reactions. Raised plasma cholesterol levels are required to accelerate atherogenesis in mice. Hypercholesterolemia results in accumulation of and oxidation of low density lipoproteins leading to activation of endothelial cells, macrophages and T cells. Several studies have demonstrated effective early reduction of atherosclerosis in hyperlipidemic mouse models by inducing immunological tolerance to modified lipids and peptides derived from apolipoprotein B (ApoB) 100, HSPs 60/65. However the effect of tolerance along with diet modification on plaque progression has not been studied in detail
Aim: The objective of the present study was to evaluate the effect of oral tolerance to a combination of ApoB and HSP60 peptides along with diet modification on atherosclerotic plaque progression in double-gene knockout ($Apob^{tm2Sgy}$ $Ldlr^{tm1Her}$/J) mouse model.
Methods: Groups of $Apob^{tm2Sgy}$ $Ldlr^{tm1Her}$/Jmice were fed a high-fat diet for 10 weeks, to establish atherosclerotic lesion. In the last 2 weeks, mice were orally dosed with combination of ApoB and HSp60 peptides or KLH followed by a shift to chow diet for the next 10 weeks. Plasma concentration of lipids were estimated using standard procedure. Quantification of atherosclerotic lesions was carried out in the aortic sinus sections stained with Elastic van Geison (EVG). Immunohistochemical analysis were carried out by indirect immunofluorescence and gene expression was quantified using real time polymerase chain reactions. Specific immune cells in the lymphoid organs were studied by flow cytometry
Results: Hypercholesterolemic mice at the end of 10 weeks of high fat diet feed had a plasma cholesterol level of 14.10 ± 0.52 mM which reduced to 10.79 ± 2.65 mM on shifting to chow diet. In spite of reduction in lipid levels, atherosclerotic lesion in the aortic sinus increased from $29.48 \pm 3.6\%$ to $42.93 \pm 2.9\%$ in control animals. Oral administration of ApoB and HSP60 peptides resulted in a 37.6% reduction in lesion progression compared to control in the aortic sinus ($42.93 \pm 2.9\%$ vs. $26.8 \pm 4.4\%$, $P = 0.01$) and descending aorta. Protection against plaque progression was associated with increase in $CD4^+$ $CD25^+$ T cells expressing Foxp3 ($P = 0.011$) and CTLA-4 ($P = 0.005$) cells in the lymphoid organs. Expression of regulatory cell markers;Foxp3 CTLA4 and TGF-β were significantly higher in aorta as shown by RT PCR analysis and the number of $CD4^+$ $Foxp3^+$ regulatory T cells was higher (2.53 ± 0.14 vs. 12.09 ± 0.43, $P < 0.001$) in the aortic sinus of the peptide-tolerized mice as observed by immunohistochemistry. Tolerance to peptides also resulted in 33.3% increase in collagen content in the lesion ($P = 0.008$), and reduction in macrophage (58.8%) and TNF-α (67.12%)in the plaque.
Conclusions: Our results suggest that diet modification in combination with oral tolerance can prevent progression of established lesion, mediated by regulatory T cells

PB 3.71-4

Aspirin inhibits the platelet-mediated expression of antithrombotic genes in monocytes

Turnbull E[1], Van Capelleveen J[2], Krishnan U[1], Wright JR[1], Samani NJ[1], Trip M[2], Sivapalaratnam S[2] and Goodall AH[1]

[1]University of Leicester, Leicester, UK; [2]University of Amsterdam, Amsterdam, The Netherlands

Background: Activation of platelets *in vivo* leads to formation of monocyte platelet aggregates, which can be raised acutely in patients suffering a myocardial infarction (MI), and play a role in thrombus biology and atherogenesis. Genome wide expression profiling of monocytes stimulated *in vitro* by activated platelets found a number of antithrombotic genes are upregulated by the platelet stimulus, including tissue factor pathway inhibitor (*TFPI*) and protein C receptor (*PROCR*). GWE profiling also found that these two genes were expressed at lower levels in platelet-stimulated monocytes from MI patients compared to matched controls.
Aims: Since the MI patients were receiving aspirin the aim of this study was to determine the effect of aspirin on expression of these two genes.
Methods: Experiments were conducted in three stages using citrated blood from healthy non-medicated volunteers: (i) whole blood was incubated for 4 h with or without therapeutically relevant doses of aspirin (5.0×10^{-4} M and 8.3×10^{-5} M), and with cross-linked collagen-related peptide (CRP-XL; 0.5 μg/mL) to activate the platelets. Monocytes were then isolated using CD14 + ve magnetic Dynabeads®; (ii) washed platelets were treated for 15 min with aspirin before reconstituting with autologous monocytes (isolated using CD14 microbeads; Miltenyi), activating with CRP-XL and incubating for 6 h; (iii) washed platelets were activated with CRP-XL for 15 min and platelets and microparticles removed by serial centrifugation, leaving the platelet releasate. Releasate was separated into high and low molecular weight fractions using 10 kDa filters. The concentrated fraction was diluted back to the original volume. Arachidonic acid metabolites were isolated using a hexane based extraction solvent. The hexane was evaporated under nitrogen gas and the lipids re-suspended in 20 μL methanol before being made up to 1 mL in RPMI1640 + glutaMAX. All three fractions were added back to autologous monocytes that had been isolated using CD14 microbeads and incubated for 6 h. All incubations were carried out at 37 °C. Total RNA was extracted before reverse transcription and qRT-PCR was carried out on all samples.

Results: In whole blood (n = 7), *TFPI* and *PROCR*, were significantly decreased by 35–50% with both low and high therapeutic doses of aspirin (P = 0.0156 for all). Platelets that were treated with aspirin (n = 5) before reconstitution with autologous monocytes produced a similar decrease to that seen in whole blood, *TPFI* (34.5 ± 21.2%; P = 0.0386) and *PROCR* (46.3 ± 9.1%; P = 0.0127) with no further decrease in expression when monocytes were also treated with aspirin. The platelet-mediated increase in expression of these two genes was shown to be induced by the platelet releasate rather than by cell-cell contact. Using the fractionated platelet releasate, *TFPI* gene expression was significantly increased ($P \leq 0.0001$; n = 9) by the lipid soluble fraction whereas *PROCR* expression was significantly increased ($P \leq 0.0001$; n = 9) by the high MW protein fraction.
Conclusions: The increase in expression of *TFPI* and *PROCR* in monocytes induced by platelets is, in part, mediated through the effect of aspirin on platelets, which contrasts with aspirin's well-established cardio-protective properties. However, while regulation of TFPI appears to be via a reduction in COX-1 metabolites of arachidonic acid, regulation of PROCR may be through a different mechanism.

PB 3.71-5
Establishment of a Lentiviral vector encoding human HGF and the infection of human ADSCs

Zhu X, Liu X, Wu J, Zhu W, Cai X and Sun Z
Anhui Provincial Hospital, Hefei, China

Background: The delivery of adipose-derived stem cells (ADSCs) for promoting tissue repair has become a potential new therapy, while hepatocyte growth factor (HGF) is an important growth factor with angiogenic, anti-firotic, and anti-inflammatory benefis.
Aims: This paper was aimed to construct a recombinant lentiviral vector encoding human HGF and to examine hHGF expression in human ADSCs after infection.
Methods: The transfer of the target gene, hHGF, using the pcDNA3.0-hHGF plasmid was verified via endonuclease digestion and DNA sequence analysis. The HGF genomic fragment was isolated from the plasmid via polymerase chain reaction (PCR) and was subsequently cloned into multiple-cloning sites of the pGC-E1 vector to generate the recombinant lentiviral vector, pGC-E1-hHGF. The recombinant lentiviral vector was verified via PCR and DNA sequencing. The three lentiviral vectors, pGC-E1-hHGF, pHelper1.0, and pHelper2.0, were cotransfected into 293T cells using Lipofectamine 2000 to generate lentiviral particles. The viral titers were determined via a one-in-one whole dilution. hADSCs were separated, cultured, and identified based on the expression of cell surface antigens and multiple differentiation potential. The hADSCs were infected with the lentiviral vector, and the infection efficiency was assessed by flow cytometry. hHGF protein expression levels were detected by western blot analysis and the concentration of hHGF in cell culture medium was determined by enzyme-linked immunosorbent assay (ELISA).
Results: The hHGF lentiviral vector was successfully generated. The final viral titers were 1×10^8 TU/mL following viral concentration. The infection efficiency in hADSCs was 53 ± 15%. Western blot and ELISA results indicated that the hHGF protein levels were much higher in hADSCs infected with hHGF lentiviral vector than those of the cells infected with the empty lentiviral vector.
Conclusion: The hHGF lentiviral vector was successfully generated, and the lentiviral vector was able to safely infect hADSCs with high infection efficiency, thereby producing cells that overexpressed hHGF, which may provide a new strategy for the treatment of ischemic heart disease (IHD) and other ischemic diseases.

PB 3.71-6
Monocyte contribution to thrombus mass and stability through gene expression

Turnbull E, Kumani S and Goodall AH
University of Leicester, Leicester, UK

Background: Rupture of an atherosclerotic plaque and the consequent exposure of pro-thrombotic molecules to the flowing blood results in the formation of a platelet rich thrombus. Platelets become activated through G-protein coupled receptors and FcγR-linked tyrosine kinase receptors on their membrane. Their subsequent degranulation results in the translocation of P-selectin and other cell surface receptors to the membrane, which allows the recruitment of monocytes and other leukocytes into the growing thrombus. We have previously shown that the interaction of platelets with monocytes can induce gene expression, including some for proteins that regulate haemostasis and fibrinolysis. Whilst platelets are thought to be the main pro-thrombotic cell present within a thrombus, the contribution of monocytes to thrombus weight and stability through gene expression is yet to be determined.
Aims: We aimed to assess the role of monocytes in an *in vitro* model of thrombosis by depleting monocytes from whole blood before forming an arterial thrombus in a Chandler loop to assess the effect in weight and fibrinolysis, and to determine whether these effects are related to the expression of some key anti-thrombotic genes previously shown to be induced in monocytes by platelets; specifically tissue factor pathway inhibitor *(TFPI)*, endothelial protein C receptor *(PROCR)* and plasminogen activator inhibitor type 1 *(PAI-1)*.
Methods: Blood from healthy consented volunteers (n = 5) was collected into citrate anticoagulant and used to form thrombi in a Chandler loop by adding 1 mL recalcified blood to a 45 cm length of 3 mm diameter PVC tubing. Blood was used either untreated or after monocytes were depleted using CD14 Dynabeads®. The loops were incubated at 37 °C for 4 h, the resulting thrombi were removed from the tubes, blotted (to remove excess fluid) and weighed, and then either homogenised and used for RNA extraction, reverse transcription and qRT-PCR, or incubated for 24 h at 37 °C in Hanks buffered saline, after which the thrombi were weighed again to calculate weight loss and the supernatant analysed for D-dimer levels.
Results: Monocyte depletion was confirmed to be 95.5 ± 2.4% (P = 0.0032; n = 5) by flow cytometry using a CD14-FITC antibody (Serotec). Initial thrombus weight for the whole blood and monocyte depleted blood samples were similar (23.7 ± 4.6 mg and 21.4 ± 4.6 mg respectively), however, there was significantly more weight loss over a 24 h period in the monocyte depleted samples compared to controls (P = 0.0169; n = 4). Monocyte depleted thrombi also showed higher fibrinolysis, measured by D-dimer release, compared to the control samples (P = 0.0056; n = 4) suggesting monocytes stabilise thrombi. All four genes studied were expressed at significantly lower levels in the monocyte depleted thrombi compared to non-depleted thrombi (n = 5). For TFPI there was a decrease of 35.0 ± 23.0% (P = 0.0272), for PROCR the average decrease was 80.3 ± 11.4% ($P \leq 0.0001$) and for PAI-1 the average decrease was 78.0 ± 13.9% (P = 0.0002). Levels of CD14 mRNA were also decreased by an average of 61.6 ± 10.4% (P = 0.0002), confirming the thrombi were depleted of monocytes.
Conclusion: This study identifies monocytes as key players in thrombus stability that may be linked to the expression of anti-thrombotic genes through the interaction of monocytes with platelets within the thrombus.

PB3.72 – Thrombophilia – IV

PB 3.72-1

Peripheral arterial thrombosis and thrombophilia

Jundt PJ, DeLoughery TG, Azarbal AF, Landry GJ, Mitchell E, Moneta GL and Liem TK

Oregon Health and Science University, Portland, OR, USA

Background: Most peripheral arterial thromboses occur in association with atherosclerotic occlusive disease or cardiac dysrhythmia. In the absence of these co-morbid conditions, patients who develop arterial thromboembolism may undergo evaluation for an underlying thrombophilia.

Aims: The objective of this study was to determine the prevalence and spectrum of thrombophilia in patients who develop unexplained peripheral arterial thromboembolism.

Methods: After approval by the institutional review board, all patients at a tertiary referral center who underwent operative thromboembolectomy of upper extremity (UE), mesenteric and renal (MR), aorto-iliac (AI), and lower extremity (LE) arteries over a 7-year period were reviewed (January 2005-December 2012). Those with known peripheral atherosclerotic occlusive disease (PAOD) or arterial injury were excluded. Thrombus distribution, previous thrombotic events, cardiac evaluation, prevalence and type of thrombophilia, co-morbidities, and clinical outcomes (mortality and major amputation) were evaluated.

Results: 231 patients underwent upper or lower extremity, mesenteric, renal, or aorto-iliac thromboembolectomy during the study period, and PAOD was present in 119. In the remaining 112 patients without PAOD, 71 (63%) had a potential cardiac etiology (dysrhythmia, valvular heart disease, congenital heart defect, paradoxical embolism or aortic mass), 40 (35%) had an abnormal thrombophilia evaluation, and 14 (12.5%) had no detectable cardiac source or underlying thrombophilia. In the absence of a cardiogenic embolism, thrombophilia was present in 66% of patients, and 7 of 40 (17.5%) patients had multiple concurrent thrombophilias. The more commonly identified thrombophilias were antiphospholipid antibodies (APA) in 16, malignancy in 12, factor V Leiden in 4, protein S deficiency in 4, protein C deficiency in 3, factor VIII elevation in 3, heparin-induced thrombocytopenia in 2 and vasculitis in 2. Five additional patients presented either with pregnancy, prior splenectomy, nephrotic syndrome, hemolytic anemia, or lipoprotein (a) elevation. Thromboembolectomy was performed in 35 UE, 16 MR, 12 AI, and 69 LE arteries, and 14 had multiple sites of thromboembolism. Thrombus location was not significantly different when comparing patients with a cardiogenic vs. thrombophilic source. Patients with a cardiogenic etiology were significantly older than patients with thrombophilia (73.8 vs. 53.3 years, $P < .004$), and they had a significantly decreased survival ($P < .044$). Patients with thrombophilia had a significantly higher number of amputations or end-organ loss ($P < .023$) and cancer-associated thrombophilia was associated with a significantly decreased survival, when compared with non-cancer thrombophilia ($P < .046$). Twelve month survival was 73%, 84% and 58% in the cardiogenic, thrombophilia and malignancy groups respectively.

Conclusion: Most patients with non-cardiogenic peripheral arterial thrombosis have an underlying thrombophilia, with antiphospholipid antibodies and malignancy accounting for the majority. Better treatment strategies are needed to improve the high mortality associated with cardiogenic and cancer-associated arterial thrombosis.

PB 3.72-3

Thrombophilia screening as part of preventive medicine? Single center experience

Sarig G[1], Higazi E[1], Avizohar O[1], Rubin L[2], Green M[2] and Brenner B[1]

[1]Rambam Health Care Campus, Haifa; [2]Haifa University, Haifa, Israel

The need of screening healthy population for thrombophilia is debatable. Since 2005, a battery of screening assays has been offered as part of preventive health services at the Rambam Health Care Campus.

Thrombophilia screening includes protein C global assay, assessment of prothrombin G20210A mutation and homocysteine level, which amount to a third of the cost compared to complete thrombophilia evaluation.

Between 2005 and 2010, 15,668 subjects visited the Rambam preventive medicine center; only 910 (5.8%) of them decided to undergo thrombophilia screening.

The aim of this study was to characterize the group that chose to have screening tests and to evaluate, using a questionnaire, the effect of thrombophilia screen results on patients' health behavior. The questionnaires were distributed at least 1 year after receiving the test results.

The population that requested thrombophilia screening was older (52 ± 9 years) and included mostly males (76%) compared to the rest of the individuals attending the preventive medicine center (48 ± 11 years and 64% males, $P = 0.0001$). Out of the 910 subjects, 15.2% were found to have abnormal protein C global assay results, 6% had the prothrombin G20210A mutation and 18.5% had high homocysteine levels. Seventy percent of the subjects found positive for thrombophilia, referred to a coagulation or hematology specialist after receiving the test results. More than half of them (56%) reported receiving recommendations to engage in physical activity, 43% to reduce their body weight, 40% to start anticoagulant prophylaxis during hypercoagulable states, 15% to stop smoking and 12% to stop or avoid hormonal therapy. Among the persons found to have thrombophilia, 83% reported maintaining regular physical activity compared to 69% of those without thrombophilia ($P = 0.022$). Approximately 2/3 of the subjects who were recommended thromboprophylaxis reported following the instructions and receiving the therapy during hypercoagulable states.

None of the subjects with or without thrombophilia, who filled in the questionnaire, developed any thrombotic event after receiving the test results.

Interestingly, 47% of women with thrombophilic risk factors, experienced previous pregnancy complications compared to 9% in women without thrombophilic risk factors ($P = 0.005$). Most pregnancy complications were miscarriages (67%), premature birth (27%) and pre-eclampsia (6%).

Notably, 77% of the subjects found to have thrombophilia, would recommend others to undergo screening compared with 64% of the subjects in whom thrombophilia was not revealed ($P = 0.021$).

In conclusion, personal knowledge of thrombophilia test results raised patients' awareness and influenced their health behavior aiming to reduce the risk of thrombosis.

Thrombophilia screening might be an important part of preventive medicine; however further studies assessing this strategy are warranted.

PB 3.72-4

Aging induces a thrombophilic phenotype independently from acute medical conditions

De Negri F[1] and Carmassi F[2]

[1]Azienda Ospedaliera Universitaria Pisana; [2]University of Pisa, Pisa, Italy

Aging is associated with an increasing prevalence of thrombotic complications, both in arterial (i.e. atherothrombosis, atrial fibrillation) and venous (i.e. venous thromboembolism) vascular bed. In fact, an activation of the coagulation cascade has been described in elderly people.

However, standard coagulation tests are not suitable to reveal a thrombotic tendency and markers of activation of coagulation have some relevant limitations. Instead, the measurement of an individual's capacity to generate thrombin captures the end result of the interaction between proteases and their inhibitors and therefore mirrors the thrombotic phenotype.

In this study we assayed plasma levels of PCR and markers of coagulation cascade activation as well as thrombin generation profile in a population of elderly patients admitted to the Emergency Department of our University Hospital. In order to take into account the possible effect of transient acute conditions, the results were compared with those obtained in healthy elderly subjects and in two younger populations, one obtained in the same setting and one composed of healthy adults.

The study included 45 subjects aged 70–106 years (mean 84.3 ± 12.6), 23 males and 22 females, consecutively admitted to the Emergency Department of Pisa University Hospital (group A). As a control group, we chose 35 subjects aged 18–69 years (mean 51.7 ± 15.9), 19 males and 16 females, also consecutively admitted to our Emergency Department (group B). Two further control groups consisted of 40 younger healthy subjects, 22 males and 18 females, aged <70 years (mean 41.0 ± 13.6) (group C) and 30 older healthy subjects, 16 males and 14 females, aged 70–95 years (mean 86.5 ± 11.8) (group D). None of the subjects participating to the study was being treated with antithrombotic or anticoagulant therapy at the time of enrollment.

Thrombin generation profile was assayed using a fluorimeter assisted by a dedicated software program (Technothrombin TGA, Technochlone, Wien).

High-sensitivity PCR (hsPCR) values in the four groups were 9.1 ± 1.5, 7.5 ± 1.5, 3.6 ± 1.1 and 8.2 ± 1.4 mg/L, respectively. The levels of fibrinogen ($P < 0.001$), D-dimer ($P < 0.01$), TAT complexes ($P < 0.05$), F1 + 2 fragment ($P < 0.02$) and tPA ($P < 0.05$) were significantly greater in the groups A and D in comparison with groups B and C, confirming the increase of coagulation activation with age; on the contrary, antithrombin III activity was lower in groups A ($P < 0.001$) and D ($P < 0.01$). Group D showed mean levels of fibrinogen ($P < 0.01$), D-dimer ($P < 0.05$), TAT complexes ($P < 0.05$) and F1 + 2 fragment ($P < 0.05$) significantly lower than those of group A.

The results of thrombin generation assay showed significant differences in lag time ($P < 0.001$), time to peak ($P < 0.01$), peak thrombin generation ($P < 0.05$), start tail ($P < 0.001$) and ETP ($P < 0.05$) in the four groups. In particular, there were highly significant differences between groups A or D and both group B and C, whereas the results of group A did not differ from those of group D and those of group B did not differ from those of group C.

These data suggest that aging induces a thrombophilic state independently from acute medical conditions.

PB 3.72-5

Congenital antithrombin deficiency-clinical phenotype in 40 patients

Prigancova T, Batorova A and Jankovicova D

University Hospital Bratislava, Bratislava, Slovakia

Background: Inherited AT deficiency is regarded as the strongest genetic factor increasing the risk of venous thromboembolism (VTE) even 20–50 fold. Most patients have AT levels between 40% and 60%. Whether the risk for thrombosis correlates with the severity of AT decrease is still not clear.

Aim: To evaluate the clinical phenotype in patients with antithrombin deficiency registered at our centre with regard to the function levels of antithrombin and gender.

Methods: The diagnosis of antithrombin deficiency was based on repeated AT testing (chromogenic assay Anrithrombin Berichrom, Siemens) and exclusion of acquired causes of AT decrease. The prevalence, type and recurrence of thrombosis, age at first thrombosis, concomitant risk factors and indefinite anticoagulant therapy were evaluated.

Results: In the group of 40 patients with inherited AT deficiency (22F/18M) with a median age of 40 years (range 2 weeks–65 years) the AT activity was of 49% (18–65%). Familial thrombosis was present in 80% of patients, but only one and one patient had concomitant heterozygous FVLeiden and prothrombin mutation, respectively. Thrombosis developed 31(78%) patients with a first manifestation at median age of 25 years (2 weaks–52 years), 27/87% patients had deep vein thrombosis (DVT), and 2 and 4 developed sinus vein thrombosis and ischemic stroke, respectively. Out of 27 DVT patients 19/70% had proximal thrombosis; 13/48% developed PE and 13/48% suffered from recurrent thrombosis. Two patients died at age of 2 weeks and 13 years due to a massive VTE and recurrent PE, respectively.

Both, symptomatic females ($n = 16$) and males ($n = 15$) developed the first thrombosis at the same median age (25 years), with similar prevalence of PE (7/44% and 6/40%, respectively). However, recurrent DVT, idiopatic VTE and indefinite anticoagulation were more frequent in males than in females (60% v.s. 25%, $P = 0.053$; 67% v.s. 19%, $P < 0.05$; and 73% vs. 58%; $P < 0.05$, respectively). The first thrombotic event in 81% symptomatic females was triggered by concomitant risk factors with most frequent pregnancy (31%) and oral contraception (31%).

The proportion of symptomatic patients was similar in the patient′s group with AT ≤40% (11/13; 85%) and AT >40% (20/27; 74%). Comparison of symptomatic patients with the AT level ≤40% ($n = 11$) and >40% ($n = 20$) showed higher prevalence of PE (64% vs. 30%, RR:2.1), recurrent VTE (55% vs. 35%, RR 1.55), idiopatic VTE (64% vs. 30%, RR 2.1) and indefinite use of anticoagulants (64% and 50%, RR 1.27) in patients with AT levels ≤40%, however, the differences were not statistically significant.

Conclusion: Our results confirmed inherited AT deficiency to be a strong risk factor with an early manifestation of VTE. In women the use of contraceptives and pregnancy were the most frequent triggers of the first thrombosis. With regard to a high frequency of recurrent thrombotic events and a potential of early death we suggets that indefinite anticoagulant therapy is justified in AT deficient patients who developed idiopatic life threatening thrombosis in very young age.

PB 3.72-6

Multicenter evaluation of the INNOVANCE Free PS Ag assay

Merz M[1], Madlener K[2], Mendez A[3] and Zimmermann R[4]

[1]Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany; [2]Kerckhoff Clinic, Bad Nauheim, Germany; [3]Cantonal Hospital, Aarau, Switzerland; [4]Universital Hospital Erlangen, Erlangen, Germany

Background: A particle-enhanced agglutination assay for the quantification of free protein S antigen in human plasma (INNOVANCE® Free PS Ag*) was developed by Siemens Healthcare Diagnostics Products GmbH (Marburg, Germany). Aim of this study was to investigate the new assay in different clinical settings.

Methods: The new assay was evaluated on BCS® XP, Sysmex® CA-7000, CA-1500 and CS-2100i* systems and compared with the STA® LIATEST® Free Protein S assay on the STA R EVOLUTION®

system (Diagnostica Stago, France) and the HemosIL™ Free Protein S assay on the ACL TOP® system (Instrumentation Laboratories, USA) by measuring >119 frozen samples. The following patient cohort was investigated: patients admitted for thrombophilia screening, patients with hereditary protein S deficiency, patients suspected for acquired protein S deficiency (e.g. Anti Vitamin K therapy, pregnancy, and severe liver disease), patients in the acute phase and patients with the FV Leiden mutation. Furthermore, diluted plasmas (<10% of all samples) were tested. Precision of the new assay was determined by testing two controls and three plasma pools covering the entire measuring range on 20 days in two runs with two single determinations ($20 \times 2 \times 2$ scheme).

Results: The overall correlation between the INNOVANCE Free PS Ag assay on the BCS XP system and comparative methods was high with a correlation coefficient of 0.966, slope of 0.95 and an intercept of 5.79% of norm for the comparison to the STA LIATEST Free Protein S assay and a correlation coefficient of 0.961, slope of 1.0 and an intercept of 6.44% of norm for the comparison to the HemosIL Free Protein S assay. Comparability of results obtained on the BCS XP system (Siemens) with results obtained on Sysmex CA-7000, CA-1500, and CS-2100i systems (all Sysmex Inc, Kobe, Japan) was excellent (correlation coefficients ≥0.994; slopes between 0.99 and 1.06; intercepts between −3.91% and −0.4% of norm).

Both, repeatability and within device CV were for all investigated controls and pools ≤2.5% on Sysmex CA-7000, CA-1500, and CS-2100i systems and ≤4.8% on the BCS XP system.

Conclusion: The new assay is well suited for the measurement of free protein S antigen. It demonstrated excellent precision, correlates well with other commercial available assays and showed an excellent comparability between different Siemens and Sysmex analyzers.

* Not available for sale in the U.S.

PB3.73 – Recurrent venous thrombosis – IV

PB 3.73-1

The risk of recurrent venous thromboembolism after a first surgery-related event a prospective cohort study

Eischer L, Eichinger S and Kyrle PA

Medical University of Vienna, Wien, Austria

Background: In contrast to patients with unprovoked venous thromboembolism (VTE), the risk of recurrence is low in patients in whom VTE occurred in association with a temporary risk factor/condition. Current guidelines recommend that these patients should receive secondary thromboprophylaxis for no longer than 3 months. The recurrence risk appears to be particularly low among patients with VTE related to surgery, but data are inconsistent and studies with a long follow-up are lacking.

Aim: To study the risk of recurrence in patients with a first VTE related to surgery.

Methods: The analysis was performed within the frame of the Austrian Study on Recurrent Venous Thromboembolism (AUREC), a prospective multi-center cohort study. Patients entered the study at the time of discontinuation of anticoagulant therapy. They were then seen at regular intervals at our study center and/or were contacted by the use of a questionnaire. Inclusion criteria were age >18 years, objectively verified symptomatic VTE, surgery within 3 months before VTE and anticoagulant treatment for at least 3 months. Exclusion criteria were previous VTE, VTE provoked by trauma or pregnancy, upper extremity DVT, cancer or requirement for extended antithrombotic treatment for other reasons. The study end point was symptomatic recurrent VTE objectively confirmed by imaging techniques.

Results: 157 patients with VTE after surgery were followed for a mean of 102 (+/−60) months. Patients were in average 49 (+/−14) years old and received anticoagulation for a mean of 8 (+/−9) months. Ninety patients (58%) were female. Ninety-four patients had DVT and 63 patients PE +/- DVT at presentation.

VTE recurred in 15 (10%) patients. Fourteen recurrences were unprovoked and one provoked by trauma (7 DVT, 8 PE +/− DVT). Nine were men, six were women. The mean age of patients with recurrence was 57 (+/−12) years as compared to 48 (+/−14) years among patients without recurrence ($P = 0.03$). The cumulative probability of recurrence was 2% (95% CI: 0–4) after 1 year, 3% (95% CI: 0–6) after 2 years, 6% (95% CI: 2–10) after 5 years and 12% (95% CI: 6–19) after 10 years.

Conclusion: The risk of recurrence among patients who had their first VTE event in association with surgery is low. Our findings support the concept of a limited duration of anticoagulation in this patient population.

PB 3.73-2

Prolonged clot lysis time as a potential risk factor for recurrent venous thrombosis; results from THE-VTE follow-up study

Karasu A[1], Baglin TPT[2], Luddington R[2], Baglin CAC[2], Rosendaal FR[1] and Van Hylckama Vlieg A[1]

[1]Leiden University Medical Center, Leiden, The Netherlands; [2]Addenbrooke's Hospital, Cambridge, UK

Background: Hypofibrinolysis, as well as a high thrombin generating potential are associated with an increased risk of a first thrombotic event. However, whether they are also associated with the risk of a recurrent thrombotic event is unclear.

Aims : We studied the association of recurrent thrombosis with reduced fibrinolysis, as measured by a prolonged clot lysis time (CLT), and with high thrombin generation as measured by endogenous thrombin potential (ETP), and the combination of these two.

Methods: Between March 2004 and December 2008, consecutive patients with a first episode of deep venous thrombosis of the leg (DVT) or pulmonary embolism (PE) from the anticoagulant service at Addenbrooke's Hospital, Cambridge and the anticoagulation clinic in Leiden were invited to participate in THE-VTE case-control study ($N = 796$). Partners of patients were invited to participate as control subjects. The patients were subsequently followed-up for recurrent venous thrombosis. All recurrent events were objectively verified using hospital records. For the current analyses, we included patients who did not use oral anticoagulants at baseline and with a valid measurement for CLT and ETP ($N = 580$). To assess the risk of recurrent thrombosis, CLT and ETP were dichotomized at different cut-off points (80th, 90th, 95th percentiles as measured in the healthy controls. Hazard ratios (HR) for recurrent venous thrombosis were calculated using Cox regression analysis with 95% confidence intervals after adjustment for age, sex and study center. The study was approved by both the Medical Ethics Committee in the Leiden University Medical Center and Addenbrooke's Hospital. Informed consent was obtained by all participants.

Results: Mean duration of follow-up of 580 patients was 5.2 years. Eighty out of 580 patients were diagnosed with a recurrence. The overall incidence of recurrence was 27.0 per 1000 person years (95% CI: 21.8–32.2).

Hypofibrinolysis, i.e. CLT above the 90th percentile (>122 min), was associated with a 1.4-fold increased risk of recurrent thrombosis (HR = 1.4, 95% CI: 0.8–2.4). For high thrombin generation, i.e. ETP above the 90th percentile (>2025 nM/min), the risk was not affected (HR = 1.1, 95% CI: 0.6–2.0). Applying different cut-off points did not change the results.

Conclusion: In this study of 580 patients followed for recurrence over 5 years, we found no effect of a high thrombin potential on recurrence, while hypofibrinolysis yielded equivocal results.

PB 3.73-3

Risk factors for recurrent events in subjects with superficial vein thrombosis in the randomized clinical trial steflux (Superficial thromboembolism fluxum)

Cosmi B[1], Filippini M[1], Campana F[2], Ghirarduzzi A[3], Avruscio G[4], Imberti D[5], Camporese G[6] and Palareti G[1]

[1]S.Orsola-Malpighi University Hospital, Bologna; [2]Bufalini Hospital, Cesena; [3]Arcispedale Santa Maria Nuova, Reggio Emilia; [4]S.Antonio Hospital, Padova; [5]G.da Saliceto Hospital, Piacenza; [6]University Hospital of Padua, Padova, Italy

Background/Aims: To evaluate risk factors for recurrent events in patients enrolled in the SteFlux (Superficial Thromboembolism Fluxum) clinical trial which compared different doses and duration of low molecular weight heparin (parnaparin) for superficial vein thrombosis (SVT).

Materials and Methods: Outpatients with acute SVT of at least 4 cm in length of the internal or external saphenous veins or their collaterals were randomized in a double blind fashion to receive either parnaparin 8500 UI aXa od for 10 days followed by placebo for 20 days or 8500 UI aXa od for 10 days followed by 6400 UI aXa od for 20 days or 4250 UI aXa od for 30 days. Outcomes were the composite of symptomatic and asymptomatic deep vein thrombosis, pulmonary embolism and SVT recurrence or extension in the first 30 days with a 60 day follow-up.

Results: Ninety-eight outcomes (14.7%) were recorded during 93 days among 664 patients (M/F: 246/418, mean age 65). After correction for treatment, outcomes during 93 days were associated with previous venous thromboembolism (VTE) and/or SVT and/or VTE family history or known thrombophilia (odds ratio-OR:1.2; 95% confidence interval – CI:1.1–2.0; $P = 0.011$), overweight)OR:1.9; 95% CI: 1.1–3.6; $P = 0.025$) and obesity (OR: 1.7; 95% CI: 0.9–3.4; $P = 0.09$). After stopping treatment, only absence of varicose veins (OR: 0.4; 95% CI 0.2–0.7; $P = 0.001$) and delay in diagnosis >6 days (OR: 2.2; 95% CI:1.2–4.2; $P = 0.001$) were associated with the risk for the developing an outcome.

Conclusions: Patients with these factors may deserve a higher intensity and/or longer treatment.

PB 3.73-4

Dyslipidemia and thrombotic complications in patients with venous thromboembolic disease (VTE)

García-Raso A, Ene G, Miranda C, Mata R and Llamas P

Fundación Jiménez Díaz, Madrid, Spain

Background: Lipids and lipoproteins can affect hemostasis by modulating the expression and function of specific procoagulant, fibrinolytic and rheological factors, therefore they could contribute to venous thrombosis. The lipid-lowering therapy in some cases may prevent the complications of VTE, as recurrence and post-thrombotic syndrome.

Methods: We included 405 patients with VTE, mean age 55.1 ± 18.1 years. The patient group consisted of 53.6% women and 46.4% men. From each patient the following risk factors were collected: hypertension, diabetes, smoking, pregnancy, abortion, acute infection, AIDS, vascular disease, malignancy, COPD, trauma, thrombophilia, oral contraceptives, chemotherapy, antidepressants/antipsychotics, immobilization, surgery, family history, air travel. Cases of recurrence and post-thrombotic syndrome were recorded. A sample of serum lipid profile was collected from each patient for the study of: total cholesterol (CHT), triglycerides (TG), HDL cholesterol (HDL) and LDL cholesterol (LDL). Also we considered as dyslipidemic patients treated with lipid-lowering drugs at the time of thrombosis.

Results: The distribution of patients according to the type of thrombosis was: DVT-legs (45.9%), PE (23.4%), DVT + PE (7.9%), DVT-arms (2.1%), TV-superface(10.6%) and TV-unusual localization (8.1%). 30.4% ($n = 123$) of patients suffered recurrent thrombosis, while 20.4% ($n = 95$) developed a post-thrombotic syndrome. 47.4% ($n = 45$) of patients with recurrent thrombotic event was diagnosed with post-thrombotic syndrome, this represents 11.1% of the total group. 38.5% ($n = 156$) of patients included in the study had dyslipidemia, of which 34.1%% ($n = 53$) had a recurrent event and 29.5% ($n = 46$) was diagnosed with post-thrombotic syndrome. Of patients with dyslipidemia who had developed recurrent thrombosis, 35.8% ($n = 19$) were not being treated. While 26.1% ($n = 12$) of patients with post-thrombotic syndrome and dyslipidemia were no lipid-lowering therapy. Patients with alterations in levels of Cht had recurrent event more frequently than patients with normal Chtlevels, in patients who were receiving lipid-lowering ($P = 0.0001$) and in those who were not treated ($P = 0.03$).

Summary: A certain percentage of patients who develop post-thrombotic syndrome or a recurrent thrombotic event suffer dyslipidemia, some of them do not follow any specific treatment. According to these results, closer monitoring of lipid levels (Cht, TG, HDL, LDL), and adequate treatment of dyslipidemia could lead to a lower incidence of these complications in patients with VTE.

PB 3.73-5

Medical literature and vena cava filters: from weak to worse, with exceptions

Girard P[1], Mismetti P[2] and Meyer G[3]

[1]Institut Mutualiste Montsouris, Paris; [2]CHU de Saint Etienne, Saint Etienne; [3]Hôpital Européen Georges Pompidou, Paris, France

Background: Inferior vena cava (IVC) filters are designed to prevent the migration of venous clots toward the pulmonary circulation. Unlike anticoagulants, whose efficacy and safety have been evaluated extensively in prospective randomized controlled trials (RCT), a detailed literature analysis in 2001 found that only 1 (0.2%) of 568 articles regarding IVC filters reported a RCT (Girard et al., Chest 2002;122:963–7).

Aim: To investigate whether the literature about IVC filters has improved over the past 12 years.

Methods: An advanced search was performed in the PubMed® database (http://www.ncbi.nlm.nih.gov/pubmed, cava filter or interruption in title, items with abstract, publication date 2001–2012). All references were imported in an EndNote® library, and classified, one by one, according to predetermined criteria. These references (period B) were compared to those from the identical search and classification performed in 2001 (period A: 1975–2000).

Results: A total of 626 references for period B were analyzed, and compared to the 568 older references (period A). The mean annual number of articles increased from 21.8/year to 52.2/year ($P < 0.001$). The proportion of case reports remained stable (31.7% vs. 31.2%), whereas there was a significant increase in the proportions of retrospective series (from 33.3% to 38.5% [$P = 0.06$]) and reviews (from 6.7% to 15.5% [$P < 0.001$]). Significant decreases were observed in the proportions of animal/*in vitro* studies (from 12.9% to 7.3% [$P = 0.002$]) and prospective series or trials (from 7.4% to 4.2% [$P = 0.016$]). Articles mentioning temporary/retrievable filters increased from 20.2% to 59.1% ($P < 0.001$). Four RCTs were published during period B: one publication was an update of the PREPIC trial (the only RCT during period A), another RCT compared two techniques for filter insertion, and the remaining 2 RCTs were a feasibility study in 34 trauma patients (Rajasekhar et al., J Trauma 2011) and a RCT in 64 cancer patients that was stopped early due to poor accrual (Barginear et al., Support Care Cancer 2012). There were at least five population-based investigations (one during period A), including one study that linked IVC filter use and decreased case-fatality rate in patients with massive pulmonary embolism (PE) treated with thrombolytics (Stein et al., Am J Med 2012). In a similar search about heparin (heparin in title, items with abstracts, period 2001–2012), 247 of 3177 articles (7.7%) were

tagged as controlled trials in PubMed®. A search for trials of filters and venous thromboembolism at http://clinicaltrials.gov found 14 studies, of which four were RCTs, including three trials with published results (see above) and one completed trial whose results are awaited (the PREPIC2 trial).

Summary/Conclusion: Over the past 12 years (2001–2012), more articles about IVC filters have been published than in the preceding 25 years. This plethoric literature reflects the increasing experience with IVC (retrievable) filters, but did not report any new adequately powered RCT designed to assess filters efficacy. Only the awaited PREPIC2 trial results should provide fresh evidence regarding the efficacy of filters in selected patients with PE. In the foreseeable future, indications for IVC filter placement will remain mostly a matter of opinion.

PB 3.73-6

Vascular's involvements in Behçet's disease

Hakem D, Berrah A, Ouadahi N, Boudjelida A, Boucelma M, Zemmour D, Ibrir M, Hamzaoui N, Habouchi A and Mansouri B

Dr Mohammad-Lamine Debaghine, Bab-El-Oued Universitary Hospital, Algiers, Algeria

Introduction: Behcet's Disease is recognized as a thrombogenic disorder with venous tropism impairment. This vascular achievement justifies first and foremost the hospitalizations of these patients in internal medical and constitutes the first cause of morbi-mortality.

Objectives : To describe the topographies and the profile following up of this vascular Behçet's disease.

Patients and Methods: Retrospective study from 1996 to 2012, excluding the thrombotic vasculitides localized at the level of the small vessels (retina, cochleovestibular, digital).

Results: We have collected 397 patients, which sex ratio is 0.33 and average age is about 31.9 years We observed 97 vascular events (24.4%) characterized by 69 deep venous thrombosis 'DVT' events (17.4%), and 28 arterial events (7%). The average delay to diagnosis of the vascular manifestations from the date of the BD diagnosis is about 4.4 years (1–9), and 5 cases (7%) revealed the BD. The DVT are divides up essentially in lower limbs (25), on cerebral topography (4%), on abdominal area (2%), on superior vein cava (2%). We noted in the others cases some unusual localization of thrombosis (six cases of intra-cardiac, upper limbs and jugular veins…). The arterial infringements are located as followed: cerebral aneurism (05), pulmonary (10), abdominal (05), heart (4), inferior limb (3), and upper limb (1). The surgical treatment is required in 11 cases. The fatal course is deplored (10) linked in aneurysms of pulmonary arterial rupture and/or to the massive pulmonary embolisms (7), Budd-Chiari's syndrome (4) and to the intestinal ischemia (1)

Conclusion: As reported in the most studies BD affects the veins more than the arteries. The vascular involvement constitutes bad factor prognosis and the major cause of increased mortality. So it's must be prevented, detected and treated prematurely (embolization, correct anticoagulation, and reduction of thrombogenous's risks factors….)

PB 3.74-1

Overview of a global clinical trial programme with turoctocog alfa, a new recombinant factor VIII: the guardian™ programme

Laguna P[1], Vdovin V[2], Rageliene L[3], Abad Franch L[4] and Lindblom A[5]

[1]Medical University of Warsaw, Warsaw, Poland; [2]Child Hematological Center of Izmaylovsky Children Hospital, Moscow, Russian Federation; [3]Vilnius University Hospital, Vilnius, Lithuania; [4]Novo Nordisk Health Care AG, Zurich, Switzerland; [5]Novo Nordisk A/S, Søborg, Denmark

Background: Congenital haemophilia A is a rare bleeding disorder that affects approximately 1 in every 5000 male births. In severe haemophilia bleeding can occur spontaneously or after minor trauma and serious complications result from bleeding into the joints, muscles, brain, or other internal organs. Novo Nordisk is developing turoctocog alfa, a new recombinant FVIII (rFVIII) for prevention and treatment of bleeding in haemophilia A. Extensive documentation of clinical safety and efficacy is a scientific and regulatory prerequisite due to the complicated structure and manufacture of this multi-domain protein. Because of the rarity of the condition, clinical trials investigating haemophilia therapeutic agents need to be multicentre/multinational, to enrol a sufficient number of patients, and to ensure that patients of different ethnicity are included.

Aims: To present an overview of a global clinical trial programme assessing the pharmacokinetics (PK), safety and efficacy of turoctocog alfa for the treatment and prevention of bleeding in relevant patient populations with severe congenital haemophilia A (baseline FVIII ≤1%).

Methods: The pre-registration clinical programme for turoctocog alfa involves seven clinical trials. The first human dose trial, performed during 2009, investigated turoctocog alfa PK and included a comparison with octocog (Advate®). The guardian[TRADEMARK]1 and guardian[TRADEMARK]3 trials were phase IIIa trials investigating safety and efficacy of turoctocog alfa in the prevention and treatment of bleeds in previously treated adult/adolescent (>12 years of age) and paediatric (<12 years of age) patients, respectively. Both trials included PK assessments, while guardian[TRADEMARK]1 also comprised a surgical subtrial. Guardian[TRADEMARK]1 and guardian[TRADEMARK]3 were both completed during 2011; participating patients were offered continued turoctocog alfa treatment in the guardian [TRADEMARK]2 extension trial, a long-term safety and efficacy trial which will continue until turoctocog alfa is commercially available in the respective countries. Two further PK trials investigated turoctocog alfa PK in Japanese subjects using different production lots. Finally, guardian[TRADEMARK]4, a phase IIIb safety and efficacy study in previously untreated patients (PUP), was recently initiated and is ongoing. Approximately 60 PUP will be enrolled and followed for ≥100 exposure days (initiated September 2012; estimated study completion date: September 2016).

Results: The PK properties of turoctocog alfa have been studied in >60 patients and shown to be comparable to those of commercially available rFVIII and plasma derived FVIII. To date, more than 210 patients have been dosed with turoctocog alfa in 18 countries worldwide (Brazil, Croatia, Germany, Israel, Italy, Japan, Lithuania, Macedonia, Malaysia, Poland, Russia, Serbia, Spain, Switzerland, Taiwan, Turkey, UK and US). The total turoctocog alfa clinical experience is in excess of 50,000 exposure days and 340 patient years. More than 110 patients have now been on preventive treatment with turoctocog alfa ≥18 months.

Summary/Conclusions: This comprehensive global clinical trials programme investigating the PK, safety and efficacy of turoctocog alfa will provide an extensive clinical database. On-going work includes defining some of the many possible further analyses of the available data. Future studies will add further important information to the

database on turoctocog alfa long-term safety and efficacy in specific patient populations.

PB 3.74-2

Coagulation Factor IX deficiency does not afford protection from pulmonary fibrosis in the experimental murine bleomycin model

Borensztajn KS[1], Cong L[2], François C[1], Crestani B[1], Daalhuisen J[2], Christophe OD[3] and Spek A[2]

[1]Inserm U700, Paris, France; [2]Academic Medical Center, Amsterdam, The Netherlands; [3]Inserm U770, Le Kremlin Bicêtre, France

Background: Animal and human studies strongly suggest the importance of the coagulation cascade in acute and chronic lung injury. Indeed, beyond their role in hemostasis, coagulation factors can signal via their cellular receptors, the protease-activated receptors.
Aim: In this study, we hypothesized that the absence of coagulation Factor(F)IX, which is essential for the initiation, amplification and propagation phases of the coagulation cascade would reduce fibrosis development and progression.
Methods: We used the murine model of bleomycin-induced pulmonary fibrosis in wild-type (WT; $n = 14$) and FIX deficient mice ($n = 13$; a model for the severe bleeding disorder hemophilia B). After 14 days, we assessed histological markers of tissue fibrosis, inflammatory cell influx in the bronchoalveolar lavage fluid (BALF), and cytokines levels in the BALF, blood and lung homogenate of the animals.
Results: Mortality during the experiment was higher in the FIX deficient mice compared to wildtypes (23% vs. 7%). The remaining FIX deficient mice ($n = 10$) developed pulmonary fibrosis to a degree similar to WT ($n = 13$). There was no significant difference in the Ashcroft score between WT and FIX deficient mice (4.011 ± 0.4 vs. 4.2 ± 0.4), in the alpha-actin score (0.94 ± 0.09 vs. 0.70 ± 0.07) and in the inflammatory cell number. In contrast, we observed in the plasma of the FIX deficient mice significant elevations in levels of cytokines IL-12, TNFα, IFNγ, MCP-1 and IL-6.
Conclusion: Hemophilic mice with a congenital deficiency of FIX are not protected against bleomycin-induced pulmonary fibrosis. These data strongly argue against an important role of the blood coagulation cascade in the progression of pulmonary fibrosis, and raise important concerns about the use of anticoagulant therapy in patients.

PB 3.74-3

New anticoagulants and their effect on platetet function

Busse J[1], Eller T[2], Dittrich M[3], Flieder T[1], Alban S[4], Knabbe C[1] and Birschmann I[1]

[1]Herz-und Diabeteszentrum, Bad Oeynhausen; [2]Johannes Wesling Klinikum Minden, Minden; [3]University of Würzburg, Würzburg; [4]Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Background: For the last 70 years, vitamin K antagonists and heparins have been the treatment of choice for prophylactic and therapeutic anticoagulation. Over the past few years, several selectively acting anticoagulants such as the direct thrombin inhibitors argatroban (A) and dabigatran (D) and the factor Xa inhibitors rivaroxaban (R) and fondaparinux (F) have been developed. They are approved for various indications like heparin-induced thrombocytopenia type II (HIT), venous thromboembolism, stroke prevention in atrial fibrillation and acute coronary syndrome.
Aims: With their increasing clinical application, it is of interest to evaluate their interferences with the complex system of haemostasis and haemostaseological assays. Here we investigated the abovementioned anticoagulants concerning their influence on platelet function.
Methods: As platelet function assay light transmission aggregometry was used. Activation of platelets was induced by ADP, arachidonic acid, epinephrine, collagen, ristocetin, A23187, PAF C-16, PMA, TRAP, U46619 and thrombin. Further, the influence of the drugs on intracellular pathways was investigated by western blot analysis using immunostaining with VASP antibodies (M4, 5C6, 16C2).
Results: Our measurements by aggregometry revealed a distinct decrease of platelet aggregation after *in vitro* incubation with supratherapeutic concentrations of argatroban (1.0 mg/mL) compared to control. Western blot analysis showed that argatroban (c = 1.0 mg/mL) induces VASP-phosphorylation in platelets. Neither therapeutic nor supratherapeutic concentrations of dabigatran (20 µg/mL), rivaroxaban (20 µg/mL) and fondaparinux (50 µg/mL) revealed a comparable effect on platelet function.
Summary/Conclusion: Based on our investigations, under therapeutic conditions platelet aggregation assays, e.g. for the monitoring of ACS, seem to remain unaffected by the investigated drugs. Although argatroban inhibits the PKA-dependent pathway and induces VASP-phosphorylation, the reduced platelet aggregation was only observed using high concentrations, whereas therapeutic concentrations had no measurable effect.

PB 3.74-5

Significantly higher level of serum amyloid A among acute coronary syndrome (ACS) than stable angina pectoris (SAP) patients in indonesian population

Puspitawati I[1], Setyawati S[2], Anggrahini DW[2], Yuantari R[2] and Sudana I[2]

[1]Clinical Pathology, Sleman; [2]Fakultas Kedokteran Universitas Gadjah Mada, Yogyakarta, Indonesia

Background: The value of Serum Amyloid A (SAA) in predicting Coronary Heart Disease was still unclear in different population and ethnics, thus, we were triggered to investigate SAA level among two spectrum of Coronary Heart Diseases; the Acute Coronary Syndrome (ACS) and the Stable Angina Pectoris (SAP) in Indonesian population.
Aims: To know the difference of SAA level between ACS and SAP patients in Indonesia.
Methods: This cross sectional study was conducted in Sardjito General Hospital, Yogyakarta, Indonesia consisted of 43 participants in Acute Coronary Syndrome group and 30 participants in Stable Angina Pectoris. All patients provided witnessed informed consent, and the study was approved by the ethics committees. The Serum Amyloid A (SAA) was measured once by quantitative sandwich enzyme immunoassay and other laboratory results was obtained from medical record. Data were analyzed using Mann-Whitney test.
Results: We found that ACS group had higher median value of SAA than SAP and healthy subjects (8.05 mg/mL, 1.39 µg/mL, respectively, $P = 0.004$). Acute Coronary Syndrome group had higher leucocyte number (10.22×10^3 cell/mL vs. 7.05×10^3 cell/mL, $P = 0.001$), and creatinine level than SAP group (1.25 mg/dL, 0.95 mg/dL respectively, $P = 0.003$). There was no difference of age, lipid profile, blood glucose level and other hematology parameter among ACS compared to SAP groups.
Conclusion: Serum Amyloid A of ACS group is higher than SAP in Indonesian population.

PB 3.74-6

Elevated plasma microparticles in chronic obstructive pulmonary disease

Kulkarni P, Yadav P, Samaria J and Dash D

Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Background: Chronic obstructive pulmonary disease (COPD), which is characterized by poorly reversible airway obstruction, is now recognized to be a systemic disorder with extrapulmonary manifestations and significant systemic comorbidity. It is an independent risk factor for cardiovascular mortality and more than 50% patients die from cardiovascular causes, particularly from coronary artery disease. Although the association between COPD and atherothrombotic risk is established, the underlying mechanisms remain unexplored.
Aim: The present study aims to explore the possibility of platelet hyperactivity underlying the increased thrombotic events in COPD.
Methods: Levels of plasma microparticles and markers specific to activated platelets were assessed in whole blood of COPD patients and age-matched controls using flow cytometry. The study was approved by the Institutional Ethics Committee and due informed consent was obtained from participants in the study.
Results: 15 cases of stable COPD patients were selected for the study along with six age-matched controls. Current smokers were excluded from either cohort. No significant differences were noted in anthropometric features, routine hematological parameters and possible confounding variables between the two groups. The severity of COPD was staged by spirometry according to GOLD guidelines and most patients (10) were found to have moderate airway disease. Level of plasma microparticles were determined by flow cytometry and found to be significantly higher in COPD patients than normal healthy controls ($P = 0.03$). However, no significant difference was observed in markers of activated platelets including P-selectin exposure, PAC-1 binding and cytosolic reactive oxygen species between the two groups.
Conclusions: Elevated level of plasma microparticles in COPD is suggestive of prothrombotic state, and can possibly be employed as marker to assess thrombotic risk. Although enhanced level of circulating microparticles underscores possibility of platelet hyperactivity, the source of these microparticles needs to be ascertained.

PB4.21 – New antiplatelet agents – II

PB 4.21-1

Different effects of antiplatelet vs. anticoagulant agents in mouse bleeding models

Vaezzadeh N, Ni R, Kim PY and Gross PL

Thrombosis and Atherosclerosis Research Institute and McMaster University, Hamilton, Canada

Background: Murine bleeding models are routinely used to investigate bleeding resulting from gene defects or administration of antithrombotic agents. Tail tip transections, which induce bleeding from venous, arterial, and microvascular sources, are most commonly used. However, alternative models, which assess bleeding in different vessels, vessel types and under different flow conditions are also used. It is not clear how such differences affect measurements of bleeding, or which methods are best suited for assessing disturbances in coagulation or platelet function.
Aims: We have used a saphenous vein bleeding model, a tail transaction model and developed a novel saphenous artery bleeding model in order to compare bleeding responses following haemostatic challenges to coagulation (unfractionated heparin [UFH]) or platelet function (intravenous infusion of an $\alpha_{IIb}\beta_3$ inhibitory antibody [Leo.H4]).
Methods: To induce bleeding from the saphenous vein, the vessel was transected, and a longitudinal incision was made along the medial surface as previously described (Buyue *et al*., (2008) *Blood* 112:3234). In the saphenous artery model, bleeding time is measured after transecting the vessel with a 27 gauge needle. Bleeding in the tail transection model was measured by blood loss over 30 min. Dose responses to intravenous infusion of UFH or Leo.H4 were derived and analyzed using GraphPad Prism assuming a sigmoidal dose response curve. Further, activated partial thromboplastin-initiated coagulation assays and impedance-based platelet aggregometry were used to characterize UFH and Leo.H4 doses, respectively.
Results: The tail, venous and arterial bleeding models were similarly sensitive in measuring bleeding after UFH infusion (EC50 = 0.07, 0.19 and 0.13 U/g, respectively). *In vitro*, an activated partial thromboplastin-initiated clotting assay showed that maximal inhibition of clotting could be achieved with doses of UFH above 0.01 U/g, which is below the EC50 values observed in all three bleeding models.
In contrast, Leo.H4 dose response curves showed that the saphenous vein bleeding model is less sensitive to $\alpha_{IIb}\beta_3$ inhibition (EC50 = 6.9 μg/mL) than either the tail transection or saphenous artery bleeding models (EC50 = 0.1 and 0.4 μg/mL respectively). A higher concentration of Leo.H4 (7.0 μg/mL) was required to inhibit ADP-induced platelet aggregation *in vitro* than to achieve EC50 in tail and arterial, but not venous bleeding models.
Summary: In conclusion, the findings suggest that coagulation is equally required for cessation of bleeding in isolated venous and arterial bleeding models, as well as in a tail tip transection model. In contrast, inhibition of platelet aggregation has a greater influence on limiting bleeding in arterial and tail bleeding models than in a venous model. In addition, *in vitro* coagulation assays are more sensitive to heparin inhibition than *in vivo* bleeding models, whereas arterial and tail bleeding models are more sensitive to $\alpha_{IIb}\beta_3$ inhibition than *in vitro* impedance-based platelet aggregometry.

PB 4.21-2

Relation between the mechanism of antiplatelet action of adenosine from *Solanum lycopersicum* and its derivate inosine

Fuentes E[1], Pereira J[2], Caballero J[1], Alarcón M[1], Pérez P[1], Astudillo L[1] and Palomo I[1]

[1]Universidad de Talca, Talca; [2]Pontificia Universidad Católica de Chile, Santiago, Chile

Background: The inhibition of the platelet function has been used in an effort to primary and secondary prevention of cardiovascular diseases. One primary prevention strategy of this type of diseases is the fruit and vegetable consumption. In this sense, in *Solanum lycopersicum* (tomatoes), it has been observed antiplatelet and antioxidant effect, among other activities. In addition, our group has recently isolated and identified adenosine from *S. lycopersicum*. Adenosine showed a potent antiplatelet activity through the inhibition of platelet adhesion, aggregation and secretion. Inosine is a naturally occurring nucleoside degraded from adenosine and studies establish that the inhibitory effect of adenosine on platelet aggregation disappears after the addition of adenosine-deaminase.
Aims: The main aim of this work is to investigate antiplatelet action mechanisms of adenosine and inosine, and explain their differential biological effects using molecular modelling (docking). As well as investigating the protective mechanisms of aqueous fraction rich in adenosine from *S. lycopersicum* on platelet function.
Methods: For platelet activation, annexin V and P-selectin expression were measured by flow cytometry. Platelet aggregation and ATP secretion were monitored by lumi-aggregometer and luciferin/luciferase reagent. Platelet adhesion and aggregation under controlled flow were performed in a BioFlux 200 flow system. Platelet cAMP levels were measured using an immunoassay kit. The adenosine/inosine docking with respect to adenosine A2A receptor was determined by homology.
To study a possible application of an aqueous fraction in high concentration of adenosine, it was evaluated in a murine thrombosis model

and platelet aggregation in humans. The protocol was approved by the Institutional Review Board of Talca University in accordance with the Declaration of Helsinki. An informed consent was signed before blood was drawn.

Results: Adenosine and inosine concentration-dependently inhibited human platelet aggregation and ATP release stimulated by ADP and collagen. Only adenosine inhibited platelet activation by annexin V ($45 \pm 5\%$, $P < 0.05$) and P-selectin expression (80 ± 3, $P < 0.05$). Moreover, adenosine and inosine reduced collagen-induced platelet adhesion and aggregated formation under controlled flow, with IC_{50} values of 0.3 mM and 0.5 mM, respectively ($P < 0.05$). At the same concentrations that adenosine inhibited platelet aggregation, significantly increased the intraplatelet cAMP levels, but not inosine.

Based in docking experiments from adenosine receptor, the main difference is that adenosine, but not inosine, forms an additional hydrogen bond between the NH_2 of the adenine group and the residues Asn253 in H6 and Glu169 in EL2 of the A2A receptor.

Aqueous fraction inhibited thrombus formation in murine model ($75 \pm 8\%$, $P < 0.05$). Moreover, 4 h after treatment, we observed a significant inhibition of platelet aggregation induced by ADP for $19 \pm 7\%$ compared to basal ($P < 0.05$) in six healthy subjects who received the aqueous fraction.

Summary/Conclusion: It is known that adenosine presents antiplatelet activity. This study allows to conclude that deamination of this molecule to inosine does not involve a loss of the described activity, but a change in mechanism. Finally, we think that aqueous fraction from *S. lycopersicum* may be used as a functional ingredient that can be included in different food matrixes.

PB 4.21-3

Pharmacokinetics, pharmacodynamics, and tolerability of LC23-1306, a novel antiplatelet agent, in healthy subjects

Chang HK[1], Shin D[2], Shin S[2], Lee H[2], Chang HK[1], Park HD[1], Jung Y[1], Song M[1], Jang IJ[2] and Yu K-S[2]

[1]LG Life Sciences, Ltd., Daejeon; [2]Seoul National University Hospital, Seoul, South-Korea

Background: LC23-1306, a reversible and active oral $P2Y_{12}$ receptor antagonist, is currently under development for the prevention of thrombotic events in patients with acute coronary diseases.

Aim: The aim of this study was to evaluate the pharmacokinetics, pharamacodynamics, and tolerability of LC23-1306 in healthy Korean subjects.

Methods: A dose-blocked, randomized, double-blind, and placebo-controlled, single ascending dose study was conducted in 60 healthy subjects, each 10 of whom received LC23-1306 at six dose levels ranging 10–600 mg or placebo in a ratio of 8:2. Blood samples were obtained for 48 h to assess the pharmacokinetics. Inhibition of platelet activity (IPA) was measured at 0 (pre-dose), 2, 8, and 24 h post-dose. The safety and tolerability were evaluated by adverse events, vital signs, ECG and clinical laboratory tests.

Results: LC23-1306 was rapidly absorbed with its median time to maximum concentration of 1.0–3.0 h. The mean terminal half-life was approximately 7.1–16.0 h, which showed an increasing tendency at higher doses. Maximum concentration and the area-under-the-concentration-time curve to the last measurable concentration increased as dose increased although it was less than dose proportional. IPA became greater as dose increased with platelet aggregation being completely inhibited at 2 h post-dose in the 100, 200, 400 and 600 mg cohorts. IPA >50% was sustained up to 24 h post-dose at doses of 200–600 mg. LC23-1306 was well-tolerated without serious adverse events. All adverse events resolved spontaneously without intervention.

Conclusions: LC23-1306 was well-tolerated after single oral administration at 10–600 mg in healthy Korean male subjects. The systemic exposure of LC23-1306 increased as dose increased. IPA was sustained effectively from 2 to 24 h in the 200–600 mg cohorts. LC23-1306 can be given once daily as an antiplatelet agent.

PB 4.21-4

Antiplatelet effect of black soybean mediated by adenosine-cAMP signaling pathway

Kim K[1], Lim KM[2], Bae O-N[3], Kang S[1] and Chung J-H[1]

[1]Seoul Natioanl University, Seoul; [2]Ehwa Womans University, Seoul; [3]Hanyang University, Ansan, South-Korea

Background: Many clinical trials have demonstrated the beneficial effects of soybean (*Glycine max*) on general cardiovascular health. Among a variety of soybeans, black soybean is known to display diverse biological activities superior to yellow or green soybeans such as in antioxidant, anti-inflammatory and anticancer activities. However, few studies have been directed on the effect of black soybean on cardiovascular function.

Aims: In this study, we aimed to investigate the effect of black soybean extract (BB) on platelet activation, a key contributor to thrombotic diseases.

Methods and Results: In the freshly isolated human platelets, BB has shown potent inhibitory activity on collagen-induced platelet aggregation while yellow soybean extract had only marginal activity. BB also attenuated serotonin secretion and P-selectin expression, important factors for the platelet-tissue interaction along with thromboxane A_2 formation. These *in vitro* results were further confirmed in ex vivo platelet aggregation measurement and *in vivo* venous thrombosis model where oral administration of BB reduced collagen-induced platelet aggregation and $FeCl_3$-induced thrombus formation significantly. A potential active ingredient for anti-platelet effects of BB was isolated and identified to be adenosine through bioassay-directed fractionation and NMR and ESI-MS analysis. These results indicate that black soybean can be a novel dietary supplement for the prevention of cardiovascular risks and the improvement of blood circulation. We further elucidated the molecular mechanism of BB-mediated antiplatelet activity and demonstrated the significant role of adenosine in BB-induced health effects. Adenosine-cAMP signaling is found to be responsible for BB-mediated effects, resulting in inhibition of collagen-stimulated platelet activation such as intraplatelet calcium increase, adhesion receptor GP IIb/IIIa expression, fibrinogen binding and further platelet adhesion/aggregation.

Conclusion: Taken together, we provide a complete understanding for molecular mechanism of BB-induced anti-platelet activity and a new insight into the role of adenosine as a bioactive compound in soybeans.

PB 4.21-5

Anopheline anti-platelet protein from a malaria vector mosquito has anti-thrombotic effects in a pulmonary thromboembolism model without compromising hemostasis

Hayashi H[1], Kyushiki H[1], Nagano K[1], Sudo T[1], Iyori M[2], Matsuoka H[3] and Yoshida S[2]

[1]Otsuka Pharmaceutical Co., Ltd., Tokushima; [2]Kanazawa University School of Pharmacy, Kanazawa; [3]Jichi Medical University, Tochigi, Japan

Background: Blood-feeding animals (e.g., mosquitoes, ticks, bats) inject saliva into hosts. The saliva has vasodilatory, anti-inflammatory and anti-thrombotic effects that facilitate smooth blood-sucking. Saliva components are considered to be attractive natural resources for drug development. We previously identified a unique anti-platelet protein, anopheline anti-platelet protein (AAPP), from the salivary gland

of female *Anopheles stephensi* (human malaria vector mosquito). AAPP specifically blocks platelet adhesion to collagen by binding directly to collagen and subsequently aggregating platelets.
Aims: To examine the potential of AAPP as a therapeutic agent, we investigated the *ex vivo* and *in vivo* anti-thrombotic effects using mice.
Methods: Effects of AAPP on whole-blood aggregation in mice were examined. AAPP was also challenged in an established model of pulmonary thromboembolism in mice. We simultaneously investigated the side-effects of the protein (prolongation of bleeding time and coagulation time). Aspirin was used as a positive control for comparison of anti-thrombotic effects.
Results: AAPP inhibits whole-blood aggregation induced by collagen at 10 mg/kg body weight. AAPP prevented pulmonary death at a lower dose (3 mg/kg) without prolongation of bleeding time compared with aspirin (100 mg/kg) that compromised hemostasis. AAPP and aspirin did not affect coagulation time. The pharmacodynamic study showed that the inhibitory effect of AAPP on whole blood aggregation decrease to 25% after 1 h from the administration.
Summary/Conclusions: These results indicate that AAPP has potential as a new anti-platelet agent with a better risk/benefit ratio than aspirin, which is the most widely used anti-platelet agent. Further study, optimization of its structure, is ongoing to improve pharmacokinetic profile.

PB 4.21-6
Interactions between vascular prostaglandins and antiplatelet agents result in profound inhibition of platelet function

White AE[1], Heptinstall S[1], Iyu D[1], Glenn JR[1] and Fox SC[2]
[1]*Nottingham University;* [2]*University of Nottingham, Nottingham, UK*

Background: It is believed that prostaglandins produced within the vasculature provide natural protection against platelet activation in man. These include the prostaglandins of the I series (especially PGI2) and of the E series (PGE1, PGE2 and PGE3). It is for this reason that high doses of aspirin, which prevent vascular prostaglandin synthesis, should be avoided.
Aims: Using antagonists selective for IP and EP receptors we have defined the receptors on platelets that mediate the effects of these four prostaglandins on platelet function. Also, we have explored the ways in which vascular prostaglandins interact with antiplatelet agents, specifically P2Y12 receptor antagonists and an EP3 antagonist, to provide enhanced inhibition of platelet function.
Methods: Platelet function was measured as platelet aggregation (platelet counting in PRP or whole blood) and P-selectin expression (flow cytometry). Intracellular VASP phosphorylation (bead assay in PRP or whole blood) was also measured. Platelet agonists were mainly U46619 and/or TRAP; receptor antagonists were CAY10441 (IP antagonist), DG-041 (EP3 antagonist) and ONO-AE3-208 (EP4 antagonist), ticagrelor, cangrelor and the active metabolite of prasugrel (P2Y12 antagonists).
Results: The overall effects of each of the prostaglandins on platelet function were inhibitory and this was accompanied by VASP phosphorylation. The inhibitory effect of PGI2 was reduced in the presence of CAY10441; that of PGE_1 was reduced in the presence of CAY10441 but not in the presence of ONO-AE3-208, demonstrating a role for IP but not EP4; in contrast the inhibitory effects of PGE_2 and PGE_3 were reduced in the presence of ONO-AE3-208 but unaffected by CAY10441, demonstrating a role for EP4 but not IP. The inhibitory effects of all prostaglandins of the E-series were enhanced in the presence of DG-041, indicating promotion of platelet function through EP3. All the P2Y12 antagonists combined with all vascular prostaglandins to provide enhanced inhibition of platelet function and in the case of the prostaglandins of the E-series there was further inhibition in the presence of the EP3 antagonist DG-041.
Conclusions: We have increased our understanding of the role of vascular prostaglandins in providing inhibition of platelet function and the ways in which they interact with existing (P2Y12 antagonists) and new (an EP3 antagonist) antiplatelet agents. The results demonstrate profound inhibition of platelet function by combinations of vascular prostaglandins and these pharmacological agents.

PB4.22 – Antiplatelet agents: miscellaneous

PB 4.22-3
A novel platelet aggregation inhibitor purified from Gloydius blomhoffii brevicaudus venom

Buyanbat A, Buyanbadrakh B, Byambasuren S, Dashnyam P and Jugder BE
Mongols Sciences Institutes, Ulaanbaatar, Mongolia

Background: Disintegrins are small, cysteine-rich proteins from various snake venoms with a high affinity to integrins which participate in platelet aggregation. Their inhibitory effect on platelet aggregation has been extensively studied and exploited in clinical interventions of many diseases including stroke and other cardiovascular disorders. *Gloydius* venom is a rich natural source of proteins possessing platelet aggregation inhibition activity.
Methods: This study presents production and purification process of a novel platelet aggregation inhibitor from *G. blomhoffii brevicaudus* snake venom and its biochemical and biological characterization. The platelet aggregation inhibitor was purified using three consecutive liquid chromatographic steps (*Blue sepharose, Q-sepharose* and *Superdex-200*). The purity and molecular weight were determined by SDS-PAGE, 2-D electrophoresis and MALDI-TOF mass spectrometry. The inhibitory activity on collagen- and ADP-induced platelet aggregation was examined in the platelet-rich rabbit plasma using the AP2110 'SOLAR' aggregometer. Proteolytic enzymatic and phospholipase activities were investigated by chromogenic (S-2251 and S-2238) and fluorogenic substrates (PED6), respectively.
Results: A single chain protein with molecular weight of 12 kDa and pI of 8.0 was purified with approximate purity of 99%. A dose-dependent activity curve analysis shows that the platelet aggregation inhibitory activity in the rabbit platelet-rich plasma was $ID_{50} = 3.26 \times 10^{-6}$ g or 542×10^{-9} M and no proteolytic activity detected.
Conclusion: In the present study, the purification process of the novel 12 kDa-protein with inhibitory activity on collagen- and ADP-induced platelet aggregation from the venom of the snake *G. blomhoffii brevicaudus* has been developed. The fact that no enzymatic activity found on chromogenic and fluorogenic substrates may indicate that our purified protein is potentially a new low molecular weight platelet aggregation inhibitor that inhibits a platelet aggregation receptor. Future work to investigate further structural and functional properties is required.

PB 4.22-4

Vipera lebetina (snake) venom components affecting hemostasis

Siigur E, Trummal K, Tõnismägi K, Aaspõllu A, Samel M, Vija H and Siigur J

National Institute of Chemical Physics and Biophysics, Tallinn, Estonia

Background: *Vipera lebetina* venom is a complex mixture of biologically active components including coagulants and anticoagulants. Factor X and Factor V activating enzymes (procoagulants), lebetase (fibrinolytic and antiplatelet), L-amino acid oxidase, disintegrin viplebedin, phospholipase A_2 (antiplatelet), etc. have been isolated and characterized in our laboratory. Nucleases are ubiquitously represented in snake venoms but, especially 5'-nucleotidase, poorly specified.

Aims: The aim of this study is to extend the antiplatelet spectrum of *V. lebetina* venom via isolation and characterization of phosphodiesterase (PDE) and 5'-nucleotidase as potential antiplatelet agents, and cloning and sequencing corresponding cDNAs.

Methods: PDE and 5'-nucleotidase have been isolated by gel filtration (Sephadex G-100 sf) and ion exchange chromatography (CM52 cellulose and TSK-DEAE). The enzymatic activity of 5'-nucleotidase is determined with 5′-AMP as substrate. PDE is localised by hydrolysis of Na-bis(p-nitrophenyl)phosphate. Platelet aggregation is performed in PRP in a Chrono-Log aggregometer. Cloning and sequencing have been performed by standard procedures.

Results: *V. lebetina* venom PDE has been purified by gel filtration and CM52 cellulose chromatography, for purification of 5'-nucleotidase three-step procedure has been used including gel filtration, cation and anion exchange chromatography. PDE has molecular mass ca 120 kDa and 5′-nucleotidase ca 60 kDa (monomeric). Protein sequence translated from the PDE-encoding cDNA comprises 828 amino acids including eight potential glycosylation sites. The cDNA encoding 5'-nucleotidase is 5'-truncated and the translated protein sequence (406 amino acids) lacks about 160 amino acids from the N-terminus. Platelet aggregation studies with 5'-nucleotidase exhibited unfortunately no change in either ADP- or collagen-induced aggregation. Probably the enzyme preparation contains some unidentified impurities affecting platelets.

Conclusions: We have isolated and structurally characterized two potential antiplatelet components from *V. lebetina* venom. Their biological properties are under investigation.

PB 4.22-5

Sodium tungstate as a potential antiplatelet agent

Diaz-Ricart M[1], Fernández R[2], Pino M[1], Caballo C[1], Escolar G[1] and Gomis R[2]

[1]Department of Hemotherapy-Hemostais. Hospital Clinic, CDB, IDIBAPS; [2]Department of Endocrinology. Hospital Clinic, IDIBAPS, Barcelona, Spain

Background: Platelet inhibition is a key strategy for management of atherothrombotic complications. Cyclooxigenase-2 and the ADP receptors are currently the more widely used antiplatelet targets. However, the existence of large inter-individual response variability to both strategies, has led to the search for alternative inhibitors.

Aims: We have investigated the antiplatelet effect of the inorganic salt sodium tungstate, with potential effect on phosphotyrosine (PTP) 1B, with proven anti-obesity actions.

Methods: Wild-type and knockout mice for the phosphotyrosine phosphatase-1B (PTP1B), on a C57BL/6Jx129/svJ mixed genetic background, were untreated or treated for a week with sodium tungstate, at a concentration of 2 g/L in water intake, to study platelet function under flow with the PFA-100, acone plate analyzer (CPA), and a flat perfusion chamber using collagen coated surfaces. In addition, aliquots of human whole blood were incubated with sodium tungstate (from 100 to 400 μM, for 1 h at 37 °C) to evaluate its effect on platelet function using the platelet function analyzer (PFA-100) and the annular perfusion chamber. Aggregometry, with platelet rich plasma, and thromboelastometry, with whole blood, were also performed with the lowest more effective concentration.

Results: In studies in mice, treatment with sodium tungstate prolonged closure time in the PFA-100 using the Col/ADP cartridge (from 148 ± 17.4 s to 272.8 ± 12.4 s, $P < 0.01$), and decreased the surface covered by platelets (%SC) on a collagen surface exposed to flowing blood (45.5 ± 5.4% to 30.7 ± 1.3%). Results in the presence of sodium tungstate were similar to those obtained in KO mice in the absence of the salt. In studies with human blood, closure times in the PFA-100 were significantly prolonged in the Col/Epi cartridge (from 141 ± 6.6 s in controls to 193 ± 23.3 s; $P < 0.05$). In adhesion studies on denuded vascular segments, the%SC and the thrombus formation (%T) decreased in the presence of sodium tungstate (from 32.9 ± 1.4% in controls to 17.9 ± 3.2%, $P < 0.005$; and from 62.9 ± % in controls to 31.6 ± 5.0, $P < 0.002$, respectively). In contrast, neither the maximal aggregating response nor the thromboelastography properties of clots were affected by the presence of the tugstate salt.

Conclusion: Presence of sodium tungstate in blood decreases the hemostatic capacity of platelets by inhibiting their adhesive and cohesive properties under flow conditions in both a mice model and in human blood. Therefore, sodium tungstate exhibits a potential antiplatelet effect. Although it may be acting on platelet PTP-1B, the precise mechanisms through which sodium tungstate exerts its action should be further explored.

PB 4.22-6

Aspirin induces platelet apoptosis

Dai K, Zhao L, Zhang W, Chen M, Zhang J, Zhang M and Ruan C

Jiangsu Institute of Hematology, Suzhou, China

Background: Aspirin is widely used in the treatment of a number of clinical conditions, such as fever, pain, strokes, and heartattacks. Although aspirin is being thought of a relatively 'safety' medicine, it also has some side effects, particularly the risk of bleeding which may be severe and lead to death. The mechanisms, however, are not totally understood. The effectiveness of aspirin has been attributed to its ability to inhibit prostaglandin production by inhibiting the cyclooxygenase (COX) enzyme. Interestingly, it has been reported recently that aspirin induces apoptosis in many cell types. Platelet apoptosis induced by either physical or chemical compounds or platelet storage occurs widely. We have reported that the glycoprotein Ibα-von Willebrand factor interaction, hyperthermia, and calmodulin antagonists induce platelet apoptosis, suggesting that platelet apoptosis might play important roles in controlling the number and function of circulated platelet under physiological conditions, or in the development of platelet-related hemorrhagic diseases.

Aims: Thus, the aim of the current study is to explore whether aspirin induces platelet apoptosis.

Methods: Washed platelets (3×10^8 /mL) were incubated with various concentrations of aspirin (2.5 mM, 5 mM, 10 mM, 20 mM) at 37 °C for 2 h. The effect of aspirin on platelet mitochondrial membrane potential ($\Delta\Psi m$) depolarization and phosphatidylserine (PS) exposure were analyzed by cell-permeable lipophilic cationic dye tetramethylrhodamine ethylester (TMRE) and annexin V binding, respectively.

Results: The data show that $\Delta\Psi ms$ depolarization and PS exposures were dose-dependently induced by aspirin in platelets. In order to further confirm that aspirin incurs platelet apoptosis, caspase-3 activation was measured in platelets incubated with aspirin by detecting 32 kD pro-caspase-3 and 17 kD cleaved caspase-3 fragment, and the result shows that aspirin induced caspase-3 activation. Furthermore, platelet shrinkage appeared in platelets incubated with aspirin (20 mM). Caspase inhibitor z-VAD-fmk inhibited apoptotic platelet shrinkage, and

blocked ΔΨm depolarization, but had no effect on PS exposure, suggesting that caspase-3 acts upstream of ΔΨm depolarization, and plays a key role in aspirin-induced platelet apoptosis. Whereas, protein kinase C (PKC), protein kinase B (PKB), p38 mitogen-activated protein kinases (MAPK), protein 53 (p53), reactive oxygen species (ROS), and mitogen-activated protein kinase kinase (MAPKK) were not involved in aspirin-induced platelet apoptosis. In addition, platelets incubated with another COX inhibitor indomethacin did not incur ΔΨm depolarazation and PS exposure in platelets.
Conclusion: Taken together, the data indicate that aspirin induces platelet apoptosis via caspase-3 activation, and independent of the COX signaling.

The role of platelet actin polymerization and agonist-induced cortactin tyrosine phosphorylation in aIIbβ3 expression, activation, cytoskeleton association and fibrinogen binding

Budnik I[1], Shenkman B[2] and Savion N[1]
[1]Tel Aviv University, Tel Aviv; [2]Sheba Medical Center, Tel-Hashomer, Israel

Background: Inhibition of actin polymerization undermines stability of platelet aggregates and reduces cortactin tyrosine phosphorylation.
Aim: To investigate the role of actin polymerization and cortactin tyrosine phosphorylation in the regulation of αIIbβ3 cell surface expression and activation, actin cytoskeleton association and ligand (fibrinogen) binding in aggregating platelets.
Methods: Blood samples were obtained from adult healthy volunteers who signed an informed consent form (approved by the Sheba Medical Center ethics committee). Platelet-rich plasma (PRP) platelets were pretreated with 10 μM cytochalasin D (CytD) or DMSO vehicle (control) for 5 min and stimulated by 10 μM ADP or pervanadate (1 mM H_2O_2 + 1 mM sodium orthovanadate); aggregation was monitored at 37 °C under stirring. Affinity of αIIbβ3-fibrinogen interaction was evaluated by rate of platelet disaggregation following addition of 4.5 μM eptifibatide. To analyze cytoskeleton composition, PRP samples were lyzed with Triton X-100 lysis buffer, and the insoluble fraction was sedimented and subjected to SDS-PAGE followed by western blot analysis using mAbs against αIIb, pY^{466}-cortactin, cortactin and β-actin. Flow cytometry was performed on 50-fold diluted PRP samples using P2 and PAC-1 mAbs indicating the expression and the activation level of αIIbβ3, respectively.
Results: Stimulation of control platelets by ADP resulted in maximal platelet aggregation (77.6 ± 5.3%). CytD had no effect on the extent of platelet aggregation. Eptifibatide added 3 min after the addition of ADP did not change the course of platelet aggregation in control samples but caused disaggregation at a rate of 51.7 ± 10.2%/min in CytD-pretreated samples. Aggregation of control platelets was accompanied by actin polymerization, association of αIIb and cortactin with cytoskeleton and cortactin tyrosine phosphorylation. CytD-pretreated platelets demonstrated partial reduction (by 17.9%) in actin polymerization and absence of cortactin tyrosine phosphorylation while cytoskeleton association of αIIb and cortactin was not affected. In order to explore the role of cortactin tyrosine phosphorylation in αIIbβ3-fibrinogen affinity, CytD-pretreated platelets were stimulated by pervanadate, a phosphatase inhibitor. Pervanadate completely overcame the inhibitory effect of CytD on cortactin tyrosine phosphorylation and induced maximal platelet aggregation (83.4 ± 6.8%) but did not overcome the decrease in αIIbβ3-fibrinogen affinity. Pretreatment of resting platelets with CytD did not significantly change the basal levels of P2 and PAC-1 binding. However, ADP stimulation of both control and CytD-pretreated samples, increased the level of P2 binding by 30.5% and 34.2% ($P < 0.001$ for both), respectively, and increased the level of PAC-1 binding by 7.2-fold ($P < 0.001$) and 3.3-fold ($P < 0.05$), respectively.
Conclusions: Inhibition of actin polymerization by CytD in activated platelets results in: (i) cortactin-actin association without cortactin tyrosine phosphorylation; (ii) αIIbβ3-actin association and increased αIIbβ3 expression; and (iii) reduction of αIIbβ3 conformational activation concomitantly with reduction of αIIbβ3-fibrinogen affinity. Thus, platelet αIIbβ3 expression, activation and fibrinogen binding (at low affinity) are not dependent on actin polymerization or cortactin tyrosine phosphorylation; however, stable aggregate formation (high αIIbβ3-fibrinogen affinity) is highly dependent on actin polymerization.

PB 4.23-2

Fibronectin unfolding and assembly: the dual role of fibronectin in platelet adhesion and aggregation

Huynh KC, Stoldt VR and Scharf RE
Heinrich Heine University Medical Center, Düsseldorf, Düsseldorf, Germany

Background: Fibronectin (FN) has been shown to decrease platelet aggregation but enhance platelet adhesion, suggesting a dual role in hemostasis. To explore the suggested dual role of FN in further detail, we tested for differences of adherent platelet and suspended platelets with regard to their effect to unfold and assemble FN upon interaction.
Methods: Isolated human plasma FN was dually labeled with alexa fluor (AF) 488 and 546 for fluorescence resonance energy transfer (FRET) analysis. Ten μg/mL of FN mixture (unlabled FN: labeled FN, ratio 10:1) was incubated with platelets in suspension (10^6/mL) or platelets (10^8/mL) spead onto immobilized FN (50 μg/mL) in HEPES Tyrode buffer supplemented with 2 mM $CaCl_2$ and 40 nM PMA. FRET signals were recorded after 0–3 h of incubation to access the unfolding of FN on platelets from both preparations. For deoxycholate (DOC) solubility assay, platelets in suspension or FN-adherent platelets were incubated with 60 μg/mL AF488 conjugated FN (FN488) in the absence or presence of agonists (10 μM ADP or 40 nM PMA). Samples of both settings were washed with 2% DOC for 2 min. Microscopic analyses were performed before and after washing with 2% DOC.
Results: Labeled FN was exposed to increasing concentrations of GdnHCl (0–4 M) to evaluate the sensitivity of FRET indicative of the unfolding of FN. FRET signals of FN in its compact conformation (0 M GdnHCl) was set at 100% and decreased to 64%, as the FN molecule extended in 1 M GdnHCl solution. Further unfolding of FN at 2 M, 3 M, and 4 M concentrations of GdnHCl reduced FRET signals to 50%, 44%, and 40%, respectively. FRET signals decreased in a time-dependent manner by 4 ± 1.3% (mean ± SD) at 1 h, 5 ± 1.5% at 2 h, and 6 ± 1.1% at 3 h, when labeled FN was incubated with adherent platelets. In contrast, there was no significant decrease in FRET signals of labeled FN alone. The same observation was made in experiments with platelets in suspension. These data demonstrated that adherent platelets but not platelets in suspension were capable of unfolding FN during incubation. Fluorescence microscopic analyses revealed that after 3 h of incubation, bound FN488 formed a DOC-insoluble fibrillar matrix at the periphery of adherent platelets. The fibril formation of FN488 was enhanced on adherent platelets upon addition of ADP or PMA. In contrast, FN488 bound to activated platelets in suspension remained extractable by 2% DOC indicative of absent fibril formation.
Conclusions: Using fluorescence techniques and a DOC solubility assay, we demonstrated that adherent platelets can progressively unfold and assemble FN forming fibrils during incubation, whereas suspended platelets do not. This observation may help explain the dual role of FN in platelet adhesion and aggregation.

PB 4.23-3

FcgammaRII mediates the intrinsic platelet activation of disintegrin, probed by alphaIIbbeta3-specific monoclonal antibodies

Huang TF and Hsu CC

Graduate Institute of Pharmacology, National Taiwan University, Taipei, Taiwan

Thrombocytopenia, a common side effect of RGD-mimetic antiplatelet drugs, is thought to be caused by drug-dependent antibodies that recognize platelet conformation-altered alphaIIbbeta3. We investigated the possible mechanisms of intrinsic platelet activation of disintegrin in combination of alphaIIbbeta3-specific mAbs. Disintegrin (e.g. rhodostomin) and monoclonal antibody raised against integrin alphaIIbbeta3 (e.g. AP2 and 10E5) individually inhibited human platelet aggregation caused by collagen. However, when disintegrin (rhodostomin) and monoclonal antibody (AP2 or 10E5) were sequentially added into platelet suspension, platelet aggregation occurred, whereas other monoclonal antibodies (7E3 and AP5) did not induce platelet aggregation in the presence of disintegrin. 7E3 inhibited disintegrin/AP2 or 10E5-induced platelet aggregation, but AP5 inhibited only disintegrin/10E5 (not AP2)-induced platelet aggregation. In the flowcytometry assay, we also found that disintegrin enhanced AP2, AP5 and 10E5, but not 7E3, binding to platelets. FcgammaRII mAb attenuated disintegrin/AP2 or 10E5-induced platelet aggregation, and also inhibited the enhanced binding of AP2 to platelet caused by disintegrin. Immunoprecipitation of the lysates of rhodostomin/AP2-treated platelets using FcgammaRII Ab showed the complex formation of integrin beta3 and FcgammaRII. These results suggest that AP2 or 10E5 triggers platelet aggregation via binding to accessible FcgammaRII and the conformation-altered integrin alphaIIbbeta3 caused by disintegrin. FcgammaRII recuitment and the complex formation of integrin beta3/FcgammaRII mediate the intrinsic platelet activation of disintegrin.

PB 4.23-4

Platelet integrin aIIbβ3 (IIb-IIIa) and cytoskeleton modulate fibrin network formation and clot stiffness

Wang C, Perez MJ, Helmke BP and Lawrence MB

University of Virginia, Charlottesville, VA, USA

Background: The ability to clot *in vivo*, either inappropriately as in thrombosis, or insufficiently as in surgical bleeding, is fundamentally linked to the blood clot's mechanical stiffness, or lack there-of. While the active role of platelets in clot mechanics is well accepted, their role in organizing fibrin fibers and regulating their growth is less well understood. Platelets associate with fibrin through the platelet integrin $\alpha_{IIb}\beta_3$ (IIb-IIIa), initiating a pathway of $\alpha_{IIb}\beta_3$-associated tyrosine kinases that transmits signals to the cytoskeleton. After $\alpha_{IIb}\beta_3$ binds to fibrin, the integrin and ligand move selectively into integrin clusters, a process that could lead to changes in extracellular fibrin organization and likely requires modulation of cytoskeletal attachment of $\alpha_{IIb}\beta_3$.
Aims: Our work explores possible downstream effects of $\alpha_{IIb}\beta_3$ cytoskeletal signaling on fibrin fiber organization and clot stiffness. We hypothesize that changes in $\alpha_{IIb}\beta_3$ cytoskeletal signaling may organize extracellular fibrin network, which may affect overall clot stiffness.
Methods: Using a novel *in vitro* model of blood plasma clotting, fibrin-platelet interactions were visualized by DIC and fluorescence microscopy. Tracer particles were also added to measure stiffness by microrheological methods. The motion of the particles was tracked with a particle tracking program implemented in Image J.
Results: In this study, we observed a strong dependence of fibrin macro-fiber formation (300 nm and greater) on fibrin's active engagement with platelet $\alpha_{IIb}\beta_3$ integrin and on platelet actin cytoskeletal polymerization. Platelet concentration was strongly correlated with greater local fibrin macro-fiber formation, where a 2-fold greater local platelet concentration lead to 10× greater fibrin macro-fiber density. The correlation of platelet concentration with fibrin macro-fiber formation agreed with findings of a previous study by Collet et al 2002 and supports the hypothesis that the action of platelets influences the extracellular organization of the blood clot. Diffusivity of 300 nm particles within platelet rich plasma 45 min after clot initiation was significantly reduced in regions of high fibrin density (100 $\mu m^2/s$) relative to regions without visible fibrin (14,000 $\mu m^2/s$). Direct visualization by DIC indicated a striking correlation of clot stiffness and the appearance of fibrin macro-fibers. Abciximab (platelet integrin $\alpha_{IIb}\beta_3$ inhibitor) reduced fibrin macro-fibers in a dose-dependent manner. Similar reductions in fibrin macro-fiber formation were induced by treatment of platelets with cytochalasin D, an inhibitor of cortical actin polymerization.
Conclusions: The observations of the study support the hypothesis that fibrin macro-fiber formation correlates with clot stiffness and that the platelet integrin $\alpha_{IIb}\beta_3$ cytoskeletal signaling regulates fibrin network structure. A deeper understanding of the relationship between stiffness and platelet and fibrin interactions may lead to the evaluation of new anti-platelet drugs that might better navigate the balance between thrombosis and surgical bleeding.

PB 4.23-5

The potencies and mechanisms by which engineered nanoparticles induce platelet aggregation are dependent upon their precise physicochemistry

Smyth E[1], Solomon A[1], Vydyanath A[1], Luther P[1], Pitchford S[2], Tetley TD[1] and Emerson M[1]

[1]Imperial College London; [2]King's College London, London, UK

Background: The emergence of nanotechnology has led to increased human exposure to engineered nanoscale structures (diameter ≤100 nm) through drug delivery systems, commercial products etc. Epidemiological and clinical work indicates that particulate matter present in air pollution is associated with increased incidence and risk of thrombotic events such as myocardial infarction and stroke. It is suggested that the nanoparticle fraction of this particulate matter may be responsible for some of the increased risk associated with ambient pollution. There is also evidence that nanoparticles can translocate the pulmonary epithelium and enter the systemic circulation. Platelet aggregation and activation underlies many thrombotic events, however there is limited information regarding the ability of engineered nanoparticles to directly influence platelet behaviour.
Aims: The primary aim was to investigate whether model engineered nanoparticles can interact with and functionally modulate platelets. The secondary aim was to assess whether this modulation is affected by particle size and surface chemistry by using 50 nm and 100 nm carboxyl, amine and unmodified model engineered polystyrene nanoparticles.
Methods: Optical aggregometry was used to assess function of platelets *in vitro*. An established murine model of platelet aggregation involving detection of radiolabelled platelets in the pulmonary circulation was employed to measure platelet function *in vivo*. Platelet activation was assessed by measuring P-selectin expression by flow cytometry.
Results: All nanoparticles tested induced concentration-dependent platelet aggregation, however carboxyl 50 nm and unmodified 100 nm particles were the most potent. All nanoparticle-induced aggregation, except for that induced by amine 50 nm particles, was inhibited by the nitric oxide donor sodium nitroprusside and the glycoprotein IIb/IIIa inhibitor eptifibatide. The ability of nanoparticles to induce concentration-dependent P-selectin surface expression reflected their ability to induce aggregation. Amine-modified 50 nm particles enhanced thrombin induced aggregation *in vitro* and this enhanced response was abolished by eptifibatide. Systemic infusion of a low concentration of amine 50 nm particles increased collagen- and thrombin-induced aggregation *in vivo*.

Summary/Conclusions: All nanoparticles investigated induced platelet aggregation with potencies and mechanisms that were dependent upon a distinct combination of size and surface chemistry. Anionic and uncharged particles induced GPIIb/IIIa-mediated platelet aggregation and signalling events similar to those occurring upon exposure to conventional platelet agonists. The sensitivity of nanoparticle-induced aggregation to the endogenous vascular regulator nitric oxide suggests a physiological protective mechanism mediated by the vascular endothelium that may reduce the cardiovascular impact of nanoparticle exposure in healthy individuals. In contrast, the ability of 50 nm cationic particles to enhance the effects of platelet agonists at low concentrations that more likely reflect potential nanoparticle exposure in humans suggest that these particles may present the largest risk to human health by either initiating or exacerbating thrombotic events. This work provides a potential mechanism by which nanoparticles with particular physicochemical properties could pose a thrombotic risk should they enter the blood either by translocating the lung or following direct introduction to the body during medical procedures.

PB 4.23-6

Role of heterotrimeric G proteins in regulation of aIIbβ3 fibrinogen affinity and aIIbβ3 cytoskeleton association

Budnik I[1], Shenkman B[2] and Savion N[1]

[1]Tel Aviv University, Tel Aviv; [2]Sheba Medical Center, Tel-Hashomer, Israel

Background: Upon platelet stimulation, integrin αIIbβ3 undergoes conformational change leading to fibrinogen binding on one end and to association with the cytoskeleton on the other end.
Aim: To investigate the role of heterotrimeric G proteins in regulation of αIIbβ3-fibrinogen interaction and αIIbβ3-cytoskeleton association in aggregating platelets.
Methods: Blood samples were obtained from adult healthy volunteers who signed an informed consent form (approved by the Sheba Medical Center ethics committee). Sole and combined activation of Gαq, Gαi and/or Gα12/13 proteins was achieved by using different combinations of the following platelet agonists and inhibitors: 10 μM ADP, 1.5 mM arachidonic acid (AA), 0.1 μM U46619 (stable thromboxane A_2 analogue), 10 μM AR-C66096 ($P2Y_{12}$ inhibitor), 10 μM MRS2500 ($P2Y_1$ inhibitor) and 0.5 mM acetylsalicylic acid (ASA; thromboxane A_2 synthesis inhibitor). Platelet aggregation was performed at 37 °C with stirring. Affinity of αIIbβ3-fibrinogen interaction was evaluated by rate of platelet disaggregation following addition of 4.5 μM eptifibatide 3 min after the agonist addition. Cytoskeleton composition (Triton X-100-insoluble fraction) was analyzed by western blot using anti-αIIb and anti-β-actin mAbs.
Results: (i) Combined stimulation of Gαq, Gαi and Gα12/13 (by ADP) leads to: maximal platelet aggregation (83.1%); maximal αIIbβ3-fibrinogen affinity – no platelet disaggregation upon eptifibatide addition; actin polymerization and maximal αIIb-cytoskeleton association. (ii) Combined stimulation of Gαq and Gα12/13 (by AA + ADP + AR-C66096) leads to: maximal platelet aggregation (87.2%); partial αIIbβ3-fibrinogen affinity (disaggregation rate, 13.2%/min); actin polymerization and marked αIIb cytoskeleton association (81.2%). (iii) Combined stimulation of Gαq and Gαi (by ADP + ASA) leads to: submaximal platelet aggregation (69.0%); decreased αIIbβ3-fibrinogen affinity (disaggregation rate, 21.6%/min); actin polymerization and mild αIIb cytoskeleton association (61.5%). (iv) Combined stimulation of Gαi and Gα12/13 (by ADP + U46619 + MRS2500 + ASA) leads to: decreased platelet aggregation (54.7%); much lower αIIbβ3-fibrinogen affinity (disaggregation rate, 62.0%/min); actin polymerization and decreased αIIb cytoskeleton association (45.3%). (v) Sole stimulation of Gαi (by ADP + MRS2500 + ASA) leads to: low-amplitude but sustained platelet aggregation (41.4%); low αIIbβ3-fibrinogen affinity (disaggregation rate, 118.5%/min); actin polymerization without αIIb cytoskeleton association. (vi) Sole stimulation of Gαq (by ADP + AR-C66096) leads to: low-amplitude and spontaneously reversible platelet aggregation; actin polymerization without αIIb-cytoskeleton association. (vii) Sole stimulation of Gα12/13 (by U46619 + ASA) leads to: no platelet aggregation but induced actin polymerization without αIIb-cytoskeleton association.
Summary: Affinity of αIIbβ3-fibrinogen binding increases in parallel to the aggregation amplitude; maximal affinity requires activation of all three G proteins. Interaction of αIIbβ3 with cytoskeleton requires activation of at least two of the G proteins and maximal affinity requires activation of all three G proteins. Sole activation of each of the G proteins is sufficient for actin polymerization. The order of contribution to platelet aggregation of combined and sole G protein activation is: Gαq/Gαi/Gα12/13 > Gαq/Gα12/13 > Gαq/Gαi > Gαi/Gα12/13 >G αi > Gαq > Gα12/13.

PB4.24 – New platelet agonists

PB 4.24-1

The endothelial cell surface enzyme, NPP-4 stimulates platelet aggregation via hydrolysis of diadenosine triphosphate to ADP and partially overcomes aspirin-mediated platelet inhibition

Ornstein L[1], Albright AR[2], Chang WC[2], Robert DM[1], Cao W[2], De La Cruz EM[2] and Braddock DT[2]

[1]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [2]Yale University, New Haven, CT, USA

Background: Platelet dense granules contain diadenosine triphosphate (Ap3A), which is released into the extracellular space during the secondary wave of platelet aggregation after platelet activation by ADP and other agonists. Ap3A has long been thought to stimulate platelet aggregation after release into the extracellular space by providing a prolonged source of ADP via hydrolysis by a slow extracellular enzyme present in human plasma. We have previously identified that enzyme as NPP-4, a member of the nucleotide pyrophosphatase/phosphodiesterase enzyme family and have shown that it is present on endothelial cell and monocyte surfaces. NPP-4 is a potent hydrolase of Ap3A capable of stimulating platelet aggregation and secretion at nanomolar concentrations via platelet ADP receptors. The aim of the current study was to determine whether NPP4, at physiologic concentrations, is capable of overcoming aspirin-mediated platelet inhibition.
Methods: We performed platelet aggregometry with citrated platelet-rich plasma (PRP) that was pre-incubated with 100 μM aspirin (ASA) or vehicle in the presence of increasing concentrations of NPP-4. Arachidonic acid (AA), ADP, Ap3A and U46619 were used as agonists to stimulate platelet aggregation. To determine whether certain NPP-4-mediated aggregation phenomena could be attributed to ADP-mediated pathways, experiments were conducted in the presence or absence of the ADP receptor antagonists MRS 2179 and MRS 2395 which block the P2Y1 and P2Y12 receptors, respectively, on platelet cell surfaces.
Results: As expected, 100 μM ASA completely inhibited platelet aggregation in response to AA and Ap3A, while it had no effect on aggregation with U46619 and resulted in attenuated aggregation with ADP compared to the ASA-free state. Addition of NPP-4 to ASA-treated PRP resulted in no improvement in either AA or U46619-stimulated aggregation, but led to an increase in aggregation amplitude in response to both ADP and Ap3A. These increases were prevented by pre-incubation of PRP with MRS 2179 and/or MRS 2395. These findings confirm an effect of ASA on ADP-mediated platelet activation pathways and suggest that NPP-4 may play a role in overcoming platelet inhibition by ASA via ADP-mediated pathways.
Conclusions: The results of these studies suggest that NPP-4 functions in hemostasis *in vivo* by augmenting platelet aggregation and release of granule contents at the site of vascular injury via ADP-mediated pathways. The ability of NPP-4 to partially overcome ASA-associated

platelet inhibition via ADP-mediated pathways suggests that NPP-4 may play a role in ASA resistance and be a target for development of novel antiplatelet therapies for use as adjuncts to currently available drugs that target the platelet directly.

PB 4.24-2

Histone deacetylase 6 (HDAC6)-mediated deacetylation of a-tubulin coordinates cytoskeletal and signaling events of platelet activation

Aslan JEJ, Phillips KG, Pang J and McCarty OJT
Oregon Health & Science University, Portland, OR, USA

Background: The tubulin cytoskeleton plays a key role in maintaining the characteristic quiescent discoid shape of resting platelets. Upon activation, platelets undergo a dramatic change in shape to mediate thrombus formation; however, little is know how the microtubule system contributes to regulating platelet shape and function.
Aims: Here we investigate the role of the covalent modification of a-tubulin by acetylation in the regulation of platelet physiology in resting and activated conditions.
Results: Super resolution microscopy analysis of the platelet tubulin cytoskeleton shows the marginal band together with an interconnected web of finer tubulin structures that collapse upon platelet activation with the GPVI-agonist, collagen related peptide (CRP). Western blot analysis reveals that a-tubulin is acetylated in resting platelets and deacetylated following a time course of platelet activation. Tubacin, a specific inhibitor of the tubulin deacetylase HDAC6, prevents tubulin deacetylation upon platelet activation with CRP. Super resolution fluorescence microscopy shows that inhibition of HDAC6 upregulates tubulin acetylation and disrupts the organization of the platelet microtubule marginal band. HDAC6 inhibitors also inhibit platelet aggregation in response to CRP and block platelet signaling events upstream of platelet Rho GTPase activation.
Conclusions: Together these findings demonstrate that acetylation signaling controls the resting structure of the platelet tubulin marginal band and has roles in organizing signaling systems that drive platelet aggregation and function.

PB 4.24-3

Phosphorothioate oligodeoxynucleotides are potent platelet activators acting toll-like receptor 9 independently

Flierl U, Yao J, Bassler N and Peter K
Baker IDI, Melbourne, Australia

Background: The use of synthetic oligodeoxynucleotides (ODN) which function as immunotherapeutic agents has become common clinical practice in the treatment of some diseases. These ODNs contain unmethylated CpG motifs and function as toll-like receptor 9 (TLR9) agonists. There are three classes of ODNs (A-C) showing differences in structure and phenotype. Class C ODNs bear a phosphorothioate backbone and a CpG containing motif which is present in a manifold greater frequency in bacterial compared to mammalian DNA. The impact of ODNs on immune cells (e.g. lymphocytes) triggering innate and adaptive immunity is quite well investigated. However, little is known about the effect of ODNs on platelets.
Aims: Investigation of the impact of class C ODN 2395 which shares homologies with bacterial DNA on platelet activation.
Methods: Human platelets (washed platelets and PRP) were incubated with the class C ODN 2395 in different modifications and concentrations (0.5 μM/1.0 μM). Platelet activation was evaluated by flow cytometry (CD62P, PAC-1 binding) and light-transmittance aggregometry. The impact of TLR9 on activation was determined by ODN pre-incubation of wild-type (WT) and TLR9$^{-/-}$ mouse platelets. Moreover, C57BL6 mice were injected with class C ODN 2395 and then subjected to ferric chloride carotid artery injury.
Results: Platelets showed significantly increased activation following pre-incubation with class C ODN 2395 (MFI PAC-1 binding: unstimulated: 5.1 ± 0.9, 0.5 μM ODN: 238.4 ± 27.3, $P < 0.01$; MFI CD62P expression: unstimulated: 7.7 ± 0.9, 0.5 μM ODN: 429.9 ± 61.5, $P < 0.01$). However, platelet stimulation with the non-phosphorothioate modified ODN 2395 did not result in increased platelet activation. TLR9 independency was observed as there was no significant difference in the extent of platelet activation between WT and TLR9$^{-/-}$ mouse platelets after stimulation with ODN 2395. Furthermore, C57BL6 mice showed a significantly shortened occlusion time after ODN injection compared to placebo treated mice following ferric chloride carotid artery injury (ODN: 267.8 ± 40 s, placebo: 606.5 ± 45 s, $P < 0.01$).
Conclusion: Phosphorothioate ODNs are potent platelet activators. As some pathogenic bacteria share homologies with ODNs which have a phosphorothioate backbone, this could constitute an additional mechanism for platelet activation in bacteremia.

PB 4.24-4

High resolution structure determination and small molecule inhibitor identification of NPP4, a procoagulant enzyme localized to brain vascular endothelium

Braddock DT[1], Albright AR[1], Chang WC[1], Ornstein C[2], Robert DM[2], Cao W[1] and De La Cruz EM[1]
[1]Yale University, New Haven, CT; [2]Dartmouth Medical School, Hanover, NH, USA

Background: We recently identified the enzyme NPP4, an uncharacterized member of the nucleotide pyrophosphatase/phosphodiesterase family, as present at high concentrations on the vascular surface of the brain, and that NPP4 promotes platelet aggregation in a dose dependent manner at physiologic concentrations of AP3A. AP3A is a small molecule stored at high concentrations in platelet dense core granules and is released upon platelet activation at high concentrations in the vicinity of the growing thrombus. Ap3A has a significantly longer lifespan in whole blood than ADP and has long been thought to promote stable thrombus formation by serving as a 'chemically masked' source of ADP. NPP4 functions upstream of the endovascular enzymes CD39 and CD73 in the metabolism adenine nucleotide phosphates, and collectively the three enzymes sequentially metabolize AP3A into ADP, Adenosine, and inorganic Phosphate. The goal of the present study was threefold: 1. To examine other sites of hemostasis for the presence of NPP4, 2. To determine the high-resolution structure of NPP4, and 3. To identify small molecule inhibitors of NPP4 useful for the *in vitro* and *in vivo* validation of the physiologic role of the enzyme.
Methods: We used flow cytometry to examine circulating hematopoietic cells for the presence of NPP4, X-ray crystallography to determine the high-resolution structure of the enzyme, and high-throughput small molecule screening to identify lead small molecules as lead inhibitors.
Results: Approximately two-thirds of human monocytes present in the bone marrow express NPP4 on their membrane surfaces. We determined the 1.5 Å molecular structure of NPP4 by X-ray crystallography in the presence and absence of its enzymatic product (AMP). Finally, we identified a high-affinity (nM) small molecule inhibitor of NPP4 that is an FDA approved drug for another indication.
Conclusions: Monocytes have a defined role in hemostasis, and the presence of NPP4 on monocyte surfaces further supports a physiologic role of NPP4 in platelet aggregation. The high-resolution structure of NPP4 allows us to understand the molecular determinants of catalysis and substrate specificity, and provides a reagent for the discovery and optimization of small molecule inhibitors. The identification of a high-affinity NPP4 small molecule which is an FDA approved drug identifies a critical reagent for establishing the physiologic role of NPP4.

Our combined studies lay the foundation for the validation of the biological role of NPP4 in hemostasis and establishes the necessary tools and reagents for the translational application of our findings into the clinic.

PB 4.24-5

Functional implications of histone deacetylases in platelet activation: a role for alpha-tubulin acetylation?

Moscardó A[1], Santos MT[2], Latorre A[2], Madrid I[3], Dasí MA[4] and Vallés J[2]

[1]IIS La Fe; [2]Research Center. La Fe University Hospital; [3]Intensive Care Unit. University Hospital La Fe; [4]Pediatric Hospital. University Hospital La Fe, Valencia, Spain

Background: Acetylation of proteins with an emergent role in the regulation of cellular metabolism is regulated by acetylase(HAT)/deacetylase (HDAC) activities, although the role of these enzymes in platelet function remains unidentified. In other cells, several deacetylases have been identified and classified into four families, including zinc-dependent deacetylases (I, II and IV) and NAD^+-dependent (family III or sirtuins). α-Tubulin is one of the proteins first recognized to be regulated by acetylation/deacetylation processes through the action of the deacetylases HDAC6 and sirtuin2. The presence of acetylated α-tubulin has been described in platelets, although its role in platelet function is not well understood. It is known that in platelets α-tubulin participates in the processes of cytoskeleton reorganization, granule release and cytosolic calcium increases (1), but it is unknown if the α-tubulin acetylation/deacetylation cycle participates in these processes.
Aim: Evaluate if deacetylases have a regulatory role on platelet function and α-tubulin acetylation.
Methods: For detection of acetylated α-tubulin, washed human platelets lysates were immunodetected with a specific antibody against the acetylated form of α-tubulin. The role of deacetylases in α-tubulin acetylation was assayed by incubating platelets (1 h, 37 °C) with specific inhibitors: trichostatin A (TSA) (inhibitor of all HDAC except sirtuins) and cambinol (sirtuin inhibitor). Functional studies of washed human platelets were performed according to previously published methodologies (2). To study dense granule release, platelets were previously loaded with ^{14}C-5HT. For the determination of calcium concentration in the cytoplasm, platelets were loaded with FURA 2AM. Platelet function was assayed with a panel of physiological agonits (collagen 0.5 μg/mL, thrombin 0.1 U/mL, U46619 0.5 μM, ADP 10 μM).
Results: In resting human platelets, several proteins were acetylated, including α-tubulin. To identify the deacetylase(s) responsible of α-tubulin acetylation/deacetylation, resting platelets were incubated with TSA or cambinol; only incubation with TSA strongly increased α-tubulin acetylation while cambinol was without effect. Furthermore, inmunoblotting experiments demonstrated the presence of HDAC6 in platelet lysates. In addition, when platelets were aggregated with collagen or U46619, HDAC6 was time-dependently incorporated to the reorganized cytoskeleton. When platelets were aggregated, α-tubulin acetylation was strongly decreased with all the agonists used. In contrast, blocking platelet aggregation with RGDS abolished the process of α-tubulin deacetylation, demonstrating the participation of platelet aggregation in this process. When we explored the functional implication of HDAC inhibition on platelets reactivity, we found that TSA treatment partially reduced platelet aggregation, dense granule release, calcium movement and cytoskeletal reorganization concomitantly with blockade of the agonist-induced α-tubulin deacetylation. Importantly, when the concentration of agonist employed overcomes the action of TSA on platelet function, α-tubulin was deacetylated, suggesting a connection between the level of α-tubulin acetylation and the platelet function.
Conclusion: We describe here for the first time that HDAC6 participates in the process of platelet activation; this effect could be mediated by the acetylation status of α-tubulin. Grants: PI07/0463;Retics06/0026.

PB 4.24-6

The role of peroxisome proliferator-activated receptor (PPAR)-r? ligands in platelet activation

Han J-Y, Choi JL, Kim BR, Goh R-Y and Park J-I

Dong-A University College of Medicine, Busan, South-Korea

Background: The mechanism of platelet production and activation is not fully understood. Recently, the ligand-activated transcription factor peroxisome proliferator-activated receptor gamma (PPARγ) has been reported to promote the formation of platelets from megakaryocytes and accelerate platelet recovery after radiation-induced bone marrow injuries.
Aims: In the present study, we analyzed whether and how PPARγ ligand and its antagonist affect platelet function *in vitro*.
Methods: Platelets were obtained from plateletpheresis products by centrifugation. Western blotting for PPARγ was performed, and bands were visualized by chemiluminescence. The effects of the potent PPARγ antagonist GW9662 and the anti-oxidant brown algae-based polyphenol complex Seanol were also evaluated. Platelet flow cytometry and aggregation tests were performed after each treatment in order to analyze the effects of the treatment on platelets.
Results: Treatment with 10 μM PPARγ ligand (15-deoxy-$D^{12,14}$ prostaglandin J_2, 15d-PGJ_2) did not significantly affect platelet expression of CD61, CD41, CD42b, CD62p, CD63, or PAC1 as measured by flow cytometry. However, the PPARγ antagonist GW9662 at a concentration of 20 μM decreased CD42b and CD62p expression, while Seanol at 25 μg/mL decreased CD63 and PAC1 expression. Studies of the effects of these treatments on other platelet function parameters including platelet aggregation, Multiplate and PFA-100 tests, are ongoing.
Conclusions: Understanding the mechanisms that underlie megakaryocyte maturation and platelet production will provide insight into new ways to enhance the production of platelets from precursor cells. Furthermore, rapid platelet recovery after stem cell transplantation can reduce both the cost of supportive therapy and the risk for bleeding. Our findings support the hypothesis that PPARγ plays a role in platelet activation, and we are now planning to investigate its involvement in areas including thrombopoiesis from cord blood and diseases such as myelodysplastic syndromes.

Convection of platelets to a growing thrombus is governed by vessel size, shear rate, and platelet size and stiffness

Mehrabadi M, Aidun CK and Ku DN

Georgia Institute of Technology, Atlanta, USA

Rapid formation of arterial thrombi requires a high platelet concentration at the walls. Despite the low concentration of platelets in blood, margination of platelets towards the walls may increase the near-wall platelet concentration several fold. Vasoconstriction in response to arterial injury and stenotic atherosclerotic plaques lead to a reduction of the lumen with a subsequent increase in the local shear rate. This study explores the relative role of vessel size, shear rate, and platelet size and stiffness on margination.
We have performed large-scale computational simulations of particulate whole blood flow. Our model includes flow of many soft red blood

cells (RBC) and platelet mechanics and particle-particle and particle-fluid interactions in blood flow. In addition to stiff platelets, we use soft platelets and large, stiff platelets, as 'model' particles to examine the physics of margination. The distance for platelet margination and platelet concentration near the wall are used as the quantitative endpoints. We found that large stiff particles marginate to the wall slowly. Next, small soft particles marginated faster, and small stiff particles marginated fastest. Thus, the smaller size of platelets is the dominant parameter driving platelet margination within the range studied. Our results further show that a high near-wall concentration (70% of the platelets in the control volume are within 6 μm from the walls) of stiff small platelets develops after relatively short lengths of 12 mm for a 40 μm channel. For comparison, 50% of soft platelet-sized particles and 30% of stiff large particles marginate to the near-wall region after 12 mm of length. The high platelet concentration in the plasma skimming layer forms much more rapidly as the lumen size is decreased. For a larger 80 μm channel, only 30% of platelets marginate to the near-wall region within 12 mm. Platelet margination rate also increases linearly with shear rate over a range of 1000–20,000 1/s; however, the development length of platelet concentration profile remains about constant as the travel distances increase with high shear. As platelet concentration near the wall may be the rate-limiting step in occlusive thrombus formation, identification of hemodynamic parameters governing platelet margination may guide us in identifying risk factors associated with atherothrombosis and suggest new ways to prevent arterial thrombosis.

PB 4.25-2

A novel approach to reduce variability in platelet flow chamber experiments by utilizing an internal control

Claesson K, Faxälv L, Bengtsson K, Robinson ND and Lindahl T
Linköping University, Linköping, Sweden

Background: The use of microfluidic devices is an established tool in studying shear-dependent platelet adhesion and aggregation. However the use of these devices and their construction are poorly standardized. Most systems utilize single-use components and thus enable only one blood sample per run and system, and the inherent variability in overall adhesion/aggregation between different runs is usually high. This complicates any attempts to compare different samples. This variability may stem from small changes in flow chamber geometries, especially since it is not uncommon with 'homemade' chamber solutions, image capture in different regions of the chamber, and the possible effect of time between runs since each sample has to be run individually.

Aims: To develop a method using an internal control for increasing experimental control and decreasing variability in platelet adhesion/aggregation assays in microfluidic devices.

Methods: Heparinized whole blood was drawn from healthy volunteers. Platelet-rich plasma (PRP) was prepared by centrifugation at 140 ***g*** for 12 min. PRP was obtained from the supernatant and RBC-rich plasma from the bottom. PRP was divided and platelets were either labeled with $DiOC_6$ or rhodamine 6G, respectively. These two markers have different excitation and emission spectra and can therefore be well separated during fluorescence microscopy. One of the portions is untreated and used as the internal control while the other can be treated with inhibitors/agonists of choice. Both the labeled platelet populations are added to RBC-rich plasma immediately before the start of the experiment.

The method was evaluated with adhesion assays performed with fibrinogen or von Willebrand factor (vWf) coated surfaces in commercial flow chambers (Ibidi), where the adhesion receptors $\alpha_{IIb}\beta$ and GPIb were blocked with abciximab and Mouse Anti-Human MoAb (Clone HIP1), respectively.

Further evaluation was performed by aggregation experiments under elevated shear stress in an in-house constructed PDMS channel with a geometry resembling a stenosed vessel. Also in this experiment the adhesion receptors $\alpha_{IIb}\beta$ and GPIb were inhibited to evaluate their participation in high-shear aggregation.

Results: This procedure eliminated the variability between flow chamber runs and therefore decreased the overall variability when comparing two different samples. The method also provided a direct and visual indication of the results. The standard deviation was lowered in comparison to the use of an external control, in the case of the vWF surface the SD was in average 155% higher without internal control for the first 3 min of measurement. The SD was calculated based on six runs, where the ratio of the control and actual sample were compared. Blocking $\alpha_{IIb}\beta$ and GPIb gave a distinct reduction in platelet adhesion, also GPIb inhibition alone, but not $\alpha_{IIb}\beta$ alone, prevented shear induced aggregation in the PDMS channel.

Summary/Conclusion: We present a method for internal control during flow experiments. This procedure will give a more reliable and precise result as well as save both time and material. As the control is performed in the same environment as the treated sample itself non-relevant variables are excluded. The method is therefore well suited for screening assays.

PB 4.25-3

Anfibatide, a novel GPIb complex antagonist inhibits platelet adhesion and thrombus formation *in vitro* and *in vivo* murine models of thrombosis

Adili R[1], Lei X[2], Zhou H[1], Wang Y[1], Hou Y[1], Dai X[3], Li BX[4] and Ni H[1]
[1]LKSKI-Keenan Research Center, St. Michael's Hospital, Canadian Blood Services, Toronto, Canada; [2]LKSKI-Keenan Research Center, St. Michael's Hospital, Univesity of Toronto, Toronto, Canada; [3]Zhaoke Pharmaceutical co. limited, Anhui, China; [4]Lee's Pharmaceutical Holdings Limited., Shatin, Hong Kong

Background: Platelet adhesion and subsequent aggregation at sites of vascular injury are required to maintain normal hemostasis; however, these processes also contribute to pathologic occlusive thrombosis. Interaction of platelet surface GPIb complex with VWF is key for initiation of platelet adhesion, particularly at high shear stress. This interaction is also essential for platelet aggregation at sites of vascular stenosis (e.g. shear rate >10,000 s^{-1}), leading to vessel occlusion. Interaction of platelet surface integrin aIIbβ3 with its ligands (fibrinogen or other ligands) mediates platelet aggregation and contributes to platelet adhesion at lower shear stress. Thus, both GPIb complex and integrin aIIbb3 are important targets for anti-thrombotic therapy. Interestingly, although several inhibitors of aIIbβ3 have been developed for antithrombotic therapies with some limitations due to bleeding complications, anti-GPIb therapy has not been developed.

Aims: To evaluate the effect of a novel GPIb complex antagonist, snake venom anfibatide, on platelet function *in vitro* and anti-thrombotic activity *in vivo*.

Methods: The effect of anfibatide on platelet function was assessed in platelet-rich plasma (PRP) and gel-filtered platelets using a platelet aggregometer. Platelet surface P-selectin expression and integrin aIIbb3 activation was assessed on anfibatide-treated platelets *in vitro* by flow cytometry. Platelet adhesion, aggregation, and thrombus formation on a collagen-coated surface were studied by perfusing anfibatide-treated or control whole blood through a perfusion chamber system at shear rates of 100–5000 s^{-1}. *In vivo* thrombus growth was monitored in real-time under intravital microscopy in both $FeCl_3$-injured mesenteric arterioles and laser-injured cremaster muscle arterioles.

Results: Anfibatide specifically inhibited ristocetin-induced human platelet aggregation. Interestingly, anfibatide did not inhibit botrocetin-induced murine platelet aggregation in PRP, suggesting its unique binding site on GPIbα. It had no significant effect on ADP- or collagen-induced aggregation in PRP, nor on thrombin-induced gel-filtered platelet aggregation. There were no detectible differences in platelet

surface P-selectin expression or β3 integrin activation when platelets were incubated with anfibatide in static condition. In *ex vivo* perfusion, anfibatide strongly inhibited murine platelet adhesion, aggregation, and thrombus formation at high shear rate (600 s^{-1} or above). It also inhibited thrombus growth at lower shear rate (300 s^{-1} or less) although its effect was less potent. In the mesenteric arteriole thrombosis model, anfibatide markedly inhibited platelet adhesion, aggregation and thrombus formation, and prevented vessel occlusion in response to $FeCl_3$ injury ($P < 0.05$). Consistent with these results, anfibatide also dramatically inhibited platelet accumulation and thrombus growth at sites of laser-injured cremaster arterioles. Importantly, we did not observe prolonged tail bleeding time or increased bleeding diathesis during surgeries in anfibatide-treated mice, which is consistent with our observation in an ongoing Phase I clinical trial in human volunteers.

Conclusions: Anfibatide inhibits ristocetin-induced human platelet aggregation but not botrocetin-induced murine platelet aggregation, suggesting its binding site may be different from other snake venoms. Anfibatide effectively inhibits platelet adhesion, aggregation, and thrombus formation and prevents vessel occlusion without significantly impairing hemostasis, indicating that anfibatide may have great potential as a new anti-thrombotic agent.

PB 4.25-4

Kinetics of thrombus formation and further characterization of the bleeding phenotype in PT-VWD hTgG233V mouse model

Kaur H, Toukh M, Corscadden K and Othman M

Queen's University, Kingston, ON, Canada

Background: The interaction between the platelet GPIb*a* and Von Willebrand factor is critical to platelet adherence to the subendothelial vasculature and thrombus formation at sites of injury. Stabilization of thrombus is supported by signaling events that are not completely defined. Platelet-type von Willebrand disease (PT-VWD) is a rare bleeding disorder caused by gain-of-function mutations in the platelet *GP1BA gene* resulting in a GPIb*a* protein that is a hyper-responsive to VWF. Mice expressing the human GPIb*a* mutation G233V showed impaired thrombus formation and bleeding phenotype similar to human PT-VWD.

Aim: To study the kinetics of thrombus formation in hTg^{G233V} mice for better assessment of the bleeding phenotype in PT-VWD and to investigate the effect of inhibition of the hyper-responsive platelet GPIb*a* on the phenotype.

Methods: *In vivo* thrombus formation was visualized using intravital microscopy following laser injury to the cremaster artery. Platelets were labelled *in vivo* by injecting Rhodamine 6G. Images were taken over 20 min to visualize platelet deposition on the arteriolar wall and occlusive thrombus formation. To assess the initial adherence of the platelets, attachment was defined as continuous interaction (for 5 s) with the endothelium by a platelet after laser-induced injury. Mice tail bleeding times were determined and measurements were terminated at 10 min. The effect of GPIba inhibition was evaluated using 6B4; a monoclonal antibody that blocks the GPIba-binding site for VWF. The inhibitor was injected through jugular vein in intravital studies and tail vein in tail bleeding time experiments. Global haemostasis was assessed by thrombelastography using citrated whole blood obtained via cardiac puncture from hTg^{WT} and hTg^{G233V} animals. In addition, blood was incubated with the inhibitor *in vitro* for 5 min prior to TEG.

Results: Intravital microscopy revealed severe impairment of occlusive thrombus in any of the hTg^{G233V} mice, whereas stable clots were formed and vessels were occluded in hTg^{WT} mice ($n = 4$). Kinetics of clot formation was determined through accumulated fluorescence intensity as a surrogate for platelet accumulation. All time points were examined and hTg^{G233V} mice showed significantly less platelet accumulation than hTg^{WT} mice $P < 0.001$ ($n = 4$). In hTg^{WT}, GPIba inhibitor had no significant effect on the time to form initial clots but significantly reduced clots' stability ($P < 0.02$). In hTg^{G233V}, there was a significant increase in the number of formed clots but these clots were not stable. Considerable individual variation in TEG parameters was shown and GPIb*a* inhibitor shortened the R and K times, increased alpha angle and MA in each of the hTg^{WT} hTg^{G233V}. All hTg^{G233V} ($n = 5$) mice had a bleeding time 10 min. On the other hand, hTg^{WT} mice ($n = 7$) had widely variable bleeding times ~3–10 min. GPIb*a* inhibitor had no effect on bleeding time in hTg^{G233V} and in hTg^{WT}.

Conclusions: This study provides further insights into the bleeding phenotype in PT-VWD mouse model and new understanding of the molecular behaviour of the hyper-responsive GPIb*a* associated in this bleeding disorder.

PB 4.25-5

The Rho GTPase effector PAK regulates thrombin- and collagen-stimulated platelet aggregation, lamellipodia formation and aggregate stability under shear

Aslan JEJ[1], Itakura A[1], Baker S[1], Haley KM[1], Tormoen GW[1], Pang J[1], Loren C[1], Chernoff J[2] and McCarty OJT[1]

[1]Oregon Health & Science University, Portland, OR; [2]Fox Chase Cancer Center, Philadelphia, PA, USA

Rho GTPase proteins regulate the dynamics of the platelet actin cytoskeleton. However, little is known regarding how Rho GTPases coordinate platelet activation and function. In this study, we characterize the role of the Rho GTPase effector p21 activated kinase (PAK) in platelet activation, lamellipodia formation and aggregate formation under shear. Stimulation of platelets with the GPVI agonist, collagen-related peptide (CRP), rapidly activated PAK in a time course preceding phosphorylation of PAK substrates LIMK1 and MEK and the subsequent activation of MAPKs and Akt. Pharmacological inhibitors of PAK blocked signaling events downstream of PAK and prevented platelet secretion as well as platelet aggregation in response to CRP. PAK inhibition also prevented PAK activation and platelet spreading on collagen surfaces. Platelet responses to thrombin, including the activation of a set of Rac1-associated PAK effectors were also abrogated by PAK inhibition. PAK was also required for platelet aggregate formation to maintain aggregate stability under physiological shear flow conditions. These results suggest that PAK serves an orchestrator of platelet functional responses following activation downstream of GPVI and PAR engagement.

Light-controlled coagulation – aptamer-templated synthesis facilitating masking and photochemical liberation of thrombin function

Rohrbach F[1], Pfeiffer F[1], Schäfer F[2], Müller J[3], Pötzsch B[3], Heckel A[2] and Mayer M[1]

[1]University of Bonn, Bonn; [2]Goethe-University Frankfurt, Frankfurt/Main; [3]University Hospital Bonn, Bonn, Germany

The serine protease thrombin is one of the central proteins in the blood coagulation cascade. Its enzymatic activity regulates various mechanisms connected to hemostasis and blood clot formation. The direction of coagulation processes to blood vessel lesions and prevention of thrombus by noninvasive systems is of great interest in hematology. Furthermore, spatiotemporal regulation of thrombin activity is not solely important in preventing thrombosis but could be a powerful tool to restrict tumor blood supply or stop uncontrolled bleeding in emergency surgeries.

Here, we present an aptamer-templated synthesis approach of a light-inducible thrombin release complex using the advantages of the existing thrombin inhibitor aptamer HD1 to form an ON switch for coagulation in human blood plasma. HD1 is functionalized with a photocleavable extension and a cross-linking moiety. The recognition of thrombin exosite I, responsible for the procoagulant functions of thrombin such as conversion of fibrinogen to fibrin and platelet aggregation, enables the aptamer to covalently cross-link to nucleophilic amino acid residues of the protein. Thereby, fibrinogen binding to exosite I is inhibited and fibrin formation, essential for blood clot formation, is prohibited. UV-irradiation of the aptamer-protein complex causes photocleavage of the linker, which results in HD1 dissociation from exosite I. Consequently the blood clotting activity of thrombin is restored. Photo-cleavage is visualized by western blot analysis and light-activated coagulation is measured in human plasma.
In summary, we designed an aptamer-based light-inducible ON-switch for thrombin function, demonstrating the great potential of aptamer-mediated, spatiotemporal control of coagulation.

PB4.26 – Platelet activation mechanisms

PB 4.26-1

A critical role of thrombin/PAR-1 in ADP-induced platelet secretion and the second wave of aggregation

Jiang L[1], Xu C[1], Yu S[1], Liu P[1], Luo D[1], Zhou Q[1], Gao C[2] and Hu H[1]
[1]Zhejiang University, School of Medicine; [2]Zhejiang University School of Public Health, Hangzhou, China

Background: The stable or second wave of platelet aggregation often observed in ADP-stimulated platelet-rich plasma (PRP) with artificially lowered extracellular calcium level have been attributed to enhanced thromboxane A_2 (TXA_2) generation and inhibition of ecto-nucleotidases activity. However, the role of thrombin in ADP-induced platelet secretion and second wave aggregation are unknown.
Aims: To investigate the role of thrombin in ADP-induced platelet activation.
Methods: We employed aggregometry, flow cytometry, immunoblotting and ELISA to determine whether and how thrombin participates in ADP-induced platelet secretion and second wave aggregation.
Results: ADP induces a phosphoinositide 3-kinase (PI3K) pathway-dependent thrombin generation, presumably resulted from the cleavage of $\alpha_{IIb}\beta_3$-associated prothrombin. Generated thrombin subsequently activates protease-activated receptor-1 (PAR-1) and mediates dense granule secretion and second wave of platelet aggregation in ADP-stimulated citrated PRP. Thus, ADP-induced dense granule secretion and second wave of platelet aggregation in PRP were similarly and non-additively blocked by thrombin inhibitor hirudin, PAR-1 antagonist SCH-79797, or PI3K inhibitor wortmannin. Moreover, ADP-stimulation caused the dissociation of prothrombin from $\alpha_{IIb}\beta_3$ and increased plasma thrombin level, both were prevented by wortmannin. Furthermore, wortmannin-inhibited second wave of platelet aggregation by ADP was restored by a subaggregation concentration of PAR-1 activating peptide SFLLRN. Blocking TXA_2 production with indomethacin or restoring extracellular calcium to physiological concentration did not influence this thrombin/PAR-1-dependence.
Conclusions: A PI3K-dependent thrombin generation and the resultant PAR-1 activation serve as an indispensable mechanism to relay the platelet activation process induced by ADP.

PB 4.26-2

Oxidised LDL activates blood platelets through NADPH oxidase-dependent modulation of the cGMP/Protein kinase G signalling cascade.

Naseem KM, Magwenzi S and Wraith K
University of Hull, Hull, UK

Background: Blood platelets are critical for haemostasis, but require regulation to prevent vascular occlusion and thrombosis. The cyclic guanosine-5'-monophosphate (cGMP) signalling pathway is a potent endogenous regulator of platelet function. Oxidised low density lipoproteins (oxLDL) may contribute to unregulated platelet activation in atherothrombosis by unknown mechanisms. We hypothesised that oxLDL increases platelet activation through modulating platelet sensitivity to cGMP signalling.
Aims: We investigated whether oxLDL activated platelets by reducing platelet sensitivity to cGMP-mediated inhibition.
Methods and Results: Platelet aggregation and accrual under physiological conditions of flow were inhibited by 8-pCPT-cGMP, a direct activator of protein kinase G (PKG). OxLDL, but not native LDL, reduced the inhibition of platelet aggregation and accrual by 8-pCPT-cGMP, without itself causing significant platelet activation. OxLDL prevented cGMP-stimulated phosphorylation of the PKG substrate, VASP (serine239), through a mechanism requiring the scavenger receptor CD36 and the generation of reactive oxygen species (ROS). To explore the role of these ROS in platelet function we used a multi-pronged approach. Firstly we found that the ability of oxLDL to modulate PKG signalling and stimulate platelet activation was prevented by cell-permeable superoxide scavengers, MnTMPyP and TEMPOL, and the NADPH oxidase (NOX) inhibitor gp91ds-tat, suggesting a role for gp91phox/NOX2. Secondly, we found that oxLDL generated ROS through ligation of CD36. Thirdly, oxLDL stimulated gp91phox/NOX2-mediated ROS generation through sequential activation of Src kinases, Syk, PLCγ2 and PKC. Fourthly, PKC-dependent phosphorylation of p47phox resulted in its translocation to the membrane compartment where it associates with p22 phox to form an active NADPH oxidase holoenzyme.
Conclusion: We show for the first time that oxLDL stimulates the generation of intracellular ROS through the activation of gp91phox/NOX2 in platelets, downstream of a CD36/tyrosine kinase signalling pathway. These data reveal a new role for oxLDL in promoting platelet aggregation through modulation of the PKG signaling pathway.

PB 4.26-3

P2X1-mediated p38 signaling enhances U46619-induced platelet secretion and aggregation

Huang Z[1], Liu P[2], Zhu L[1], Li N[1] and Hu H[2]
[1]Karolinska Institute, Stockholm, Sweden; [2]Zhejiang University, Hangzhou, China

Background: Platelet ATP receptor $P2X_1$ is an ion channel that evokes a rapid calcium influx and sequential signal events, such as activation of calmodulin, ERK2, and myosin light chain kinase. Through autocrine and/or paracrine mechanisms, ATP induces $P2X_1$ activation, and can subsequently amplify platelet reactions initiated by other agonists, including Thromboxane A2 (TXA_2). It is, however, poorly understood how $P2X_1$ activities influence TXA_2-stimulated platelet acativation
Aims: To elaborate the molecular mechanisms of $P2X_1$ engagements in U46619-induced platelet secretion and aggregation.
Methods: Platelet aggregation was monitored by aggregometry. Platelet secretion was measured as P-selectin expression using flow cytometry. Immunoblotting was employed to monitored platelet proteins phosphorylation.
Results: The $P2X_1$ inhibitor NF449 (1 μM) inhibited platelet P-selectin expression induced by a low concentration of U46619 (0.3 μM) (32.0 ± 2.0% vs. 43.4 ± 3.0%, approximately 26% relative inhibi-

tion; $n = 5$; $P < 0.05$). Similar to NF449, the p38 inhibitor SB203580 (10 μM), but not the ERK inhibitor U0126 (10 μM), inhibited U46619-induced platelet P-selectin expression (16.2 ± 2.8% vs. 27.5 ± 4.7% of vehicle; $n = 4$; $P < 0.05$). No additional inhibition was observed when NF449 and SB203580 were combined (16.1 ± 2.2%; $n = 4$). Adding exogenous α,β-Me-ATP (0.5 μM) at 1 min after U46619 stimulus increased platelet P-selectin expression by 26% ($n = 6$; $P < 0.05$). The enhancement was abolished in the presence of SB203580. In consistence with above results, 0.3 μM U46619-induced platelet aggregation was similarly decreased by NF449 (1 μM), SB203580 (10 μM), or $P2X_1$ predesensitization with α,β-Me-ATP (0.5 μM). Immunoblot analysis showed that α,β-Me-ATP (2 μM) caused rapid and reversible p38 phosphorylation. U46619-induced platelet p38 phosphorylation was decreased by $P2X_1$ predesensitization with α,β-Me-ATP. Intriguingly, $P2X_1$-p38 pathway seems to be effective to only platelet activation induced by low concentrations of U46619 but not high concentrations. The latter was evidenced by the results showing that α,β-Me-ATP supplementation or p38 blockade had no effect on platelet activation induced by higher concentration of U46619, such as 3 μM.

Conclusions: Activation of $P2X_1$ ion channel potentiates platelet secretion and aggregation initiated by low doses of U46619 and via p38 signaling pathway. Hence, the $P2X_1$ action may be an important mechanism for more robust platelet responses when only mild stimuli are present.

PB 4.26-4

Characterization of losartan effects on platelets

Jandrot-Perrus M, Jiang P and Loyau S

Inserm U698, Paris cedex 18, France

Background: Losartan, a selective, competitive inhibitor of the angiotensin II type I receptor, is routinely used to treat hypertension. It has been reported to have antithrombotic effects in animal models dependent on NO/prostacyclin and direct antiplatelet effects were described *in vitro*: competitive inhibition of U46619 binding to the thromboxane A2 receptor (TPR) *(Guerra-Cuesta JI et al. J Hypertens 1999)* and interaction with GPVI *(Grothusen C et al. Arterioscler Thromb Vasc Biol, 2007*; *Ono K et al. J Med Chem 2010*).

Aims: This study was aimed to better characterize *in vitro* the effect of losartan on platelets and to elucidate its mechanism of action.

Methods: Experiments were performed on PRP and washed platelets from healthy donors who had not taken medication for at least for 10 days. Samples were preincubated with increasing concentrations of Losartan (0–50 μg/mL) before measuring platelet aggregation and P-selectin exposure. Platelet activation was triggered by arachidonic acid (AA, 1.5 mM), APD (10 μM), thrombin-receptor activating peptide (TRAP 20 μM), the thromboxane A2 analogue U46619 (1 μM), type I collagen (Horm, 1 μg/mL), convulxin (Cvx, 0.5 nM), or the anti-FcgRIIA antibody IV.3 cross-linked by anti-mouse IgG Fab'2. Platelet adhesion to immobilized collagen was analysed using whole anticoagulated blood in flow conditions (1500 s^{-1}). GPVI binding to collagen was measured using recombinant soluble dimeric GPVI (GPVI-Fc). GPVI dimerisation/clustering was analysed by flow cytometry using the specific antibody 9E18 (*Loyau S et al. Arterioscler Thromb Vasc Biol 2012*).

Results: Losartan up to 50 μg/mL had no effect on AA, TRAP or Cvx-induced platelet aggregation and P-selectin exposure. Losartan (50 μg/mL) inhibited the second wave of aggregation in response to ADP and dose-dependently inhibited U69919- and collagen-induced platelet aggregation. However, the losartan IC50 was six times higher for U46619 than for collagen-induced platelet aggregation (18 vs. 3 μg/mL) suggesting that the inhibition of collagen-induced platelet activation was partly independent of the effect of losartan on TPR. This was confirmed by the observation that losartan still inhibited the collagen-induced residual platelet aggregation of indomethacin-treated platelets. When blood preincubated with losartan (10 μg/mL) was perfused over collagen, less platelet aggregates were formed as compared to control conditions. Losartan up to 100 μg/mL slightly reduced the binding of the anti-GPVI monoclonal antibody 9O12 to GPVI-Fc and had no effect on the high affinity binding of GPVI-Fc to collagen suggesting that losartan does not occupy the collagen-binding site on GPVI. However, interestingly, losartan (10 μg/mL) inhibited the binding of the 9E18 antibody to platelets incubated with collagen suggesting that losartan blocks collagen-induced GPVI clustering.

Conclusion: Losartan inhibits collagen-induced platelet adhesion, activation and aggregation. This effect is, at least partly, independent of TPR inhibition, and does not rely on the inhibition of the protein tyrosine kinase pathway since it does not impact FcgRIIA activation. Our data suggest that the inhibition, by losartan, of collagen-induced GPVI clustering could reduce platelet reactivity and contribute to its antithrombotic effect. The relevance of this effect in losartan-treated patients is under investigation.

PB 4.26-5

Sex-specific differences in platelet activity

Berger J[1], Becker RC[2], Lobach I[1], Ortel TL[2] and Williams R[2]

[1]NYU Langone Medical Center, New York, NY; [2]Duke University Medical Center, Durham, NC, USA

Background: Women and men have important differences to the pharmacodynamic response and clinical outcomes following the use of antiplatelet therapy. A sex-specific difference in baseline platelet activity is one potential mechanism.

Aim: We sought to examine platelet activity when stratified by sex.

Methods: A total of 542 healthy volunteers (349 women and 232 men) underwent light transmission aggregometry in response to epinephrine, ADP and collagen. Platelet aggregation >60% was considered to be hyperreactive. Principal Components Analysis (PCA) was used to infer principal combinations of the three platelet activity measures.

Results: Women were older (29 ± 9.1 vs. 26 ± 7.0, $P < 0.001$) and less frequently white (60% vs. 73%, $P = 0.002$) compared with men. Smoking and body mass index was similar between groups. In the overall population, stimulation with submaximal epinephrine (2 μM), ADP (1 μM) and collagen (2 μM) concentrations elicited a distinct, bimodal pattern of platelet aggregation in this population. Maximum aggregation was greater in women than men for epinephrine (43.7% ± 33.8 vs. 38.6% ± 31.6, $P = 0.07$), ADP (26.7% ± 25.8 vs. 19% ± 19.5, $P < 0.01$), and collagen (72% ± 25.7% vs. 69.6 ± 23.3, $P = 0.25$). Compared with men, women were significantly more likely to be hyperreactive to epinephrine and ADP. After adjustment for age and race, sex was independently associated with platelet hyperreactivity to epinephrine and ADP. Platelet aggregation in response to epinephrine, ADP and collagen using PCA is significantly associated with sex ($P = 0.01$).

Conclusion: Women have significantly increased baseline platelet activity compared with men. Studies are needed to determine whether a differential sex-specific response to antiplatelet therapy can be attributed to this underlying sex-specific difference in baseline platelet activity.

PB 4.26-6

The cellular prion protein PrPC regulates platelet signaling and activation

Aslan JEJ[1], Mariante RM[2], Mizurini DM[2], Alvez Americo T[2], Gomes F[2], Monteiro Q[2], McCarty OJT[1] and Linden R[2]

[1]Oregon Health & Science University, Portland, OR, USA; [2]Universidade Federal do Rio de Janeiro, Rio De Janeiro, Brazil

Background: Prion diseases manifest through the conversion of the cellular prion protein, PrPC, to its pathogenic scrapie form, PrPSc, to result in protein aggregation and disease. In healthy cells, PrPC serves as a signaling scaffold at the cell surface to regulate signaling processes

in an undetermined manner. Interestingly, platelets express abundant PrPC which has hypothesized roles in platelet physiology.
Aim: Our study was designed to characterize the role of PrPC in platelet function.
Results: Upon stimulation of platelets in solution with agonists including collagen and thrombin, PrPC is externalized to the platelet surface. PrPC also localizes to the cell surface as platelets encounter immobilized surfaces of fibrinogen or collagen. Immunofluorescence microscopy supports a model of PrPC externalization in which PrPC traffics in granules first to platelet filopodia and ultimately to the platelet surface, suggesting that PrPC has roles in signaling complex formation at sites of filopodial anchoring and actin organization. PrPC upregulation at the platelet surface was abolished by tyrosine kinase inhibition but not Rho GTPase inhibitors, suggesting that PrPC mobilization is an early event in platelet activation.
Conclusions: These signaling studies, together with studies of platelets from PrPC mouse models suggest that PrPC may regulate signals downstream of platelet agonist and substrate receptor binding to early phases of platelet activation.

PB 4.27-1

Non-uniform distribution of coagulation factors on the membrane of activated platelets

Podoplelova NA[1], Golomysova A[2], Ataullakhanov F[1] and Panteleev MA[1]

[1]Center for Theoretical Problems of Physicochemical Pharmacology; [2]Faculty of Physics, Lomonosov Moscow State University, Moscow, Russian Federation

Introduction: All major reactions of blood coagulation proceed on the negatively charged phospholipid membranes. The interaction proteins of with phospholipid membranes leads to a dramatic acceleration of the reaction rate. A possible mechanism for this acceleration of the reaction rate is increase of the local concentrations of the factors. To investigate further this phenomenon, we examined binding of fluorescentlylabeled coagulation factors with the phosphatidylserine-exposing platelets using confocal microscopy.
Aims: To Investigate distribution of coagulation factors on the membrane of activated platelets.
Materials and Methods: FX was covalently labeled with fluorescein. Platelets were activated at 2×10^{7}/mL with thrombin (100 nM), thrombin(100 nM) + CRP (10 μg/mL) or ionophore(10 μM) in the presence of 2.5 mM $CaCl^{2+}$ for 10 min. They were incubated with FITC-labeled 2% (v/v) annexin V, 500 nM fX, fIXa or prothrombin for 5 min, and were imaged with microscope Zeiss Axio Z1.
Results: Annexin V, which was the specific marker for phosphatidylserine, was non-uniformly distributed on the membrane of activated platelets. There was a small convex area region with high concentrations of annexin V. That region was observed for different types of activation (ionophore, thrombin, thrombin + CRP). fX, fIXa and prothrombin were distributed simularly. The area region with high concentration of factor usually had surfase 10–20% of the platelets membrane. Mathematical modeling showed that this distribution of the factors entering into tenase accelerates the reaction at lease by an order of magnitude.
Conclusions: The coagulation factors are distributed non-uniformly on the membrane of activated platelets. The location of clotting factors in a small area region of the membrane of activated platelets can lead to a significant acceleration of coagulation reactions.

PB 4.27-2

Assessment of platelet inhibition and its stability during aspirin and clopidogrel treatment

Timur AA[1], Murugesan G[2], Zhang L[3], Barnard J[3], Bhatt DL[4] and Kottke-Marchant K[2]

[1]Cleveland Clinic, Cleveland, OH; [2]Robert J. Tomsich Pathology and Laboratory Medicine Institute, Cleveland Clinic, Cleveland, OH; [3]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [4]Harvard Medical School, Boston, MA, USA

Background: Assessment of platelet inhibition and its stability is crucial for patients with coronary syndromes and those undergoing percutaneous coronary intervention (PCI).
Aims: To assess platelet inhibition and its stability using different platelet function assays and to seek correlation and agreement between these tests.
Methods: Samples from 58 patients who underwent PCI and were on both aspirin and clopidogrel were collected at hospital discharge following PCI (visit-1) and at 30–90 days (visit-2). Platelet function was measured using light transmission aggregometry with arachidonic acid (LTA-AA) and ADP (LTA-ADP), VerifyNow (Aspirin; ARU and P2Y12; PRU), *ex vivo* TxB_2, urinary 11dhTxB_2, and VASP (PRI) assays. Patients were categorized as poor responder (PR) to aspirin based on ARU ≥550, LTA-AA ≥20%, TxB_2 ≥1 ng/mL or 11dh TxB_2 ≥1500 pg/mg of creatinine and PR to clopidogrel with PRU ≥240, PRU ≥208, LTA-ADP ≥40%, PRI ≥50%, or PRI ≥66%.
Results: Depending on platelet function assay, 3–33% of patients in visit-1 and 5–28% in visit-2 were aspirin PR while persistent aspirin PR (PR in both visits) were 2–9%. Similarly, 10–35% of patients in visit-1 and 14–45% in visit-2 were clopidogrel PR and 5–28% were persistent clopidogrel PR. There was a significant difference between visit-1 and visit-2 measures of PRU, LTA-ADP, and PRI which were higher in the second visit (P-value <0.05). Analysis of data quartiles between visits revealed moderate but the highest agreement for PRU (κ = 0.46, 95% CI = 0.29, 0.63, P-value <0.001) and PRI (κ = 0.4, 95% CI = 0.23, 0.57, P-value <0.001). Based on binary data, agreement between two visits was: high for PRU (cut-off 240; κ = 0.7, 95% CI = 0.47, 0.93, P-value <0.001) and PRI (cut-off 66%; κ = 0.69, 95% CI = 0.42, 0.95, P-value <0.001), moderate for LTA-ADP (κ = 0.57, 95% CI = 0.22, 0.93, P-value <0.001), poor for 11dhTxB_2 (κ = 0.31, 95% CI = −0.1, 0.72, P-value = 0.019), and absent for ARU, LTA-AA, and TxB_2. Comparison of platelet function assays in a visit indicated a poor agreement between PRU and LTA-ADP (κ = 0.26, 95% CI = 0.08, 0.44, P-value <0.001), and PRU and PRI data quartiles (κ = 0.36, 95% CI = 0.19, 0.54, P-value <0.001). A poor to moderate agreement was also present between PRU (cut-off 240) and LTA-ADP (κ = 0.33, 95% CI = −0.07, 0.73, P-value <0.001), and PRU (cut-off 208) and PRI (cut-off 50%) (κ = 0.42, 95% CI = 0.16, 0.68, P-value <0.001) binary data.
Conclusion: There is overall stability in platelet inhibition. However, its assessment is influenced by the platelet function assay utilized. Clopidogrel-related assays display a higher agreement in the assessment of platelet function compared to aspirin-related assays. Compliance and effective dose of the regimens should be strictly followed.

PB 4.27-3

Platelet aggregation behavior in the perioperative period of vascular surgery

Calderaro D[1], Pastana AF[1], Rocha TRF[2], Gualandro DM[1], Yu PC[1], Carmo GAL[1], D'Amico EA[2], De Luccia N[2], Puech-Leão P[2] and Caramelli B[1]

[1]Heart Institute (InCor) ; [2]Clinics Hospital University of São Paulo, São Paulo, Brazil

Background: Cardiovascular complications are common after vascular surgeries and atherothrombosis is a determinant factor. The perioperative maintenance of aspirin is recommended for risk control.

Aims: Our purpose is to evaluate the behavior of platelet aggregation (PA) and its relation with cardiovascular events (CVE) in the perioperative period of vascular surgical patients under chronic aspirin therapy.
Methods: The protocol was approved by the local ethics committee and we obtained written informed consent from the patients. We analyzed PA before surgery for 191 patients and in 163 of them PA was reassessed after surgery. Maximum extent aggregation was evaluated on an impedance aggregometer (Chrono-log/USA) after blood exposure to different agonists: collagen 1 μg/mL; collagen 2 μg/mL; collagen 5 μg/mL and arachidonic acid (AA) 0.5 mM. We defined the following CVE, during hospitalization: acute coronary syndromes, isolated troponin elevation, ischemic cerebrovascular event, cardiovascular death and vascular reoperation. The independent pre-operative predictors of CVE were identified in a logistic regression model and the paired T-test was used for PA behavior evaluation. The mean of the individual differences between post and pre-operative PA tests (delta PA) were compared between patients with and without CVE.
Results: The incidence of CVE was 22% and its predictors were: dyslipidemia (OR 3.90; IC95% 1.32–1.51; $P = 0.014$), anemia (OR 2.64; IC95% 1.19–5.85; $P = 0.017$), trans operative hemodynamic instability (OR 4.12; IC95% 1.87–9.06; $P < 0.001$) and PA with AA >11 $^{\Omega}$ (OR 2.48; IC95% 1.07–5.76; $P = 0.034$). There was a significant decrease in PA after exposure to collagen 2 μL/mL ($10.43^{\Omega \pm 5.14\ X\ 8.14\ \Omega} \pm 4.45$; $P < 0.001$), collagen 5 μL/mL ($16.75^{\Omega \pm 5.79\ X\ 14.68\ \Omega} \pm 5.51$; $P < 0.001$) and AA ($5.80^{\Omega \pm 5.74\ X\ 3.83\ \Omega} \pm 5.30$; $P < 0.001$). Delta PA was higher among patients with CVE, when compared to patients without CVE: $-4.58^{\Omega \pm 7.33\ X\ -1.35\ \Omega \pm} 5.89$; $P = 0.007$(response to collagen 5 μL/mL) and $-3.76^{\Omega \pm 6.18\ X\ -1.44\ \Omega} \pm 6.12$; $P = 0.045$ (response to AA).
Conclusions: Highest PA in response to AA is a predictor of CVE, indicating that a pro-thrombotic status is a determinant factor toward the occurrence of perioperative complications. The decrease in PA after surgery is possibly related to perioperative consumption that is greater in patients with thrombotic complications.

PB 4.27-4

Binding of factor X to the activated platelet membrane demonstrates a multistep dissociation process that allows hysteresis effects

Podoplelova NA, Ataullakhanov F and Panteleev MA
Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Introduction: Activation of blood coagulation factor X (fX) by fIXa occurs at physiologically significant rates only in the presence of Ca^{2+}, fVIIIa and negatively charged phospholipid membrane. The activated platelets are physiological source of negatively charged phospholipid membranes. Binding to platelets is the first step in the activation of factor X and its understanding is a prerequisite for the analysis of their mechanisms.
Predominant binding of factor X (fX), a major coagulation zymogen, to the phosphatidylserine(PS)-positive subpopulation of platelets was shown earlier, but was poorly characterized. In additionwe recently discovered a new PS-positive subpopulation of platelets (Topalov et al. Arterioscler Thromb Vasc Biol 2012, 32:2475–2483). Here we studied interaction of factor X with all three subpopulations of activated platelets.
Methods: FX was covalently labeled with fluorescein. Platelets were activated at 2×10^8/mL with 100 nM thrombin in the presence of 2.5 mM $CaCl_2$ for 10 min. They were incubated with FITC-labeled fX at for different time periods, diluted (if required), and immediately analyzed with an Accuri C6 cytometer. Fluorescence intensity was converted to a mean number of molecules per platelet using a calibration curve prepared with Green Flow Cytometry Intensity Calibration Kits.
Results: In this work was shown, factor X binds with the two subpopulations of PS-positive platelets predominantly (50,000–60,000 molecules fX per platelet, $K_d = 1340 \pm 290$ nM, $n = 3$). Binding, was calcium -depended, reversible andspecific as determined in the experiments in the presence of excess unlabeled factor. Prothrombin competed with fX for binding sites on the membrane. Unexpectedly, kinetics of dilution-induced fX dissociation from the PS-positive platelets revealed a multistep process, with a rapid (1–2 min) step followed by a plato. As a result, the overall binding and dissociation process was a hysteresis-like process possing a kind of 'memory'.
Conclusions: Binding of fX to both PS-positive subpopulations is calcium-depended, reversible, specific, but with a possibility of competition with prothrombin. Most importantly, this is a hysteresis-like process possessing a 'memory' that can be important for reactions in flowing blood.

PB 4.27-5

Mean platelet volume interactions with glycoprotein IIb-IIIa and Ib content and platelet aggregation in acute coronary syndrome patients and healthy volunteers

Mazurov A[1], Khaspekova S[1], Zyuryaev I[1], Yakushkin V[1], Sirotkina OV[2], Zaytseva N[3] and Ruda M[1]
[1]Russian Cardiology Research and Production Complex, Moscow; [2]Petersburg Nuclear Physics Institute, Saint-Petersburg; [3]North-Western State Medical University, Saint-Petersburg, Russian Federation

Increased mean platelet volume (MPV) is an independent risk factor of cardiovascular thrombotic events. In this study we investigated interactions of MPV with glycoprotein (GP) IIb-IIIa and GP Ib content and platelet aggregation in patients with acute coronary syndrome (ACS, $n = 116$) and healthy volunteers ($n = 31$). Patients and healthy volunteers gave written informed consent for participation in the study. In ACS patients blood was collected at days 1, 3–5 and 8–12 after disease onset. MPV was measured in haematological analyzer. GP IIb-IIIa and GP Ib numbers on platelet surface were measured using ^{125}I-labeled monoclonal antibodies. Platelet aggregation was induced by 5 and 20 μM ADP in ACS patients and by 1.25, 2.5, 5 and 20 μM ADP in healthy volunteers and was evaluated by turbidimetric method. GP IIb-IIIa and GP Ib genetic polymorphisms were identified using RT-PCR or PCR-RFLP. Plasma thrombopoietin (TPO) was measured by ELISA. Strong direct interactions were detected between MPV and GP IIb-IIIa and GP Ib content in both ACS patients (at all time points after disease onset) and healthy volunteers – correlation coefficients (r) from 0.439 to 0.645, $P < 0.005$ (for all correlations). Direct correlations were also revealed between the numbers of both glycoproteins – r from 0.504 to 0.566, $P < 0.002$ (for all correlations). GP IIb-IIIa and GP Ib genetic polymorphisms (GP IIIa Leu33Pro, GP Ibα Thr145Met and GPIbα (-5)T/C [Kozak]) were identified in ACS patients and appeared to have no significant impact on GP IIb-IIIa and GP Ib expression. Modest direct correlations between MPV and platelet aggregation (maximal level) were registered at day 1 of ACS in patients whose blood was collected after aspirin but before clopidogrel uptake – $r = 0.445$, $P = 0.003$ ($n = 43$) and $r = 0.318$, $P = 0.036$ ($n = 44$) for 5 and 20 μM ADP respectively. No correlations between these parameters were observed when patients received clopidogrel in addition to aspirin (patients who had already received clopidogrel at day 1 and all patients at later time points). No effects of GP IIIa Leu33Pro polymorphism on platelet aggregation were detected at all time points. In healthy volunteers significant correlation was revealed between MPV and platelet aggregation only for 2.5 μM ADP ($r = 0.404$, $P = 0.022$) and for other ADP doses it did not reach significant level ($r = 0.320$, $P = 0.074$, $r = 0.328$, $P = 0.067$ and $r = 0.245$, $P = 0.183$ for 1.25, 5 and 20 μM ADP respectively). Weak but significant direct correlation was revealed between MPV and plasma TPO which was determined in patients at day 1 of ACS ($r = 0.286$,

$P = 0.005$). The data obtained indicated that increased MPV is associated with increased amount of GP IIb-IIIa and GP Ib and increased platelet aggregation activity. At least in some ACS patients production of large hyper-reactive platelets, containing high amounts of GP IIb-IIIa and GP Ib, might be stimulated by increased TPO.

PB 4.27-6

Elevated prevalence and stability over time of high on-treatment platelet reactivity in patients with ischemic cerebrovascular disease

Rivera J[1], Jover E[2], Sánchez Guiu I[1], Rodríguez JM[3], Bernal A[1], Iniesta JA[3], Antón AI[1], Vicente V[1] and Lozano ML[1]

[1]Centro Regional de Hemodonación, Hospital Universitario Morales Meseguer; [2]Hospital Universitario Virgen de la Arrixaca; [3]Hospital Universitario Reina Sofía, Murcia, Spain

Background: Ischemic stroke and transient ischemic attack (TIA) are a main cause of morbidity and mortality worldwide, and up to 25% of them are recurrent. Aspirin is the most used drug for secondary prevention of acute and long-term treatment of cerebrovascular disease (CVD). However, evidence that many patients have recurrent vascular events while on aspirin, led to alternative therapies such as clopidogrel or, more controversial, aspirin plus clopidogrel combination therapy. High on-treatment platelet reactivity (HTPR), referred to as limited inhibition of platelet function achieved by an antiplatelet therapy, has recently emerged as a potential risk factor for recurrent vascular events, and whether patients with HTPR phenotype may benefit from intensified antiplatelet treatment is under debate. In the setting of CVD there is scarce information on the prevalence HTPR and on the stability over time of on-treatment platelet reactivity phenotype (HTPR or No-HTPR).

Objective: To investigate, by means of different platelet function tests, the frequency and stability of a HTPR phenotype in patients with ischemic stroke/TIA, under treatment with antiplatelet therapy.

Patients and Methods: Platelet reactivity was assessed on 18 patients (50%M, 72.4 ± 9.9 years) with ischemic stroke/TIA 1 week (D7) after prescription of clopidogrel (75 mg/day), in monotherapy (39%) or associated to aspirin (61%), and again at day 90th (D90), by means of four methods Light transmission aggregometry (LTA), VASP, Verify Now® $P2Y_{12}$, and INNOVANCE® PFA P2Y. HTPR was defined as: LTA-ADP 5 μM >46%, LTA-ADP 10 μM >70%; PFA-100-P2Y closure time <106s; VerifyNow $P2Y_{12}$, PRU >235, VASP, PRI >50%.

Results: All tests detected a marked inhibition of platelet reactivity towards ADP in these CVD patients, as a result of clopidogrel therapy, that was similar at D7 and D90. Correlations between results of platelet reactivity with either test at D7 and D90, and between measures on either day with the different assays were low-to-moderate. The prevalence of HTPR in these CVD patients was highly assay dependent: with 5 mM LTA-ADP, 50% both on D7 and D90; 10 mM LTA-ADP, 5.5% at D7 and 16.6% at D90; PFA-100-P2Y, 38.9% at D7 and 55.5% at D90; Verify Now $P2Y_{12}$ 55.5% at D7 and 61.1% at D90; VASP, 44.4% at D7 and 27.7% at D90. There was, at best, only moderate agreement (k statistic <0.5) between these tests in categorizing patients with or without HTPR both at D7 and D90. Interestingly, our study also showed that 55–90%, depending on the platelet method/criteria used, maintained their platelet reactivity phenotype, HTPR or no-HTPR, over time.

Conclusions: A high prevalence of HTPR is observed in CVD patients, although the value is highly influenced by the method used to assess platelet function and the HTPR definition. Different methods correlate and agree poor-to-moderately between each other. The new PFA-100 P2Y point-of-care system is equivalent to other assays in evaluating HTPR on CVD patients. In most CVD patients the platelet reactivity phenotype perceived soon after prescription of clopidogrel seems to remain stable over time. As the clinical meaning of HTPR is uncertain, our data do not apply to individualizing therapy in CVD.

PB4.28 – Platelet function in health and disease

PB 4.28-1

The platelet delta granule storage pool increases in pregnancy

Gunning WT[1], Cekova E[1], Simo H[1], Patel A[1] and Karnitits JV[2]

[1]University of Toledo Medical Center; [2]The Toledo Hospital, Toledo, OH, USA

Background: Pregnancy induces numerous systemic physiological changes including hematologic adaptations for the labor and delivery process. Postpartum hemorrhage (PPH) is a major cause of maternal morbidity and mortality and most often related to atony. Other risk factors have been established for the etiology of PPH, but bleeding diatheses, while recognized, appear to be rare. Few studies of PPH or other bleeding complications related to parturition and platelet dysfunction have been published, most of which have been case reports. We have become aware that patients diagnosed with delta granule storage pool deficiency (δ-SPD) have not experienced bleeding complications related to parturition at our hospital. Platelet δ-SPD is a bleeding diathesis related to a decreased number of platelet dense granules presenting with common symptoms of platelet dysfunction including epistaxis, easy bruising, mucosal bleeding and heavy menstrual bleeding. To our knowledge, a prospective study of the platelet dense granule storage pool during the state of pregnancy and parturition bleeding complications has not been evaluated.

Aims: The purpose of our study was intended to evaluate the platelet dense granule storage pool as a potential risk factor for PPH and anesthesia related hemorrhagic complications.

Methods: Pregnant women being seen in a tertiary hospital obstetrics clinic for routine prenatal check-up were approached for participation in our Institutional Review Board approved study. Participants included by informed consent were asked to provide a blood sample and to complete a pictorial menses score-sheet and a bleeding checklist (based upon the Vincenza bleeding questionnaire). To date 157 women have been enrolled. Platelet dense granules were enumerated using established electron microscopy (EM) protocols. CBCs collected for routine prenatal workup as well as immediately post partum will be assessed including estimated blood loss at parturition. Blood obtained from non-pregnant age matched women ($n = 40$) served as controls.

Results: The mean number of dense granules/platelet (DG/PL) has been found to be significantly increased (5.12 ± 0.14) in pregnant women when compared to non-pregnant controls (4.21 ± 0.09 DG/PLT). The average age of participants is 24.2 ± 4. Completed bleeding scores average 0.96 ± 0.10 (normal <5) and pictorial menorrhagia scores average 197.9 ± 15.14 (normal <185). Of the women with a score >186, all had a normal bleeding score but 22.6% (31/137) had menses pictorial scores consistent with a clinical diagnosis of heavy menstrual bleeding (ranging from 198 to 660). Blood for EM was diluted in ACD venipuncture tubes and thus unsuitable for CBC determination. Not all participants have delivered to date and data is currently being collected from patient medical records to assess hemoglobin and hematocrit values obtained during prenatal care and post partum and will be presented.

Summary/Conclusions: These data suggest that the platelet δ-storage pool is altered in pregnancy and may be responsible for the maternal thrombotic response needed during labor and delivery to control blood loss. Our preliminary results were unexpected and have stimulated future plans for which we will obtain multiple blood samples during and after pregnancy in a more focused and controlled study.

PB 4.28-2

Essential thrombocythemia and polycythemia vera thrombotic or bleeding diathesis? flow study results

Kapfhammer E[1], Petrides PE[2] and Reininger AJ[3]

[1]*Klinikum Großhadern, München, Germany;* [2]*Hematology Oncology Center, Munich, Germany;* [3]*Baxter Innovations GmbH, Vienna, Austria*

Background: Thrombocythemia (ET) and polycythemia vera (PCV) exhibit increased platelet counts that are thought to explain their major complications, i.e. thrombotic events and embolism, and ensuing morbidity and mortality. Use of anti-aggregatory drugs is recommended to prevent these thromboembolic complications. However at platelet counts exceeding 1 mio/μL the thrombotic diathesis reverses into a spontaneous bleeding tendency due to an acquired von Willebrand factor deficiency, especially of the large VWF multimers. The von Willebrand factor usually mediates the interaction between platelets and vascular injury site, especially in areas of high haemodynamic shear stress.

Aim: We performed an *in vitro* flow study with ET or PCV blood to assess the overall effect of VWF large multimer deficiency and simultaneous acetylsalicylic acid treatment on platelet aggregation. To determine the role of the single contributing factors we crosswise exchanged plasma and platelets of patients and healthy donors.

Methods: Our study involved 12 patients with essential thrombocythemia or polycythemia vera with platelet counts over 1 mio/μL on low dose acetylsalicylic acid treatment. None of them had any prior thrombotic or bleeding event. As control group we analyzed blood from 11 healthy volunteers. Platelet aggregation on fibrillar collagen type I was recorded with videomicroscopy in a wall parallel flow chamber with subsequent off-line image analysis. Platelet receptor expression was analyzed with flow cytometry.

Results: Patient platelets tested in patient plasma demonstrated reduced aggregate forming capacity on collagen under high shear stress in contrast to the healthy control. Replacing patient platelets with platelets of healthy volunteers (at normal platelet counts) and keeping the patient plasma increased aggregate formation under moderate shear rates. Flow experiments using healthy subject plasma and platelets, but adjusting platelet counts to over 1 mio/μL, demonstrated maximal aggregation in less than half the time of normal conditions. In addition, prior acetylsalicylic acid intake in healthy controls led to a 50% aggregate reduction in spite of high platelet counts. Flow cytometry of ET and PCV platelets demonstrated reduced expression of the platelet receptor integrin alpha-2bbeta3. Analysis of plasma VWF confirmed lack of large multimers.

Conclusion: We hypothesize that in ET and PCV patients two mechanisms are operational that balance the underlying thromboembolic diathesis: deficiency of the large VWF multimers and reduced expression of integrin alpha-2bbeta3 receptors. Our results demonstrate that these compensatory mechanisms are effective at high shear rates but not sufficient at moderate shear rates to counter the prothrombotic tendency. Therefore we consider the use of antiaggregatory drugs an important therapeutic option for the prevention of thrombosis and embolism in such patients.

PB 4.28-3

Risk-stratification of essential thrombocythemia patients for arterial, venous thromboses and for microcirculatory disturbances

Posfai ER[1], Marton I[1], Széll M[2], László Z[2] and Borbényi Z[1]

[1]*University of Szeged, ;* [2]*University of Szeged, Szeged, Hungary*

Background: Advanced age (over 60 years) and previous thromboses are well established risk factors for thrombosis in essential thrombocythemia (ET) patients. Recently, the impact of novel risk factors, such as JAK2 V617F; MPL W515L/K mutational status or leukocytosis has been investigated.

Aims: To evaluate the cardiovascular major risk factors (hypertension, cigarette smoking, diabetes mellitus, and hyperlipidemia) JAK2 V617F, MPL W515L mutations impact on the thrombotic events of ET patients.

Methods: *Study participants:* One hundred and one patients (29 males; 72 females) with median age: 61 years [range: 14–95 years] diagnosed with essential thrombocythemia between 1999 and 2011 at our Department were enrolled to the study.

Laboratory methods DNA was isolated from EDTA-stabilized peripheral blood samples, and screened for the JAK2 V617F, MPL W515L mutations with an allele-specific PCR method.

Statistical analysis: Patients were stratified into subgroups according the presence or absence of thrombotic events which were compared by a series of variables such as age, presence of JAK2 V617F and MPL W515L mutations, measured platelet and leukocyte counts at diagnosis, cardiovascular risk factors, and thrombotic events before and after diagnosis. Mann-Whitney tests were performed to explore overall effects of these variables. Multivariate binary logistic regression was also run to estimate the probability of thrombotic events.

Results: JAK2 V617F-positivity was proven in 61 patients. MPL W515L mutations could be detected in 16 patients. Compared to the data published so far, the incidence of thrombosis was higher in our study group. Fifty-one thrombotic events were recorded in the prior history of ET patients, (before the clinical diagnosis of ET): myocardial infarction events in 16 cases (15.8%), ischemic stroke or transient ischemic attack in six cases (5.9%), venous thrombotic events in 11 cases (10.9%), and microcirculatory disturbances in 26 cases (25.7%). During the follow up period, 23 new thrombotic events were recorded: myocardial infarction in three cases (3%), ischemic stroke or transient ischemic attack in 10 cases (9.9%), venous thrombosis in three cases (3%) and microcirculatory disturbances in 13 patients (12.9%).

The univariate analysis of the individual cardiovascular risk factors, revealed that the presence of diabetes mellitus ($P = 0.581$), high blood preassure ($P = 0.119$), and cigarette smoking ($P = 0.293$) were not associated with an increased risk of thrombosis. However, hyperlipidaemia ($P = 0.032$) was associated with a significantly increased risk of thrombotic events. Multivariate binary logistic regression analysis confirmed that the probability of recurrent thrombotic events is significantly higher in patients who had prior history of thrombosis ($P = 0.071$), especially in the view of prior myocardial infarction events ($P = 0.030$). Nevertheless, the expected prognostic value of JAK2 V617F, MPL W515L mutations for thrombosis could not be detected in our patients.

Summary/Conclusions: Despite the low number of patients, it might be seen that further risk factors also play a role in the development of thrombotic events. Therefore, we purpose that identifying and eliminating modifiable risk factors such as cardiovascular risk factors might be greatly beneficial in the complex management of ET patients.

PB 4.28-4

Omega-3 Alpha linolenic acid interferes with platelet rolling and adhesion to von Willebrand factor

Stivala S[1], Reiner MF[1], Lüscher F[1] and Beer JHJ[2]

[1]*Physiology Institute, Zurich;* [2]*Cantonal Hospital Baden, Baden, Switzerland*

Background: The plant-derived omega-3 fatty acid (FA) alpha-linolenic acid (ALA) may constitute an attractive cardioprotective alternative to fish-derived n-3 FA. We have previously shown that ALA reduces experimental atherosclerosis and platelet-dependent thrombosis in mice.

Aim: To further analyse the inhibitory effect of ALA on platelet function, specifically platelet rolling and adhesion to vWF and collagen under flow.

Methods: For platelets adhesion to collagen, citrate-anticoagulated blood from healthy donors was incubated with vehicle (ethanol) or ALA (30 μM) for 1 h at room temperature. Platelets were labelled in parallel with the fluorescent dye calcein. 48-wells plates (Bioflux) were coated with equine collagen (100 μg/mL) for 1 h, followed by blocking with 0.5% BSA in PBS for 10 min. Blood was added to the well of the plate and a flow shear of 10 dyne/cm^2 was applied for 10 min. At the end of the experiment 6–8 pictures were taken along the whole channel in order to visualize the thrombi. The total thrombus area was calculated with the Bioflux software. For platelet adhesion to vWF, citrate- and EDTA-anticoagulated blood were used (the latter to analyse exclusively GPIb-mediated adhesion). Aliquots from each sample were incubated with vehicle (ethanol) or ALA at 7.5/15/30 μM final concentrations for 1 h at room temperature. Platelets were stained with calcein in parallel with the vehicle/ALA treatment. Plates were coated with human vWF at 100 μg/mL for 1 h at room temperature, then blocked with 0.5% BSA in PBS. At the end of the treatment, blood was added to the plate and a shear flow of 100 dyne/cm^2 (corresponding to a shear force of 2500 s^{-1}) was applied for 10 min. Pictures were taken every 5 s. The platelet-covered area and the platelet rolling velocity were calculated with the Bioflux software.

Results: After incubation with ALA, thrombus formation on collagen (measured as thrombus-covered area) was reduced (162,193 μm^2 vehicle vs. 87,883 μm^2 ALA, $n = 5$). Similarly, platelet adhesion to vWF and platelet aggregation were dose-dependently reduced by ALA, the difference becoming statistically significant at the higher ALA concentration (platelet-positive area: 64,112 μm^2 vehicle vs. 21,102 μm^2 ALA, $n = 6$, $P = 0.018$). A reduction in GPIb-mediated platelet adhesion was also observed with EDTA-anticoagulated blood (platelet-positive area: 99,781 μm^2 vehicle vs. 70,405 μm^2 ALA, $n = 6$, $P = 0.016$). Analysis of single platelets showed an increased rolling speed in platelets from the ALA-treated samples compared to vehicle (velocity: 0.75 μm/s vehicle vs. 1.56 μm/s ALA, $n = 10$, $P = 0.023$). Incubation with ALA did not change GPIb surface expression, as shown by flow cytometry (MFI: 3217 vehicle vs. 3477 ALA, $P = 0.3$) and glycocalicin in plasma as measured by ELISA (2.29 μg/mL vehicle vs. 2.37 μg/mL ALA, $P = 0.35$).

Conclusions: ALA inhibits platelet adhesion and aggregation to collagen and vWF, and it reduces GPIb-vWF binding without affecting the receptor expression. Possible mechanisms include alteration of the membrane microdomains (lipid-rafts) and of GPIb clustering-signalling from/to these domains.

PB 4.28-5

Platelet aggregations in thrombus and thrombopoiesis in bone marrows visualized by *in vivo* molecular imaging and contribution of inflammatory cytokines

Nishimura S and Nagasaki M

The University of Tokyo, Tokyo, Japan

Objective: The mechanism by which thrombotic vessel occlusion occurs independently of plaque development or endothelial cell (EC) disruption remains unclear, largely because of an inability to visualize thrombus formation, especially at the single-platelet level in real time.

Methods: Therefore, we developed *in vivo* imaging technique based on single- and multi-photon microscopy, and we assessed dynamic cellular interplay in thrombosis models. We visualized that rapidly developing thrombi composed of discoid platelets without EC disruption was triggered by ROS photochemically induced by moderate power laser irradiation.

Results: Using this technique, we elucidated that Lnk (adapter protein) regulates integrin signaling leading to stabilization of developing thrombus *in vivo*. We established the efficient culture system of human iPS-derived platelets, and we confirmed the functional role *in vivo*. These artificial platelets can circulate, and contribute to their thrombus formation, indicating the clinical usefulness considering the cell therapy for future.

In addition, we elucidated the contribution of inflammatory cytokines, ROS, and integrin signaling to our thrombosis models. The inflammatory cytokines TNF-alpha and IL-1 could be key components of the EC response, acting through regulation of von Willebrand factor mobilization to the cell surface. Thrombus formation was then initiated by the binding of platelet GPIb-alpha to endothelial von Willebrand Factor in our model, and this effect was inhibited by the ROS scavenger N-acetylcysteine. Actin linker talin-dependent activation of alphaIIb-beta3 integrin in platelets was required for late phase thrombus stability.

We also visualized the megakaryocyte dynamics during thombopoiesis in living bone marrows, and both proplatelet productions and fragmentation were revealed. We identified novel humoral factors which programmed these steps, which synergistically work with thrombopoietin for efficient platelet production *in vivo*.

Summary: In sum, using our imaging system can be a powerful tool to analyze thrombus formation. We clarified the mechanism of discoid platelet aggregations on undisputed endothelium. The initial platelet aggregation subsequently leads to irreversible integrin- and actin-dependent thrombus development. Inflammatory cytokine signaling in ECs also played pivotal role.

PB 4.28-6

Plasma levels of soluble receptor protein-tyrosine kinases Mer and Tyro3 are increased in acute coronary syndrome patients

Jun W[1], Yuliang M[2], Jie Z[2], Ying S[2], Songsong L[2], Jingzhong Z[2], Lei Z[2] and Ning L[2]

[1]Beijing Jishuitan Hospital; [2]Peking University, People's Hospital, Beijing, China

Backgroud: Growth arrest-specific protein (Gas6) and its receptors Axl, Mer, and Tyro3 have numerous roles in inflammatory diseases, cancer, and thrombosis. These receptors could be cleaved by metalloproteinases to form soluble receptors. Recent reports suggested they might have important roles in the progress of Acute Coronary Syndrome (ACS).

Aims: To investigate the roles of Gas6 and its receptors in the progress of acute coronary syndrome and their correlation with thrombin generation and atherosclerotic plaque stability.

Methods: Sixty-six ACS patients and 42 healthy controls were recruited in this study. Plasma levels of Gas6, sAxl, sMer, and sTyro3 in ACS patients were examined by enzyme-linked immunosorbent assay (ELISA) and compared to those in the gender and age compared control group. The correlation of plasma levels of those proteins with clinical indices was further examined.

Results: Plasma levels of sMer, sTyro and sAxl were significantly increased in ACS patients compared to those in age and gender compared controls ($P < 0.01$, $P = 0.0006$ and $P = 0.0387$, respectively). However, there was no significant difference in plasma Gas6 level between ACS group and control group ($P = 0.6568$). After percutaneous coronary intervention (PCI), there was no significant difference in plasma levels of Gas6, sMer, sTyro3 and sAXL between ACS group and control group ($P > 0.5$). Plasma levels of sMer and sTyro3 were significantly correlated with thrombin-antithrombin complex (TAT) formation ($P = 0.0138$ and 0.0255, respectively).

Conclusions: Compared to control group, plasma levels of sMer and sTyro3 were significantly increased in ACS patients. In ACS, atherosclerotic plaques may not be the source of sMer and sTyro 3. However, plasma levels of sMer and sTyro3 were correlated with thrombin-antithrombin complex generation. They may come from thrombin stimulated inflammatory cells in circulation.

PB4.29 – Acquired and immune thrombocytopenia

PB 4.29-1

The immature platelet fraction is susceptible to the platelet size and useful for screening of macrothrombocytopenia from immune thrombocytopenia

Miyazaki K[1], Koike Y[2], Danbara M[1], Horie R[1] and Higashihara M[1]
[1]Kitasato University School of Medicine, Sagamihara; [2]Tokyo Hitachi Hospital, Tokyo, Japan

Background: The immature platelet fraction (IPF) is a useful parameter indicating thrombopoietic activity to differentiate the causes of thrombocytopenia. We previously reported that the percentage of IPF (%IPF) is negatively correlated to the platelet count among ITP patients, and not among myelodysplastic syndrome (MDS) patients. We also noticed that some MDS patients exhibited extremely high% IPF values, which were dissociated from the percentages of reticulated platelets (%RP) measured by flow cytometry. Such discrepancies were also observed in hereditary macrothrombocytopenias, which are sometimes difficult to be distinguished from ITP, because ITP also exhibits increased number of reticulated platelets in a slightly larger size. Once misdiagnosed, a hereditary macrothrombocytopenia patient might be subjected to an invasive treatment such as splenectomy. In order to avoid such mistreatments, a clear marker to differentiate macrothrombocytopenia is desperately needed.
Aims: To elucidate the mechanisms of the aberrant increase of IPF among macrothrombocytpenic patients, and search for a useful parameter to distinguish macrothrombocytopenia from ITP
Methods: The IPF values and other platelet indices of various hereditary macrothrombocytopenia were determined using Sysmex XE-2100 automatic hematology analyser in the blood samples. Platelet count and other parameters of platelet, such as MPV, PDW and P-LCR were measured simultaneously. Phosphorylation of myosin light chain was also examined to estimate activation status. Sixteen individuals from 12 families of hereditary macrothrombocytopenia were enroled in this study. We also monitored the IPF during EDTA-induced aggregation, platelet agglutination by macroglobulinemia and cold-storage. The morphological changes of platelets were also examined on the blood film.
Results: The IPF values were about five times higher in MYH9 disorders (%IPF 48.0 ± 1.8) and about 1.5 times higher in other macrothrombocytopenias (%IPF 17.0 ± 2.2) than immune thrombocytopenic patients with similar platelet counts (%IPF 9.3 ± 0.4). These results suggested that the platelet size affect the IPF value. However it still remains the possibility that some factors other than the size might make an influence on the IPF. No one knows whether large platelets are functionally identical to normal platelets except for the size. In order to exclude the possibility, we next examined the changes of IPF values during EDTA aggregation, agglutination by macroglobulinemia and cold-storage. The IPF was significantly increased under these conditions in a time dependent manner along with forming platelet clumps. Durnig cold-storage, each platelet increased in size with fewer granules probably due to degranulation, and a couple of platelets stuck to each other to form a few tiny clumps. The IPF was strongly influenced by a few tiny platelet aggregates rather than other platelet indices, such as mean platelet volume (MPV), platelet-large cell ratio (P-LCR) and platelet distribution width (PDW).
Conclusion: IPF is susceptible to the platelet size, and could be a useful parameter for screening of macrothrombocytopenia from ITP.

PB 4.29-2

Abnormal lipid rafts related signaling in T lymphocytes in immune thrombocytopenia patients

Zhang X, Zhang D, Li H, Yang Y, Fu R, Zhang L and Yang R
Institute of Hematology and Hospital of Blood Diseases, Tianjin, China

Backgrounds: The lipid rafts are dynamically variable cell membrane microdomains containing special lipid. The receptor-mediated reaction between the proteins promotes the aggregation of the lipid rafts and the signal transduction. Any lymphocytes state changes may result in the accumulation of lipids in the cell membrane lipid rafts, causing a greater area of lipid rafts formation. Therefore, abnormal changes in the size and structure of the lipid rafts will affect their stability, and may lead to abnormal signal transduction and pathological states. Immune thrombocytopenia (ITP), as an autoimmune disease, has confirmed cellular immune abnormalities associated with T lymphocytes. So far, no study on the relationship of lipid rafts and ITP was reported.
Aims: To further clarify the important role of lipid rafts in immune signaling processes, and to provide new clues to new treatments for ITP.
Methods: The $CD4^+$ and $CD8^+$ T lymphocytes were isolated by flow cytometry from the ITP patients and the healthy controls, and cells were stained with fluorescence-labeled cholera toxin subunit B(CTB), which binds the raft-associated glycosphingolipid GM1. GM1 levels on the lipid rafts of the $CD4^+$ and $CD8^+$ T lymphocytes were measured by confocal microscope. To verify whether the T-cell activation may cause the aggregation of lipid rafts, peripheral blood T lymphocytes were stimulated by anti-CD3/CD28 antibodies after 48 h culture. To determine whether MβCD inhibits TCR-mediated lipid raft clustering, anti-CD3/CD28 antibodies-activated $CD4^+$ and $CD8^+$ T lymphocytes were treated with MβCD. The T cell proliferation and the secretion of the IFN-γ in the culture supernatant were also measured.
Results: Twenty-five patients and 20 healthy controls were enrolled in this research. Compared to the healthy controls, in ITP patients, GM1 levels on the lipid rafts of the $CD4^+$ and $CD8^+$ T lymphocytes were both significantly elevated, indicating that T lympocytes in ITP patients are automatically and strongly activated(CD4: $P = 0.014$; CD8: $P = 0.045$). When activated by anti-CD3/CD28 antibodies for 48 h culture, GM1 levels on T lymphocytes of healthy controls also increased when compared with unactivated normal T lymphocytes (CD4: $P = 0.553$;CD8: $P = 0.313$), but not as significantly as the activated T lymphocytes of ITP patients(CD4: $P = 0.005$;CD8: $P = 0.003$). Meanwhile, it demonstrated that the anti-CD3/CD28 antibodies strongly enhanced lipid raft clustering on T lymphocytes in ITP patients when compared with the unactivated patients group(CD4: $P = 0.047$;CD8: $P = 0.007$), suggesting that the threshold of the T cells activation from patients with ITP decreased. There were no significant differences on the GM1 levels between the unactivated ITP patients and the healthy controls(CD4: $P = 0.064$;CD8: $P = 0.150$), which might indictate that after 48-h 'rest' the T cell lipid raft aggregation were reversed. As we expected, MβCD could blockade the T lymphocytes activation, both in the lipid raft aggregation and the T cell proliferation. No significant differences were found in the same patients who were previously untreated and then got remission(CD4: $P = 0.140$;CD8: $P = 0.100$), indicating the lipid raft aggregation might be not related with the disease progression.
Conclusion: In ITP patients, the T lymphocytes abnormal lipid raft aggregation is proved to be associated with the pathological T cell activation. And the depletion of the lipid raft can reverse the over-reacted T lymphocytes in ITP patients.

PB 4.29-3

Alloimmune thrombocytopenia masking a bernard soulier syndrome in a congenital nephrotic syndrome of the Finnish type (nphs1)

Baccini V[1], Elkaim E[2], Ghalloussi D[1], Rousset-Rouviere C[2], Frere C[3], Chambost H[4], Morange PE[1], Tsimaratos M[2] and Alessi M-C[1]

[1]UMR Inserm 1062; [2]Service de Néphrologie Pédiatrique; [3]Laboratoire d'Hématologie; [4]Service d'Hématologie Pédiatrique, Marseille, France

Background: A male child developed a nephrotic syndrome due to glomerular sclerosis soon after birth. He carries double homozygote mutations on the chromosome 19 in the major podocyte slit diaphragm protein, the nephrin, and was diagnosed NPHS1. A high level of consanguinity was evidenced in his family and his parents are first cousins. Few days after birth, the platelets count was 9 G/L. Hb level was 182 g/L. No infection, disseminated intravascular coagulation, haemangioma, splenomegaly were evidenced. In the bone marrow, megakaryocytes were normally present and with a normal morphology. A thrombocytopenia has never been described in NPHS1 patients; In addition one of his cousins, carrying the same nephrin mutations, did not exhibit thrombocytopenia indicating no relation between NPHS1 and the observed thrombocytopenia.

Aims: To investigate the etiology of this thrombocytopenia.

Results: Platelet immunology investigation detected alloantibodies against HPA5b antigen in the mother. Maternofoetal alloimmunization was straightforward with genotyping in the two parents and the propositus.

Platelet transfusions (apheresis platelet concentrates) were rapidly initiated twice a week, in parallel with treatment for NPHS1. The child was daily supplemented with albumin, thyroxin, antithrombin and IV immunoglobulins, received angiotensin converting enzyme inhibitor and non steroidal anti inflammatory drug. A nephrectomy is already plan and he will be placed on the waiting list for renal transplantation.

Intriguingly 2 months after birth, severe thrombocytopenia was still present and managed with platelet transfusions every 6 days. This prompted us to pursue platelet exploration. Study of platelet morphology occasionally revealed giant platelets. Parents' platelet counts and mean platelet volume were normal. Flow cytometry revealed a moderate decrease in GPIb levels in both parents (MFI mother and father vs. range of control values: 16.8 and 17.9 vs. [21.2–39.9] AU) suggesting that parents can carry GPIb/IX heterozygous mutation. By immunofluorescence we confirmed the absence of GPIb expression in the propositus's megakaryocytes whereas GPIIbIIIa was normally expressed. At the age of 4 months, the propositus was free of platelet transfusions for 3 weeks with a platelets count between 30 and 50 G/L. This allows us to confirm a total absence of GpIb expression at the platelets' surface but a normal expression of GPII/IIIa. GPIb/IX genes (Chr 22 and 3) are under sequencing.

Conclusion: We described a case carrying an association of hereditary diseases in a context of high consanguinity level. Immunofluorescence on megakaryocytes helped us to detect GPIb/IX deficiency in this complex situation involving platelet polytransfusion and immunization.

PB 4.29-4

Type I interferon dampen platelet production and function

Rivadeneyra L[1], Pozner G[1], Negrotto S[1], Fondevila C[2], Gomez RM[3] and Schattner M[1]

[1]Institute of Experimental Medicine – National Academy of Medicine – CONICET, Buenos Aires; [2]Bazterrica Clinic, Buenos Aires; [3]Biotechnology and Molecular Biology Institute – CONICET, UNLP, La Plata, Argentina

Background: We have previously shown that infection of human $CD34^+$ cells with Junin virus (arenavirus causative of Argentine hemorrhagic fever) or Poly(I:C), a synthetic double-stranded RNA that mimics viral replication, results in an impaired platelet production with no quantitative changes in megakaryocyte generation that was associated with the production of type I interferon (IFN-I). These findings identified IFN-I as a new regulator that selectively affects the last steps of megakaryocyte lifespan, and suggested a potential mechanism for thrombocytopenia in Argentine hemorrhagic fever and other diseases associated with increased type I IFN levels.

Aim: To further analyze the megakaryocyte/platelet function abnormalities mediated by IFN-I and explore whether the levels of IFN-I produced during a viral infection are associated with quanti/qualitative alterations of thrombopoiesis.

Methods: *In-vitro:* Cord blood human $CD34^+$ cells were stimulated with thrombopoietin (50 ng/mL) and treated with different concentrations of Poly(I:C), strong inducer of IFN-I, or with human recombinant IFN-beta at day 7 of culture. After 14 days, CD61 expression and fibrinogen binding in platelets were evaluated by FACS. *In-vivo*: 8–10 week old C57BL/6 female mice were daily intravenously inoculated with Poly(I:C) (100 μg/mouse) and blood samples were taken at 24, 48 and 72 h. Platelet count was determined with a veterinary cell counter. P-selectin expression and fibrinogen binding in peripheral platelets were evaluated by FACS. Plasmatic IFN-beta levels were determined by ELISA. Results represent the mean ± SEM of 5–6 experiments.

Results: While the number of CD61 copies on the membrane of *in-vitro*-generated platelets after Poly(I:C) or IFN-I treatment was similar to control samples, fibrinogen binding of thrombin-stimulated platelets was significantly inhibited (85% and 69% of maximal inhibition respectively, IC_{50}: 6.5 mg/mL and 7.6 U/mL for Poly(I:C) and IFN-I respectively). When mice were inoculated with Poly(I:C), a reduction of 28, 54 and 67% in the platelet count was observed at 24, 48 and 72 h respectively. The mean platelet volume was 8 and 13% higher than control values at 48 and 72 h respectively ($P < 0.01$), indicating a slight but significant bone marrow response to the decreased platelet count. While thrombin-induced fibrinogen binding and P-selectin externalization of platelets from mice that were treated for 24 or 48 h with Poly(I:C) were not different from control animals, both responses were significantly reduced after 72 h (complete turnover of the platelet population) (51 and 33% lower than the control value respectively, $P < 0.05$) suggesting an inhibitory effect at the bone marrow level rather than an effect on peripheral platelets. The IFN-beta levels in plasma from treated animals were significantly higher than those found in controls (89 ± 19, 101 ± 26, 126 ± 21 pg/mL at 24, 48 and 72 h respectively, vs. 41 ± 9).

Conclusions: Our data suggest that treatment of mice with Poly(I:C) inhibits platelet generation and function associated with an increase in the levels of plasmatic IFN-I. These findings were also supported by the *in-vitro* data in human cells and may explain the defects observed in platelet production/function as a consequence of viral infections.

PB 4.29-5

Lack of association between NR3C1 polymorphism and glucocorticoid resistance in Chinese patients with immune thrombocytopenia

Xuan M, Yang Y, Li H, Fu R, Zhang D, Zhang X and Yang R

Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder involving autoantibody- and cell-mediated increased platelet destruction and/or decreased platelet production. First-line therapy of ITP comprises applying glucocorticoid and/or intravenous immunoglobulin. But resistance to glucocorticoids (GCs) is an intractable problem in therapy for ITP. Because GCs exert their effects through glucocorticoid receptor (GR), being a GR gene, NR3C1 is thought to connect with individual differences in glucocorticoid responsiveness during GCs treatments.

Aims : The purpose of this study was to analyze the correlations between three novel SNPs of NR3C1 and GCs responsiveness in Chinese patients (Han ethnic) with ITP.
Methods: We analyzed the frequency of three novel single nucleotide polymorphisms (SNPs) of NR3C1 in ITP patients and evaluated the role of these genetic variants in GCs therapy. Four hundred and seventy-three patients with ITP and 160 healthy controls were recruited. Patients were allocated into GCs-responsive (n = 358) and -non-responsive group (n = 115). All subjects of the three groups were genotyped by PCR-RFLP (restriction fragment length polymorphism) method for the *Bcl*I, N363S and ER22/23EK polymorphisms. Assess the statistical differences of genotypes between ITP and controls, and those between GCs- responsive and non-responsive group.
Results: In healthy controls, *Bcl*I-GG/GC/CC occurred with 0.581/0.35/0.069 frequency. In ITP patients, *Bcl*I-GG/GC/CC was found with 0.617/0.353/0.03 frequency. There was no statistically differences between ITP and controls (P = 0.070). In GCs-responsive and -non-responsive group, *Bcl*I-GG, GC, CC occurred with frequencies of 0.628/0.352/0.02 and 0.583/0.357/0.061 respectively. No correlations in the variants of *Bcl*I was found between the GCs-responsive and -non-responsive group (P = 0.086). Neither N363S nor ER22/23EK polymorphism was observed in all 636 participants.
Conclusion: The *Bcl*I polymorphism is not related to response of glucocorticoids in patients with ITP. Furthermore, we did not observe N363S and ER22/23EK polymorphism in Chinese Han population.

PB 4.29-6

Liver X receptor (LXR) activation influences murine platelet count only under normolipidemic conditions

Van Der Stoep M[1], Li Z[1], Van Der Sluis RJ[1], Van Berkel TJC[1], Van Eck M[1], Hoekstra M[1] and Korporaal SJA[2]

[1]Leiden Academic Centre for Drug Research, Leiden; [2]University Medical Center Utrecht, Utrecht, The Netherlands

Background: We recently showed that hypercholesterolemia induces altered platelet characteristics as well as hyperreactivity in mice and humans[1,2]. Activation of the cellular cholesterol sensors liver X receptor (LXR) β, which is an oxysterol-activated nuclear receptor that tightly regulates intra- and extracellular cholesterol homeostasis, also modifies platelet responsiveness[3]. Therefore, LXRβ might be a potential target for the treatment of atherothrombosis.
Aim: The current study aims to elucidate the influence of hyperlipidemia on LXR-induced changes of platelet characteristics.
Methods: Experiments were performed with apolipoprotein E knockout (apoE KO) mice, a commonly used hyperlipidemic mouse model, or their wildtype (WT) littermates. ApoE deficiency in mice results in extremely elevated plasma VLDL and LDL cholesterol levels on regular chow diet (5.7% (w/w) fat and no added cholesterol). To study the effect of the synthetic LXR agonist T0901317 on platelets during normalization of plasma cholesterol levels, apoE KO mice were fed a Western-type diet (WTD; 15% (w/w) fat, 0.25% cholesterol) for 3 weeks and were subsequently transplanted with WT bone marrow (BM) to restore plasma apoE levels and normalize plasma lipid levels. Then the mice were fed T0907317 (10 mg/kg/day) mixed with regular chow diet for 6 weeks.
Results: The elevated plasma total cholesterol (TC) levels of ApoE KO mice on chow (546 ± 58 mg/dL vs. 61 ± 6 mg/dL in WT mice, $P < 0.001$) or WTD (764 ± 118 mg/dL, $P < 0.001$) were associated with significantly lower platelet counts (73% and 84% of control, respectively; $P < 0.001$), suggesting that hyperlipidemia affects platelet turnover. Normalization of plasma TC levels by transplantation of WT BM into apoE KO mice (from 984 ± 90 mg/dL to 81 ± 6 mg/dL; $P < 0.001$) resulted in a slightly increased platelet count (865 ± 83 × 10^9/L) compared to apoE KO BM-transplanted mice (TC = 436 ± 45 mg/dL, platelet count = 692 ± 106 × 10^9/L, ns). LXR activation by T0901317 raised plasma TC levels in both WT BM- and apoE KO BM-transplanted mice (182 ± 11 mg/dL and 859 ± 78 mg/dL, respectively). However, T0901317 significantly raised platelet count in WT BM-transplanted apoE KO mice (1325 ± 107 × 10^9/L vs. 865 ± 83 × 10^9/L, $P < 0.01$) but left the platelet count in apoE KO BM-transplanted mice unchanged (664 ± 74 × 10^9/L vs. 692 ± 107 × 10^9/L).
Summary/Conclusions: Activation of LXR by T0901317 leads to increased platelet counts, but only under normolipidemic conditions. This effect of hyperlipidemia on LXR function should be taken into account when evaluating LXR as potential target for prevention of atherothrombosis.

PB4.30 – Microparticles and disease – III

PB 4.30-1

Thrombin generation caused by microparticles in patients with atherosclerosis of the vessels of the lower extremities

Matvienko O, Namestnikov Y, Golovina O, Saltykova N and Smirnova O

Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Atherosclerotic diseases are accompanied by activation of blood cells and endothelium that can lead to microparticles (MP) release. MP expresses tissue factor (TF) and procoagulant phospholipids on their surface that can enhance prothrombogenic potential of blood plasma.
Aim: To estimate MP-associated thrombin generation in the group of patients with atherosclerosis of the vessels of the lower extremities
Methods: This research included 29 patients (10 females and 19 males) at the age from 44 to 77 with atherosclerosis of the vessels of the lower extremities. Reference blood samples were obtained from 54 healthy controls. Thrombin generation was measured in platelet-free plasma with Calibrated Automated Thrombinogram Assay method (CAT). Following reagents (Trombinoscope BV, The Netherlands) were used: «MP-reagent», containing negatively charged phospholipids (4 μM), «PRP-reagent», containing rTF (1 pM), and «FluCa"�kit». CTI (40 mg/mL) was added to inhibit contact activation. Following parameters were derived: endogenous thrombin potential (ETP, nM-min), peak thrombin activity (Peak, nM), and rate of thrombin generation (R, nM/min). Data were described by non-parametric methods using the median (Me), 50% confidence interval (CI) and Mann-Whitney U test (Statistica 6.0). $P < 0.05$ was considered sighnificant.
Results: The role of procoagulant phospholipids of MP in thrombin generation was studied with «PRP-reagent» but there were no reliable differences between patients and controls when it was used. Significant differences was found when was used «MP-Reagent» with CTI. This reagent makes it possible to estimate thrombin generation which depends on TF. There was increase ETP, Peak and R in the patients group compared with controls (ETP: Me-807.50, CI: 712.50–1282.00 vs. Me-566.50, CI: 462.25–708.00, $P < 0.01$; Peak: Me-92.09, CI: 60.04–129.62 vs. Me: 46.25, CI:32.91–67.21, $P < 0.001$; R: Me-20.98, CI: 6.76–33.18 vs. Me-7.34, CI: 5.17–12.58, $P < 0.01$).
Conclusion: MP enhances thrombin generation and increase prothrombogenic potential of patients with atherosclerosis of the vessels of the lower extremities due to TF expressed on their surfaces.

PB 4.30-2

Circulating microparticle number and function vary with age: a study of 120 healthy blood donors

Enjeti A, D'Cruz A, Seldon M and Lincz L

Calvary Mater Hospital Newcastle, NSW, Australia

Background and Aims: Information on circulating Micrparticles(MP) in normal subjects is fragmented and incomplete. The aim was to conduct a thorough evaluation of MP subsets and pro-coagulant function in healthy individuals and to determine how general clinical and biochemical demographics influence MP levels and/or function.

Methods: Citrated blood sample were collected from 120 healthy volunteer blood donors after receiving informed consent. Platelet free plasma was prepared using a standardized published protocol. MP subsets were enumerated by Flow cytometry(BDFACS Canto) after staining with specific antibodies for platelets(CD41), endothelial cells (CD105), tissue factor(CD142), white blood cells(CD45), monocytes (CD14) and red cells(CD235a). Counting beads using an ISTH protocol was employed. Coagulant function was assessed by the Xact assay on a BCS coagulation analyser and by thrombin generation using a Calibrated Automated Thrombogram(CAT) on a thrombinoscope. An ELISA was undertaken for Annexin V expression. Hormonal and lipid analysis – FSH, LH, testosterone, oestradiol, progesterone as well as HDL, LDL, cholesterol and HDL/LDL ratios were measured by standard biochemistry techniques. A total of 108 samples were finally analysed according to age, gender, body mass index (BMI), full blood counts, smoking status, hormones and lipid profile. For analysis, the cohort was divided into three age groups (G): ≤29 years(G1, $n = 31$), 30–59 years(G2, $n = 60$) and ≥60 years(G3, $n = 17$). STATISTICA software was used for all analyses.

Results: A total of 108 subjects were finally analysed which included 60 males and 48 females. Twenty were smokers. The mean age was 40 years (range 16–73). The mean BMI was 26.5(range 17.5–46.9). All full blood count parameters were within normal range. Platelet MP (median 38.8/μL) were highest at ages ≤29 and ≥60 and significantly lower($P = 0.00013$) in G2(30–59 years). A similar ''U'' shaped curve was noted for red cell, tissue factor and Annexin V expressing MP, while the opposite trend was noted for endothelial MP. In the functional analysis, CAT results were similar to that of platelet MP, with ETP, time to peak, and lag time showing a significant reduction in the middle aged G2 group but elevated in G1 and G3. There were no significant differences in the Xact test or the ELISA for phospholipid content between the three groups. There were no gender differences in levels of circulating MP except for monocyte microparticles that were significantly ($P = 0.0014$) higher in males. Multivariate modelling did not show any specific variable, including BMI, full blood counts, lipid or gender specific hormonal parameters, predictive of microparticle number. Interestingly, smokers showed a reduction in red cell, TF and Annexin V expressing MP.

Conclusions: Considerable variability with age was observed in MP counts and thrombin generation, but not in phospholipid dependent pro-coagulant properties. The most significant finding was that of lower MP levels in those between ages 30–59 years compared to those either younger or older than this group. This is an important finding, which has bearing on interpretation of levels of circulating MP in pathological states. The physiological explanation for this finding is not yet apparent. The differences noted in smokers need more extensive evaluation.

PB 4.30-3

Microparticles in aneurismal subarachnoid hemorrhage: role in acute and delayed cerebral ischemia

Artoni A, Conte V, Tripodi A, Merati G, Scalambrino E, Passamonti SM, Bucciarelli P and Martinelli I

Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milan, Italy

Background: Microthrombosis has been demonstrated in early and delayed cerebral ischemia after aneurismal subarachnoid hemorrhage (aSAH). Markers of coagulation activation as microparticles (MPs) are an established risk factor for thrombosis. We tested the hypothesis that levels of microparticles might correlate with (i) aSAH severity (ii) early cerebral ischemia (ECI) and (iii) delayed cerebral ischemia (DCI).

Methods: Consecutive aSAH patients (age 18–80) admitted to our department between November 2011 and September 2012 were included in the study. Total Mps (AnnexinV+), platelet Mps (PLT-MPs, AnnexinV+/CD41+), tissue factor MPs (TF-MPs, AnnexinV+/CD142+), and endothelial MPs (E-MPs, AnnexinV+/CD144+) were measured by flow cytometry in venous blood samples, obtained at early (<3 day) and delayed phase (7–10 days). Multi-parameter MRI was performed to evaluate ischemic damage and vasospasm at the same timepoints. Levels of MPs were evaluated comparing patients according to (i) SAH severity (World Federation of Neurological Surgeons score) (ii) ECI severity and (iii) occurrence of delayed complications (vasospasm and DCI).

Results: Twenty-five patients (age 57 ± 12 years) were included in the analysis. Overall increased levels of MPs were observed at early phase after aSAH when compared to controls (334, IQR 80–775 vs. 64 IQR 40–147, $P = 0.0024$). In the early phase no significant differences in MPs level were observed in patients with different aSAH severity (MPs tot 436, IQR 76–918 vs. 313 and IQR 83–638 respectively, $P = 0.56$). Interestingly patients with most severe ECI (MPs tot 95, IQR 47–178 and 69, IQR 28–95 vs. 37 IQR 34–39, Kruskal-Wallis test $P = 0.19$) and DCI (MPs tot 131, IQR 74–281 and 53 IQR 35–361 vs. 46 IQR 19–117, Kruskal-Wallis test $P = 0.29$) showed the highest values of MPs, but this trend did not reach statistical significance, probably because of the the still small sample size small number of patients included in the study.

Conclusions: Microparticles and microthrombosis may increase the severity of early and delayed ischemic damage after aneurismal SAH. A larger number of patients are required to confirm this preliminary observation.

PB 4.30-4

Platelet microparticles: biomarkers of arterial thrombus formation?

Böing AN[1], Hau C[1], Lacroix R[2], Dignat-George F[3], Sturk A[1] and Nieuwland R[1]

[1]Academic Medical Center, Amsterdam, The Netherlands; [2]Aix-Marseille University; [3]CHU La Conception, APHM, Marseille, France

Background: Most platelet microparticles (PMP) in fresh plasma of healthy humans do not bind annexin V or lactadherin, thus questioning the role of PMP as a procoagulant risk factor. Because the release of PMP requires not only platelet activation (Blood 2009; 113: 1112–1121) but also the binding of fibrinogen to glycoprotein IIb (J Biol Chem 1993; 268: 14586–9), we hypothesize that PMP may reflect arterial thrombus formation/degradation.

Aim: To investigate the role of fibrinogen binding on the release and composition of PMP after *in vitro* thrombus formation

Methods: Citrate-anticoagulated blood was collected from healthy subjects ($n = 4$–6). Platelet rich plasma was prepared, and incubated

for 5 min at 37 °C under stirring conditions in a multiplate aggregometer. After 5 min, ADP (10 mM) was added, and after 30 min the incubation was stopped, supernatant was collected and analyzed by flow cytometry.

Results: In fresh plasma 13,980 ± 8419 CD61+ PMP ($n = 6$) were detectable, of which only 2% stained for lactadherin and 5.6% for P-selectin (CD62p). Upon addition of ADP, platelet aggregation occurred immediately, and the number of CD61+ PMP increased to 21,624 ± 5310. The newly formed PMP all expose P-selectin, do not bind lactadherin, do not support coagulation (fibrin generation test), inflammation (whole blood test), or fibrinolysis (plasmin formation). In the presence of abciximab (reopro), the formation of novel PMP is entirely abolished. Thus, the release of PMP exposing P-selectin requires not only platelet activation but also fibrinogen binding *in vitro*.

Conclusions: Our results confirm earlier studies that both platelet activation and fibrinogen binding are both essential for the release of PMP. Because the concentration of PMP exposing P-selectin is associated with aging, peripheral arterial disease and myocardial infarction (Clin Chem 2006; 52: 657–64), we hypothesize that PMP exposing P-selectin may by a marker of arterial thrombus formation/degradation rather than being a risk factor for thrombosis.

PB 4.30-5

Elevated circulating platelet microparticles determine thrombus occlusion in acute coronary syndrome

Hartopo AB[1], Puspitawati I[2], Muntazhar MZ[2], Aji S[2], Gharini RP[2], Setianto BY[2], Taufiq N[2] and Dinarti LK[2]

[1]Universitas Gadjah Mada; [2]Universitas Gadjah Mada, Yogyakarta, Indonesia

Background: Early steps of coronary artery thrombosis involve platelet activation. Activated platelet generates microparticles which convey prothrombotic activity. Platelet microparticles (PMP) may provide additional thrombus burden after coronary plaque rupture, thus leads to aggravated coronary thrombus occlusion in culprit vessel in patients with acute coronary syndrome.

Aims: To investigate whether elevated circulating PMP associated with level of coronary thrombus occlucion in acute coronary syndrome.

Methods: Consecutive patients admitted to Intensive Coronary Care Unit with acute coronary syndrome were enrolled. Circulating PMP were isolated from platelet-poor plasma (PPP) of citrated-venous blood which was drawn within 24 h of admission. CD42b-PE was labelled into PPP and PMP was detected with flow cytometry. Platelet counts, mean platelet volume (MPV) and platelet distribution width (PDW) were measured. Acute coronary syndromes were classified as ST-elevation myocardial infarction (STEMI), non-STEMI and unstable angina, respectively reflect coronary thrombus occlusion levels. Major adverse cardiac events were also documented.

Results: Forty-one patients were analysed. STEMI, indicating coronary total thrombus occlusion and distal myocardial infarction, had significantly highest circulating PMP (6329.74/μL; $P < 0.05$). Non-STEMI, the less severe coronary thrombus, had lower circulating PMP (3990.18/μL). Whereas unstable angina, the mildest event, had lowest circulating PMP (2051.62/μL). Circulating PMP did not significantly correlate with platelet count ($r = 0.220$), MPV ($r = -0.192$) or PDW ($r = -0.071$). Major adverse cardiac events during hospitalisation were not affected by circulating PMP (3852.99 vs. 4268.70/μL; $P = 0.81$).

Conclusion: Elevated circulating PMP determines aggravated thrombus occlusion following acute coronary syndrome. However, it does not associate with major adverse cardiac events.

PB 4.30-6

Increased procoagulant microparticle levels in women with recurrent pregnancy loss

Patil RK[1], Ghosh K[1], Shetty S[1] and Satoskar P[2]

[1]National Institute of Immunohaematology NIIH (ICMR) ; [2]Nowrosjee Wadia Maternity Hospital, Mumbai, India

Background: Pregnancy loss is the most common complication of pregnancy affecting up to 15% of reproducing couples and recurs in 2% to 3% of them. Despite a wide range of investigations, no apparent cause can be found in large number of cases. A defective maternal hemostatic response leading to hypoxia secondary to thrombosis of the uteroplacental vasculature has been hypothesized to subsequently lead to fetal loss. This may include impairment of trophoblast invasion, villitis, and placental microthrombi. Hereditary thrombophilia and antiphospholipid antibodies have been extensively described as risk factors for pregnancy loss. More recently, a new maker has emerged: the cell-derived circulating procoagulant microparticles, which have been reported to have a major role in many thrombosis complicated diseases.

Aim: To analyze the prevalence and significance of circulating procoagulant microparticles (MP) in women suffering from pregnancy loss (PL), both recurrent and unexplained fetal loss and characterize their cellular origin.

Methods: 115 women (60 with early losses, 24 with late and 31 with both early and late PL) with no other presumptive etiological causes (anatomic, genetic or hormonal) were analyzed in the present study for the common thrombophilia markers (i.e. lupus anticoagulant, anti-cardiolipin antibodies, anti-b2GP1 antibodies, annexinV antibodies, protein C, protein S, antithrombin III, factor V Leiden mutation and MTHFR C677T) and for MPs of different cellular types i.e. total procoagulant annexin V MPs, procoagulant platelet(CD41a), endothelial(CD146, CD62e), leukocyte(CD45), erythrocyte(CD235a) MPs as well as tissue factor (TF) expressing MPs. The results were compared with 20 non pregnant healthy women. Methodology for analysis of MPs has been standardized on BD FACS Aria flow cytometer by participating in the 'Vascular Biology SSC workshop: standardization of FCM-based PMP enumeration'.

Results: Thirty seven women were found positive for any of the thrombophilia markers analyzed. Nine were positive for lupus anticoagulant, five for anti-cardiolipin antibodies, three for anti-b2GPI antibodies, 10 for annexin V antibodies and in all, 20 patients had one or more acquired thrombophilia markers. Among the hereditary thrombophilia, seven had reduced protein C levels, 10 had reduced protein S, five had reduced antithrombin III, three were factor V leiden heterozygotes and three were homozygous for MTHFR. No significant differences were seen in the MP profile of women with or without any thrombophilia marker. Total annexin MPs, total TF expressing MPs and endothelial MPs, both constitutive and activated, were found significantly increased($P < 0.05$) in women with PL of all categories (early, late & early and late) when compared to the control group. Differences in platelet and leukocyte MP levels were not found to be significant.

Conclusion: Our findings suggest that MPs are associated with the pathogenesis of PL and may contribute in uteroplacental thrombosis. In addition, the presence of elevated endothelial and TF expressing MPs at a distance (3–24 months) from the adverse pregnancy event suggests a continued chronic endothelial damage or activation which might be one of the causes of recurrent pregnancy loss. Although none of the patients in this study had any thrombotic episode, it is possible that this might become apparent in pregnancy.

PB4.31 – Atherosclerosis: risk factors

PB 4.31-1

Can we identify patients at risk of recurrent coronary artery disease?

Madan G, Sangeeta M, Sharma A, Kakkar VV and Vangala RK
Thrombosis Research Institute, Bangalore, India

Background: Premature coronary artery disease (CAD) occurs at an earlier age in South Asians compared with other ethnic groups. Infection and inflammation show a positive association with the disease. In our previous studies we have shown that pathogen burden specifically Cytomegalovirus (CMV) infection in combination with inflammatory markers show significant association with CAD and recurrent CAD in Indians (Heart. 2012;98(13):982–987). Further global proteome analysis may give more biomarkers for better risk assessment for these events.
Aim: This study was aimed at identifying new biomarkers by performing comparative global proteome analysis for improvement of risk assessment of recurrent CAD.
Methods: 240 age and gender matched subjects (60 healthy controls, 120 CAD affected and 60 recurrent CAD) were selected for a case control study from ongoing Indian Atherosclerosis Research Study (IARS). The information regarding inclusion, exclusion criteria and process of sample collection, and data storage have been published (Indian Heart J, 2010;6:286–95). All the blood samples were collected after overnight fasting of 12–14 h and stored at −80 °C. The sero positivity for CMV was established using neutralizing antibody titer values for each sample. Global proteomic analysis was performed using Surface Enhanced Laser Desorption/Ionization CM10 arrays on serum samples of these subjects. Support Vector Machine method for risk stratification of CAD affected and Tagident software for protein identification. STRING database was used to build the network topology followed by analysis using Cytoscape v.2.8.3 software.
Results: We have identified 39 significantly differentially expressed protein peak (m/z) patterns of which 19 peaks were detected for CAD affected and 20 peaks in recurrent CAD subjects. We used the 20 significant peaks from affected vs. recurrent disease subjects for risk assessment and found that two peaks corresponding to beta-defensin and histatin-3 were significantly associated with recurrent CAD. The odds ratio for beta-defensin was 7.49 (95% CI 2.57–21.9, *P*-value 0.0001) and for histatin-3 it was 1.4 (95% CI 1.02–2.13, *P*-value 0.042) in recurrent CAD subjects. Furthermore, when these markers were combined with conventional risk factors the odds ratio improved to 8.97 (95% CI 2.87–28.04, *P*-value 0.0001). All the 39 proteins were used in network construction, the comparison of the two networks (CAD affected vs. controls and CAD affected vs. recurrent), suggests that the proteins like serpin peptidase inhibitor A1 (), compliment C3 (C3), compliment C5AR1, were significant in both the networks. Proteins like amyloid beta A4 (APP), Pro-opiomelanocortin (POMC) and vasoactive intestinal peptide (VIP peptides) were significant in CAD affected vs. controls but not in those with recurrent disease. New proteins representing infection pathway beta-defensin, histatin-3 and others such as vascular endothelial growth factor A (VEGF-A), growth related alpha protein (GROA), natriuretic peptide B (BNP), and cardiac phospholamban (PPLA) were identified only in the recurrent subjects.
Conclusions: These findings suggest that beta-defensin and histatin-3 may add value to risk assessment for recurrent CAD and further validation in larger cohort is needed. Our data also suggests that infection and immune system proteins may play a major role in recurrent disease.

PB 4.31-2

Risk factors associated with myocardial infarction in venous thromboembolism patients

Laliberté F[1], Nutescu E[2], Lefebvre P[1], Damaraju CV[3], Rondeau-Leclaire J[1], Bookhart BK[3], LAMori JL[3], Schein J[3] and Kaatz S[4]
[1]Groupe d'analyse, Montréal, Canada; [2]The University of Illinois at Chicago, Chicago, IL; [3]Janssen Scientific Affairs, Raritan, NJ; [4]Hurley Medical Center, Detroit, MI, USA

Background: Some of the newer oral anticoagulants have been associated with a heightened risk of myocardial ischemic (MI) events. Data is currently lacking in evaluating risk factors associated with MI in venous thromboembolism (VTE) patients, a population which is commonly treated with anticoagulants.
Aims: The purpose of this study was to identify risk factors associated with MI in VTE patients.
Methods: Health insurance claims between 01/2004 and 09/2008 from the Ingenix IMPACT database were analyzed. Subjects aged ≥18 years with ≥1 year of continuous insurance coverage before the index VTE were identified as of the date of their first VTE diagnosis (index deep vein thrombosis, pulmonary embolism, or both). Patients' histories were analyzed up to the earliest date between health plan disenrollment and lack of follow-up data. The risk of MI for VTE patients with 1, 2, and ≥3 major risk factors (age, gender, hypertension, diabetes, hyperlipidemia, cardiovascular diseases, family history of cardiovascular diseases, chronic kidney disease, obesity, and smoking) as identified by published guidelines was reported. Multivariate Cox proportional hazards models were conducted to identify the most predictive risk factors associated with MI, adjusting for region, insurance, years (2005–2008), baseline medications and healthcare costs.
Results: Of 177,885 VTE patients identified, 4412 (2.5%) developed an MI during a mean follow-up period of 1.3 years. The most frequent major risk factors for MI at baseline were hypertension (46.4%), cardiovascular disease (40.1%), and hyperlipidemia (39.2%). The proportions of patients with 0, 1, 2, or ≥3 major risk factors were 28.9%, 19.1%, 16.2%, and 35.8%. Previous MI, age (≥65 years), coronary artery disease, and hypertension were the risk factors most predictive of MI, with adjusted hazard ratios (HRs; 95% CI) of 5.47 (5.01–5.97), 1.78 (1.66–1.91), 1.60 (1.48–1.74), and 1.42 (1.31–1.55), respectively. Adjusted HRs (95% CI) for VTE patients with 1, 2, ≥3 major risk factors relative to no major risk factor were 2.34 (1.94–2.81), 3.21 (2.67–3.85), and 6.93 (5.85–8.22), respectively.
Conclusions: Traditional major cardiovascular risk factors are very prevalent and predicative of MI in VTE patients. Having multiple major risk factors significantly increases the probability of developing MI events in VTE patients.

PB 4.31-3

Further evidence in support of the association between atherosclerosis and venous thrombosis

Milan M, Vedovetto V, Dalla Valle F, Pesavento R and Prandoni P
2nd Chair of Internal Medicine, Padua University Hospital, Padua, Italy

Background: Ten years ago a strong association between subclinical atherosclerosis and venous thrombosis was found (Prandoni et al., N Engl J Med 2003;348:1435–41). In that study patients with primary pulmonary embolism (PE) and those with previous venous thromboembolism (VTE) were excluded.
Aims: In a new unselected cohort of patients with VTE older than 50 years, including patients with primary PE and patients with previous VTE, we assessed the prevalence of symptomatic and that of subclinical atherosclerosis. In addition, we compared the prevalence of atherosclerotic disease between patients with unprovoked VTE and patients with VTE triggered by acquired risk factors.

Methods: Patients meeting the eligibility criteria were interviewed for history of previous episodes of symptomatic atherosclerosis (including coronary heart disease, transitory or well defined ischemic stroke and arteriopathy of the lower limbs). If the medical history was negative, the presence of vessel wall plaques was investigated through the bilateral ultrasound assessment of carotid arteries with the adoption of standard methods and criteria. After adjusting for age, risk factors for atherosclerosis, thrombophilia and previous VTE, we calculated the odds ratio (OR) and its 95% CI for (either symptomatic or subclinical) atherosclerosis in patients with unprovoked VTE vs. those with a secondary event. The study was approved by the local ethics committee and for all patients written informed consent has been obtained.
Results: Out of 202 consecutive VTE patients meeting the eligibility criteria, 119 (58.9%) referred with an unprovoked VTE, and 83 (41.1%) with a secondary VTE. The mean age (±standard deviation) of study patients was 73.8 ± 10.6 years, 90 (45.1%) were males, 54 (26.7%) presented with primary PE and 40 (19.8%) with previous VTE. No appreciable differences were seen between the two patients' groups in terms of baseline features. A history of symptomatic atherosclerosis was recorded in 42 (35.3%) patients with unprovoked VTE and in 26 (31.3%) with a secondary event. Of the remaining 134 patients, the presence of at least one carotid plaque was recorded in 42 of the 77 (54.5%) patients with unprovoked VTE and in 22 of the 57 (38.5%) with secondary thrombosis. The adjusted OR for either symptomatic or subclinical atherosclerosis in patients with unprovoked as compared to those with secondary VTE was 1.8 (95% CI 1.2–4.1).
Conclusions: The study results, obtained in a broad number of unselected patients over 50, expand those of our previous publication and confirm that an important association does indeed exist between atherosclerosis and unprovoked VTE.

PB 4.31-4

The relationship of FII, FVII, FXIII and fibrinogen levels with conventional risk factors in patients with and without coronary artery disease

Bronic A[1], Ferencak G[2], Lenicek Krleza J[3] and Bernat R[4]
[1]Clinical Hospital Center Sestre Milosrdnice, Zagerb; [2]Outpatients Clinic Medicol, Zagreb; [3]Paediatrics Clinic, Zagreb; [4]Magdalena Special Hospital for Cardiology and Cardiovascular Surgery, Krapinske Toplice, Croatia

Background: A number of coagulation factors are required for the cascade of biochemical reactions leading to fibrin formation. The aim of the study was to investigate the relationship between haemostatic factors II(FII), VII(FVII), XIII(FXIII), fibrinogen and conventional coronary artery disease (CAD) risk factors in order to enhance understanding of phenotypic variation in haemostatic factor levels in patients and clinical controls.
Materials and Methods: The study was performed according to Helsinki Declaration and was approved by the *Magdalena* Special Hospital for Cardiovascular Surgery and Cardiology Ethic Committee. Association analysis was carried out in 242 subjects with ³ 50% stenosis in at least one of the major coronary vessels (CAD+) and 138 subjects with angiographically excluded disease (CAD-). Data regarding body mass index (BMI), presence of arterial hypertension (AH), diabetes, smoking status or history of myocardial infarction (MI) was obtained on admission. Blood collection and processing were performed according to standardized procedures. Established risk factor ratio (ERF) was calculated by dividing total cholesterol by HLD-cholesterol. Fibrinogen was determined by Clauss method; FII and FVII by single step clotting assays and FXIII by chromogenic assay on a BCS analyzer (Siemens Diagnostics, Marburg, Germany). Bivariate correlations between variables were analyzed with Pearson's correlation coefficient, and trendlines were calculated with linear regression analysis. Significance was taken as $P < 0.05$.
Results: Median of the FII, FVII, FXIII and fibrinogen levels was not significantly different between the CAD- and CAD+ patients (108.5 vs.111.0; 120.6 vs.117.1, 93.2 vs.90.9, 2.5 vs.2.6, respectively) ($P > 0.05$). Females have higher values in compare to males (FII:113.6 vs. 105.9, $P = 0.005$; FVII:131.5 vs. 117.9, $P = 0.006$, FXIII:100.6 vs. 92.0, $P = 0.001$, FIB:3.18 vs. 2.8, $P = 0.006$). Fibrinogen correlated with age (R:0.124, $P = 0.05$), FXIII(R:0.285, $P = 0.01$) and FII (R:0.162, $P = 0.01$). Furthermore, FII correlate with BMI (R:0.117, $P = 0.05$), ERF(R:0.174, $P = 0.01$) and FVII (R:0.741, $P = 0.01$) whereas FVII values correlated with ERF(R:0.118, $P = 0.05$) and smoking($R = -0.105$, $P = 0.01$). In clinical controls FII, FXIII, FVII activities correlated with AH (R:0.192; 0.263, 0.296 at $P < 0.05$, respectively). Obtained fibrinogen values were higher in females than in males(3.1 vs 2.4, $P = 0.03$). Fibrinogen correlated with FXIII (R:0.405; $P < 0.01$), but in males also with age(R:0.234) and smoking (R:0.243). In CAD patients FII correlated with age(R:0.130, $P < 0.05$), AH(R:0.195, $P = 0.01$), ERF(R:0.205, $P = 0.01$), FVII (R:0.795, $P = 0.01$) and fibrinogen(R:0.154, $P < 0.05$). Females had a higher FII levels(115.7 vs. 107.8, $P = 0.07$) that correlated with BMI (R:0.279, $P < 0.05$), and higher FXIII in compare to males (99.9 vs. 88.6, $P = 0.02$). FVII was higher in smokers(121.3 vs. 112.3, $P = 0.030$). Fibrinogen correlated with FXIII (0.195, $P = 0.01$). Overall, multiple regression analysis revealed age, sex, AH, EFR and fibrinogen to be independent predictors of FII clotting activity, predicting ~11% of the variability; AH, ERF and fibrinogen to be independent predictors of FVII clotting activity, predicting ~4% of the variability; age, sex, AH and fibrinogen to be independent predictors of FXIII activity, predicting ~11% of the variability; smoking, sex and age to be independent predictors, that explain ~15% of the fibrinogen variability.
Conclusion: The obtained data suggest that different combination of conventional risk factors may have different effects on coagulation factor activities in different patient's subgroups. However, more extensive study has to be performed in order to determine a combination of relevant factors contributing to the difference in clotting factor activities.

PB 4.31-5

Subclinical atherosclerosis in patients infected with Human Immunodeficiency Virus. Early predictors

De Larrañaga GF[1], Aranda F[1], Oliva S[1], Bottaro E[2], Bendezú K[1], Gonzalez R[1], Chamorro J[1], Camicia G[1], Lucero A[1] and Perés Wingeyer S[1]
[1]Hospital of Infectious Diseases F. J. Muñiz; [2]Helios Salud, Caba, Argentina

Background: Patients infected with Human Immunodeficiency Virus (HIV+) have a greater burden of clinical and sub-clinical atherosclerotic disease (SA) compared to the general population. The main causes of SA in HIV+ are multiple pro-atherogenic metabolic abnormalities related to Antiretroviral Therapy, early immune senescence (consequence of chronic immune activation), and an individual's genetic background. Subsequently, early biomarkers might help to identify HIV+ subjects who are at an elevated risk of SA and guide the development of therapeutic interventions.
Aims: The purpose of this study was to identify early predictors of SA in HIV+, specifically endothelial and genetic markers.
Methods: We measured plasma von Willebrand Factor (vWF) (LIATEST-Stago), the −2518 A/G polymorphism in the monocyte chemoattractant protein (MCP-1) gene (PCR/RFLP) and blood lipids. SA was considered to be present when carotid intimate media thickness (IMT) was >1.0 mm at any site. IMT was measured by echo-doppler in 70 HIV+. Patients were divided according to the absence (SA-, $n = 40$) or presence (SA+, $n = 30$) of SA. We also assessed traditional coronary risk factors, HIV disease characteristics and treatment. The study was approved by the ethics committee and subjects gave informed consent.
Results: The groups were comparable in sex, waist circumference, duration of HIV infection, viral load, smoking habits, alcohol use, illegal drug use, co-infection by hepatitis virus C and the use of protease

inhibitors ($P > 0.05$). There were no significant differences in the −2518 A/G MCP-1 genotypic ($P = 0.915$) distributions between the groups.

Significant differences ($P < 0.05$) were noted between SA- and SA+ patients, specifically, age (37 vs. 47 years old), co-infection with hepatitis virus B (15 vs. 40%), current CD4+ T cell count (398 vs. 498 cells/μL), LDL cholesterol (85 vs. 109 mg/dL) and triglycerides (105 vs. 159 mg/dL). The nadir of CD4+ (207 vs. 54 cells/μL), months of exposure to treatment (56 vs. 72), total cholesterol (163 vs. 179 mg/dL) and vWF (111 vs. 140%) were different between SA- and SA+ patients, although these differences did not reach statistical significance. We included those variables in a logistic regression model. Previously, we categorized the variables according to the median values obtained or the international criteria as follows: nadir of CD4+ (50 cells/μL), current CD4+ T cell count (350 cells/μL), triglycerides (150 mg/dL), age (37 years old) and vWF (110%).

Predictive factors for the development of SA included an age of more than 37 years (OR = 16.69; 95% CI: 2.67–104.36, $P = 0.003$), vWF of more than 110% (OR = 13.05; 95% CI: 2.36–72.12, $P = 0.003$), CD4+ cells of more than 350 cells/μL (OR = 27.75; 95% CI: 3.87–198.80, $P = 0.001$), and triglycerides levels of more than 150 mg/dL (OR = 3.94; 95% CI: 1.02–15.26, $P = 0.047$).

Conclusions: In our HIV+, age and the level of triglycerides were risk factors for the development of SA, as has been previously reported. High current CD4+ levels as a consequence of immune status improvement could be a key factor in the progression of atherosclerosis via a synergistic effect with inflammation. The level of vWF has the promise to be an attractive study variable that could be used to differentiate between SA risk groups.

PB 4.31-6

Comprehensive analysis of global gene expression and microRNA profile in coronary artery disease

Shanker J, Arvind P, Sathyamurthy Y, Jambunathan S, Nair J, Setty P and Kakkar V

Thrombosis Research Institute, India, Bangalore, India

Background: Studying the global gene expression and microRNA (miRNA) profile can provide a better understanding on the genetic basis of Coronary Artery Disease (CAD)

Aims: The aim of the present study was to perform global transcriptome profiling to identify novel genes/pathways for CAD, supported by miRNA profiling to understand epigenetic regulation of candidate gene expression.

Methodology: Blood whole transcriptome profiling was undertaken in 13 CAD patients and 11 asymptomatic controls while miNA profile was analyzed in 14 cases and 10 controls, respectively, using the Agilent microarray platform. The study participants were selected from the ongoing Indian Atherosclerosis Research Study (IARS). Information on both gene expression and miRNA was available for 10 cases and 8 controls. Validation of microarray findings was done in 100 cases and 100 matched controls for 10 putative candidate genes showing high differential expression. Gene expression and miRNA data were analyzed with 'R' program and Gene Spring software respectively.

Results: 343 genes were significantly up regulated and 151 genes were down regulated in cases relative to the controls (Fold change >2, $P < 0.05$). Gene assigned based on functional category primarily belonged to inflammation and immune response pathways, cell signaling, regulation and proliferation, coagulation, lipid and insulin metabolism, matrix degeneration and early growth response. Down-regulated genes included those associated with anti proliferation, protein and calcium signaling and other basic cellular processes.

Analysis of candidate gene expression showed *CXCL1, EGR3, IL8, PTGS2* and *CD69* to be up regulated and *IFNG* and *FASLG* to be down regulated among cases ($P \leq 0.05$), the trend being comparable to the microarray findings. *EGR3* and *IL8* genes in particular showed 9-fold and 8-fold differential expression. Three miRNAs, miR-144*, miR-96 and miR-1260, were significantly up regulated while miR-185* was found to be down regulated in the cases as compared to the controls. Of note, the expression levels of *ADAMTS18* and *KCTD16*, which are predicted gene targets of miR-96, were lower in CAD patients in the microarray dataset.

Summary/Conclusion: Combining global gene expression and miRNA data can improve our understanding on the underlying molecular pathogenesis of atherosclerosis.

PB 4.32-1

Association of obesity markers and atherothrombotic biomarkers in coronary artery disease

Shanker J, Ravindran V, Bhasker D, Hebbagodi S and Kakkar V

Thrombosis Research Institute, India, Bangalore, India

Background: Metabolic disturbances mediated by obesity and associated biomarkers can increase the risk of Coronary Artery Disease (CAD). The Adipose tissue releases a number of important hormones such as Adiponectin and Leptin, pro-inflammatory biomarkers that interact with other blood-borne atherothrombotic biomarkers and thus regulate the progression of heart disease.

Aims: We investigated the association between obesity markers and key circulating biomarkers in a family-based cohort of angiographically confirmed CAD patients and unaffected family members participating in the Indian Atherosclerosis Research Study (IARS)*.

Methods: Obesity markers depicting central obesity (body mass index-BMI) and visceral obesity (waist circumference -WC, Hip circumference – HC and waist-hip-ratio – WHR) were measured in 287 CAD patients and 477 unaffected family members. A wide panel of plasma/serum biomarkers were measured by standard methods and included the following – Lipids (total cholesterol-TC, triglycerides, High density lipoprotein cholesterol-HDL-c, Low density lipoprotein-cholesterol-LDL-c, Apolipoprotein-Apo- A1 and -B100, Lipoprotein (a)-Lp(a)), Coagulation factors (Factor VII.c, Fibrinogen), Inflammatory markers (IL6, hsCRP), Adipokines (Adiponectin, Leptin), Adhesion molecules (P-selectin, sICAM), Oxidative stress markers (OxLDL, Myeloperoxidase-MPO), antibody titers against common pathogens (cytomegalovirus, C pneumonia, H pylori and HSV), heat shock proteins (HSP-60, -65, -70) and other novel biomarkers (Cystatin C, secretory phospholipase A2-sPLA2, Neopterin). Multivariate analysis and correlations were performed to test the association of the biomarker panel across the obesity marker quartiles using SPSS version 17.0 software. Age and gender were considered as covariates.

Results: Mean levels of BMI, WC and WHR were higher in CAD affected than unaffected subjects, but statistically significant difference was seen only for WHR ($P = 0.002$). There was stronger correlation of BMI with WC ($r = 0.73$, $P < 0.0001$) than with WHR ($P = 0.20$). The best linear association was seen of BMI and WC with Adiponectin, Leptin and PAI-1 followed by hsCRP, FVII.c, Fibrinogen and lipids, particularly triglycerides and HDL-c ($P < 0.001$). In addition, WC showed significant association with ApoA1, ApoB100 ($P = 0.0001$), sICAM and p-selectin ($P <\leq 0.04$), Ox-LDL ($P < 0.0001$) and sPLA2 ($P < 0.0001$). This data was supported by strong correlation of WC and BMI with Leptin (0.56), Adiponectin (−0.28), PAI-1(0.32), sPLA2 (0.22), hsCRP (0.17) and Fibrinogen (0.22). Further analysis is in progress.

Summary/Conclusion: Waist circumference appears to be an excellent representative marker of visceral adiposity and shows strong association with a number of established and new atherothrombotic biomarkers in Asian Indians. Significance of these biomarkers in predicting new/recurrent coronary events will also be discussed.

*The rationale and design of the IARS has been published in Indian Heart journal 2010, 62:286–95.

PB 4.32-2

Free leptin, carotid plaque phenotype and relevance to related symptomatology: insights from the OPAL-Lille carotid endarterectomy study

Elkalioubie A[1], Zawadzki C[2], Chinetti-Gbaguidi G[3], Corseaux D[2], Juthier F[4], Haulon S[4], Staels B[3], Susen S[2], Van Belle E[2] and Dupont A[2]

[1]EA2693, Univ Nord de France, UDSL; [2]EA 2693, Univ Lille Nord de France; [3]Inserm U1011, Univ Lille Nord de France, Lille Pasteur Institute; [4]Cardiovascular and Pulmonary, and Hematology Department, University Hospital, Lille, France

Background: Free leptin, an adipose tissue-derived cytokine, exerts important cardiovascular effects, but its role on human atherosclerotic carotid plaque phenotype and related symptomatology is unknown.
Aims : This relationship was assessed in 146 consecutive patients (71 asymptomatic and 75 symptomatic) scheduled for carotid endarterectomy.
Methods and Results: Free leptin was assessed in serum (9.7(4.6–19.7) ng/mL, range 0.47–107) and carotid plaques (0.075(0.040–0.163) ng/mg protein) (median [percentiles 25–75%]). Serum and plaque free leptin concentrations were positively correlated to each other ($P < 0.0001$, $r = 0.726$). Serum free leptin concentrations were independently and negatively associated with plaque-related symptomatology (ß = −0.066, 95% CI: −0.124; −0.007). Regarding plaque phenotype, histological examination revealed plaque Vascular Smooth Muscle Cell (VSMC) content and VSMC to macrophage area ratio to be significantly higher in asymptomatic patients compared to symptomatic ones (39.3(35.9–55.0) vs. 20.4(17.7–26.3), $P = 0.0003$, 6.8(2.6–31.4) vs. 1.4(0.6–2.0), $P = 0.014$, respectively). When serum or plaque leptin concentrations were above median value, plaque VSMC to macrophage area ratio and VSMC content or proliferation index were significantly higher in carotid plaque compared to concentrations below median value ($P < 0.019$). Interestingly, via ERK, Smad-2 and Akt activation, at 20 ng/mL, leptin induced a migratory signal and higher collagen synthesis in human VSMC, followed by a VSMC proliferative response at the concentration of 75 ng/mL.
Conclusions: We reported serum free leptin to be a marker of carotid plaque-related symptomatology. Free leptin could modulate plaque phenotype via direct effects on human VSMC.

PB 4.32-3

Nicotinic acid/laropiprant: negative effects on vascular function

Cioni G[1], Marcucci R[1], D'Alessandri G[2], Fedi S[1], Alessandrello Liotta A[1], Mannini L[1], Fatini C[1] and Abbate R[1]

[1]University of Florence, Florence; [2]USL3, Pistoia, Italy

Background: Lipoprotein (a) is an atherothrombotic marker, damaging vessels indirectly by its capability to alter fibrinolysis, and directly, by its similarity with an LDL protein. Nowadays, the only pharmacological approach able to modify Lp(a) levels is niacin at high doses.
Aims: To assess the behaviour of lipid profile, haemoreological profile and endothelial function in secondary prevention patients treated with niacin/laropiprant.
Methods: 45 consecutive patients, all presenting Lp(a) >300 mg/dL, with previous adverse cardiovascular event (acute coronary syndrome, stroke, peripheral artery disease, retinal occlusion, sudden hypoacousia) and multiple comorbidities, were treated daily with 2000 mg of nicotinic acid/40 mg laropiprant and optimal statin therapy, in addition to cardiovascular medications according to current guidelines, for 12 months. Cholesterol, triglyceride, HDL-c, LDL-c, Lp(a), high-sensitive-PCR levels and haemoreological profile were analysed by fasting venous sampling. Endothelial function was assessed by peripheral arterial tonometry (PAT).
Results: After 12-month treatment the levels of triglycerides (118.71 ± 84.58 mg/dL vs. 88.86 ± 61.14 mg/dL), LDL-c (119.20 ± 35.81 mg/dL vs. 96.41 ± 36.98 mg/dL) and Lp(a) (1146.19 ± 451.54 mg/L vs. 776.79 ± 326.26 mg/L) were significantly reduced ($P = 0.002$, $P = 0.002$, $P < 0.0001$), instead HDL-c levels (52.89 ± 18.04 mg/dL vs. 60.14 ± 17.46 mg/dL) increased ($P = 0.029$). No differences in hsPCR levels were found. Unexpectedly, regarding blood viscosity, red cell deformability (0.3351 ± 0.3422 vs. 0.3128 ± 0.0392) and aggregation (63.80 ± 8.90% vs. 60.78 ± 5.70%) were impaired ($P = 0.023$ and $P = 0.077$, respectively) after 12 months. Accordingly, PAT values were lower after treatment (2.12 ± 0.77 vs. 1.77 ± 0.38, $P = 0.044$).
Conclusion: Niacin is significantly able to improve lipid profile, particularly by reduction of Lp(a). Despite these behavioural effects, nicotinic acid/laropiprant seems to negatively affect blood viscosity and endothelial function, suggesting a possible explanation of the negative results of HPS2-THRIVE study.

PB 4.32-4

Oxidized LDL: a link between atherosclerosis and Alzheimer's disease?

Faria MC, Grossi MF, Gonçalves GS, Carvalho MG, Sousa LP, Silveira JN and Silva IO

Federal University of Minas Gerais, Belo Horizonte, Brazil

Background: Shared risk factors for both atherosclerosis and Alzheimer's disease (AD) have raised interest in understanding vascular mechanisms probably involved in neurodegeneration. Atherosclerosis of intracranial arteries has been described as a risk factor for dementia which points to the role of vascular changes in AD development. A vascular and/or inflammatory biomarker present in both atherosclerotic diseases and AD, could not only unveil pathological pathways but also help in Alzheimer's diagnosis. Oxidized LDL (oxLDL) is a known mediator of vascular injury and atherosclerosis as it stimulates endothelial cells to produce chemoattractants that recruit monocytes into the vessel wall in addition to inducing smooth muscle cells proliferation.
Aims: After we observed in our studies that AD patients presented increased circulating products of lipid-peroxidation and a higher frequency of the epsilon4 APOE gene allele (strongly associated with both atherosclerotic cardiovascular disease and AD), we aimed to investigate the lipid profile of those patients and whether their oxLDL circulating levels were also increased. Our ultimate goal was to observe if oxLDL could represent an abnormal parameter in AD, linking its pathological pathways with atherosclerosis.
Methods: Through *Enzyme-linked Immunosorbent Assay* (ELISA), we measured the oxLDL levels in the serum of 40 elderly individuals with no cognitive impairment (controls) and 40 AD patients, selected in the Academic Hospital at the Federal University of Minas Gerais, Brazil, after informed consent by themselves or relatives. We also evaluated the participants' lipid profile through biochemical analysis. The study was approved by the ethics committee of the respective university.
Results: Surprisingly, the oxLDL levels for controls (126.32 ± 122.30 mg/dL) were higher than those for AD patients (71.05 ± 100.50 mg/dL), $P = 0.016$.
The levels of LDL, HDL and total cholesterol were similar for both groups. VLDL levels in the control group (22.10 ± 15.35 mg/dL) were higher than in the AD group (13.91 ± 7.13 mg/dL), $P < 0.0001$, and triglyceride levels were also higher for the controls (110.50 ± 76.80 mg/dL) compared to AD patients (69.57 ± 35.70 mg/dL), $P < 0.0001$.
Although higher for the control group, the VLDL and triglyceride levels were still under their clinical cut-offs.
Studies by other researchers have associated statin use with decreased oxLDL levels, but in our study statin use was more prevalent in the control group, which presented higher levels of oxLDL compared to AD patients. This unexpected lower oxLDL levels could be a conse-

quence of a more controlled diet for the AD patients; thus, it would be interesting to investigate the oxLDL levels of individuals with mild cognitive impairment who progressed to AD after follow up. It would also be beneficial to investigate if microglial cells of AD patients express more scavenger receptors that bind to oxLDL than the ones of healthy elderly controls.

Conclusion: The oxLDL serum levels were not increased in Alzheimer's disease patients compared to controls; therefore, we were unable to describe a link between atherosclerosis and this disease based on this parameter.

PB 4.32-5

Plasma salusin-beta levels in health and atherosclerotic cardio- and cerebro-vascular diseases

Fujimoto K[1], Watanabe T[2], Shichiri M[3] and Koyama T[1]

[1]Tokyo Medical and Dental University, Tokyo; [2]Tokyo University of Pharmacy and Life Sciences, Tokyo; [3]Kitasato University School of Medicine, Sagamihara, Japan

Background: Salusin-a and salusin-b are related vasoactive peptides biosynthesized from the same precursor, prosalusin. Salusin-a has been demonstrated to exert anti-atherogenic effects. While Salusin-b has the ability to temporally induce potent hypotension, this peptide also accelerates the development of atherosclerosis by enhancing macrophage foam cell formation and vascular smooth muscle cell proliferation. Salusin-b is highly expressed in human coronary atherosclerotic lesions. Despite the potent hemodynamic and pro-atherosclerotic activities of salusin-b, its presence in human circulation remains largely undetermined, because of its unique physicochemical properties.

Aims: We recently established a sandwich ELISA for salusin-b, overcoming technical difficulties by including a low dose of NP-40 in the assay system. We measured salusin-b in healthy human plasma and examined whether there were physiological variations using the sandwich ELISA. Furthermore, we investigated plasma salusin-b levels in patients with coronary artery disease (CAD) or cerebrovascular disease (CVD).

Methods: After obtaining informed consent, venous blood samples were collected from 106 healthy volunteers and 80 patients with CAD or CVD. The plasma was then pretreated and salusin-b levels were measured using the sandwich ELISA.

Results: Plasma salusin-b levels were 4.1 $\pm$ 0.9 nM in healthy volunteers, and did not differ significantly between males (n = 64) and females (n = 42). Age was not associated with the levels. Plasma salusin-b levels were lower in the morning than in the daytime. Both patients with CAD and CVD had significantly higher levels of plasma salusin-b compared with healthy volunteers (5.4 $\pm$ 1.3 and 5.3 $\pm$ 1.4 nM, both $P < 0.0001$).

Summary/Conclusion: These results indicate that plasma levels of salusin-b exhibit a circadian rhythm with levels lower in the morning. In addition, salusin-b is significantly higher in patients with atherosclerotic CAD or CVD. We provide insights into the potential use of salusin-b as a reliable biomarker and therapeutic target for atherosclerotic cardio- and cerebrovascular diseases.

PB 4.32-6

Urinary Biomarker discovery for coronary artery disease risk prediction using global proteomic analysis

Madan G, Sangeeta M, Sharma A, Kakkar VV and Vangala RK

Thrombosis Research Institute, Bangalore, India

Background: Diagnosis of premature coronary artery disease (CAD) is a major concern and several studies have focused on using the urinary proteome approach due to non-invasive biofluid collection, low complexity and stability of proteins. These studies are more important in Indian population where premature CAD is increasing at alarming rate.

Aim: In this study we have analyzed global proteomic profile analysis of urinary proteome of Asian Indians to identify biomarker profile for premature CAD risk prediction.

Methods: 407 age and gender matched subjects were selected for a case control study from ongoing Indian Atherosclerosis Research Study (IARS) (Indian Heart J, 2010;6:286–95) which was designed according to the guidelines of World Medical Association Declaration of Helsinki and Indian Council of Medical Research and approved by Institutional Ethics Committee. Patients living in India for at least two generations were enrolled after signed informed consent was obtained (male $\leq$60 years and female $\leq$63 years at onset of disease, diagnosed as CAD without any major diseases like cancer or liver failure) All the urine samples were collected after overnight fasting of 12–14 h and stored at -80 °C. Global proteomic analysis of urine samples were performed using Surface Enhanced Laser Desorption/Ionization-Time of Flight (SELDI-TOF) on three different arrays cationic CM10 (204 CAD affected and 203 unaffected), anionic Q10 (80 CAD affected and 79 unaffected) and metal binding IMAC30 (196 CAD affected and 195 unaffected) chips. For risk prediction model development, we used four different statistical methods namely Support Vector Machine (SVM), Multilayer perception Artificial Neural Network (ANN), Discrimination Analysis (DA) and Logistic Regression (LR).

Results: 118 significantly differently expressed protein profiles were identified from SELDI-TOF analysis in all the arrays. The CM10 array gave 55 peaks, 29 peaks in Q10 and 34 in IMAC array chips. Four different statistical analyses (SVM, ANN, DA and LR) were performed for developing risk assessment algorithm for each array type. In each of the statistical methods half of the samples were used for validation in a blind test. In all the array types, SVM based algorithm gave the significant risk assessment. In CM10 array the SVM based risk stratification had sensitivity of 91.22%, specificity of 67.13%, AUC of 0.961, Q10 array sensitivity of 82.93%, specificity of 79.22%, AUC of 0.921 and IMAC: sensitivity of 78.76%, specificity of 80.30%, AUC of 0.878. Furthermore, we identified that five protein peaks corresponding to myotropin, prepronociceptin, StAR-related lipid transfer protein 5, D-amino acid oxidase activator, and integral membrane protein 2C as significant proteins in the above SVM based model for risk assessment.

Conclusions: Our data suggests that urinary proteome profile can be used to identify new biomarkers which may be related to premature CAD in Asian Indians. Further studies of integrating the genomic data (gene expression and single nucleotide polymorphism) using bioinformatics tools are underway for developing systems biology based risk assessment.

Homocysteine plasma levels influence fibrinolytic capacity but not *in vitro* cleavage of fibrin by exogenous plasmin in patients with pulmonary embolism

Cellai AP[1], Lami D[2], Antonucci E[2], Marcucci R[2], Fiorillo C[2], Becatti M[2], Cenci C[2], Mannini L[1], Abbate R[2] and Prisco D[2]

[1]AOU-Careggi; [2]University of Florence, Florence, Italy

Background: Hyperhomocysteinemia (HHcy) affects haemostasis and shifts its balance in favour of thrombosis. *In vitro* and *in vivo* studies suggested that HHcy may impair fibrinolysis either by influencing the plasma levels of fibrinolytic factors or by altering the fibrinogen structure.

Aims: We investigated the influence of mild HHcy levels on plasma fibrinolytic potential by using Clot Lysis Time (CLT) and fibrin sus-

ceptibility to plasmin-induced lysis in 94 patients with previous pulmonary embolism (PE) and no pulmonary hypertension.
Methods: CLT was measured as lysis time of tissue factor (TF)-induced clots exposed to exogenous tissue Plasminogen Activator (t-PA). The rate of '*in vitro*' plasmin-mediated cleavage of fibrin β-chain was assessed over a 6-h period on fibrin clots, which were obtained by exposition to thrombin of purified fibrinogen. Homocysteine plasma levels were measured by Abbott Imx immunoassay and we considered as altered values the plasma levels above 15 μM according to the literature. Fibrinolytic components were also measured by ELISA or functional tests.
Results: In 68 patients homocysteine levels were below 15 μM (NHcy) and in 26 they were above (HHhcy). Significant differences were observed between the two groups regarding plasma fibrinolytic potential ($P = 0.016$), TAFIact ($P = 0.02$), t-PA(0.008) and PLG (0.037), but not for the other fibrinolytic components and for the rate of plasmin-mediated cleavage of fibrin β-chain. The HHcy-patients had a three-fold higher risk to have an impaired fibrinolysis. Instead, a multivariate logistic regression analysis adjusted for significances of univariate showed that HHcy(OR:5.2 95% CI: 1.7–15.9; $P = 0.003$) and BMI (OR:1.1 95% CI: 1.0–1.3; $P = 0.01$) resulted indipendently associated with impaired fibrinolytic activity.
Conclusions: HHcy affects TAFI-mediated hypofibrinolysis but not fibrin(ogen) structure or function as documented by fibrin degradation analysis.

PB 4.33-2
Real time imaging of plasminogen binding to platelet-rich micro-thrombus and its effective lysis by tPA infusion *in vivo*

Urano T, Tanaka A, Brzoska T and Suzuki Y
Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: The detail how thrombolysis takes place after microthrombus is formed at vascular injury site.
Aim: To elucidate the mechanism of thrombolysis in the vasculature, we analyzed the process of plasminogen-binding to laser-induced microthrombus and tPA-induced its lysis in mice using intra-vital fluorescence microscopy.
Method: Mesenteric vein of green fluorescent protein expressing transgenic mouse (GFP-mouse) was irradiated by laser-beam through objective lens of fluorescence confocal microscopy and platelet-rich micro-thrombus was formed. The accumulations of GFP expressing platelets as well as Alexafluor 568 labeled plasminogen (Glu- or mini-plg) on injured vessel wall were monitored by an increase in the corresponding fluorescent intensity with time course, and their distributions were analyzed. The process of tPA-induced effective clot lysis was also analyzed.
Results: (i) Glu-plg accumulated in a time-dependent manner to the center of micro-thrombus, where phosphatidylserine (PS) was exposed on platelets surface and fibrin was formed. (ii) The bindings of Glu-plg in the presence of EACA (approximately 20 mM) or after treatment by carboxy-peptidase (approximately 10 U/mL), and that of mini-plg were significantly less than that of Glu-plg alone. (iii) Though the micro-thrombus was resistant to clot lysis for 3 h, the effective clot lysis was initiated by intra-venous tPA infusion.
Summary: Glu-plg appeared to accumulate in the center of micro-thrombus in a time-dependent manner by binding to either activated platelets' surface or formed fibirn in a lysine binding site dependent mechanism. Such accumulation of Glu-plg, however, was not sufficient and the subsequent tPA infusion was required for the effective clot lysis.

PB 4.33-3
Kinetic and thrombolytic properties of streptokinase-polyethylene glycol conjugates

Mukhametova L[1], Aisina RB[1], Gulin D[1], Gershkovich KB[2] and Varfolomeyev SD[2]
[1]*Lomonosov Moscow State University;* [2]*Emanuel Institute of Biochemical Physics of RAS, Moscow, Russian Federation*

Background: Streptokinase (SK), a widely used thrombolytic drug, is an effective plasminogen activator. Some limitations to SK therapy have been imposed by its significant side effects on plasma proteins, rapid clearance from the circulation, antigenicity and instability of plasmin (Pm)*SK complex to proteolysis. SK therapy is accompanied by bleeding as a result of the exhaustion of plasma fibrinogen.
Aims: To improve of SK properties by its modification with nonantigenic polyethylene glycol (PEG).
Methods: PEG of 2 and 4 kDa (PEG2 and PEG4) were activated with 1,1'-carbonyldiimidazole and imidazole carbamate derivatives of the polymers were dialyzed. Purified SK was modified with activated PEG in the ratio 1:500 (M:M) during 0.5, 2, 3 and 4 h. Stability of SK и SK-PEG conjugates in human plasma was traced by fall of their fibrinolytic activity using Christensen method. Kinetics of plasmin (Pm)*SK и Pm*SK-PEG stoichiometric complexes formation was measured by rise in the hydrolysis rate of Pm substrate. Kinetic parameters (k_{pg} and K_{Pg}) of Glu-Pg activation by Pm*SK и Pm*SK-PEG complexes were determined using conjugated method in the presence of Pm substrate. Thrombolytic activity of SK and SK-PEG conjugates was measured by lysis kinetics of human plasma clot immersed in plasma using cathetometer, fibrinogen level in plasma was measured using developed by us method.
Results: Optimal durations for SK conjugation with activated PEG2 and PEG4 were found to be 1 and 2 h owing to the loss of SK fibrinolytic activity did not exceed 15–25% at modification degree of its lysine ε-amino groups 49–52% in 1 h and 52–53% in 2 h with PEG2 and PEG4. These modification degrees of SK had no effect on the formation rate and amidase activity of stoichometric complexes of Pm*SK-PEG2 and Pm*SK-PEG4 but increased in stability of SK-PEG conjugates in human plasma *in vitro*: the $t_{1/2}$ of fibrinolytic activities decline were 60 and 110 min for two SK-PEG2, 90 and 120 min for two SK-PEG4 derivatives, 50 min for unmodified SK. As compared with Pm*SK, both k_{pg} and K_{Pg} values of Glu-Pg activation by Pm*SK-PEG2 and Pm*SK-PEG4 complexes with two modification degrees of SK decreased and the catalytic efficiency of Pg activation (k_{pg}/K_{Pg}) by these complexes was some lower or higher than that by Pm*SK. The SK-PEG2 and SK-PEG4 derivatives retained *in vitro* 88–85% and 68–62.5% of SK thrombolytic activity, respectively. The SK-PEG conjugates caused the lesser depletion of plasma fibrinogen than equal dose of unmodified SK: $t_{1/2}$ of plasma fibrinogen level fall was 26 min for SK, 36 and 38 min for SK-PEG2, 90 and 120 min for SK-PEG4 derivatives.
Conclusions: Conjugation of SK by PEG extends its half-life in plasma and protects Pm*SK-PEG complexes from proteolysis. Obtained SK-PEG2 и SK-PEG4 derivatives retained great bulk of SK thrombolytic activity and caused a lesser side effects on plasma proteins *in vitro* than equal dose of unmodified SK. Moreover, according to literature data derivatization of SK by PEG substantially reduced the SK antigenicity.

PB 4.33-4
Insights from a mathematical model of fibrinolysis

Bannish B[1], Keener JP[2], Weisel J[3] and Fogelson AL[2]
[1]*University of Central Oklahoma, Edmond, OK;* [2]*University of Utah, Salt Lake City, UT;* [3]*University of Pennsylvania, Philadelphia, PA, USA*

Background: Mathematical models can be powerful tools when laboratory experimentation is impossible or inconvenient (due to technologi-

cal limitations, cost, time constraints, etc.) We have developed a 3-dimensional multiscale mathematical model that accurately predicts many observed characteristics of both single fiber and clot lysis. Fibrinolytic therapy for stroke patients often involves administration of tissue-type plasminogen activator (tPA), however, bleeding complications can arise post-treatment. More recently, local administration of plasmin via catheter has been suggested as a possible treatment strategy.

Aims: The aim of this research is to develop mathematical models of fibrinolysis that can be used to test potential fibrinolytic therapies. Specifically, we aim to accomplish the following: identify a safer, more effective tPA-variant that could be bioengineered; test the effectiveness of both tPA-variants and plasmin as thrombolytic agents under various conditions (e.g., in different clot structures, or in the presence of fibrinolytic inhibitors).

Methods: We use a 3-dimensional multiscale mathematical model to investigate fibrinolysis of pre-formed clots, initiated by various types of molecules. The microscale model contains detailed biochemistry and represents a single fiber cross section. Data from the microscale model are used in a macroscale model of a 3-dimensional fibrin clot. To test different treatment strategies, we include different molecules in the macroscale model to initiate lysis. Patterns and rates of lysis are recorded. Promising results from the theoretical experiments can be tested in a laboratory.

Results: We find that a tPA-variant with a larger-than-physiological dissociation constant results in faster lysis rates. Interestingly, there is an optimal K_d value, as lysis rates begin to decrease if the dissociation constant is too large. Lysis rates are often larger when degradation does not proceed as a front moving across the clot, but rather occurs in many places throughout the clot simultaneously. We also find that activated thrombin activatable fibrinolysis inhibitor (TAFIa) has only a small effect on tPA-mediated lysis in the absence of α_2-antiplasmin (α_2-AP), but can almost completely stop lysis in the presence of α_2-AP.

Summary/Conclusions: We use a mathematical model of fibrinolysis to assess potential fibrinolytic treatments. Model results suggest that a tPA-variant that binds less strongly to fibrin will elicit faster lysis. The presence of inhibitors can greatly affect the progression of lysis, and should be considered when assessing thrombolytic therapies.

PB 4.33-5

The impact of bradykinin-potentiating peptide on fibrinolytic activity of blood plasma on the model of diabetes mellitus 1 type

Shubina T

Moscow State University, Moscow, Russian Federation

Background: The development of diabetes mellitus type 1 (DM), accompanied by hyperglycemia and glucosuria, leads to negative changes in the system of hemostasis – increase of coagulation potential and depression of fibrinolytic activity of blood. Therefore, the search for new approaches to prevention and treatment of complications in this pathology is very timely. Bradykinin-potentiating peptides (BPP) by preventing the splitting of bradikinina and inhibition of the angiotensin-converting enzyme able to influence positively on the hemostasis system and endothelial function, which is violated in diabetes.

Research objective: To evaluate the impact of a single intravenous injection bradykinin-potentiating peptide 9a (BPP9a) on indicators fibrinolysis and blood sugar level of rats on the model of diabetes mellitus type 1 (DM).

Materials and Methods: The experience was carried out on non-linear white male rats weighing 200–350 g. DM caused by the single-injection to v. jugularis solution alloxan in a dose of 37.5 mg/kg. The analyzed peptide (Serva) provided an experimental animal with DM single intravenous dose of 5*10–4 mg/kg. The control rats with diabetes similarly provided equal amount of saline solution. Blood for examination was taken: before the introduction of alloxan and on the background of the development Board: after 1 h, one and 2 weeks after the introduction of the peptide. In the blood plasma was determined: the of euglobulin clot lysis (ECL), the total fibrinolytic activity (TFA), plasmin activity (PA) and plasminogen activator activity (tPA). Quantitative determination of glucose in the blood was carried out with the help of biochemical analyzer One Touch Horizon (USA).

Results: About 1 h after injection BPP9a in the experimental group significantly ($P < 0.05$) reduced the level of glucose in the blood compared with the value in these rats prior to its adoption. The normal level of glucose (4.7 mM) in the experimental group was observed in about 1 week in comparison with the control (of 8.0 mM), and then the difference between the groups is leveled. In rats of experimental group after 1 h after the introduction of the peptide ECL unreliably lengthens in comparison with the control, while in the blood plasma, a decrease of TFA, PA-and tPA. One week ECL in both groups did not differ, in the test there was an increase in TFA in six times, PA 14 times and tPA in 3.5 times compared with the control. Two weeks after the introduction of peptide ECL in experimental animals correspond to the normal values, and values TFA, PA, tPA were three times higher than the control group.

Conclusion: The data obtained suggest that a single intravenous injection of the BPP9a in the dose of 5*10–4 mg/kg to rats with alloxan, got diabetes caused a decrease of the level of glucose in the blood within 1 h after injection, which has been stable for 1 week, and also increase of enzymatic fibrinolytic activity within 2 weeks of the experiment.

PB 4.33-6

Diagnosis performance of thromboelastography to assess tissue plasminogen activator induced fibrinolysis

Godier A[1], Parmar K[2] and Hunt BJ[2]

[1]Hopital Cochin, Paris, France; [2]St. Thomas' Hospital, London, UK

Background: Fibrinolytic activation is a component of acute coagulopathy of trauma and the extent of activation correlates with disease injury score and clinical outcome [1]. It is not possible to measure the extent of fibrinolytic activation with standard emergency laboratory tests, but thromboelastography is able to detect fibrinolytic activation but this has not been fully validated.

Aims: To investigate the diagnostic performance of thromboelastography (TEGÒ Haemonetics Corp., MA, US) to detect tissue plasminogen activator-induced fibrinolysis in an *in vitro* study.

Methods: Blood was drawn from 10 healthy volunteers using flawless venepuncture into 0.105 M sodium citrate and divided into aliquots. Fibrinolytic activation was generated by adding tissue plasminogen activator (tPA), at four different concentrations: 0; 0.2; 1 (values similar to the concentrations seen in plasma drawn from bleeding trauma patients) and 4 nM.

TEG assays were performed in triplicate on each whole blood sample: KaolinTEG, RapidTEG (tissue factor is added to kaolin-activated TEG to activate both intrinsic and extrinsic coagulation pathways) and functional fibrinogenTEG. Recorded parameters were Reaction time (*R*), time to clot formation (K), Maximal Amplitude (MA), percentage lysis LY30, LY60 and functional fibrinogen level (FLEV).

To assess if the delay between sampling and performing TEG test is relevant, tests were performed immediately after spiking tPA, 15 and 30 min later. Platelet poor plasma was produced and frozen immediately. Plasmin anti-plasmin complex (PAP) were measured by ELISA and fibrinogen levels by Clauss assay.

Results: Adding 1 and 4 nM tPA increased tPA antigen concentration and PAP, whereas 0.2 nM tPA had no effect. Clauss fibrinogen levels decreased from 2.72 g/L to 2.47 g/L with 4 nM tPA.

In KaolinTEG, only 4 nM tPA increased R and decreased MA. K was not modified whatever tPA concentrations. Hyperfibrinolysis was detected only with 4 nM tPA: LY30 and LY60 were higher than 7.5%

(respectively 48 ± 14 and 74 ± 8%). 1 nM tPA significantly increase lysis but in a non relevant way (<2% and <6% respectively for LY30 and LY60). With RapidTEG, all values were in normal range, except LY30 and LY60, which were increased with 4 nM tPA. 4 nM tPA induced a decrease in FLEV, from 3.37 to 2.46 g/L as well as in Clauss fibrinogen concentration from 2.72 to 2.47 g/L. Increasing delay between sampling and performing tests increased PAP levels, percentage lysis and decreased fibrinogen concentration.

Summary/Conclusions: TEG tests did not detect moderate fibrinolytic activation. Clot lysis parameters are the most sensible to detect fibrinolysis. RapidTEG detected fibrinolytic activation more rapidly than kaolinTEG. Hyperfibrinolysis induced fibrinogen decrease. Delay between sampling and performing tests modified tests results.

PB 4.34-1

Assessing the extent of fibrinogenolysis by t-PA seen in bleeding trauma patients and what is the extent of its inhibition by tranexamic acid using an *in vitro* model

Godier A[1], Parmar K[2] and Hunt BJ[2]

[1]Hopital Cochin, Paris, France; [2]St. Thomas' Hospital, London, UK

Background: Systemic fibrinolysis contributes to the acute coagulopathy of trauma (ATC), and is known to correlate with the extent of injury and clinical outcome [1]. ATC is also characterized by a decrease in fibrinogen concentration [2], although its cause has not been adequately studied.

Aims: To investigate the effects of a tissue-plasminogen activator (t-PA) on fibrinogen levels in an *in vitro* model and the effects of tranexamic acid (TXA) on this model.

Methods: Ethical committee approval was obtained to draw blood from healthy volunteers and collected into 0.105 M sodium citrate. Fourteen different concentrations of tPA between 0.05 and 60 nM were added to aliquots of whole blood. Thromboelastography (TEGÒ Haemonetics Corp., MA, US) was performed, assessment included measuring functional fibrinogen level (FLEV). At the same time a sample was drawn off to prepare platelet poor plasma (PPP), which was frozen immediately to later perform a Clauss fibrinogen assay.

The effects of TXA were assessed in this model on four different tPA concentrations: 0; 1 nM (close to the concentrations observed in severe trauma patients), 4 nM and 20 nM (close to the concentrations used for thrombolysis), using 4 TXA concentrations: 0; 0.003 mg/mL; 0.03 mg/mL and 0.3 mg/mL (equivalent to the TXA concentration of the CRASH2 trial [3]). Kaolin TEG was performed on each of the 16 samples. Recorded parameters were Reaction time (*R*), Maximal Amplitude (MA), clot strength (G), percentage lysis LY30 and Maximum rate of Lysis (MRL). Fibrinolysis was assessed on PPP by plasmin anti-plasmin complex (PAP) measurement and fibrinogen concentration was measured with the Clauss method.

Results: tPA induced fibrinogenolysis, with a concentration-dependant decrease in fibrinogen level, as measured by FLEV (from 3.8 ± 0.6 to 1.3 ± 0.2 g/L and for Clauss assay from 2.9 ± 0.5 to 0.9 ± 0.1 g/L at 60 nM tPA). FLEV and Clauss fibrinogen were well correlated ($r^2 = 0.734$). tPA induced fibrinolysis as it increased PAP, LY30 and MRL, but decreased MA and G. It had no effect on R.

TXA alone had no effect on TEG parameters, FLEV, Clauss fibrinogen concentration or PAP levels. The lowest TXA concentration partly corrected MRL whereas the others normalized MRL and LY30. TXA corrected MA and G and partly protected fibrinogen against fibrinogenolysis in a concentration-dependant manner. TXA had no effect on PAP.

Summary/Conclusions: tPA induced fibrinolysis and fibrinogenolysis in a concentration dependant manner. TXA did not affect plasmin activation but reduced fibrinogenolysis, consistent with its known action as a competitive inhibitor of plasminogen. These results suggest that TXA should be given in ATC to prevent fibrinogenolysis and thus potentially may reduce the need for fibrinogen supplementation.

PB 4.34-3

Increased fibrinolysis on blood outgrowth endothelial cells (BOEC) from chronic thromboembolic pulmonary hypertension (CTEPH) patients

Mangles SE[1], Paschalaki KE[2], Starke RD[3], Millar CM[1], Randi AM[3] and Laffan MA[1]

[1]Centre for Haematology, Faculty of Medicine, Imperial College London; [2]Vascular Science/Airway Disease Dept, NHLI, Imperial College London; [3]Vascular Science, NHLI, Faculty of Medicine, Imperial College London, London, UK

Pulmonary hypertension (PH) is a rare but disabling disorder estimated to affect 30–50 individuals per million. PH is characterised by increased pulmonary vascular resistance, causing an increase in pulmonary artery pressure leading to right ventricular heart failure, progressive disability and death. Chronic thromboembolic pulmonary hypertension (CTEPH), a distinct category of PH, is a condition in which the initiating event is either overt or occult pulmonary embolism. Why some patients develop CTEPH after PE is not clear. It is believed that the persistence of thrombus is a prerequisite for the development of PH following PE. Failure to lyse thrombi is thought to create altered blood flow triggering abnormal vascular remodelling. We hypothesised that defective fibrinolysis on the surface of the pulmonary endothelium causes progression from PE to CTEPH.

The study of a patient's endothelium is complicated by the difficulty in accessing tissue for analysis. We used a recently developed technique to study the endothelial cells in patients with CTEPH in comparison to healthy controls. We isolated and cultured blood outgrowth endothelial cells (BOEC) from the mononuclear fraction of peripheral blood. Discrete colonies of BOEC appeared between days 7–21 in culture. Cells were then passaged to obtain confluent BOEC monolayers with characteristic endothelial cobblestone morphology. Endothelial identity was confirmed with a range of endothelial markers including VWF and VE-Cadherin. 17 patients (M = 7, F = 10) and 10 (M = 8, F = 2) controls were recruited. BOECs were isolated from 10 patients and six controls. All experiments were carried out between passages 4–7 in culture.

Thrombin generation and fibrinolysis was investigated on BOEC from patients or controls. Clot formation was triggered by exogenous tissue factor (TF) (5 pM) or by upregulating endogenous TF expression in BOEC with tumour necrosis factor (TNF-α) treatment (1.0 nM for 5 h). Clot lysis was promoted by addition of exogenous tPA (150 ng/mL). Lysis time was calculated as described (Lisman et al Gastroenterology 2001;121:131–139). Thrombin generation was measured using a modified calibrated automated thrombogram (CAT) assay as described (Hemker et al Curr Opin Haematol 2004;11:170–175).

Following addition of TF, mean lysis time on unstimulated CTEPH BOECs was shorter than that of control BOECs (minutes +/-SEM, 53.68+/−2.15 and 62.69+/−2.79 respectively; $P = 0.04$). Mean lysis time on TNF-α-stimulated CTEPH BOECS (34.42 min) was also significantly shorter than control BOECs (minutes +/-SEM, 35.86+/−3.11 and 52.22+/−4.67 respectively; $P = 0.016$). No difference was seen between patient and controls in the peak thrombin generated

after addition of TF (Control 248.74 nM thrombin, CTEPH 218.25 nM thrombin) or after TNF-α stimulation (Control 80.03 nM thrombin, CTEPH 79.46 nM thrombin). Thus the difference in lysis times is not attributable to differences in thrombin generation.
In conclusion we successfully isolated BOEC from patients with CTEPH and healthy controls in order to evaluate thrombin generation and fibrinolysis. We observed no difference in thrombin generation but surprisingly we observed a shorter clot lysis time, i.e. faster fibrinolysis on CTEPH patient BOECs compared to controls. Further investigation at the molecular level is ongoing to establish the mechanism for this increase fibrinolysis and its relationship to the development of CTEPH.

PB 4.34-4

Spatial clot lysis rate is regulated by clot growth rate

Zhalyalov AS[1], Shibeko AM[2], Panteleev MA[3] and Ataullakhanov F[2]
[1]*Center for Theoretical Problems of Physicochemical Pharmacology, Moscow;* [2]*HemaCore LLC, Moscow;* [3]*National Research Center for Hematology, Moscow, Russian Federation*

Background: The clot growth is a spatially heterogeneous process, and when it occurs in the patients with stroke, deep vein thrombosis or thromboembolism under fibrinolytic therapy, it is followed by rapid clot lysis due to artificial overactivation of lytic system. Clot growth activator is located on the vessel wall, while fibrinolytic activator is distributed all over the blood volume, so the patterns of clot lysis, as well as its interactions with blood coagulation system, are not explored yet.
Aims: In order to investigate the spatial aspects of clot lysis and its interaction with clot growth, we developed an in silico model of fibrin clot formation and dissolution, which was validated using *in vitro* experiments.
Methods: Mathematical model consisted of 35 PDEs simulated spatial clot growth and lysis in a 1D area 3 mm long. Clot growth was initiated by TF located at $x = 0$ coordinate, and tissue plasminogen activator (TPA) was distributed evenly in the whole area of simulation. Our model included the whole coagulation cascade, save the FXII contact pathway, leading to thrombin generation, which activated fibrinogen, as well as the fibrinolytic system equations describing TPA, 2 forms of plasminogen (lys- and glu- forms), plasmin, their complexes with fibrin, PAI, antiplasmin. The model described coagulation and fibrinolysis factors diffusion and reaction fluxes. Equation system was solved numerically with the COMSOL 4.3a software package using the finite element method. The relative tolerance was 0.1%; the element size was 0.01
Results: Clot lysis rate was not sensitive to any alterations of fibrinolytic system parameters, like changes in plasmin affinity with fibrin, rate of fibrin degradation, rate of plasmin activation or inhibition(<3% change for all cases). In contrast, increase of clot growth rate by supplementing the system with phospholipids or factor XIa caused increase of the clot lysis rate ($r = 0.997$). Also, we predicted in our in silico simulations that high level of TPA will cause the decrease of clot lysis rate and increase the lysis lagtime due to depletion of plasminogen before the clot is formed. These results were confirmed in our *in vitro* model.
Conclusions: We assume that spatial lysis of fibrin clot cannot be absconded from the clot formation: the latter not only forms the media where the first can propagate, but it also defines how fast lysis will occur. All that makes one suggest that spatial clot lysis can work like a time delayed clot termination, and the activation signal cannot facilitate its efficacy.

PB 4.34-5

Hemostatic alterations induced by Micrurus tener tener venom in C57BL/6 mice

Salazar M[1], Salazar AM[1], Taylor P[1], Rodriguez-Acosta A[2], Sanchez E[3], Carvajal Z[1] and Guerrero B[1]
[1]*Instituto Venezolano de Investigaciones Cientificas (IVIC), Caracas;* [2]*UCV, Caracas, Venezuela;* [3]*Department of Chemistry and the National Natural Toxins Research Center, TX, USA*

Background: *Micrurus* genus is mainly known for the neurotoxic effect produced in the victims. However, it have been described experimentally cardiotoxicity, myotoxicity, edematogenic effect and hemorrhagic activity in mouse skin. Recently, we described the hemostatic activity *in vitro* induced by *Micrurus* venoms (*M. tener tener*, *M. fulvius fulvius* and *M. isozonus*).
Aim: Due to the poor knowledge of the hemostatic effects induced *in vivo* by these venoms, we evaluated the alterations in this system by *M. tener tener* in C57BL/6 mouse.
Methods: Lethality of crude venom was determined by intraperitoneal (IP) injections into mice and expressed as LD_{50}, which was calculated according to the method of Spearman-Karber (1978). Male mice were injected with a sub-lethal dose in 200 μL of sterile saline solution and control mice were injected with 200 μL of sterile saline solution. Blood samples, about 1 mL per mouse, were collected by cardiac puncture under anaesthesia in CO_2 chamber. Hematologic (hemoglobin, hematocrit, leukocyte count, differential leukocyte count and platelets count) and hemostatic parameters (fibrinogen and endogenous fibrinolytic activity) were measured at 72 h after venom injection.
Results: LD_{50} of *M. tener tener* crude venom was 0.99 mg/kg (19.8 μg/mice). After IP injection of 8 μg/animal crude venom, the mice presented hemorrhage in the abdominal cavity. In comparison with control mice, the treatment with crude venom induced a decrease in hemoglobin concentration (11.9 ± 2.0 vs. 14.1 ± 2.2 g/dL; $P < 0.05$) and hematocrit ($32 \pm 17\%$ vs. $38 \pm 2\%$), but there was not an important change in the other hematological parameters. The venom also decreased fibrinogen values (211 ± 71 vs. 277 ± 38 mg/dL; $P < 0.05$). Additionally was observed an increase in the endogenous fibrinolytic activity (26.00 ± 37.40 vs. 158.71 ± 44.41 mm^2; $P < 0.05$).
Conclusions: Our results indicate that *M. tener tener* venom has toxins that are able to alter the vascular integrity and can affect directly the hemostatic system inducing an exacerbated fibrinolytic process that may be associated with the hemorrhagic manifestation in mice. These findings are related with fibrino(geno)lytic activity described previously for this venom. This is the first report *in vivo* of the effects induced by *M. tener tener* on the hemostatic system, particularly on the fibrinolytic system.

PB 4.34-6

The Factor VII activating protease (FSAP) regulates fibrin clot structure and fibrinolysis by direct interaction with fibrinogen

Etscheid M[1], Lankes J[1], Beer N[1], Rannou O[2] and Kanse S[3]
[1]*Paul Ehrlich Institute, Langen;* [2]*Justus-Liebig-University, Giessen, Germany;* [3]*Institute of Basic Medical Sciences, Oslo, Norway*

Background: Factor VII activating protease (FSAP) is a plasma protease that can activate FVII and plasminogen activators as well as inhibit tissue factor pathway inhibitor (TFPI), thereby accelerating coagulation and fibrinolysis. Cleavage of the fibrinogen Aa and Bb chain by FSAP has also been reported, but its impact is not clear.
Aims: Systematic investigation of FSAP's influence on clot structure and fibrinolysis.
Methods: Interaction of FSAP with plasmin(ogen) and fibrin(ogen) was measured by ELISA, and processing of fibrinogen by FSAP was

analyzed by SDS-PAGE. Plasmin activity was measured chromogenically. Clot formation and fibrinolysis of FSAP-treated purified fibrinogen or plasma was studied by turbidity as prothrombin time and as clot lysis time, respectively, or by thrombelastometry. For fibrinolysis studies, fibrinogen was pre-incubated with FSAP after which thrombin/tPA and $CaCl_2$ were added to initiate clotting and fibrinolysis. The clot structure formed by FSAP-treated or control fibrinogen in the presence of fluorescence-labeled fibrinogen was visualized by laser scanning confocal microscopy (LSM).

Results: Binding of FSAP to plasminogen was seen without preference for any particular domains within plasminogen. FSAP did not activate plasminogen, nor did FSAP significantly increase plasminogen activation in the presence of pro-uPA or pro-tPA. Interaction of FSAP with fibrin and fibrinogen could be observed, but was decreased in the presence of plasminogen. Vice versa, FSAP decreased binding of plasminogen to fibrinogen and fibrin. Incubation of fibrinogen with FSAP led to the disappearance of the Aα- and the Bβ-chains with apparently unchanged γ-chain. Upon pre-treatment with FSAP, purified fibrinogen and diluted plasma, as well as plasma depleted of uPA or tPA, showed strongly reduced clot lysis time values. A reduced clot firmness and shorter lysis time of FSAP-pretreated plasma could be seen by ROTEM analysis. In confocal microscopy FSAP-treated fibrinogen showed a different fibrin clot structure with thinner fibers compared to untreated fibrinogen. This change in fibrin structure was not seen with aprotinin-treated FSAP.

Summary/Conclusion: FSAP binds to plasmin(ogen), but plasminogen activation is not affected. Despite this, a clear acceleration of fibrinolysis of purified fibrinogen or plasma can be observed in the presence of FSAP. This effect seemed to be independent of FSAP's pro-uPA and pro-tPA-activating properties, but is more likely a direct influence of FSAP on fibrinogen. Specific binding of FSAP to fibrin(ogen) was also observed. In the presence of FSAP purified fibrinogen formed clots with thinner and denser fibrin fibers than control clots. Presumably the cleavage of the Aα chain by FSAP causes an impaired lateral aggregation of fibrin fibers, thus preventing the formation of thicker fibrin fibers, and may account for an accelerated clot lysis time. In conclusion, FSAP's influence on clot structure is a new parameter that deserves attention when evaluating the contribution of FSAP to thrombosis and haemostasis.

Analysis of neutralizing and non-neutralizing anti-canine FVIII antibodies in hemophilia A dogs treated with FVIII gene therapy

Hough CA[1], Vidal B[1], Ahlin J[1], Brown C[1], Harpell L[1], Powell S[1], Arruda V[2], Ozelo MC[3] and Lillicrap D[1]

[1]Queen's University, Kingstoon, Ontario, Canada; [2]The Children's Hospital of Philadelphia, Philadelphia, PA, USA; [3]University of Campinas, Campinas, SP, Brazil

Background: Intravenous infusions of canine factor VIII (cFVIII), and various gene delivery strategies in hemophilia A dogs have generated anti-FVIII antibodies.

Aim: To evaluate the anti-FVIII immune response in three hemophilia A dogs following cFVIII gene therapy.

Methods: Prior to entering this study, each dog had received a single infusion of canine cryoprecipitate. To prevent an immune response to cFVIII, dog #2 received six weekly infusions of cyclophosphamide beginning the day before gene delivery and dog #3 was pre-treated with eight infusions (10 U/kg) of recombinant BDD cFVIII. The gene delivery involved autologous blood outgrowth endothelial cells (BOECs) that were genetically modified to express BDD-cFVIII. Cells were implanted in a fibrin-based scaffold in the omentum. cFVIII activity and antigen, anti-cFVIII IgG2, and inhibitory FVIII antibodies were measured for at least 1 year after cFVIII gene delivery.

Results: No functional cFVIII was detected in any of the gene therapy treated dogs and in dogs #1 and #2 this was attributed to the appearance of a transient, low level (<4.5 BU) inhibitor. However, no inhibitors were ever detected in dog #3. In dogs #1 and #3, cFVIII antigen levels peaked at 47% and 20% respectively and although levels slowly declined, they persisted for a year post-gene delivery. IgG2 anti-cFVIII antibodies were not initially detected in dogs #1 and #2 however, levels rapidly increased to >100,000 ng/mL with the appearance of inhibitors. Flow cytometry of BOECs exposed to thrombin indicated that this component of the fibrin matrix cleaves PAR-1 leading to increased expression of IL-6 and MCP-1, both of which contribute to the immune response in the treated dogs. With a view to induce immunological tolerance to cFVIII, dog #3 received eight intravenous infusions of recombinant BDD cFVIII prior to receiving gene delivery. Although no inhibitors were detected, low levels (83 ng/mL) of anti-FVIII IgG2 appeared after the first infusion and rose to a maximum level of 546 ng/mL by the 7th cFVIII infusion. Levels increased to >1000 ng/mL after gene delivery but dropped to <1.000 ng/mL within 7 days and only rose above 1000 ng/mL when the dog received subsequent infusions of cFVIII. After each of the last three infusions, FVIII:Ag did not return to baseline levels and surprisingly, FVIII:Ag levels peaked to 300% normal levels within 30 min of infusing cFVIII. We used a canine FVIII peptide library to identify antibody binding sites. Nine binding sites were identified, six of which were mapped to non-functional sites in the A2, A3 and C1 domains and 3 to canine residues 32–56, 313–347 and 2312–2331 which respectively encompass a FXa inactivation cleavage site, the APC binding/cleavage site and the phospholipid binding site.

Conclusion: Thrombin used to produce the fibrin-based scaffold contributes to the development of low-level inhibitors while pre-infusions of cFVIII appear to modulate this response. IgG2 antibodies bind to the FXa inactivation and APC binding sites to prolong circulation of cFVIII antigen but also bind to the phospholipid binding site, rendering the FVIII inactive.

PB 4.35-2

Structural and functional characterization of clinical phase 1 and phase 2/3 material of BAX 855, a PEGylated recombinant FVIII

Turecek PL, Schrenk G, Graninger M, Gritsch H, Matthiessen P, Rottensteiner H, Kaliwoda M, Ehrlich HJ and Scheiflinger F

Baxter Innovations GmbH, Vienna, Austria

Background: Baxter and Nektar have developed a longer acting recombinant FVIII (BAX 855), which is manufactured by stably coupling PEG using Nektar technology to Baxter's full-length rFVIII bulk drug substance from its protein-free rFVIII manufacturing process.

Aims: To corroborate the controlled production process of BAX 855, batches from clinical Phase 1 and Phase 2/3 production were characterized with respect to their structural and functional properties.

Methods: The primary structure of BAX 855 was investigated using a tryptic peptide mapping approach. The composition of the N-linked oligosaccharides were determined by normal phase chromatography with fluorescence detection of released and labeled N-glycans. PEGylation site distribution and detailed analysis of the consistency of PEGylation was investigated by activating BAX 855 with thrombin. The resulting PEGylated and non-PEGylated fragments were separated using RP-HPLC and the bound PEG was measured for each thrombin fragment. PEGylation site distribution was confirmed by two-dimensional electrophoresis (2-D DIGE). Dynamic light scattering and Fourier-transformed infrared spectroscopy (FTIR) were used to monitor the consistency of the 3-dimensional structure of BAX 855. Assays to functionally characterize BAX 855 included FIXa cofactor activity, time course of thrombin-mediated activation and inactiva-

tion, thrombin generation capacity and susceptibility to activated protein C. Finally, the binding affinity and capacity of BAX 855 to VWF and the clearance receptor LRP were determined.
Results: Tryptic peptide mapping of BAX 855 resulted in a sequence coverage of 94% with high consistency between batches. Composition of the N-linked oligosaccharides showed a similar pattern for BAX 855 and unmodified rFVIII. Importantly, BAX 855 batches from clinical Phase 1 and Phase 2/3 production showed comparable distribution and extent of PEGylation. Two-dimensional electrophoresis confirmed high similarity of the spot and band patterns of clinical Phase 1 and 2/3 batches, indicative of high consistency of the manufacturing process. The mean hydrodynamic diameter of BAX 855 was between 35 and 38 nm as measured by dynamic light scattering; several BAX 855 batches showed almost overlapping FTIR absorbance spectra. Functional characterization of BAX 855 revealed characteristics similar to those of unmodified rFVIII in all assays used. Binding affinity and capacity to VWF was similar between BAX 855 and rFVIII. Interaction with the clearance receptor LRP was altered by PEGylation of rFVIII, shown by a decreased binding capacity.
Summary/Conclusions: BAX 855, a PEGylated rFVIII development product, can be manufactured reproducibly without changes to the protein structure and retaining its functional activities.

PB 4.35-3

Global haemostatic assays in monitoring the effect of bypassing agent therapy in haemophilia A patients with inhibitors- an in-vivo prospective crossover study

Tran HTT[1], Bjørnsen S[1], Ueland T[2], Pripp AH[3], Tjønnfjord G[4] and Holme PA[4]

[1]Oslo University Hospital; [2]Research Institute of Internal Medicine; [3]Department of Biostatistics and Epidemiology; [4]Institute of Clinical Medicine, Oslo, Norway

Background: The optimal dosing of bypassing agent (BPA) therapy in haemophilia patients with inhibitors is challenging due to a lack of standardized method for monitoring its haemostatic response. Several small case-reports have demonstrated the potential of global haemostatic assays, thromboelastography (TEG) and thrombin generation assay (TGA), in monitoring the effect of BPA therapy but prospective clinical study is lacking. Moreover, the adjuvant therapy of tranexamic acid may improve haemostatic outcomes of BPA treatment but has been little studied due to safety concerns.
Aims: We aimed to study the ability of TEG and TGA in monitoring the effect of the BPA, activated prothrombin complex concentrates (aPCC) and recombinant FVIIa (rFVIIa), given with and without tranexamic acid (TXA) in haemophilia A with inhibitors. In addition, the individual response to each treatment arm was evaluated.
Methods: We conducted a prospective clinical crossover study including haemophilia A patients with high titer inhibiors ($n = 6$), age between 22 and 6 that had signed informed consent. The study was approved by the Regional Committee for Medical and Health Research Ethics. On the first study day the participants received aPCC (75 IU/kg intravenously) while on the second study day aPCC was given concomitantly with TXA (20 mg/kg orally). Blood sampling was performed at baseline, 15, 30, 60, 120, 180 and 240 min post-treatment on both days for TEG, TGA analysis and DIC monitoring. After a washout period of 14 days the subjects were crossed over to rFVIIa (90 μg/kg intravenously) without and with TXA. Blood sampling and experimental set up was repeated as for the aPCC study arm. Time response effect was evaluated using TEG parameters clotting time (CT/second), maximum clot firmness (MCF/mm^{-1}), maximum-velocity (maxV/mm/second) and time to maxV (ttMaxV/second). Similarly, TGA parameters such as lagtime (LT/minute) endogenous thrombin potential (ETP/nM), time to peak (ttpeak/minute) and peak thrombin (nM) were analysed.
Results: TEG: Mean CT and ttMaxV declined rapidly at 15 min timepoint after infusion of BPA, thereafter it increased almost linearly whereas MaxV raised and reach its maximum at this timepoint. MCF and AUC increased following the treatment as well but less than with other parameters. The most significant difference in MCF and AUC were achieved in blood containing tPa. Here, MCF and AUC increased by threefold in the presence of TXA compared to without.
TGA: The LT and ttpeak was decreased after the infusion of BPA whereas the ETP and peak thrombin increased rapidly and reached its maximum at 15 min timepoint. There was no difference in TGA result following the treatment with or without TXA. The individual haemostatic response was observed for study participants.
Conclusions: The study demonstrated that TEG and TGA are valuable methods in assessing the haemostatic effect of BPA therapy, providing an opportunity to individualized the treatment. Some parameters seemed to be more robust than other in monitoring the effect such as ETP, peak thrombin in both PRP and PPP in TGA and CT and MCF/AUC in TEG.

PB 4.35-4

Improved strategy for rapid genetic analysis of hemophilia A

Dardik R, Zivelin A, Azar- Avivi S, Kornbrot N, Dvir A, Kenet G and Martinowitz U

Institute of Thrombosis and Hemostasis, Tel Hashomer, Israel

Background: Hemophilia A is a bleeding disorder caused by deficiency or impaired function of factor VIII (FVIII). FVIII is encoded by a large and complex gene (F8) comprised of 26 exons spanning 186 kb, located at the most distal region of the long arm of the X chromosome (Xq28). About 50% of severe hemophilia cases are caused by intron 22 inversions in the F8 gene. The remaining 50% include mainly missense mutations spread over the gene, with about 1500 unique mutations causing hemophilia A reported up to date. In view of this mutation heterogeneity, examination of potential hemophilia A carriers for definite determination of their carrier status and further prenatal diagnosis offered to the carriers are commonly based on linkage analysis using short tandem repeat (STR) markers. Accurate genetic analysis of hemophilia A using STR markers should be based on at least 2 markers: one intragenic and one extragenic marker, or two extragenic markers located at the 3' and 5' ends of the F8 gene. The aim of this approach is to exclude recombination between the marker used for analysis and the hemophilia-causing mutation.
Aims: 1. To improve the sensitivity of Inverse-shifting PCR (IS-PCR) assay for analysis of intron 22 inversions in the FVIII gene.
2. To identify additional extragenic STR markers proximal to the 5' region of the FVIII gene, which is very close to the chromosome X telomere, since to date, the majority of extragenic STR markers useful for analysis of hemophilia A are located at the 3' region of the F8 gene.
Methods: Genomic DNA samples were prepared for IS-PCR as described elsewhere (Fujita et al., J. Thromb. Haemost. 2012, 10:2099–2107). PCR fragments specific for the normal, inversion type I and inversion type II patterns were amplified separately, using two sets of primers for each ('nested' PCR system).
Potential new STR markers were identified by searching the telomeric region of the X chromosome for dinucleotide repeats (UCSC website, http://genome.ucsc.edu/). The polymorphic nature of the potentially polymorphic regions was either confirmed or excluded by fluorescent PCR analysis of 20 chromosomes.
Results: 1. Using the 'nested' PCR system, we significantly improved the sensitivity of IS-PCR assay for detection/exclusion of intron 22 inversions in the FVIII gene.
2. Using the above approach, we identified five new STR markers at the distance of 100–1 Mb from the 5' end of the F8 gene, in addition to only 2 STR markers previously identified in this region.

Summary: We suggest an improved strategy for rapid genetic analysis of hemophilia A, based on a 'nested' PCR system for detection/exclusion of intron 22 inversions, followed by fluorescent PCR analysis of 14 highly polymorphic STR markers (2 intragenic, 7 and 5 at the 5' and 3' ends of the F8 gene, respectively). During the period of 2009–2012, this approach enabled us to perform accurate genetic diagnosis of hemophilia A, complying with the requirement of at least 2 polymorphic markers, in 239 potential carriers and 36 male fetuses of established carriers.

PB 4.35-5

The inhibition mechanism of factor ? Trp1707Ser mutation associated inhibitors

Wu X[1], Lu YL[2], Wang XF[2], Ding QL[2], Dai J[2], Xi XD[3] and Wang HL[3]

[1]Shanghai Institute of Hematology, Ruijin Hospital; [2]Clinical Laboratory Department, Ruijin Hospital; [3]Shanghai Institute of Hematology, Ruijin Hospital, Shanghai, China

Background: Inhibitor formation and development following replacement therapy has become a major complication in the treatment of hemophilia A patients. F8 gene mutation has been elucidated as a key factor corresponded to the inhibitor formation. The inhibition mechanism of various gene mutation types may also differ as the different specificities of formed inhibitors.
Aims: Here we investigated the inhibitor mechanism of FVIII Trp1707Ser missense mutation associated inhibitors.
Methods: Plasma contained inhibitors were interacted with different fragments of FVIII (Heavy chain, light chain, A1, A2, A3, C1, C2), and corrected test was used to measure the remaining FVIII:C(%)by adding pooled normal plasma. Western blot was applied to further confirm the binding reactions which employed fragments as antigens and biotin-labeled purified inhibitors as antibodies. After completely interacting recombinant FVIII with inhibitors, the complex was added to microparticles coated with vWF or phospholipids. Then Anti-FVIII A1 domain antibodies were used to detect the FVIII binded to vWF or phospholipids. The FIXa and FVIIIa complex formed by interacting FIX with different concentrations of FVIIIa and inhibitor complexes was used to activate FX, and the apparent dissociation constant (Kd) for FVIIIa binding was calculated by the kinetic results.
Results: Corrected method detected that the remaining FVIII:C were increased when inhibitors interacted with heavy chain, light chain, A2 and C2 domain. No significant differences were seen in the A1, A3 and C1 domain reactions. Western blot further confirmed the previous results as bands were seen when heavy chain, light chain, A2 and C2 were used as antigens. No significant binding was detected when FVIII and inhibitor complex was added compared with only FVIII. Kd for FVIIIa binding showed that the binding capacity of FVIII and inhibitor complex were significantly lower than only FVIII.
Conclusion: The binding sites of the inhibitors of FVIIITrp1707Ser mutation were in the A2 domain of heavy chain and C2 domain of light chain. Inhibitors binding to A2 domain may affect FVIII to activate FIX as a cofactor, and inhibitors binding to C2 domain may block the interations of fVIII with phospholipids and vWF.

PB 4.35-6

Copy number variation (CNV) within the F8 gene causing haemophilia A; gene dosage determination of gross gene deletions/duplications by MLPA

Jenkins VP[1], Keenan C[1], O'Shea E[1], White B[1], O'Donnell JS[2] and O'Connell N[1]

[1]St. James's Hospital; [2]Trinity College, Dublin, Ireland

Background: Haemophilia A (HA) is caused by genetic lesions in the factor 8 (*F8*) gene. The most common mutations causing severe haemophilia A are inversion events involving either *F8* intron 22 or intron 1 repeats. Typically other causative mutations are detected by re-sequencing of the entire *F8* coding regions. Gross gene deletions or duplications in *F8* are rare molecular events that render direct sequencing methods uninformative and complicate molecular characterisation and diagnosis of carrier status. Multiplex Ligation-Dependant Probe Amplification (MLPA) allows the determination of gene dosage by simultaneously screening for the loss or duplication of intragenic target sequences using gene specific probes. Comparison of patient data with normal controls allows for the determination of copy number variation (CNV) within patients and potential carriers.
Aims: To identify copy number variation (gene dosage) in patients with gross deletions and suspected duplications within the *F8* gene, and determine carrier status in female relatives.
Method: The SALSA MLPA P178-B1 *F8* probe mix (MRC Holland) was used to determine gene dosage in a group of HA patients whose *F8* gene failed to amplify or where direct sequencing was uninformative. The probe mix contains 36 probes spanning all 26 *F8* exons, DNA specific and sex specific controls, and nine extragenic controls. Gene dosage of each exon was determined using Coffalyser software (MRC Holland) and the U.K. National Genetics Reference Laboratory (NGRL, Manchester) MLPA macro spreadsheet. Copy number variation was determined by comparing patient and carrier data with a series of sex matched normal controls. Peak height ratios (Coffalyser) and dosage quotients (DQ's; NGRL) were subject to statistical analysis within each software package. Coffalyser predicted the homozygous loss (HO Loss) or gene amplification in male patients and the loss of heterozygosity (LOH) in female carriers. The NGRL spreadsheet calculated the probability of deviating from the 'normal' dosage hypothesis.
Results: MLPA analysis allowed confirmation of gross exonic deletions in four families affected by severe HA. Deletions of exons 1–14, deletion of exon 15, and deletion of exon 26 in two unrelated cases were confirmed. MLPA analysis of female relatives of the affected patients was performed and data analysed using both Coffalyser and NGRL macros. Identical predictions of carrier status and normal gene dosage were obtained using both macros. A family with mild HA was also investigated as two affected males appeared to be heterozygous for a known HA point mutation within exon 14 (p.Arg717Trp). On analysis, both patients exhibited duplication of exon 14 and exon 18. The well established mild phenotype in this family is in accordance with the point mutation. This suggests that the duplicated regions are not pathogenic and do not disrupt *F8* mRNA synthesis.
Conclusion: MLPA is a simple and useful technique for identifying gene deletions and duplications, and provides a straightforward method for carrier determination for X-linked disorders. Variations in gene copy number are not always necessarily pathogenic as described here for a family with mild HA and a gene duplication event.

PB4.36 – Haemophilia A: Clinical – XIV

PB 4.36-1

Correlation between phenotype and genotype in a large unselected cohort of 621 PUPS (previously untreated patients) with severe haemophilia A

Carcao M[1], Van den Berg HM[2], Ljung R[3] and Mancuso ME[4]

[1]Hospital for Sick Children, Toronto, Canada; [2]University Hospital Utrecht, Utrecht, The Netherlands; [3]Lund University & Skåne University Hospital, Mälmo, Sweden; [4]Angelo Bianchi Bonomi Hemophilia/Thrombosis, Milan, Italy

Background: Phenotypic variability is well recognized in patients with severe hemophilia A (SHA). A few studies mainly in adults treated lifelong on demand suggest that bleeding phenotype correlates with factor VIII gene (F8) mutation; patients with non-null mutations (e.g. mis-

sense) appear to have a milder phenotype than those with null mutations (e.g. inversions). Nowadays, the widespread use of prophylaxis started at very young ages has changed the natural history of SHA. Even patients not started on prophylaxis but treated on-demand may be treated with different on-demand regimens thus affecting their disease phenotype. In this light, the period from birth to start of prophylaxis may represent the most suitable period to define the intrinsic bleeding phenotype of a patient with SHA.

Aims: Our aim was to analyze the very early phenotypic expression of SHA in 621 consecutively enrolled, well characterized previously untreated patients (PUPs) and to correlate this with patients' (F8) mutation type.

Patients and Methods: Patients were born between 1/01/2000 and 31/12/2009 and were enrolled, with informed consent, into the Rodin/Pednet Hemophilia Registries. Detailed information was collected on bleeds and treatment for the first 75 exposure days or until inhibitor development. F8 mutation type was known for 531 patients; 402 (76%) had null mutations and 129 (24%) had non-null mutations. We considered as markers of bleeding phenotype: ages (i) at diagnosis (only for patients with a negative family history of hemophilia); (ii) at first bleed; (iii) at first joint bleed; (iv) at second joint bleed and (v) at start of prophylaxis. Additionally the time elapsed between first and second joint bleed was determined. All outcomes were censored for start of prophylaxis and inhibitor development.

Results: Median age (in months) for all patients (including those with unknown mutations) at diagnosis was 8.8; at first bleed 9.6; at first joint bleed 14.8; at second joint bleed 20.2; and at start of prophylaxis 16.7. Median time elapsed between the first and second joint bleeds was 2.3 months. Compared to children with non-null mutations children with F8 null mutations were diagnosed at a median of 1.8 months earlier (8.3 vs. 10.1; $P = 0.04$), experienced a first bleed at a median of 1.2 months earlier (9.7 vs. 10.9; $P = 0.009$), and experienced a first joint bleed at a median of 2.3 months earlier (13.8 vs. 16.1; $P = 0.05$). No statistically significant differences were observed between mutation groups in age at second joint bleed, time elapsed between the first and the second joint bleeds and in age at start of prophylaxis.

Summary/Conclusions: PUPS with F8 null mutations show a slightly more severe phenotype (vs. PUPS with non-null mutations) as evidenced by earlier ages at diagnosis, at first bleed and at first joint bleed. However, these differences were modest and as such not likely to impact on decisions regarding when and how to start prophylaxis. We speculate that these relatively modest differences in disease phenotype at very young ages might, become larger as the children age. Further follow-up is needed to confirm this hypothesis.

PB 4.36-2

Evaluation of unfavourable cardiovascular risk factors and metabolic syndrome in young haemophilics

Erbas M[1], Zulfikar B[2], Ozdemir N[3] and Aydin A[4]

[1]Istanbul University, Cerrahpasa Medical Faculty; [2]Istanbul University, Cerrahpasa Medical Faculty and Oncology Institute; [3]Istanbul University, Cerrahpasa Medical Faculty, Pediatric Hematology Dept. ; [4]Istanbul University, Cerrahpasa Medical Faculty, Pediatric Metabolism Dept., Istanbul, Turkey

Background: Increased risk of unfavourable cardiovascular risk factors has been defined in the aging population of haemophilia however they were less investigated in young haemophilics.

Aim: The purpose of this study is to assess obesity, hypertension, metabolic variables, insulin resistance and metabolic syndrome in young people with haemophilia.

Methods: From February 2010 to November 2010, 48 haemophilia A and B patients (87% severe factor deficiency) and 35 age and sex matched healthy controls <40 years old were included. Blood pressure, anthropometric measurements, body mass index, waist circumference, blood pressure, fasting glucose and insulin levels, serum lipids and diet history were evaluated. Insulin resistance was estimated by HOMA-IR (Homeostasis model assessment of insulin resistance) formula. According to the criteria of International Diabetes Federation, metabolic syndrome was defined. The study was approved by the ethics committe.

Results: The mean age of the haemophilics was 21 years (range 6–40 years). Most of them were on prophylaxis (66% of haemophilia A and 50% of haemophlia B), others were on demand therapy. Artropathy was present in 62% of haemophlia A and 67% of haemophilia B patients and mainly in patients over 18 years old. Only few of these were getting physiotherapy (5% of haemophilia A and none of the haemophilia B patients). Forty-six percent of the haemophilics over 18 years old were obese, however none of the patients younger than 18 years old had obesity. Obesity was more prevalent in haemophilics with arthropathy ($P = 0.017$). When metabolic syndrome was assessed in different age groups, none of the patients <10 years old had metabolic syndrome, 7% of patients between 10 and 18 years old and 25% of haemophilics between 18 and 40 years old had metabolic syndrome. Fifty percent of the haemophilics between 18 and 40 years old were prehypertensive or hypertensive. Fasting blood glucose levels of haemophiliacs were higher ($P = 0.02$) compared to controls. When haemophilics and controls over 10 years old were compared for metabolic syndrome, no significant statistical difference was found (19.5% and 10% respectively, $P = 0.34$).

Conclusion: Overall life expectancy and quality of life among people with haemophilia have increased in recent years, primarily because of the advances in factor replacement therapy. However older patients who had been treated with on demand therapy have still a variety of orthopedic problems. Our study showed that obesity, hypertension and metabolic syndrome are frequent problems especially in haemophilics with arthropathy. Early prevention and management of overweight, obesity, and their sequelae must be addressed in clinical practice in order to maximize the overall health of the haemophilia population. Our sudy showed that prehypertension and hypertension are common in young haemophilics. Blood pressure measurements should be a part of standard care in haemophilia patients early in their life.

PB 4.36-3

Development of Factor VIII inhibitors and its association with HLA Class I and II alleles in Pakistani hemophilia A patients

Naz A, Ahmed S, Nadeem M and Shamsi T

National Institute of Blood Disease and Bone Marrow Transplantation Center., Karachi, Pakistan

Background: Severe form of hemophilia A is a major cause of life threatening hemorrhages. Factor VIII inhibitors are developed in approximately 15–25% of hemophiliacs who receive the Intravenous Factor VIII products. These neutralizing antibodies inhibit the substituted F VIII. A lot of research is under going globally to determine the environmental and genetic predictors of F VIII neutralizing antibodies.

Objective: To investigate the association between HLA class I and II alleles and the development of Factor VIII inhibitors in Pakistani Hemophilia A patients.

Material and Method: A case control study was carried out in the department of thrombosis and hemostasis, National Institute of Blood Disease and Bone Marrow Transplantation after approval of Institutional review board. Patients of Hemophilia A were divided into two categories one that had developed inhibitors and other without inhibitors. Healthy donors of bone marrow transplantation were included as control group. Genomic DNA of all participants was extracted from peripheral blood using Qiagen column based technique. Identification of HLA A, B and DRB1 alleles was amplified by Polymerase chain reaction sequence specific primers (PCR-SSP) of low resolution kit

(Olerup SSP HLA A-B-DR SSP, Stockholm, Sweden). Simple descriptive and chi square test were applied for statistical analysis of data using SPSS version 17.0.

Result: Total 125 participants were studied. Of 75 hemophilia A patients with mean age 11.5 ± 8.25 were categorized into two groups, one who had developed inhibitors (n = 25) exhibiting from >3.0 to 192.0 Bethesda units and other who had no inhibitors (n = 50). The frequency of HLA A3, A32, B40, DRB1*11 alleles was high in patients with no inhibitors as compared to control group and patients with inhibitors ($P < 0.01$). On the other hand only HLA B8 allele showed an increased association with patients with inhibitors as compared to patients without inhibitors and control group ($P < 0.01$).

Conclusion: HLA Class I and II alleles can be used as a predictor of development or non-development of inhibitors in patients with severe hemophilia A in Pakistan. A prospective study with larger sample size employing high resolution HLA typing will help in substantiating the results.

PB 4.36-4

Laboratory control of replacement therapy in severe hemophilia A patients

Balandina A[1], Zapariy A[2], Polokhov DM[3], Yakovleva V[3], Kargaltsev A[3], Konyashina NI[3], Polyanskaya TU[3], Kopylov KG[3] and Ataullakhanov F[1]

[1]Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow; [2]HemaCore LLC, Moscow; [3]Scientific Center for Hematology, Moscow, Russian Federation

Background: Some hemophilia A patients exhibit different bleeding phenotypes despite the similar base factor VIII concentration (FVIII:C) and need a different strategy of the factor replacement therapy.

Aims: To estimate the utility of different hemostasis assays for laboratory control of replacement therapy in severe hemophilia A patients under prophylactic and on-demand regimes as well as during surgery.

Methods: 17 severe hemophilia A patients (FVIII:C < 1%) were included in the study; three of them were examined before the surgery. Frequency of bleedings was 0–6 per month. Activated partial thromboplastin time (aPTT), FVIII:C, thrombin generation test (TGT), thromboelastography (TEG) and Thrombodynamics were performed. Thrombodynamics is a new assay based on a spatial fibrin clot growth registration; the stationary clot growth rate (Vst) was registered. Test of pharmacokinetics included 4–5 days washing period and blood sampling before and 0.5, 1, 3, 6, 24, 48 h after 50 IU/kg of FVIII infusion.

Results: Seven of nine patients on the prophylaxis therapy had 0–2 bleeding case per month, two patients had more than three bleedings per month. Thrombodynamics in 1 h after FVIII infusion demonstrated Vst ≥22 μm/min in all patients with low bleeding frequency and Vst <22 μm/min in patients with high bleeding frequency. $T_{1/2}$ for FVIII:C was more than 18 h in 6 of 7 patients with low bleeding frequency, $T_{1/2}$ <18 h in others. Endogenous thrombin potential (ETP) in TGT in 24 h after infusion was more than 800 nM*min in 6 of 7 patients with low bleeding frequency and ETP <800 nM*min in others. No clinical correlation with aPTT or TEG was observed for any time points.

In 5 patients with the therapy on-demand $T_{1/2}$ was in agreement with bleeding tendencies, while Vst and ETP showed this agreement only in three of them.

Three patients underwent a major orthopedic surgery. The surgical blood loss was 1.4, 2.1 and 0.85 L for patients #1, 2 and 3 respectively; bleeding period was prolonged in patient #2 to two days in comparison with 1 day for patients #1 and 3. Vst values correlated with surgical blood loss: Vst was 21.5 μm/min for patient #2 and 30.0, 24.0 μm/min for patients #1 and 3 respectively. $T_{1/2}$ and ETP did not show any agreement with the clinical observations ($T_{1/2}$ was 10.2, 10.4 and 12.0 h, ETP was 740, 847 and 784 nM*min for patients #1, 2 and 3 respectively).

Conclusions: Thrombodynamics, TGT and pharmacokinetics can be used for laboratory control of replacement therapy in severe hemophilia A patients.

PB 4.36-5

ORTHem 15–25: French retrospective national survey of different treatment regimens in patients with severe (factor VIII or IX = 2%) haemophilia A and B between 15 and 25 years old

Meunier S[1], D'Oiron R[2], Chambost H[3], Guillet B[4], Dolimier E[5] and Villette B[5]

[1]Haemofilia Treatment Center, Edouard Herriot Hospital, Lyon Cedex; [2]Haemophilia Treatment Centre, AP HP-Bicêtre Hospital, Le Kremlin-Bicêtre; [3]Haemophilia Treatment Centre, La Timone Hospital, Marseille; [4]Haemophilia Treatment Centre, Pontchaillou Hospital, Rennes; [5]Baxter Healthcare Corporation, Maurepas, France

Background: Prophylaxis has been widely used in young children to preserve joint status. Arguments to further maintain prophylaxis in adulthood are scarce.

Aim: To assess the treatment modalities and their determinants in persons with severe (FVIII/IX ≤2%) haemophilia A (HA) or B (HB), without inhibitor at inclusion, aged 15–25 years.

Methods: A national retrospective multicenter survey was offered to all French HTCs. Patients with haemophilia diary at least partially completed and receiving over the past 12 months and up to 3 years, one of the three following regimens could be included: Long-Term Prophylaxis (LTP), On-Demand (OD) treatment or 'Other' regimen. Distribution of patients was analyzed regarding age class ([15–18],] 18–21], >21), type (A or B) and severity (<1%, [1–2%]) of haemophilia, type of mutation (null, non null, inversions), absence or presence of family history of haemophilia or viral infection, history of intracranial haemorrhages (ICH), history of inhibitors, age at first treatment, first haemarthrosis and first LTP.

Results: 212 patients were analyzed, 169 (79.7%) in LTP, 40 (18.9%) in OD and 1.4% in 'other' regimen. The analysis focused only on LTP and OD groups. The median age was 18.9 years in the LTP vs. 22.0 years in the OD group ($P < 0.001$). LTP was correlated with younger age ($P < 0.003$), HA ($P < 0.007$) and FVIII/IX <1% ($P < 0.002$). Patients with null mutations tend to use more often LTP ($P = 0.058$). No correlation with the intron 22 inversion ($P = 0.386$), family history of haemophilia ($P = 0.081$), IHC ($P = 0.581$) or inhibitors ($P = 0.121$) could be found.

The younger age class (15–18 years) started the first period of prophylaxis earlier ($P < 0.001$) compared to the two others. LTP patients were younger at first treatment, first haemarthrosis and first prophylactic treatment: 1.45 vs. 2.44 ($P = 0.002$), 3.25 vs. 4.88 ($P = 0.002$), 7.15 vs. 11.15 ($P = 0.001$) (years), respectively. The average duration of LTP was 11.0 ± 4.0 years and that of OD regimen was 11.3 ± 7.9 years. The main reasons for initiation of LTP were appearance of haemarthrosis (50.9%), a target joint (42.0%) or a high number of bleeding (38.1%); reasons for OD regimen were a mild bleeding phenotype (47.5%), constraint related to prophylaxis (40.0%) or absence of arthropathy (35.9%). The median dose in LTP was 34 IU/kg/injection (IQ 30–40) with a median frequency of three times a week. The median number (0.00) of days of hospitalization per year for bleeding events was similar for the two regimens ($P = 0.067$). The total number of bleeding episodes recorded for a period of 12 months was smaller in the LTP group ($P = 0.014$), but the number of target joints and haemarthrosis were similar (LTP/OD: 5 vs. 4 and 1 vs. 1, respectively).

Conclusions: In this French survey, almost 80% of 212 patients with severe haemophilia (FVIII/IX ≤2%) aged 15–25 years received LTP

for an average of 11 years. LTP was more frequent in younger age class, severe and HA types. Overvalue of the proportion of patients receiving LTP cannot be excluded due to the inclusion criteria.

PB 4.36-6

Implementing pharmacokinetic (PK)-guided dosing in hemophilia; a discrete choice experiment (DCE) in an international cohort of hemophilia professionals ('OPTI-CLOT' studies)

Lock J[1], Urhan G[2], Driessens H[3], Brons P[4], van Gorkom BAPLaros-[4], Van Der Meer FJM[5], Smiers FJW[5], De Bekker-Grob EW[6] and Cnossen MH[1]

[1]Erasmus Medical Center – Sophia Children's Hospital, Rotterdam; [2]Erasmus MC – Sophia Children's Hospital, Rotterdam; [3]Netherlands Hemophilia Patient Society, Badhoevedorp; [4]Radboud University Nijmegen Medical Center, Nijmegen; [5]Leiden University Medical Center, Leiden; [6]Erasmus Medical Center, Rotterdam, The Netherlands

Background: Hemophilia is a rare X-linked bleeding disorder, caused by a deficiency of clotting factor VIII (hemophilia A) or IX (hemophilia B). The cost of treatment of hemophilia weights heavily on national health care budgets and is estimated at €130 million annually in the Netherlands, mainly clotting factor concentrates. Treatment includes prophylactic intravenous administration of the deficient clotting factor several times a week to prevent bleedings. These infusions are roughly aimed at raising clotting factor plasma levels above the threshold of 1% to prevent joint damage and subsequent long term disability. Pharmacokinetic (PK)-guided therapy in hemophilia using a population-based model generated by Bayesian analysis is available. This makes individualized dosing regimens based on PK-guided dosing possible. Earlier studies have reported a 30% reduction of clotting factor consumption without an increase in bleeding when prophylaxis is dosed according to a PK-profile. Despite guidelines supporting PK-guided dosing, it has still not been implemented as standard of care for a number of hypothetical reasons.
Aims: Quantification of barriers and facilitators of individualized PK-guided dosing of clotting factor as part of standard hemophilia care in hemophilia professionals. Currently, this study is also being performed in patients and parents in a multicenter setting in theNetherlands.
Methods: An international DCE survey was conducted during the World Federation of Hemophilia Conference inParis, 2012 among 91 hemophilia professionals from 28 countries with varying prophylactic treatment strategies. A panel latent class model was used to quantify the trade-offs between five barriers and facilitators for PK guided dosing: number of blood samples necessary to construct PK-profile; frequency of prophylactic infusions after PK-profiling; frequency of repeated PK-profiling; risk of bleeding; and cost for society.
Results: All barriers and facilitators of PK-guided dosing proved to be important for hemophilia professionals' preferences, except for the number of blood samples necessary to construct PK-profile. Reduction of risk of bleeding was the most important facilitator to implement PK-guided dosing; the most important barrier was a high frequency of prophylactic infusions as a consequence of PK-profiling. In general, hemophilia professionals displayed a positive attitude towards PK-guided dosing, although preference heterogeneity was substantial. Hemophilia professionals required a cost saving for society of 34.2% (CI: 21.7% to 57.3%) and 5.1% (CI: −2.7% to 12.9%) to compensate for daily prophylactic infusions ór infusions every other day, instead of twice a week. Hemophilia professionals from countries without a prophylactic dosing strategy had a lower probability to accept daily PK-guided dosing than hemophilia professionals from countries with a prophylactic dosing strategy.
Conclusions: Hemophilia professionals show an overall favourable attitude towards PK-guided dosing, especially if the risk of bleeding or cost for society is reduced, and if a frequency of daily PK-guided dosing is avoided. Hemophilia professionals from countries without a prophylactic dosing strategy had a lower probability to accept daily PK-guided dosing.

PB 4.37-1

Different neutralizing effects of factor VIII concentrates associated with von willebrand factor and the inhibitor epitopes

Yada K, Nogami K, Kenichi O, Minami H and Shima M

Nara Medical University, Kashihara, Nara, Japan

Background: Factor (F)VIII inhibitors, whose epitopes are localized to the A2 and C2 domain(s), develop as alloantibodies in patients with hemophilia A. The neutralization therapy by FVIII replacement is utilized as hemostatic treatment for hemophilia A patients with inhibitors classed as low responder, while the bypassing agents as recombinant (r)FVIIa and activated prothrombin complex concentrates (APCC) are used for those classed as high responder, but the effects may depend on various properties of these inhibitors. Some group reported the anti-C2 type 2 inhibitors associated with an antibody-dependent reduced rate of FVIIIa release from von willebrand factor (VWF) (Blood 1999). We have recently reported that the bypassing agent rFVIIa could activate FVIII directly even in the presence of anti-FVIII inhibitors and the inactivation was moderated by anti-C2 type 1 antibodies (Thromb Haemost. 2011), and another bypassing agent APCC could also activate FVIII in the presence of anti-FVIII inhibitors similarly to rFVIIa (ASH abstract #1178, 2011).
Methods: In this study, to investigate the effects associated with the properties of the inhibitors in the neutralization therapy, the coagulation function in timed-reaction of mixtures with FVIII (1 IU/mL) and anti-FVIII alloantibodies with distinct epitopes (2.5 BU/mL) were evaluated by global coagulation assays as thrombin generation test and clot waveform analysis.
Results: Thrombin generation assay revealed that the decrease rates of peak thrombin in anti-C2 type 1 inhibitors were ~3-fold or 10–20-fold greater than those in anti-A2 type 1 or anti-C2 type 2, respectively. Compared to FVIII alone, the mixture of FVIII/VWF with anti-C2 type 1 or anti-A2 type 1 mildly or little reduced the decrease rates by ~10% or <5%, respectively, whilst that with anti-C2 type 2 enhanced by ~2-fold, reflecting the property of anti-FVIII antibodies on the FVIII-VWF association. Anti-FVIII monoclonal antibodies showed similar patterns of reaction with anti-FVIII polyclonal. Clot waveform analysis also showed that coagulation parameters in 2-h reaction of FVIII with anti-A2 type 1 or with anti-C2 type 2 were ~3- or ~6-fold greater compared to anti-C2 type 1, respectively.
Conclusion: We demonstrated that the neutralizing effects of FVIII in the presence of anti-FVIII inhibitors differed with epitope of inhibitors. It should be important to determine the properties of inhibitors for prediction of the effects on FVIII-neutralization therapy and choice of the treatment using FVIII concentrates or FVIII/VWF complex concentrates, and the results could have significant therapeutic implications.

PB 4.37-2

Pharmacokinetics, efficacy, and safety of BAY 81-8973, a full-length plasma-protein-free recombinant factor VIII product: results from the LEOPOLD trial

Saxena K[1], Lalezari S[2], Oldenburg J[3], Delesen H[4], Shah A[5], Tseneklidou-Stoeter D[4] and Maas Enriquez M[4]

[1]Boston Children's Hospital, Boston, MA, USA; [2]National Hemophilia Center, Chaim Sheba Medical Center, Tel-Hashomer, Israel; [3]University Clinic Bonn, Bonn, Germany; [4]Bayer Pharma AG, Wuppertal, Germany; [5]Bayer HealthCare Pharmaceuticals, Montville, NJ, USA

Background: BAY 81-8973 is a full-length recombinant factor VIII (rFVIII) product manufactured without use of animal- or human-derived proteins in the fermentation and purification steps.

Aims: To demonstrate the pharmacokinetic (PK) noninferiority of BAY 81-8973 vs. sucrose-formulated rFVIII (rFVIII-FS) and to assess the efficacy and safety of BAY 81-8973 for treatment of bleeds and prophylaxis in hemophilia A

Methods: This multinational, randomized, open-label study is part of the Long-Term Efficacy Open-Label Program in Severe Hemophilia A Disease (LEOPOLD; ClinicalTrials.gov identifier: NCT01029340). Males aged 12–65 years with severe hemophilia A were eligible if they had ≥150 exposure days to any FVIII product and no history of FVIII inhibitors. For the phase 1 PK study, patients received a single 50-IU/kg dose of BAY 81-8973 and rFVIII-FS, separated by ≥3-day washout. Blood samples for PK testing were collected periodically up to 48 h postdose. PK parameters analyzed included maximum concentration (C_{max}), C_{max} divided by dose per body weight ($C_{max\ norm}$), area under the curve (AUC), half-life ($t_{½}$), volume of distribution at steady state (V_{SS}), mean residence time (MRT_{IV}), and clearance (CL). For the phase 2/3 efficacy and safety study, patients received 20–50 IU/kg BAY 81-8973 2–3 times/week for 12 months. BAY 81-8973 potency was based on chromogenic substrate assay per European Pharmacopoeia (CS/EP) and chromogenic substrate assay/label adjusted to mimic one-stage assay potency (CS/ADJ; dose was ~18% higher because of potency differences between the two assays). Patients crossed over from one potency group to the other after 6 months. Repeat BAY 81-8973 PK analysis was conducted at 6 or 12 months. The primary efficacy endpoint was the annualized number of total bleeds in each 6-month potency period. Patients also received BAY 81-8973 during major surgeries. All patients provided written informed consent; the protocol was approved by each site's independent ethics committee/institutional review board.

Results: Valid PK measurements were available for 26 patients (mean age, 30.6 years). The 90% CIs for the AUC and C_{max} ratios of BAY 81-8973 to rFVIII-FS were above the lower limit of the prespecified interval of 0.80–1.25 demonstrating noninferiority. Analysis of variance using 95% CIs showed that AUC, $t_{½}$, and MRT_{IV} were significantly higher and CL was lower after administration of BAY 81-8973 vs. rFVIII-FS ($P < 0.02$). No significant differences between treatments were seen for $C_{max\ norm}$ or V_{SS}. No relevant changes were seen in BAY 81-8973 PK after 6 or 12 months of treatment. Sixty-two patients (mean age, 31.5 years) received BAY 81-8973 prophylaxis for 12 months. Median annualized number of total bleeding episodes was 1.0 in the combined CS/EP and CS/ADJ groups (mean, 3.8; range, 0–26.1), without clinically relevant differences between potency periods. BAY 81-8973 maintained hemostasis in seven patients undergoing eight major surgeries. Incidence of treatment-related adverse events was low in all study phases (≤7%); no patient developed inhibitors.

Conclusions: In previously treated patients with severe hemophilia A, BAY 81-8973 PK were noninferior to those of rFVIII-FS. BAY 81-8973 was efficacious in preventing and treating bleeding episodes, with few treatment-related adverse events.

PB 4.37-3

Treatment of bleeding episodes in subjects with haemophilia A with long-lasting recombinant Factor VIII Fc fusion protein (rFVIIIFc) in the Phase 3 A-LONG study

Ragni M[1], Josephson N[2], Mahlangu J[3], Pasi J[4], Perry D[5], Powell J[6], Shapiro AD[7], Krassova S[8], Greblikas F[8], Nugent K[8], Brennan A[8], Luk A[9] and Pierce GF[8]

[1]Of Pittsburgh and the Hemophilia Center of Western Pennsylvania, Pittsburgh, PA, USA; [2]Puget Sound Blood Center, Seattle, WA, USA; [3]Haemophilia Comprehensive Care Centre, Johannesburg, South Africa; [4]Barts and the London School of Medicine and Dentistry, London, UK; [5]Addenbrookes Hospital, Cambridge, UK; [6]University of California Davis Health System, Sacramento, CA, USA; [7]Indiana Hemophilia and Thrombosis Center, Indianapolis, IN, USA; [8]Biogen Idec, Weston, MA, USA; [9]Biogen Idec Hemophilia, Weston MA, USA

Background: A long-lasting monomeric recombinant factor VIII Fc fusion protein (rFVIIIFc) for the treatment of haemophilia A has been developed using Fc technology to extend half-life over currently available rFVIII products. rFVIIIFc is comprised of a rFVIII molecule genetically linked to the Fc domain of human immunoglobulin G_1 (IgG) with no intervening sequence. Fc fusion technology utilises the endogenous IgG cycling pathway to prolong the half-life of therapeutic proteins. A 1.5-fold increase in half-life was demonstrated in the recently completed pivotal phase 3 study (A-LONG), which evaluated the safety, efficacy, and pharmacokinetics (PK) of rFVIIIFc when used for prophylaxis, to treat acute bleeds, and in the surgical setting, in previously treated subjects with severe haemophilia A.

Aims: To evaluate the treatment of bleeding episodes with rFVIIIFc in the pivotal A-LONG study.

Methods: Eligible male subjects ≥12 years old, with severe haemophilia A (<1 IU/dL [1%] endogenous FVIII), a history of ≥150 documented prior exposure days (ED) to FVIII, and no history of FVIII inhibitor, received either individualised prophylaxis (25–65 IU/kg every 3–5 days; Arm 1), weekly prophylaxis (65 IU/kg dose; Arm 2), or episodic (20–50 IU/kg; Arm 3) treatment. The number of bleeding episodes, number of injections, and median dose required to resolve bleeding episodes were evaluated. Efficacy assessments by subject and investigators were recorded.

Results: Overall, 165 subjects from 60 centres were enrolled (Arm 1, $n = 118$; Arm 2, $n = 24$; Arm 3, $n = 23$) and 92.7% of subjects completed the study. In total, 757 bleeding episodes (Arm 1 = 209; Arm 2 = 92; Arm 3 = 456) were treated in 106 of 163 subjects. To achieve resolution of a bleed, 87.3% of bleeds required a single injection of rFVIIIFc, and 97.8% required ≤2 injections. By study arm, 85.6%, 80.4% and 89.5% of bleeding episodes in Arms 1, 2 and 3, respectively, were resolved with 1 injection of rFVIIIFc. The median dose per injection required for resolution of bleeding was 27.4 IU/kg, and the median total dose required was 28.2 IU/kg. The median number of injections required for resolution of a bleeding episode was consistently 1.0 across treatment arms, regardless of type or location of bleed, or time of administration of treatment. Overall, subject assessment of response to treatment with rFVIIIFc was excellent or good for 78.8%, 64.8% and 79.7% of injections in Arms 1, 2, and 3, respectively. The investigators' global assessment of subject response to their assigned rFVIIIFc regimen was rated as excellent or effective for 99.4%, 100% and 98.1% of responses in Arms 1, 2 and 3, respectively.

Summary/Conclusions: Long-lasting rFVIIIFc provided effective control of bleeding episodes in the pivotal A-LONG study. The majority of bleeding episodes required only one injection. Subject response to rFVIIIFc regimen (rated by investigators) and response to bleeding events rated by subjects, were excellent or good/effective. rFVIIIFc offers the potential of a reduced injection frequency for treatment of bleeds in patients with severe haemophilia A.

PB 4.37-4

Does prophylactic factor replacement prevent asymptomatic microscopic haematuria in adult people with severe haemophilia?

Teoman S[1], Ar MC[2], Cengiz M[3], Kececi D[1], Eskazan AE[4], Salihoglu A[1], Gültürk E[1], Aydin SO[1] and Baslar Z[1]

[1]Istanbul University Cerrahpasa Medical Faculty, Istanbul; [2]Istanbul Training and Research Hospital, Istanbul; [3]Sarkisla State Hospital, Sivas; [4]Diyarbakir Training and Research Hospital, Diyarbakir

Background: Asymptomatic microscopic haematuria has been reported to occur in up to 20% of people with moderate/severe haemophilia before the introduction of coagulation factor replacement therapy. In the era of modern haemophilia treatment, however, the significance and frequency of haematuria is unknown.

Aim: The aim of the present study was to establish the frequency of asymptomatic microscopic haematuria among adult people with severe haemophilia and to determine the impact of prophylactic factor replacement on the occurrence of haematuria.

Methods: Fifty-five adult people with severe haemophilia A and B have been evaluated on 69 outpatient admissions for microscopic haematuria by urine examination. Microscopic haematuria was defined as the presence of ≥3 red blood cells in the urine sediment prepared via standard methods. Patients with urinary symptoms were excluded. None of the patients were positive for inhibitors. Factor levels and the treatment modality (on demand vs. prophylactic) of the patients, as well as the time (in days) from the last factor infusion were recorded.

Results and Conclusion. : In 9 of the 69 admissions patients were found to have asymptomatic haematuria (13%). No significant difference in the frequency of haematuria was observed between the patients with on demand treatment and those on prophylaxis ($P = 0.268$). These findings suggest that about 1/10 of people with severe haemophilia present with microscopic haematuria without any urinary symptoms. Prophylactic factor replacement does not necessarily prevent haematuria. This should be considered in the management of bleeding in people with severe haemophilia. The absence of haematuria should always be confirmed prior prescribing antifibrinolytic agents for the treatment or prevention of bleeding episodes.

PB 4.37-5

Ageing, haemophilia A and associated bleeding disorders – whose problem is it?

Robinson GJ[1], Schuster J[2] and Rangarajan S[2]

[1]The Haemophilia Soceity, London; [2]Basingstoke Haemophilia Comprehensive Care Centre, Basingstoke, UK

Background: Due to the success of treatment and care within haemophilia and associated bleeding disorders, the UK have a growing population who are now enjoying living longer and entering a unique period of history in relation to their own health and care which needs to be explored and understood.

Aims: A pilot study set out to investigate patients, carers and health professional's attitudes towards ageing, health and social care needs with a view to developing a consistent and high quality health and social care framework for haemophilia and associated bleeding disorders in the UK.

The impact these attitudes have upon self-management and ageing was investigated with a view to informing discussion around the development of associated guidelines relating to caring for a senior population within their own homes, clinics, hospital, nursing and retirements homes, therefore covering the full spectrum of bio psychosocial care.

Methods: The phenomenological approach has been used to examine experiences in ageing and bleeding disorders. Sixty patients (age range 40+), seven carers and six health professionals participated in focus group discussions on haemophilia, ageing and current available health and care support services and preferences relating to desired services for the future.

Results: The results indicate uncertainties around solutions to increasing difficulty with venous access as a result of lack of self-efficacy and memory problems. Concerns over access to haemophilia centres as a consequence of increasing disability and poor mobility were stressed. A reluctance to accept dependency on others and attitudes related to poor knowledge base within the general nursing community/nursing/care homes were associated with fear and scepticism of quality of service and treatment delivered for current and future co-morbid conditions.

A lack of skilled general community nurses who can give administer IV treatments has been echoed throughout the meetings. Preferences for further development into E Health and multi-disciplinary meetings to ensure effective communication with other health teams were expressed.

Conclusions: Guidelines should provide standards for both health and social care; they should also be developed to promote the wellbeing of all those aging and living with haemophilia for which these services are destined. Upgrade existing services which should include an increase of community haemophilia nurses and better communication with GP'S. The development of screening and preventative services within haemophilia centres, training manuals should be disseminated as a guide to competent authorities, accredited bodies and care agencies operating in this area.

PB 4.37-6

Impact of children with inhibitors on caregiver burden

DeKoven M[1], Pham H[2], Lee W[1], Powers J[1], Kelley L[3], Cooper D[2] and Wisniewski T[2]

[1]IMS, Alexandria, LA; [2]Novo Nordisk, Princeton, NJ; [3]LA Kelley Communications, Georgetown, USA

Background: Haemophilia is a bleeding disorder that can be classified as mild, moderate or severe depending on plasma level of clotting factors. Inhibitors are alloantibodies that can develop after exposure to replacement therapy with coagulation factor VIII or IX products and are presently considered the most serious complication in the treatment of haemophilia. Since treatment of haemophilia is typically provided at home by parents and relatives (i.e. caregivers), caregiver burden may be impacted by inhibitor complications.

Aims: To compare the overall burden of caregivers of children with and without inhibitors.

Methods: A questionnaire with six domains (emotional stress, financial, sacrifice, medical management, child's pain, and transportation) and burden visual analogue scales (B-VAS) was developed based upon the peer-reviewed literature and previous survey findings. Questions for each domain were answered using a scale of 1–5 where '1'represented 'never burdened' and '5' represented 'nearly always' burdened. B-VAS utilized a scale from 0 to 10 with 0 indicating 'no burden' and 10 indicating 'worst burden'. High burden was defined as those with a total burden score greater than the observed mean score of 80. Logistic regression was used to adjust for confounders including age, gender, income, education, marital status, disease severity, haemophilia type, inhibitor status, bleeding episodes, time taken off work, treatment type, time since diagnosis and distance from haemophilia treatment center. IRB approval was obtained.

Results: 310 caregivers completed the survey; 30 reported taking care of a child with an inhibitor. Most respondents ($N = 274$, 88%) were mothers between 18 and 54 years. The average age of the child for whom care was provided was 10.04 (SD 4.57). Mean total burden scores for all respondents were 80.79 (SD 20.14). Unadjusted results showed that compared to non-inhibitor patients, caregivers of children with inhibitors had statistically significant higher total burden scores (96.17 vs. 78.65, $P < 0.0001$), B-VAS scores (5.57 vs. 3.44, $P < 0.0001$) and all six burden domains: Child's pain (3.90 vs. 3.48, $P < 0.0096$);

emotional stress (3.15 vs. 2.73, $P < 0.0005$); financial burden (3.01 vs. 2.46, $P < 0017$); transportation (3.22 vs. 2.42, $P < 0.0001$); sacrifice (2.98 vs. 2.13, $P < 0.0001$); medical management (2.38 vs. 2.00, $P < 0.0009$). After controlling for confounders, having a household income >$100,000 USD ($P < 0.05$) was associated with less burden whereas taking time off work in the previous month ($P < 0.003$) and caring for a child with inhibitors ($P < 0.001$) were associated with greater burden. Adjusted odds ratios indicated that caregivers of children with inhibitors were 5.37 (95% CI 1.98–14.58) times more likely to have high burden compared to caregivers of children without inhibitors.

Conclusions: Caregivers of children affected by inhibitors to FVIII/FIX replacement therapy were significantly more burdened than caregivers of children without inhibitors. The burden of caregivers should be considered when assessing the psychosocial aspects of managing patients with inhibitors.

PB4.38 – Haemophilia A: Clinical – XVI

PB 4.38-1

Immunological detection of factor VIII antibodies in congenital and acquired haemophilia A

Batty P[1], Moore GW[2], Platton SJ[1], Maloney JC[2], Bowles L[1], Pasi J[3], Rangarajan S[2] and Hart DP[3]

[1]Royal London Hospital; [2]Guy's and St Thomas' NHS Foundation Trust; [3]Barts and the London School of Medicine and Dentistry, QMUL, London, UK

Background: The Nijmegen Bethesda assay is the gold standard for detection of Factor VIII (FVIII) antibodies, albeit with significant inter-laboratory variability. However, it may miss low titre antibodies or those without direct inhibitory capacity. This may not have immediate clinical repercussions but the true rate of anti-FVIII immunological activity in clinical studies may be underestimated. This could compromise the significance of surrogate markers of inhibitor risk. A FVIII ELISA kit (Hologic, previously GTI Diagnostics) has previously been described. This detects both inhibitory and non-inhibitory FVIII antibodies. This assay does not form part of standard laboratory practice in the United Kingdom. We present a large cohort describing the application of this FVIII ELISA in routine laboratory practice.

Aims: To compare anti-FVIII antibody detection by the Bethesda assay and FVIII ELISA in congenital and acquired haemophilia A in two large haemophilia treatment centres.

Methods: All routine inhibitor samples from patients with congenital and acquired haemophilia A were tested in parallel using the Bethesda assay and FVIII ELISA. These were subdivided based on diagnostic information provided at the time of venepuncture. Samples were defined as being positive if the Bethesda assay was ≥0.7 BU/mL and/or if the ELISA optical density (OD) was greater than that of the kit control.

Results: Four hundred and ninety seven samples (240 patients) were tested in parallel by Bethesda and ELISA: 140 patients with severe haemophilia A (291 samples); 86 patients with non-severe haemophilia A (129 samples); 14 patients with acquired haemophilia A (77 samples). Sixty three samples were positive by the Bethesda assay, median 1.2 BU/mL (0.7–978) and 75 positive by ELISA, median OD 0.978 (0.204–3.363). There were 40 discrepant samples: 14 Bethesda positive/ELISA negative; 26 Bethesda negative/ELISA positive. Comparing the assays for all samples the ELISA demonstrated a sensitivity of 77.8%, specificity 94.0%, positive predictive value (PPV) 65.3% and negative predictive value (NPV) of 96.7%. In the sub-group analysis of patients with acquired haemophilia A the ELISA demonstrated a sensitivity of 100%, specificity 82.9%, PPV 36.8% and NPV 100%, with 12 samples found to be positive by ELISA, but negative by the Bethesda assay.

Conclusions: Detection of FVIII antibodies by ELISA offers a simple method of batch testing, complementing the Bethesda assay. This test does not require modification for residual FVIII levels. Immunological detection of anti-FVIII antibodies may have as yet unforeseen predictive applications, e.g. risk of relapse in acquired haemophilia A. The reasons for ELISA and Bethesda assay discrepancy and resulting clinical significance needs to be defined through prospective collaborative studies.

PB 4.38-2

Long-term anti-FVIII antibody response in Bethesda-negative haemophilia A patients on continuous replacement therapy

Klintman J, Hillarp A, Berntorp E and Astermark J

Lund University, Malmö, Sweden

Background: Patients with haemophilia A may develop non-neutralizing anti-FVIII antibodies (NNA) that escape detection by the Bethesda assay, but are detected using immune-based assays. Recently, we and others found NNAs to be directed, not only towards non-functional parts of the protein, but towards all regions of the FVIII protein. We also showed in a cohort of brother pairs with haemophilia A, a heterogeneous antibody response towards different FVIII products. However, the clinical relevance and the natural history of NNA remain unclear.

Aims and Method: We have followed a cohort of unrelated subjects with haemophilia A, on continuous replacement therapy, for 4 years with the goal of exploring the long-term development of NNA using an ELISA assay.

Results: Ten of 78 subjects (12.8%) exhibited an immune response that was transient and heterogeneous, and none of the subjects developed an inhibitor towards FVIII during the study period. In order to investigate the potential clinical relevance of NNA, the result of the ELISA assay was examined in relation to clinical variables. No associations between a positive ELISA assay and age, *F8* mutation or PAC implantation was found. We found a trend towards an increased NNA risk in HCV positive subjects. Interestingly, patients with NNA had significantly fewer bleeding episodes ($P = 0.048$) compared with NNA-negative subjects.

Conclusion: The results indicate that the immune response towards FVIII within an individual may vary over time, and that anti-FVIII antibodies may potentially exert not only detrimental effect on FVIII protein, but hypothetically protective or potentiating effects as well. However, the clinical impact of NNA still remains unclear and requires further investigation.

The study was approved by the regional research ethics committee for southern Sweden.

PB 4.38-3

Carrier and prenatal diagnosis in sporadic haemophilia A and B families in China

Lu Y

Ruijin Hospital affiliated to Medical College of JiaoTong University, Shanghai, China

Background: About 1/3 of haemophilia families were sporadic families. Carrier and prenatal diagnosis in these families is necessary and it is important to determine the origins of the mutations.

Aims: In this report, we made genetic diagnosis of 40 sporadic HA families and three sporadic HB families.

Methods: LD-PCR and PCR were adopted for the screening of the INV22 and INV1 respectively. The F8/F9 coding and boundary sequences were analyzed by sequencing. Seven STR sites related to F8/F9 gene were combined together to apply to the linkage analysis

respectively. ABI PRISM SNaPshot ddNTP Primer Extension kit was used to analyze the chimerism. We assessed the sensitivity of the primer extension PCR method for detecting the mosaicisms by a mutant/wild DNA mix experiment.

Results: Tests showed that these 40 HA families were caused by INV22 (13/40), small insertions(6/40), small deletions(5/40), missense mutations(10/40) and nonsense mutations(6/40). The three sporadic HB families were all caused by missense mutations. From the linkage analysis, we confirmed that the origin of the mutations. For INV22 positive families, eight were from the maternal grandfathers (MGF) with no INV22 mutations and the others from the carrier maternal grandmothers (MGM). For the other INV22 negative families, 13 index's mothers were normal according to the DNA sequencing, the other 14 were carriers, in which six of the mutations were from MGM and the others from the MGF. The origin of the mutations were form the maternal grandfathers in all of the HB families. Mosaicism was identified in two families with the mutation of c.G96085T, c.T32874A in HA families and c.A32772T in HB familiy respectively. For the HA families, somatic mosaicism was identified in both of the grandmother's blood and oral cells with the percentage of 10.62% and 11.01% mutant (c.G96085T) respectively. 33% mutant (c.T32874A) was detected in the index's mother's blood cells while the formal DNA sequencing demonstrated the normal results. In HB family, the maternal grandfather's oral mucosa cells possessed wild-type as well as mutant F9 genes and the percentage of the mutation was 14.4%. We estimated the limit of the mosaicism detection as 2% mutant allele.

Conclusions: Based on the present study, we can reasonably suggest that intron 22 and 1 inversions screening combined with the linkage analysis using seven STR sites are available for carrier detection and prenatal diagnosis in Chinese HA families and the direct sequencing of F9 gene combined with the linkage analysis are available for diagnosis in Chinese HB families. The extention primer PCR method is a good approach to detect the mosaicism and can give information which may prove valuable in determining the origin of new haemophilia mutations, and in counselling relatives as well.

PB 4.38-4

Quality of hemophiliacs treatment in India – a survey

Sachdeva A, Ramzon M, Gulati R, Dinand V and Yadav S

Sir Ganga Ram Hospital, Delhi, India

Background: India with a population of 1.2 billion would have approximately 75,000 hemophiliacs. The problems with management of hemophilia in developing countries are poor awareness, inadequate diagnostic facilities and scarce factor concentrates for therapy.

Aims: This study describes the epidemiology and health services offered to hemophiliacs in India.

Methods: Survey was done through organizing hemophilia awareness camps with workshops in 12 cities of North India in last 2 years by expert hemophilia team. A detailed survey form was filled to know the quality of care in hemophiliacs.

Results: The survey included 403 patients with median age of 13 years (range 1.5–65 years) (73.7% were <20 years of age). Hemophilia A and B constituted 90.3% and 9.7% with severe, moderate and mild disease in 70.5%, 22.3% and 7.2% respectively. Half of patients had family history of hemophilia. Median age of clinical presentation was 1 year (range: birth to 20 year). At the time of first diagnosis of hemophilia, 67%, 29.5% and 3.5% patients had spontaneous, traumatic and procedural bleeding respectively. Majority of patients (90.4%) were being treated on demand, 39/403 (9.6%) were not even exposed to factor therapy yet (receiving alternative treatment). At the time of diagnosis 22.3% patients received factor replacement therapy, 61% received alternate form of treatment in the form of blood transfusion, fresh frozen plasma or cryoprecipitate and 16.7% received minimal or no treatment. The most common manifestation seen was target joint in 247/403 (61.3%) of patients. Single target joint was involved in 215/403 (53.3%) patients with knee joint in 43.7%, elbow 7.4%, hip 2%, shoulder 1.2% and ankle in 0.7%. Two and three target joints were present in 28/403 (6.9%) and 4/403 (1%) respectively. Clinical (Child instrument) and Orthopedic joint scores were pathetic in these patients. Permanent disability was present in 155/403 (38.5%), of these 15.1% were using crutches. Inhibitor levels were not checked in majority (>95%) of patients. Most of patients were using ice packs (63%) and tranexemic acid (55%) for their bleeding episodes, crutches (15.1%) for disability, 27.8% different NSAIDS, 8.2% codeine, 20% paracetamol, 1% homeopathic and 1% antispasmodic as pain killers. Virological studies for HIV, hepatitis B and C were performed in 10.6%, 11.4% and 10.2% of patients respectively. Two patients were positive for HIV, Hep B and HCV each. Not more than 10 patients were covered with insurance or reimbursement policies. Only few states governmental agencies are providing factor replacement free of cost. Major reasons for not using regular factor replacement were economical, followed by illiteracy. Secondary prophylaxis was opted by 6.7% of patients and none opted for primary prophylaxis.

Conclusion: Although this survey does not cover the whole country uniformly, it gives a snap view of health care services offered to 403 patients with hemophilia in India. Access to factor replacement is limited by economical constraints. More emphasis should be put on comprehensive services and prophylactic factor replacement to improve quality of life in developing countries.

PB 4.38-5

The impact of hemarthropathy on the QoL of Korean patients with severe hemophilia A: The critical level of hemarthropathy for the QoL

Jun S[1], You CW[2], Shin HJ[1] and Han JW[3]

[1]Pusan National University Hospital, Busan; [2]Eulji university Hospit, Daejeon; [3]Yonsei University College of Medicine, Seoul, South-Korea

Background: It is acknowledged that as the degree of hemarthropathy approaches a certain critical level, the disabled physical state may markedly affect the QoL of hemophiliacs. However, the critical level of hemarthropathy may be different in different countries because the QoL could be influenced not only by the physical state but also by socio-cultural environments across countries.

Aims: The impact of hemarthropathy on the QoL in Korean hemophilia A patients were investigated to find out the critical level of hemarthropathy in these patients.

Methods: This study was conducted in 27 severe hemophilia A patients over 17 years old who were registered at a single hemophilia treatment center. Depending on observed Pettersson scores of these patients at the start of study, they were divided into three groups, P (Pettersson score) £10, P 11~19 and P³20 groups. The QoL of each patient, assessed by the SF 36 (Korean version), was compared between the groups. In addition, a correlation analysis was conducted between Pettersson scores and scales of the SF36 to assess the impact of hemarthropathy on the QoL.

Results: In the present study, Pettersson scores were significantly correlated with physical health scales (PF, BP, GH) and physical component summary (PCS). None of the scores of the SF36 scales were different between the P£10 and P11~19 groups. In contrast, the scores of PF and MH scales were significantly different between the P11~19 and P³20 groups. When changes in the scores of each scale in the SF36 were observed according to changes in Pettersson scores, the average P score of 13.0 ± 2.7 was thought to be the critical level of hemarthropathy because above that level, hemarthropathy and physical and mental health of the patients rapidly deteriorated.

Conclusions: The progression of hemarthropathy to the critical level should be delayed as long as possible to prevent or to delay a rapid deterioration of the QoL of Korean patients with hemophilia.

PB 4.38-6

Social determinants of quality of life in persons with hemophilia

Dolatkhah R[1], Fakhari A[2], Zakaria Pezeshki M[3], Shabanlouei R[4], Gholchin M[4] and Tavassoli N[4]

[1]Hematology and Oncology Research Center, Tabriz University of Medical Sciences; [2]Associated Professor of Psychiatry, Clinical Psychiatry Research Center; [3]M.D. Associate Professor, Program for Estimation of Pretest Probability; [4]Hematology and Oncology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran

Background: The availability of safe and effective factor replacement therapies, in persons with hemophilia (PWH), has in some countries answered the basic need for treatment of these patients. In countries and regions where factor replacement and other treatment facilities are not enough available, Psychosocial support may help PWH, to cope with their disease and related problems. Meanwhile, most of the social determinants evaluations in PWH have been a component of quality of life (QoL) questionnaire – based studies.

Aims: This study is designed to evaluate the QoL in adult PWH, by focusing on social determinants of QoL and their relationship with health related dimensions, in Tabriz hemophilia treatment center (HTC) of Iran.

Material and Methods: The survey instrument was a self-report 36 items questionnaire, 'A36 Hemofilia – QoL', which is a disease specific questionnaire for the assessment of the health-related QoL in adults living with hemophilia. A total of 100 Hemophilia A and B, mild to severe, over 17 years old participated in this study within 1 year.

Results: A36 Hemofilia-QoL Total score (TO) was 71.88(±26.89 SD), which was in the range of moderate to good. Dimensions covered by this survey were classified as good to moderate for Physical Health 16.37 (51.15%), Treatment Satisfaction 5.39 (67.37%), Treatment Difficulties (60.62%). Other dimensions were classified as moderate to poor for Daily Activities 7.20 (45%), Joint Damage (5.52%), Pain 3.50 (43.75%), Emotional Functioning 9.26(46.3%), Mental Health 5.8 (48.41%), Relationships and Social Activities 9.58 (47.9%). Patients who treat in our HTC, had better QoL score ($P = 0.000$), and education has a significant impact on the social aspects of QoL ($P = 0.18$). The QoL was very poor in urban area in contrast to patients who lived in the city (54.45 vs. 74.21, respectively). Single patients have a better QoL than married patients (76.56 vs. 68.50, respectively).

Conclusion: Our results showed that PWH who live in urban areas have very poor QoL and more disease complications, because of less replacement therapies and lack of awareness of their diseases. Serious designed works strongly recommend for this group of PWH.

PB4.39 – Haemophilia A: Clinical – XVII

PB 4.39-1

Peak FVIII levels and time spent in hemostatically effective FVIII range post-infusion correlates with improved efficacy for prophylaxis in hemophilia A: a closer look at the other end of the curve

Valentino LA[1], Collins PW[2], Pipe S[3], Blanchette VS[4], Schroth Ph[5], Fritsch S[6], Ewenstein BM[7] and Spotts G[5]

[1]Rush University Medical Center, Chicago, IL, USA; [2]University Hospital of Wales, Cardiff, UK; [3]University of Michigan, Ann Arbor, MI, USA; [4]Hospital for Sick Children, Toronto, Canada; [5]Baxter Healthcare, Westlake Village, CA, USA; [6]Baxter Innovations GmbH, Vienna, Austria; [7]Baxter Healthcare, Research and Development, Westlake Village, CA, USA

Background and Aims: We previously demonstrated that increasing time with a FVIII concentration below 1 IU dL(−1) is associated with increased total hemorrhages and hemarthroses in severe hemophilia A patients treated with regular prophylaxis regimens (Collins PW, et al. J Thromb Haemost 2009; 7: 413–20). Targeting trough levels at ≥1% above baseline using PK-guided dosing at 72 h intervals has been demonstrated to be an effective treatment strategy (Valentino LA, et al. J Thromb Haemost 2012; 10: 359–367). In this study, subjects on PK-guided dosing experienced a median annual bleed rate (ABR) of 2.0 (range 0–17.1) representing a 96% reduction in ABR from on-demand therapy. The individual FVIII half-lives (median: 11.7 h; range: 7.3–30.7; IQR: 10.1–13.6; 5–95% percentiles: 7.7–21.4), and therefore, the FVIII dose/infusion (median 41.3 (IU/kg), range 18.9–84.9) varied widely in the study cohort. This allowed examination of the role of treatment- and patient-related variables other than FVIII trough in achieving low ABRs in patients using individualized regimens.

Methods: Data from subjects prescribed PK-guided dosing given every third day ($n = 34$) were examined. Average Cmax was estimated using the individual IVR values for each subject and their average dose per prophylactic infusion. AUC/week and time spent above 5, 10, 20, 30, or 40% FVIII levels (i.e, within hemostatically effective, non-hemophilic range) in each subject were extrapolated using parameters from individual PK profiles and actual infusion records. Negative binomial multivariate regression model was used for analysis with age and BMI as covariates.

Results: The estimate for Cmax ranged from 24.3 to 167.5% (median 70.9%). A significant relationship between lower Cmax and increased risk for bleeding was seen (All bleeding $P = 0.0004$; joint bleeding $P = 0.0013$). Similarly, time spent above 30% and 40% FVIII levels showed a significant relationship with lower ABR (all bleeds, $P = 0.0034$ and $P = 0.0012$, respectively). Similar significant relationships were found in all AUC/week variables tested (e.g., above 5%, 10%, and 20%); both AUC and time spent variables are strongly correlated with average Cmax. A substantial reduction of ABR during prophylaxis as compared with on-demand therapy was seen in each subject however many of those with higher ABR on prophylaxis appeared to have had more bleeding episodes during the preceding on-demand period and had a lower% ABR reduction on prophylaxis. Otherwise no other parameters examined (e.g., age, BMI, number target joints, compliance) appeared different amongst these subjects.

Summary and Conclusion: These results demonstrate a relationship between higher Cmax values and/or time spent within 'hemostatically effective' FVIII range and better prophylactic efficacy in subjects on PK-guided dosing given every third day. While targeting FVIII trough at >1% above baseline is generally effective, this strategy *alone* may not be suitable for all patients, especially those with high ABRs on on-demand therapy, and with longer FVIII half-lives, who require lower FVIII doses to maintain the specified trough levels. These findings may have significant implications for the development of optimal individualized PK-guided prophylactic dosing regimens with unmodified FVIII concentrates as well as with the modified longer-acting FVIII molecules currently in development.

PB 4.39-2

Self-efficacy in the Dutch pediatric population; Reliability and validity of the Hemophilia Self-Efficacy Scale (HSES)

Lock J[1], Raat H[2], Hijmans CT[3], Peters M[3], Tamminga YJ[4], Leebeek FWG[2], Moll HA[1] and Cnossen MH[1]

[1]Erasmus Medical Center – Sophia Children's Hospital, Rotterdam; [2]Erasmus Medical Center, Rotterdam; [3]Academic Medical Center – Emma Children's Hospital, Amsterdam; [4]University Medical Center Groningen, Groningen, The Netherlands

Background: In all patients with chronic diseases, self management capacities of the patient and caretakers with regard to the disease are of importance. Especially in hemophilia patients on prophylaxis, adequate judgement and motivation considering adherence to prescribed

therapy, and behaviour are important skills; summarized by the term self-efficacy. Previous studies have demonstrated that a well developed capacity towards self-efficacy is associated with greater adherence and less clinical manifestations of disease. Therefore, it is important to quantify a patients' self-efficacy and to formulate interventions to modify self-efficacy skills.

Aims: To assess the reliability and validity of a novel scale measuring disease-specific perceptions of self-efficacy in patients with hemophilia on prophylactic clotting factor replacement therapy.

Patients and Methods: Children from three Dutch Hemophilia Treatment Centers with severe and moderate hemophilia on prophylactic treatment were included. Exclusion criteria were: prophylactic treatment <1 year, presence of inhibitors and language difficulties. Parents and children aged 10–18 years filled out the study questionnaire. Written informed consent and ethical approval was obtained.

The Hemophilia Self-Efficacy Scale (HSES) consists of 12 items relating to participants' perceptions of their ability to function on a day-to-day basis and to manage symptoms (e.g. bleedings episodes) and therapeutic interventions in hemophilia. This instrument is based on the validated Sickle Cell Self-Efficacy Scale with the concept of the ability towards 'self-care'. This incorporates an individuals' perceptions of both disease symptoms and the patients' abilities to cope with or reduce these symptoms.

Response choice ranged from 'not at all sure' to 'very sure' on a 5-point Likert scale. Higher scores reflect greater self-efficacy, the total score range is 12–60. Psychometric properties (construct validity including Cronbach's alpha, discriminative validity, test-retest reliability) were empirically assessed. Convergent validity was tested with previously validated generic measure of related construct (General Self-Efficacy Scale (GSES). Predictive validity was assessed by computing correlations between HSES total score and reported health-related quality of life in the previous month (Haemo-QoL).

Results: A total of 53 parents and 28 adolescents filled out the questionnaire (response rate 79%). Median age of the children was 11.4 years (IQR 8.1–13.9). Test-retest reliability was measured in a subgroup ($n = 55$). Mean of total score was 55.5 (SD 4.7, range 38.0–60.0). Construct validity: mean Cronbach's alpha was good for the total score (0.8). The scale had no floor effects but did have a ceiling effect of 21%. Test-retest Pearson correlation was positively significant (0.8; $P < 0.001$). Correlation between disease specific self-efficacy and GSES was statistically significant (Pearson correlation 0.5, $P < 0.001$). The reported Haemo-QoL correlated significantly to HSES scores (Pearson correlation −0.33, $P = 0.02$), indicating that higher self-efficacy was associated with higher quality of life.

Conclusions: HSES is a reliable and valid tool to asses patients' self-efficacy in patients with severe or moderate hemophilia and prophylactic treatment. In our study, high self-efficacy correlates with higher quality of life reported by HaemoQol, underlining the importance of evaluation of capacity towards self-efficacy.

PB 4.39-3

Recombinant activated factor VII use for surgical/invasive procedures in congenital haemophilia with inhibitors and acquired hemophilia: analysis from 10-year Japanese post-marketing surveillance

Takedani H[1], Shima M[2], Horikoshi Y[3], Koyama T[4], Fukutake K[5], Kuwahara M[6] and Ishiguro N[7]

[1]IMSUT Hospital of the Institute of Medical Science, Tokyo; [2]Nara Medical University, Kashihara; [3]Shizuoka Children's Hospital, Shizuoka; [4]Tokyo Medical and Dental University, Tokyo; [5]Tokyo Medical University, Tokyo; [6]Novo Nordisk Pharma Ltd., Tokyo; [7]Nagoya University, School of Medicine, Nagoya, Japan

Background: Patients with congenital haemophilia with inhibitors (CHwI) and acquired haemophilia (AH) are at risk of bleeding complications during surgical/invasive procedures, since replacement therapy for the missing coagulation factor is ineffective. Therefore, management of bleeding requires the use of bypassing agents, such as recombinant activated FVII (rFVIIa, NovoSeven®). To investigate the safety and efficacy of rFVIIa in the treatment of bleeding during surgical/invasive procedures in Japanese patients, data from Japanese post-marketing surveillance was analysed.

Methods: A multi-centre, observational study was conducted from May 2000 to March 2010. The dosing regimen of rFVIIa was decided based on the institutional practice at each centre. The rFVIIa dosing regimen and adverse events were recorded, and the clinical efficacy evaluated according to three criteria: (i) blood loss (during a procedure) compared with that expected from previous surgeries in haemophilia patients; (ii) effectiveness of bleeding control (during a few days post-procedure), and (iii) maintenance of bleeding control (during a few weeks post-procedure until removing stitches). Patient follow-up was for 6 months to evaluate other complications.

Results: Twenty-two patients with congenital haemophilia A underwent 38 surgical/invasive procedures (orthopaedic: 43%, central venous access device: 16%, dental/oral: 16%, gastrointestinal: 11%, small incision/suture: 11%, thoracic: 5%). Of these 38 procedures, 92% were evaluated as 'blood loss as expected or less' and 89% as 'effective in bleeding control, i.e. bleeding was stopped completely or reduced considerably'. Bleeding control was maintained in 95% procedures after wound closure. Seven congenital haemophilia B patients underwent 13 surgical/invasive procedures (orthopaedic: 62%, central venous access device: 15%, dental/oral: 8%, gastrointestinal: 8%, small incision/suture: 8%). Of these, 69% were evaluated as 'blood loss as expected or less' and 77% as 'effective in bleeding control'. Bleeding control was maintained in 95% of procedures. Five patients with AH underwent five surgical/invasive procedures (gastrointestinal: 40%, dental/oral: 20%, obstetrics: 20%, central nervous system: 20%). Of these, 60% were evaluated as 'blood loss as expected or less' and 80% as 'effective in bleeding control'. In 60% of procedures, the bleeding control was maintained. Activated prothrombin complex concentrate was used when bleeds were not controlled with rFVIIa. Thrombophlebitis occurred in an 11-year-old male with congenital haemophilia A with an inhibitor. He underwent elbow surgery with continuous infusion of rFVIIa, and a mild thrombophlebitis of a superficial vein was observed in the arm in which the catheter was placed. The thrombophlebitis resolved naturally. The case was determined to be related to rFVIIa administration.

Conclusions: rFVIIa provided adequate haemostasis for the majority of surgical/invasive procedures in patients with CHwI and AH, without serious adverse reactions. The efficacy and safety profile for Japanese patients was similar to the published data from other countries.

PB 4.39-4

The first review of global spontaneous adverse event reports for a third generation recombinant factor VIII concentrate (Octocog Alfa): 10 years of safety experience

Berg R, Gringeri A and Reininger AJ

Baxter Innovations GmbH, Vienna, Austria

Background: The low number of spontaneous Adverse Event (AE) reports in rare disorders and the variety of reporter sources such as physicians or patients require a thorough understanding of reporting trends to evaluate safety data. Spontaneous reporting represents an important tool to identify Adverse Drug Reactions previously unrecognized in the clinical development process. Regional or local databases, e.g. FDAs FAERS, EUHASS, are subject to different reporting cultures or research questions that hold a potential for biased perspective. Pharmacovigilance activities of Marketing Authorization Holders provide a unique, global picture allowing to identify and thereby minimize potential bias.

Aims: The a priori assumption that all biologics of one class have a similar safety profile can be hazardous: e.g., manufacturing processes may result in different safety profiles. Herein we provide a comprehensive 10-year overview of Octocog Alfa safety profile since its first marketing authorization as determined by the longest and largest dataset of spontaneous AE reports published for a 3rd generation rFVIII.
Methods: The global safety database for Octocog Alfa was reviewed for all spontaneously reported AEs (excluding solicited reports) received between July 2003 and September 2012. Reporting trends were analyzed per reporting sources and regions. Important AEs such as inhibitor formation are further discussed.
Results: More than 13 billion international units of Octocog Alfa were distributed during the review period, corresponding to an estimated 87,000 patient-years of exposure. A total of 648 spontaneous AE reports were received. Of these, 311 AE reports included information on the development of factor VIII inhibitors. The reporting rate of FVIII inhibitors for both PUPs and PTPs remained stable over time suggesting the absence of safety signals. Five spontaneous AE reports included the event of an anaphylactic reaction. Significant differences were observed for reporting trends in individual countries with respect to reporting rates as well as per reporting source. For the US, total numbers of AE reports from patients and healthcare professionals such as nurses and pharmacists by far exceed the number of AE reports received from physicians. This is in sharp contrast to other regions, such as Japan, where AE reports from physicians dominate spontaneous reporting. Globally, consumer reports included a higher percentage of non-serious events compared to reports from physicians. In addition consumers and healthcare professionals were focused on different types of AEs. The often cited Weber-effect (the increase of the absolute number of AE reports during the first 2 years of product marketing with a subsequent reporting decrease thereafter despite increasing sales) could not be observed.
Summary/Conclusions: Despite the complexity of AE reporting trends, the 10-year review of spontaneous AE reports received globally for Octocog Alfa did not result in the detection of previously unrecognized risks or product quality issues. This data is usually not disclosed publicly but is important information to confirm the premarketing safety profile given the limited sample size needed for licensing FVIII therapeutics. Data derived from spontaneous reporting is an integral part of the overall safety profile of a product and needs to be taken into account for optimal treatment decisions.

PB 4.39-5

National Haemophilia Registry of China – a developing registry

Xue F, Yang R and Zhang L
Blood Disease Hospital, Chinese Academy of Medical Science, Tianjin, China

Background: In Jaunary 2010, as a result of continuous efforts to raise the awareness at authority level, the ministry of health of china launched the Haemophilia data management system project.
Aims: The aim of this summary is to describe the development of the China National Haemophilia registry.
Methods: National hemophilia registry of China is a registry to collect the information of patients with hemophilia or other inherited bleeding disorders. It's a government authorized, medical centres participated registry. One national registry centre and 31 provincial centres were established. National hemophilia registry centre(Blood disease hospital, PUMC) is responsible for merging, analyzing the data centralized from all provincial centre. All the provincial registry centres are medical centres and responsible for collecting and transfer the data of whole province using both stand-alone entry software and web-based entry programme protected by password. The National identification number is used as the unique ID and marker for routine duplicate management.
The system will generate a general data and presented on web-site for public. The privacy of patients entered would be fully preserved during registered.
Result: The data analyzed here are from January 2010 to December 2012, total 10,652 patients entered in the registry, including 9055(85%) hemophilia A(HA) patients, 1298(12.2%) hemophilia B (HB) patients, 54(0.5%) vWD patients and 245(2.3%) patients with rare bleeding disorders.
There are 6600(72.9%) severe, 1691(18.7%) moderate, 668(7.4%) mild and 96(1%) unknown type HA and 874(67.3%) severe, 290 (22.3%) moderate, 124(9.6%) mild and 10(0.8%) unknown type HB patients enrolled in the registry. Age distribution of patients <13-year old is 27% for HA and 24% for HB, between 14 and 18-year old is 11% for both HA and HB, between 19 and 60-year old is 56% for HA and 58% for HB, more than 60- year old is 2% for HA and 4% for HB. At last, 4% HA patients and 3% HB patients do not have age data.
Among 1345(15%) HA and 243(19%) HB patients have HBs-Ag data, 80(5.9%) HA and 17(7%) HB patients have positive result. Among 1273(14%) HA and 235(18%) HB patients have HCV-Ab data, 171 (13.4%) HA and 31(13.2%) HB patients have positive result. There are 31 HA and 1 HB patients detected with HIV-Ab, constitute 2% and 0.4% of patients who have HIV infection data.
Refer to the first bleeding age, 6437(71.1%) HA and 246(19.0%) HB patients presented before 2-year old, 1718(20.0%) HA and 277(21.3%) HB between 2 and 7-year old, 654(7.2%) HA and 134(10.3%) HB between 7 and 18-year old, 246(2.7%) HA and 72(5.6%) HB older than 19-year old.
Summary/Conclusions: The national hemophilia registry comprises a great deal of data on variant aspect of patients. However it also has some shortcomings need to be updated or modified in future to obtain more precise and dynamic information of patients. For example, because the stand-alone software cannot be allied with electronic chart used by variant centres, the data cannot be updated in time. We will continue update the system to make it more useful in improving healthcare condition of China.

PB 4.39-6

Comparison of a ELISA FVIII inhibitor assay with the Nijmegen Modified Bethesda assay in patients with inherited and acquired haemophilia A

Riddell A, Pickering WM, Lawler P, Yildiz L, Drebes A and Yee T
Royal Free London, London, UK

Backgound: FVIII inhibitors are usually detected and quantified using Nijmegen modified Bethesda (NMB) assays or enzyme-linked immunosorbent assays (ELISAs). Current UKHCDO guidelines recommend testing patients with severe haemophilia after a wash out period of 24 h and in those patients with mild or moderate haemophilia a heat inactivation step of patient plasma can be used prior to testing.
Aims & Methods: To compare NMB assay in heat inactivated plasma samples (90 min @ 56 °C) with ELISA method (FVIII Antibody Screen – GTI Diagnostics, USA) using normal plasma. Patients were included even if the trough factor VIII level, either due to endogenous or treatment related FVIII was >1 IU/dL.
Results: In total 160 samples were tested {including patient samples with severe HA (n = 82), Moderate HA (n = 7), mild HA (n = 18), and acquired HA (n = 51)}. Of 160 samples, 103 were negative by NMB assay and of these seven were positive by the ELISA inhibitor assay (two with severe HA, three with mild HA and one with acquired HA). 57/160 patient samples were NMB positive of which 10 samples were negative by the ELISA inhibitor assay. All 10 samples were from four patients with acquired HA and had NMB levels ranging from 0.7 to 2.2 BU and FVIII:C levels ranging from 40 to 109 iu/dL. The 51 samples with acquired HA came from 12 patients in whom FVIII levels ranged from <1 to 118 iu/dL and NMB unit levels that ranged from 1 to 73,000 BU.

Discussion: 4% of samples in this study showed a discrepancy with the NMB assay with higher positivity by ELISA. Low titre inhibitors are not uncommon in severe haemophilia A and it is possible that the ELISA detects FVIII inhibitors at an earlier point than the NMB assay or that they are non-neutralising FVIII antibodies and not significant. The negative ELISA results in the acquired HA samples but positive with NMB assays is hard to explain, and it may be related to epitopes not recognised by the ELISA. Heat inactivation of plasma from patients with acquired HA for use in the NMB assay is useful especially when FVIII levels are within the reference range (>50 IU/dL), as it allows detection of low titre FVIII antibodies and therefore it may help decide on the duration of immunosuppression before tapering and preventing relapses. In conclusion the value of both these assays should be explored with correlation to clinical endpoints.

PB4.40 – Heparin-induced thrombocytopenia (HIT): Clinical – III

PB 4.40-1

Frequent off-label use of fondaparinux in patients with suspected acute heparin-induced thrombocytopenia (HIT) – final results from the GerHIT multi-centre registry study

Schindewolf M[1], Steindl J[1], Beyer-Westendorf J[2], Schellong S[3], Dohmen PM[4], Brachmann J[5], Madlener K[6], Pötzsch B[7], Klamroth R[8] and Lindhoff-Last E[1]

[1]Goethe University Hospital Frankfurt/M., Frankfurt am Main; [2]University Hospital Carl Gustav Carus, Dresden; [3]Municipal Hospital Dresden Friedrichstadt, Dresden; [4]Heart Centre Leipzig, University of Leipzig, Leipzig; [5]Klinikum Coburg, Coburg; [6]Kerckhoff-Klinik, Bad Nauheim; [7]University Hospital Bonn, Bonn; [8]Vivantes Klinikum im Friedrichshain Berlin, Berlin, Germany

Background: In life-threatening HIT, alternative anticoagulation with a non-heparin anticoagulant is strictly recommended. However, off-label use with fondaparinux has been reported in the literature.
Aim: The aim was to collect data on the 'real-life' management of patients with suspected acute HIT.
Methods: In a national multi-centre registry study, the 4T's scores for the clinical probability of HIT were determined retrospectively in 261 patients diagnosed with HIT between 01/2005 and 10/2009. Only patients with a score of ≥4 points and treatment with at least one dose of argatroban (A), lepirudin (L), danaparoid (D), or fondaparinux (F) were included for evaluation of laboratory diagnostic strategies and prescription practices of anticoagulants.
Results: 195 patients were included. The 4T's scores were 4/5/6/7/8 points in 46 (23.6%)/50 (25.6%)/74 (38.0%)/13 (6.7%)/7 (3.6%) patients, respectively. The median treatment duration before HIT was 6.0 (unfractionated heparin [UFH]), 7.0 (low-molecular weight heparin [LMWH]), and 10.0 days (UFH/LMWH). During heparin therapy, 53 (27.2%) thromboembolic events, 5 (2.6%) skin lesions, 1 (0.5%) amputations, 24 (12.3%) Hb-relevant bleedings, and 2 (1.0%) deaths occurred. A functional heparin-induced platelet activation assay was performed in 96.9%, an immunogenic PF4/heparin-dependent ELISA was performed in 89.2%, a particle gel immunoassay was used in 12.3%, and a serotonin-release assay none of the patients. The alternative monotherapy strata were: argatroban in 16.4%, lepirudin in 2.1%, danaparoid in 23.6%, fondaparinux in 40.0% of the patients; the sequential therapy strata were: AF in 5.6%, DA in 5.6%, DL in 2.1%, and DFL in 0.5% of the patients.
Summary/Conclusion: The laboratory diagnostic strategy for HIT in Germany is mostly (>96%) based on the recommended 2-step strategy (immunogenic plus functional assay). Regarding therapeutic approaches, fondaparinux is widely applied off-label in up to 50.3% of the patients with acute suspected HIT and a high clinical pretest probability (median 4T's score: 6 points).

PB 4.40-2

Apixaban as an alternate anticoagulant for the management of patients with heparin-induced thrombocytopenia

Walenga JM, Prechel M, Hoppensteadt D, Escalante V, Chaudhry T, Jeske W and Bakhos M

Loyola University Medical Center, Maywood, IL, USA

Background: Heparin-induced thrombocytopenia (HIT), an immune mediated disorder due to antibodies generated against platelet factor 4 (PF4) complexed with heparin, is associated with a pronounced hypercoagulable state, thrombin generation, endothelial cell damage, and upregulation of an inflammatory state. Anticoagulant alternatives to heparin that do not interact with HIT antibodies are needed for anticoagulant management. Intravenous use direct thrombin inhibitors have been proven effective but their use is associated with a bleeding risk and drug-specific limitations. For prevention and long-term anticoagulation, oral warfarin is used despite its shortcomings including protein C reduction and skin necrosis. Fondaparinux is used off-label by some. Apixaban is a new small molecule, direct acting oral FXa inhibitor that may be considered for the anticoagulant management of patients with HIT.
Methods: In order to determine if there is a lack of functional platelet activation for apixaban in the presence of HIT antibodies, the two traditional and widely used clinical laboratory tests for the diagnosis of HIT were utilized: the ^{14}C-Serotonin Release Assay (^{14}C-SRA; using washed platelets) and the heparin-induced platelet aggregation assay (PA-HIT; using platelet rich plasma). HIT antibodies from multiple patients and platelets from different donors were employed to assure the robustness of the data. The response to apixaban concentrations covering the clinical dose range (0.05–50 mg/mL) was compared to the response obtained with unfractionated heparin (UFH; 0.1 and 100 U/mL).
Results: In the ^{14}C-SRA (n = 35) and in the PA-HIT (n = 37), only baseline negative platelet activation and aggregation responses with all HIT specimens were observed at all apixaban concentrations (average across all concentrations: 11 ± 4% serotonin release and 8 ± 3% aggregation, respectively; mean ± SEM; positive responses are >20%). In comparison, UFH gave strong positive responses to each of the same HIT antibody specimen/platelet donor combinations (82 ± 3% release and 78 ± 6% aggregation at 0.1 U/mL; $P < 0.01$ vs. apixaban). Comparative studies demonstrated strong responses for enoxaparin (n = 10; 73 ± 5% release and 62 ± 7% aggregation at 10 mg/mL) equal to UFH and no positive response for fondaparinux (n = 20) in both test systems.
Conclusions: This study demonstrated a consistent absence of platelet activation with apixaban in the presence of HIT antibodies using two different methodologies. Based on the inert response of apixaban in these *in vitro* studies and because this drug is structurally unrelated to heparin, apixaban is not expected to contribute to the propagation of the HIT syndrome. Since apixaban is an inhibitor of thrombin generation it is expected to have an additional benefit in blunting the hypercoagulable state observed in HIT. Apixaban may provide an option for oral anticoagulation in patients with HIT, particularly for the extended management and prevention of HIT. Clinical trials to determine safe and effective anticoagulation regimens during the various clinical phases of HIT are warranted.

PB 4.40-3

Rapid exclusion of the diagnosis of immune HIT by AcuStar HIT and heparin-induced multiple electrode aggregometry: a prospective monocenter study

Minet V[1], Bailly N[2], Baudar J[2], Walbrecq S[2], Chatelain C[2], Chatelain B[2], Dogné J-M[1] and Mullier F[2]

[1]University of Namur, Namur, Belgium; [2]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: Immune heparin-induced thrombocytopenia (HIT) is a severe adverse reaction of heparin treatment, potentially leading to life-threatening thrombosis. Early and accurate diagnosis is essential but remains challenging. The combination of an immunological and a functional assay improves HIT diagnosis. We have recently shown, in a retrospective study on 106 inpatients in CHU UCL-Mont-Godinne-Dinant, Belgium, that the combination of 4T's rule, AcuStar HIT (immunological assay) and heparin-induced multiple electrode aggregometry (HIMEA) (functional assay) with optimized cut-offs is useful for rapid and accurate diagnosis of immune HIT. This led to a proposal of diagnostic algorithm for immune HIT based on 4T's rule, AcuStar HIT, and HIMEA. Briefly, when 4T's score is ≤3, no additional laboratory test is required because HIT is considered very unlikely. When 4T's test score is >3, AcuStar HIT is performed: (i) when positive, HIMEA is performed; (ii) when negative, HIT is considered very unlikely. In case of negative Acustar HIT and 4T's test score is >6, HIMEA is performed.

Aims: The primary objective of this study was to explore prospectively the performances of our optimized diagnostic algorithm on inpatients suspected of HIT. The secondary objective was to evaluate performances of 4T's rule, AcuStar HIT and HIMEA in comparison to the clinical outcome.

Methods: This study initially included 99 consecutive unselected inpatients with clinically suspected immune HIT. 4T's rule was calculated. AcuStar HIT-Ab (PF4-H), AcuStar HIT-IgG (PF4-H), and HIMEA tests were performed, and clinical outcome collected. AcuStar HIT-IgG (PF4-H) and HIMEA were performed in case of positive AcuStar HIT-Ab (PF4-H) or 4T's rule >6. Sensitivity and specificity of 4T's rule, AcuStar HIT-Ab at manufacturer's cut-off and at our cut-off as well as the overall diagnostic strategy were calculated using clinical outcome as the reference.

Results: One patient had the diagnosis of immune HIT. Among the 99 patients, 58 presented a low pre-test probability (≤3/8). None of these 58 patients had immune HIT. AcuStar HIT-IgT (cut-off >9.41) presented one false positive, also positive with AcuStar HIT-Ab (cut-off >2.89). The negative HIMEA allowed diagnostic exclusion. Among the 41 patients presenting a medium-high pre-test probability (>3/8), AcuStar HIT-IgT was 100.0% concordant to the clinical outcome. The only patient affected by immune HIT was positive on AcuStar HIT-IgT, AcuStar HIT-Ab and HIMEA. AcuStar HIT-IgT at our cut-off (>9.41) and at manufacturer's cut-off (>1.00) both showed sensitivity of 100.0% with a specificity of 99.0% and 89.8%, respectively. Sensitivity and specificity of 4T's rule are 50.0% and 58.8%. Overall, our optimized diagnostic algorithm showed sensitivity and specificity of 100.0% in this patient cohort.

Conclusion: We demonstrated in this prospective study that our optimized algorithm is a rapid and accurate diagnostic tool to exclude the diagnosis of immune HIT.

PB 4.40-4

Prospective comparison of the HIT expert probability (HEP) score vs. the Warkentin's 4T's score in a quaternary care center

Farahani N, Kitahara S and Tcherniantchouk O

Cedars-Sinai Medical Center, Los Angeles, CA, USA

Background: Heparin-induced thrombocytopenia (HIT) can be an elusive, difficult diagnosis when multiple comorbidities exist; a common issue in patients of tertiary and quaternary care centers. Currently, clinicians' routinely employ the Warkentin's 4T's score to assess and quantify the pre-test probability of actual HIT. More recently, the novel Heparin Expert Probability (HEP) score has been developed in hopes of supplanting the 4T's score as a model that is easier to use and more predictive of HIT.

Aim: To prospectively evaluate and compare Warkentin's 4T score vs. the HEP score and their correlation with (i) PF4 optical density and (ii) serotonin release assay (SRA).

Methods: From May 2011 to February 2012, we evaluated 453 consecutive HIT lab tests. We further evaluated 49 patients (86 cases) that exhibited positive polyspecific PF4 assays (OD >0.40) with 4T's score, HEP score, and serotonin release assays (SRA). Residents rotating on the coagulation service determined the 4T's/HEP scores, which were later confirmed by one of two coagulation consultants.

Results: For PF4 OD = 0.41–0.99, the mean and 95% confidence interval (CI) for 4T's/HEP scores were 3.2 ± 0.7 and 2.8 ± 1.1, respectively. For PF4 OD = 1.0–1.99, the mean and 95% CI for 4T's/HEP scores were 3.5 ± 1.2 and 2.5 ± 2.2, respectively. For PF4 OD ≥2.0, the mean and 95% CI for 4T's/HEP scores were 4.3 ± 2.0 and 4.6 ± 4.7, respectively.

For SRA-negative patients, the average 4T's/HEP scores were 3.3 and 2.2, respectively. For SRA-positive patients, the average 4T's/HEP scores were 4.4 and 5.0, respectively. The p-values for the comparison of the mean score between SRA-positive and SRA-negative individuals for 4T's/HEP scores were 0.13 and 0.088, respectively.

Discussion: The average 4T's score demonstrated an incremental increase with increasing PF4 optical densities. In contrast, the average HEP scores did not demonstrate an incremental increase with increasing PF4 optical densities (i.e. the average HEP score was lower for OD 1.0–1.99 than for OD 0.4–0.99 and did not demonstrate a positive correlation).

The HEP score did not distinguish between SRA-positive and SRA-negative patients (mean HEP score of 5.0 vs. 2.6, $P = 0.08$). Therefore, the HEP score is not more predictive of HIT than the 4T's score. This is in contrast to a previously published, retrospective study comparing HEP vs. 4T's as they relate to SRA results.

Since no differences were found between the HEP and 4T's score in their ability to correlate with SRA and because 4T better correlated with OD, we advocate for the use of the 4Ts score. Furthermore, the 4T score is easier to recall and relatively straightforward than the HEP score which can be complex and cumbersome.

PB 4.40-5

Cost-effective HIT diagnosis: utilizing IgG-specific PF4 assays reduces the number of confirmatory serotonin release assays without missing true HIT

Farahani N, Tcherniantchouk O and Kitahara S

Cedars-Sinai Medical Center, Los Angeles, CA, USA

Background: Heparin-induced thrombocytopenia is a pro-thrombotic, potentially fatal entity requiring integration of clinical and laboratory data for diagnosis. No widely standardized laboratory approaches for diagnosis exist and there is debate as to whether a polyspecific or IgG-specific PF4 assay is superior for screening. The polyspecific assay has a low threshold to call 'positive' (OD >0.40) and may result in high false positive HIT diagnoses that can produce costly outcomes, includ-

ing confirmatory serotonin release assay (SRA) testing and/or treating non-HIT, thrombocytopenic patients with expensive direct thrombin inhibitors (DTIs) that carry a bleeding risk.

Aim: Compare polyspecific vs. IgG-specific anti-PF4/heparin ELISAs (PF4) to determine whether the IgG assay can reduce confirmatory SRA testing (expensive send-out with long turn around time), without missing true HIT, and/or unnecessary treatment with DTIs.

Methods: 453 HIT work-ups (4T's score, polyspecific PF4) were reviewed (05/2011–02/2012), including 86 work-ups on 49 patients with polyspecific OD ≥0.4. The manufacturer recommends reporting results as 'positive' (OD ≥0.4) or 'negative'. In our lab, we additionally report the numerical OD values: 'negative' 0–0.39; 'borderline' 0.4–0.84; 'positive' 0.85–2.79; 'strong positive' ≥2.80. For patients with OD >0.4, SRA testing and an IgG-specific PF4 was performed (GTI, PF4 kits).

Results: 29 patients had 'borderline' polyspecific PF4 (OD 0.4–0.84); none were SRA-positive; corresponding IgG PF4 was 0.07–0.73. Nineteen patients had 'positive' polyspecific PF4 (OD 0.85–2.79); 7 of 19 were SRA-positive; corresponding IgG PF4 was 0.29 to >3.0. One patient had 'strong positive' polyspecific PF4 (OD ≥2.80); one of one was SRA-positive; corresponding IgG PF4 was 1.86. HIT work-up was requested more than once in 15/49 patients; 1/15 converted from borderline to positive SRA.

Discussion: Laboratories performing PF4s should report the numerical OD values. Since most U.S.laboratories use the same kits (according to CAP surveys), we propose the following interpretive ranges for the IgG-specific PF4 correlating with the degree of suspicion for true HIT:

Negative: OD <0.4
Intermediate positive: 0.4 ≤ OD <1.0
Positive: OD ≥1.0

Previous literature suggested that an IgG-specific assay could miss rare cases of non-IgG-mediated HIT; however, in this study, cases with PF4 ≥ 1.0 by the polyspecific assay were also positive by the IgG assay. Therefore, the IgG assay did not miss any true HIT.

True clinicopathologic HIT diagnoses confirmed by SRA were made in 8 of 20 patients (40%) with positive polyspecific PF4. DTI was or could have been stopped after negative SRA results were obtained on three patients with strongly positive PF4 (by either polyspecific or IgG assay). Therefore, since PF4 is a screening assay (sensitive but not specific), an SRA is required to confirm HIT in such cases.

The use of IgG PF4 reduced 'borderlines' by 75% (22 of 29 borderline polyspecific PF4 were negative by IgG PF4). Had the IgG assay been used, these cases would not have required SRAs and 6 of 14 patients (43%) who had received DTI would not have received the drug.

In conclusion, utilization of the IgG-specific PF4 assay can help reduce the number of confirmatory SRAs performed and also reduce DTI utilization.

PB 4.40-6

Incidence of Heparin-induced thrombocytopenia in sick children who used unfractioned heparin for prophylaxis in intensive care unit

Kavakli K, Mursalov G, Karapinar B, Karapinar DY, Balkan C and Karadas N

Ege University Children's Hospital, Izmir, Turkey

Heparin is the standard therapy for the prevention of venous thromboembolism in children. Heparin-induced thrombocytopenia (HIT) is a well-known serious adverse effect related with heparin therapy or prophylaxis. Although HIT affects up to%5 of adult patients treated with unfractionated heparin (UFH), prospective studies are so rare in children in respect of incidence.

Aim of this study was to determine the incidence of HIT in UFH-exposed children for prohylaxis. Patients who used treatment doses of UFH were excluded. Only ICU patients were included. We performed a prospective single center phase-IV study in Ege University Children's Hospital after approved by Ethics Commitee and Ministry of Health. Children who exposed to UFH for any time in ICU service were eligible for study. Study group consists of 28 ICU patients. Mean age was 52 month (range: 1–204). Thirteen of patients were female and others were male. All patients used diluted UFH for flushing to maintain patency of central lines in the ICU.

Blood samples were collected for platelet counts (CELL DYN 3700 counter, Abbott), anti-Heparin/PF4 antibody (ELISA)(Asserachrom HPIA-Ig G, Diagnostica Stago) and Heparin-induced platelet agregation tests (APACT-4004, Tokra) before and after 10 days (median) (range: 7–15) of first UFH exposure.

After 2 years of prospective observation, we have not found any single patient diagnosed as HIT by clinical findings and confirmed by laboratory analysis. Significant dropping (>50%) of platelet count after 10 days of heparin exposure was observed in only four ICU patients. Only one patient had below <150.000/mm^3. However, ELISA and agregation tests were negative for these patients. Reasons for thrombocytopenia were evaluated for underlying medical conditions as trauma, pneumonia and sepsis. They were not evaluated as HIT. In one another ICU patient, ELISA test was found border-line positive (O.D: 1.374) (positive controls: 1.35 ± 0.34). However, no thrombocytopenia and no activation in agregation related heparin studies were found. This result was evaluated as false-positivity for ELISA. However, mean OD values for ELISA test was found significantly elevated after heparin exposure (before heparin: 0.119 ± 0.061 vs. after heparin: 0.258 ± 0.262)(Wilcoxon test; $P < 0.0001$). Elevated heparin-induced agregation response (more than >20% after heparin exposure) was not determined in any ICU patient.

In routine clinical practise, infants with requiring admission to ICU are particularly at risk of venous thromboembolism and likely to be exposed to heparins for prevention and treatment. However, in this single center phase-IV study, we have not found prospectively any HIT positive patient among 28 ICU patients. Reasons for low incidence may be dilution of heparin, lower and prophylactic doses, short exposure time and medical vs. surgical intervention. UFH Heparin seems to be safe agent for children with ICU for prophylaxis.

PB 4.41-1

Variant Bernard Soulier syndrome with ambiguous mutation data: a diagnostic dilemma

Cutler J[1], Drew A[1], Moore G[1], Madan B[2], Mitchell M[1] and Okoli S[2]

[1]GSTS Pathology; [2]Guys and St Thomas' NHS Trust, London, UK

Bernard-Soulier syndrome (BSS) is a rare autosomal recessive bleeding disorder, with an estimated frequency of 1:1,000,000, characterized clinically by mucocutaneous bleeding, post traumatic haemorrhage, and menorraghia in females. The classic laboratory findings are macrothrombocytopenia, absent ristocetin-induced platelet aggregation and absent or markedly reduced expression of the Glycoprotein Ib-IX-V complex on platelet surfaces. Genetic abnormalities have been identified in three of the genes encoding the sub units of the GP Ib-IX-V complex, *GP1BA*, *GP1BB* and *GP9*. No mutations causative of BSS have been reported in *GP5*, and this is consistent with a lack of requirement for GPV expression for expression of the other subunits of the GPIb-IX-V complex.

We present a young patient with a complex clinical history, in whom non classical laboratory findings complicate the diagnosis of BSS.

A 20 year old Zimbabwean female, with no family history of bleeding, had a long personal history of recurrent epistaxis, haematemesis and menorraghia. She also suffers from migraine, epilepsy and asthma. Initial investigations resulted in a presumptive diagnosis of ITP, and she received treatment on that basis.

She recently presented with severe acute abdominal pain, haematuria and haematemesis necessitating blood transfusion. Further investiga-

tive work-up revealed a macrothrombocytopenia and a markedly reduced platelet aggregation in response to ristocetin alone. A full panel of platelet glycoprotein expression studies showed normal levels of glycoproteins Iba and IX. This prompted molecular analysis of the *GP1BA, GP1BB & GP9* genes to confirm the diagnosis of BSS. The exons and splice junctions of the three genes were PCR amplified and sequenced, and the only variant detected was a homozygous c.488C>A substitution within exon 3 of *GP9*. This base change predicts the replacement of the native Alanine at codon 163 with an Aspartic Acid (pAla.163Asp). This change has not been previously reported as causative of BSS, but results of 5/6 *in silico* software algorithms support this change being pathogenic. It is, however, reported as a very low frequency polymorphism in the African population, with a Minor Allele Frequency of 0.0018. This frequency results from seven heterozygous individuals from a total of 2624: No individuals homozygous for c.488A were recorded.

The c.488C>A variant may represent the first pathogenic *GP9* substitution which produces mutant complexes that appear on the cell surface essentially at normal levels, in a similar manner to the *GP1BA* variant Bolzano (c.515C>T). Our findings demonstrate that, in cases of macrothrombocytopenia, reduced ristocetin induced platelet aggregation may be sufficient for a diagnosis of BSS to be made even in the absence of a reduction in glycoprotein expression. The vast amount of SNP data, generated by genome projects will increasingly present interpretive challenges in assessing variants of unknown clinical significance in specific patient populations. Further, the curation of SNP and locus specific mutation databases does not always favour the distinction between pathogenic and benign variants. In BSS, as in other autosomal recessive disorders, the finding of a small number of heterozygous individuals should not preclude the variant from being considered potentially pathogenic in the homozygous state.

PB 4.41-2

Mild bleeding diathesis in 10 patients due to functional deficiency of plasminogen activator inhibitor type 1 (PAI-1)

Iwaniec T[1], Zdziarska J[2], Wypasek E[3], Undas A[3], Padjas A[1], Musial J[1] and Skotnicki AB[2]

[1]Jagiellonian University Medical College; [2]Department of Hematology Jagiellonian University Medical College; [3]Institute of Cardiology, Jagiellonian University Medical College, Cracow, Poland

Background: Plasminogen activator inhibitor type 1 (PAI-1) down-regulates fibrinolysis and plays an important role in maintaining homeostasis of the coagulation system. PAI-1 deficiency is one of the rarest bleeding disorders, described for the first time in 1989. Quantitative or qualitative PAI-1 deficiency causes hyperfibrinolysis and mild to moderate bleeding tendency, mainly mucocutaneous. The disorder is difficult to diagnose as available PAI-1 activity assays lack sensitivity in the lowest range. The true prevalence of this condition is not known.

Aims: The aim of this study was to identify cases of PAI-1 deficiency among patients referred to our clinic due to bleeding symptoms.

Methods: In every patient with a history of bleeding (spontaneous/excessive bleeds from at least two anatomical localizations or bleeds from one localization with family history of bleeds) standard coagulation test were performed to exclude common coagulation disorders: platelet count, APTT, PT, thrombin time, fibrinogen activity, von Willebrand factor activity (at least twice), platelet aggregation tests, factor VIII, IX and XI activity. If no abnormality was detected, PAI-1 activity was measured with Berichrom PAI (Siemens, Germany). In patients with decreased PAI-1 activity PAI-1 antigen level was measured with ELITEST PAI-1 (Hyphen BioMed, France). Alpha2-antiplasmin deficiency was excluded. Blood samples were drawn between 8 a.m. and 10 a.m. as PAI-1 plasma level shows a diurnal variation and reaches highest levels in the early morning.

Results: PAI-1 activity was measured in 93 patients and was decreased in 10 females (0–1.5 U/mL, mean 0.6 U/mL, normal range 2.0–7.0). Repeated measurement from separate plasma samples showed concordant results (0.2–1.4 U/mL, mean 0.8 U/mL). PAI-1 antigen level in all 10 patients was normal or moderately decreased (22–62 ng/mL, mean 39.5, normal range 30–60 ng/mL). All 10 patients suffered from menorrhagia, nose and/or gum bleeds and excessive bleeding post surgery, delivery or tooth extraction. Eight suffered from mild iron deficiency anaemia. Four patients required blood transfusion at least once in their life. Nine patients had positive family history for bleeds. Tranexamic acid treatment was tried in six patients with good results.

Summary/Conclusions: PAI-1 deficiency should be taken into consideration in the differential diagnosis of bleeding patients. Results must be interpreted with caution, however, until standardized diagnostic assays will be available. We can suspect, that bleeding symptoms in our patients are caused by PAI-1 functional defect. Good response to antifibrinolytic treatment supports this hypothesis.

PB 4.41-3

Congenital Factor XIII deficiency in women; a systematic review of literature

Sharief L, Davies J, Pollard D, Lee CA and Abdul-Kadir R

Royal Free Hospital NHS Foundation Trust, London, UK

Background: Factor XIII deficiency is a rare congenital bleeding disorder. There is a paucity of data in the literature about obstetrics and gynecological problems in women affected with Factor XIII deficiency.

Aims: To examine gynecological problems and obstetrical complications and outcome in women with congenital FXIII deficiency

Methods: An electronic search was performed to identify the published literature on PUBMED, EMBASE, BIOSIS Previews, Journals @OVID and CINAHL Plus databases using the following keywords: 'congenital factor XIII deficiency' AND 'women OR Pregnancy'. A total of 34 relevant articles were found and included in this systematic review; 23 case reports and 11 case series dating from 1964 to 2012.

Results: A total of 120 women were identified. Menorrhagia (28%) was the second most common bleeding symptom. Ovulation bleeding was reported in 10% of women. Among 60 women, 189 pregnancies were reported; of these, 125(66.2%) resulted in a miscarriage with history of recurrent miscarriage observed in 16(27%) women. Among the 129 pregnancies without prophylactic therapy, 122 resulted in a miscarriage and only seven progressed to viability stage. Out of 64 pregnancies reaching viability status, ante partum hemorrhage occurred in four pregnancies while postpartum hemorrhage was seen in 15 (23%) of cases.

Conclusion: Women with congenital Factor XIII deficiency suffer significant bleeding complications. Menorrhagia and ovulation bleeding are common gynecological problems and possibly more prevalent than reported. Pregnancies in women with Factor XIII deficiency have a significant risk of miscarriage, placental abruption and postpartum hemorrhage if not on prophylaxis treatment.

PB 4.41-4

Solvent-detergent plasma abolished severe bleeding tendency and normalized procoagulant activity in Calibrated Automated Thrombogram both in plasma and platelets of a FV deficient patient

Virtanen L[1], Jouppila A[1], Joutsi-Korhonen L[2], Lemponen M[2] and Lassila R[2]

[1]Helsinki University Central Hospital; [2]Helsinki University Central Hospital, Coagulation Disorders Unit, Helsinki, Finland

Background: Congenital FV deficiency is a rare (1:1,000,000) bleeding disorder with varying bleeding tendency. Our patient, a 43-year-old

woman got diagnosis of FV deficiency at the age of 6 months. She has suffered from severe bleeding symptoms, including mucosal, intra-abdominal and muscular bleeds and hemarthrosis. The bleeds have occurred cyclically about every 10–14 days. For the last 4 years, we have treated her with prophylactic solvent-detergent (S/D) plasma (Octaplas®, 2 units) infused every 2 weeks. The treatment has not shown any adverse effects and clinical efficacy has been excellent. She has not had any clinically relevant bleeds during prophylactic plasma replacement.

Aims: We studied coagulation variables and platelet functions before and after adminstration of S/D plasma.

Methods: Citrated blood samples were collected to assess, APTT, prothrombin time (PT, with Owren and Quick methods), thrombin time, antithrombin, FV, FVIII, fibrinogen, protein C and S, von Willebrand factor (VWF) (VWF:RCo and antigen). Thrombin generation was measured with calibrated automated thrombogram (CAT®, Thermo Labsystems) in platelet-poor (PPP) (1 pM or 5 pM TF) and platelet-rich plasma (PRP) (1 pM TF) without adding corn trypsin inhibitor. Agonist (collagen, ADP, arachidonic acid, TRAP) -induced platelet aggregation (Multiplate®) and platelet function analyses (PFA-100®) were performed in whole blood. The PFA® was cross-supplemented with normal PPP.

Results: At baseline 2 weeks after plasma infusion the patient had undetectable FV activity, APTT >100 s, normal PT (131%) with Owren but highly elevated (INR 8.0) with Quick method (Coagucheck®). All other coagulation test results and Multiplate® were normal. In PFA collagen/ADP-triggered closure time (CT) (mean 131 s, SD ± 19, $n = 8$) was prolonged while collagen/EPI-triggered CT (mean 135 s, SD ± 24, $n = 9$) was normal. Thrombin generation was completely undetectable in CAT® both in PPP and PRP. After S/D plasma infusion (at 2 h) FV inclined to 12–18%, but this was enough to normalize APTT (33 s). In whole blood INR measured with Coagucheck (with Quick method) decreased from 8.0 to 1.7–1.9. Collagen/ADP-triggered CT in PFA® remained somewhat elevated and unchanged after plasma infusion. Supplementation of patient plasma with normal PPP corrected the prolonged collagen/ADP-triggered CT in PFA. Intriguingly, simultaneously thrombin generation increased above that of normal control both in PPP and PRP. Specifically, in PPP the thrombin peak increased 1.6-fold and in PRP time to peak shortened.

Conclusions: After administration of regular prophylactic S/D plasma replacement therapy in every 2 weeks abolished the severe bleeding tendency without any adverse effects. The patient did not experience any bleeds. Although plasma infusion increased FV activity only to 12–18%, less than claimed for the threshold for proper hemostasis, it normalized APTT and in CAT® reversed the FV-associated deficiency in plasma and PRP of the patient. Mere factor V coagulation activity assessment failed to associate with clinical efficacy of the regular S/D plasma supplementation.

PB 4.41-5

An international systematic study for the assessment of bleeding phenotype in platelet type von Willebrand disease

Kaur H[1], Scovil S[1], MacEachern K[2], James PD[1] and Othman M[1]
[1]*Queen's University;* [2]*St Elizabeth Health Care, Kingston, Canada*

Background: Rare bleeding disorders such as platelet type von Willebrand disease (PT-VWD) pose diagnostic challenges and remain under-reported. Definitive information about the presenting bleeding symptoms and the need for haemostatic support during times of haemostatic challenge such as pregnancy, childbirth and surgery is lacking. Specific guidelines regarding the diagnosis and treatment together with appropriate patient monitoring are compromised by the limited understanding of the clinical phenotype. Quantitation of bleeding symptoms using a standardized bleeding questionnaire that produces a valid bleeding score (BS) has proven to be useful in the diagnosis of mild bleeding disorders. So far, there have been no systematic studies to evaluate the bleeding phenotype in PT-VWD.

Aim: To highlight the importance of bleeding score in assessing bleeding phenotype and its variability in PT-VWD patients together with systematic assessment of the laboratory phenotype. The study also Aims to investigate the value of an electronic bleeding questionnaire (eBQ) in international studies on rare bleeding disorders.

Methods: An electronic version of the condensed MCMDM-1VWD questionnaire was developed as a web application using the PHP scripting language and MySQL relational database platform. Security was ensured by using password protection, database encryption and encrypted transfer protocols. Electronic questionnaire responses collected via the application were validated to ensure congruency with the MCMDM1-VWD scoring key and thus maintain the same specificity and sensitivity as the original questionnaire. Internal validation and archiving of data at the point of entry eliminated transcription/interpretation error and allowed automatic computation of the BS upon completion of the questionnaire. A call for study participation was made available on ISTH website and individual participation was invited by emails sent to potential collaborators. Each investigator was provided with a unique ID and passcode to fill the online eBQ during a patient's clinic visit (http://pt-vwd.org/ebq/). Full systematic laboratory analysis will be performed on plasma obtained from PT-VWD patients worldwide including conventional haemostatic tests, specific VWF related tests as well as thromboelastography.

Results: To date, five PT-VWD patients (1 male and 4 females) from four countries representing different platelet GP1BA mutations: M239V (1 patient), G233V (2 patients) and D235Y (2 patients) have participated. The average age of participants was 46.4 (range: 34–67). The bleeding scores were variable (mean = 9.6, range: 3–17). Variability was seen in BS even in patients with similar mutations and appeared independent of patient age. Post-operative bleeding occurred in 3 (60%) patients. Menorrhagia was not the most common symptom in female patients. One patient experienced gastrointestinal bleeding without additional mucocutaneous bleeding symptoms. The eBQ was tested in 50 normal females, three of which showed abnormally high scores and are currently under investigation for VWD type 1.

Conclusions: The eBQ helps standardize recording of phenotypic data related to PT-VWD patients and objectively assesses the bleeding phenotype. This is not only of value in PT-VWD, but also in patients with other suspected rare bleeding disorders. Automatic computation of the BS improves efficiency in terms of time and resources for international studies.

PB 4.41-6

Long-termed secondary prophylaxis in rare factor deficiencies of children in eight cases

Salcioglu Z[1], Akcay A[1], Tugcu D[1], Sayilan Sen H[1], Aydogan G[1], Akici F[1], Gokce M[1], Aktay Ayaz N[1], Siraneci R[1] and Baslar Z[2]
[1]*Istanbul Kanuni Sultan Suleyman Education and Research Hospital;* [2]*Istanbul University, Cerrahpasa Medical School, Internal Medicine, Istanbul, Turkey*

Rare factor deficiencies (RFD) cover the deficiencies of fibrinogen, Factor II, Factor V, Factor V + VIII, Factor VII, Factor X, Factor XI, Factor XIII, and vitamin K associated factors. Many national and international study groups conducted studies regarding the diagnosis and treatment of rare factor deficiencies in 2000s. The existence a mortality and morbidity risk associated with severe bleedings has brought the search for prophylaxes related to these disorders into the agenda. In addition, the good results obtained with primary and secondary prophylaxes in haemophilia cases have attracted the attention to the possibility that the same consideration could also be applied to rare factor deficiencies. Prophylaxis is recommended in these patients if such severe bleedings as central nervous system bleedings, gastrointestinal bleedings, and articular hemorrhages recur. Our prophylaxis application related to eight congenital rare

factor deficiency cases being followed at our clinic comprising of five patients with Factor VII deficiency, one patient with afibrinogenemia, one patient with FV deficiency, and one patient with Factor X deficiency were evaluated in our article. Application ages of our patients ranged between 2 weeks and 7 years of age. Six of them were boys and two were girls. Prophylaxis was applied due to intracranial bleeding to three of our Factor VII deficiency patients, for gastrointestinal system bleeding to one of them, and for the development of chronic hemarthrosis and hemarthrosis that requires the application of radioisotope synovectomy to one patient. 20 mcg/kg active recombinant FVII was used once a week in the prophylaxis of our FVII deficiency cases. Transition to two doses a week was required for one patient. Prophylaxis is being applied with 30 IU/kg prothrombin complex concentrate 2 days a week to our patient with Factor X deficiency for recurring central nervous system bleedings and with 50 mg/kg fibrinogen every 2 weeks to our patient with afibrinogenemia for recurring intramuscular bleedings causing severe pain and difficulty of walking. Our patient with FV deficiency to whom prophylaxis is applied due to intracranial bleeding, on the other hand, receives 20 mL/kg fresh frozen plasma once a week. The prophylaxis periods of our patients range between 10 months and 7 years. The observation as well as clinical and laboratory findings of our patients together with the details related to their prophylaxis processes were presented in our proceedings accompanied with the relevant literature.

PB 4.42-1

Health-related quality of life and Caregivers' burden in partners of persons with haemophilia

Lindvall K[1], Von Mackensen S[2], Elmståhl S[1] and Berntorp E[1]
[1]*Lund University, Malmö, Sweden;* [2]*Institute of Medical Psychology, Hamburg, Germany*

Background: Assessment of HRQoL in haemophilia is important on one hand to provide information for clinical decision making and on the other hand to verify which impact has haemophilia on patients but also on their partners. Advances in haemophilia care and prophylactic treatment throughout life have improved HRQoL for patients and the older haemophilia population has different needs compared to the younger population. In countries with a long tradition of prophylaxis, patients with haemophilia have nearly reached the same life expectancy as the general population and have to face the same problems related to co-morbidities and cognitive impairments as the general population. These co-morbidities may influence the HRQoL of haemophilia patients; on the other hand these problems are supposed to have a further impact on the burden of partners of haemophilia patients in terms of financial, physical and psychological aspects.
Aim: A cross-sectional single-centre cohort study in partners of adult haemophilia patients was performed in Malmö, Sweden aiming to assess the burden of the disease on partners of haemophilia patients. The study was approved by the Regional Ethical Review Board in Lund, Sweden.
Method: Study subject-rated outcomes were filled in by partners (SF-36, Visual Analogue Scale of Interference, Caregivers' Burden Scale) and haemophilia patients (SF-36, VAS of Interference, Haemo-QoL-A, HEP-Test-Q).
Results: A total of 108/150 eligible partners of haemophilia patients (72%) participated. Mean age for partners was 44.7 years and for patients 47.1 years. The majority of couples were married (65.7%). In average couples were together since 19.8 years and had in average 1.7 children. Patients and their partners reported in general a quite similar HRQoL; by contrast partners reported significant better HRQoL in the domains 'physical functioning' ($P < .001$) and 'general health' ($P < .031$). No significant difference compared to the General Swedish population for the respective age group 45–54 years was found.
Partners of haemophilia patients across different severities reported lower HRQoL in the domain 'emotional role' of the SF-36 ($P = <.041$), with highest impairments for partners of moderately affected patients.
Interference of haemophilia with daily life measured by means of the VAS showed significant difference between partners and patients, ($P < .001$); partners reported less interference with their daily life (Mean = 12.32) compared to patients (Mean = 23.10).
Partners reported in general low burden of haemophilia in the Caregivers Burden Scale. No differences across haemophilia severity groups were found. 'Emotional involvement' was the biggest burden in the mild and moderate group, while in the severe group 'general strain' was the biggest burden. In addition 'isolation' was a big burden in moderate partners.
Conclusion: Partners of haemophilia patients reported in general good HRQoL and a low burden of the disease except for partners of moderate patients where a decreased HRQoL and higher burden was reported. In Sweden patients start prophylaxis at an early age with lifelong treatment which is probably the reason for low impact of the disease in partners seen in this study. For partners to a PWH with severe joint problems, a higher impact of the disease in partners may be foreseen.

PB 4.42-2

Congenital FXI deficiency: evaluation of bleeding phenotype and correlation with FXI activity (FXI:Act)

Santoro C[1], Di Mauro R[1], Baldacci E[1], Mercanti C[1], Abbruzzese R[1], Barone F[1], Bochicchio RA[2], Parlanti L[1] and Mazzucconi MG[1]
[1]*Hematology, Sapienza Univeristy;* [2]*Clinical Pathology, Sapienza Univeristy, Rome, Italy*

Background: Bleeding phenotype in FXI deficiency is variable and generally related to surgery/trauma. Moreover, there is a poor correlation between bleeding and baseline FXI:Act.
Aim: To retrospectively describe the hemorrhagic phenotype of our FXI deficient population and to relate the phenotype with FXI:Act.
Patients and Methods: Since 1973, we have been following 94 FXI deficient patients from 65 different families: 43 F, 51 M; diagnosis median age: 28.7 years (0.9–83.9); median follow-up: 0.9 years (0.1–36.2); median FXI:Act of all patients: 38% (range 0.5–69%; normal values: 70–140); FXI:Act ≤1% in five patients, >1 ≤ 5% in 12, >5 ≤ 10 in 3, >10 ≤ 20 in 6, >20 ≤ 70 in 68. Excessive bleeding is reported as described in medical records.
Results: Fifty six patients experienced bleeding episodes not surgery-related: ecchimoses in 27, hematomas in 2, epistaxes in 23, gastrointestinal hemorrhages in 14, meno-methrorrhagia in 2, hematuria in 4, post-traumatic intracranial hemorrhage in 1, gum bleeding in 1, pulmonary bleeding in 1.
Prior to diagnosis, 64 patients underwent 133 surgeries (93 major, 40 minor). Prophylactic treatment was administered in 3/133 procedures: tranexamic acid (TA) in 1, fresh frozen plasma (FFP) in 2. Twenty eight/133 (21%) post-surgery hemorrhages were reported in 19 patients; in 12/28 cases, transfusional therapy (FFP and/or red blood cells units) was needed. Median FXI:Act of bleeder patients was 28% (0.5–53%). Twenty nine spontaneous deliveries (SD) and eight caesarian sections (CS) were performed without prophylaxis: 4 post-partum hemorrhages occurred (patients FXI:Act: 2, 6, 27, 52.3% respectively). In three cases transfusional therapy was necessary. Forty nine patients underwent dental surgeries without prophylaxis: 17 experienced haemorrhages at least after one procedure (bleeders median FXI:Act: 11%, [1–57%]). In one case FFP was necessary to stop the bleeding.
After diagnosis, 23 patients underwent 34 surgeries (14 major, 20 minor). Prophylactic treatment was administered in 23/34 procedures: TA in 7, FFP in 2, desmopressin in 4, FFP + TA in 8, desmopressin + TA in 2. The only bleeding reported (1/23, 4%) was after an

emergency appendectomy performed under TA administration, in a patient whose FXI:Act was 2.8%. In 2/11 surgeries performed without prophylaxis, an excessive bleeding was reported but transfusional therapy was not necessary; FXI:Act was 29% for both bleeder patients. Four SD and five CS were performed with prophylaxis: FFP in 4, TA in 2, desmopressin in 3. No post-partum hemorrhages occurred. Sixteen patients underwent 20 dental surgeries; prophylactic treatment was administered in 15/20 procedures without any bleeding complications: TA in 6, FFP + TA in 4, FFP in 4, desmopressin + TA in 1. During two dental procedures performed without prophylaxis, patients bled excessively; their FXI:Act was 6% and 45% respectively.
Conclusions: We confirm the wide variability in bleeding phenotype in FXI deficient patients, not related to the FXI:Act levels. Moreover we highlight that a good management of prophylaxis treatment dramatically reduces the percentage of bleedings in case of surgery (21% vs 4%), deliveries and dental procedures. Because of the low correlation between FXI:Act and the phenotype, we highlight the need of laboratory-based prognostic factors for a better management of these patients.

PB 4.42-3
A novel mutation in downstream half of wasp gene correlates with worse clinical presentation of the Wiskott-Aldrich syndrome

Medina S[1], Siqueira LH[1], Colella MP[1], Vilela M[2] and Ozelo MC[1]
[1]INCT do Sangue Hemocentro Unicamp (University of Campinas); [2]Faculty of Medical Sciences, Campinas, Brazil

Background: Wiskott-Aldrich syndrome (WAS) is a rare recessive disease characterized by thrombocytopenia, eczema, recurrent infections, microthrombocytopenia and an increased risk of autoimmunity and malignancy. In this syndrome the gene of Wiskott-Aldrich protein (WASP) is affected; it is located on chromosome X-p11.22-p11.23, encomprises 12 exons and encodes for a protein of 502 amino acids. WASP is selectively expressed in hematopoietic stem cells and is involved in cell signaling and reorganization of the cytoskeleton. Mutations in the WASP gene may also be associated with other mild manifestations such as X-linked thrombocytopenia (XLT) and X-linked neutropenia (XLN).
Aim: To correlate the mutational status of the WASP gene with clinical manifestations in Wiskott-Aldrich syndrome.
Patients and Methods: In this study, we collected peripheral blood samples from three patients and their mothers, performed genomic DNA extraction from the leukocyte pool and sequenced WASP gene.
Results: Case 1. JCM, male, 4 years old, with mild hemorrhagic manifestations since 9 months old, with no family history of bleeding or thrombocytopenia. He had platelet counts ranging from 23 to 208×10^9/L and low mean platelet volume (MPV), ranging from 5.6 to 6.5 fL (lower normal limit: 7 fL). He did not show any evidence of immunodeficiency or eczema (WAS clinical score: 1). Molecular analysis of WASP gene identified a missense mutation in exon 2, resulting in an amino acid change (p.T45M). Both the clinical presentation and the location of the found mutation (exon 2) are compatible with the diagnosis of X-linked thrombocytopenia. Case 2. JCF, male, 18 months old, with severe thrombocytopenia ($<20\times 10^9$/L) and severe hemorrhagic history, frequently requiring platelet transfusions. He also displays serious immunodeficiency and extensive eczema. Upon molecular investigation, it was detected the presence of p.E133K mutation in exon 4 of WASP gene. Case 3. LSMN, male, 6 months old, who has had scattered petechiae and recurrent gastrointestinal bleeding since birth with severe microthrombocytopenia. Since 4 months old he has eczema and recurrent infections. This child has a family history of a brother who died at 6 months old with similar bleedings and recurrent infections. Molecular assessment of WASP gene revealed a mutation that has not been previously described, with an insertion in intron 11, leading to involvement of exon 11.
Summary/Conclusion: WAS implicates a spectrum of clinical manifestations ranging from mild thrombocytopenia or neutropenia to severe cases of microthrombocytopenia, eczema, immunodeficiency, and increased susceptibility to autoimmune diseases and cancer. Generally lighter manifestations of the syndrome are associated with mutations in exons 1 and 2 of WASP gene, as observed in the first case described. More severe manifestations, such as those observed in cases 2 and 3, are caused by mutations affecting other regions of the gene, occurring predominantly in its downstream half. Thus, this new mutation found in case 3 and the clinical presentation of this patient are in agreement with previous data, confirming that the clinical phenotype of WAS is strongly influenced by the effect of the mutation in WASP gene.

PB 4.42-4
Changes in FXIII levels during various stages of pregnancy

Sharief L[1], Peyvandi F[2], Lawrie AS[3], Mackie IJ[3], Smith C[1], Davies J[1] and Abdul-Kadir R[1]
[1]Royal Free Hospital NHS Foundation Trust, London, UK; [2]U.O.S Hemophilia and Thrombosis Center, Milan, Italy; [3]Haemostasis Research Unit, London, UK

Background: Coagulation factors show significant changes during pregnancy, most factors showing a progressive increase until the end of gestation. There is only limited data on factor XIII level, its reference range and its variation during pregnancy.
Aims: To assess changes in factor XIII and establish the reference range for factor XIII activity during normal pregnancy.
Methods: A cross sectional study was performed on 376 women who were at various stages of normal non-eventful pregnancies. Blood samples were collected during first trimester (gestational age 0–12 weeks, $n = 116$), second trimester (gestational age 13–28 weeks, $n = 132$) or third trimester (gestational age 29–42 weeks, $n = 128$). Factor XIII was assayed on a CS-5100 analyser (Sysmex UK Ltd, Milton Keynes, UK) using a chromogenic reagent (Berichrom FXIII chromogenic assay kit. Siemens Healthcare Diagnostics, Marburg, Germany). The manufacturers declared normal reference range for this reagent is 70–140 μ/dL. Data from the clinical samples were found to be normally distributed, therefore, reference ranges were calculated using the mean and two standard deviations.
Results: The mean +/− SD (observed range) Factor XIII activity was 111.7 ± 29(57–186) IU during first trimester, 96 ± 26 (38–162) IU during second trimester, and 83.4 ± 21(27–142) IU during third trimester. 95% Reference intervals of Factor XIII activity were measured during the first (54–169 IU; six results <70 IU), second (45–147 IU; 15 results <70 IU), and third (42–125 IU; 34 results <70 IU) trimester of pregnancy. There was a statistically significant reduction in the FXIII activity between each trimester of pregnancy ($P < 0.0001$; ANOVA).
Conclusion: Relative to the manufacturer's reference range, this study has shown that some women have a significantly decreased level of factor XIII activity during a normal uneventful pregnancy. However, further investigation of those women with apparently decreased FXIII levels is required before the reference ranges of FXIII in normal pregnancy can be properly established.

PB 4.42-5
Inhibitor in congenital factor VII deficiency, report of two cases

Baghaipour MR, Rastegar Lari G, Shervinrad M, Ravanbod S and Jazebi M
Comperehencive Hemophilia Care Center, Tehran, Iran

Factor VII deficiency (FVIID) is a congenital rare autosomal recessive bleeding disorder with the incidence of 1/300,000 to1 in 500,000. We

present a two cases of congenital FVIID, who had received intermittent intravenous recombinant activated factor VII (rFVIIa) that has experienced factor VII inhibitor production. Factor VII deficiency is a life threatening bleeding disorder with prevalence of one symptomatic case out of half a million individuals. Fresh frozen plasma, prothrombin complex concentrates, factor VII concentrates and (or) recombinant activated factor VII (rFVIIa) are considered for treatment of factor VII deficiency.

We present two boys (4 and 8 years old) with congenital FVII deficiency. Both of them were diagnosed after intracranial bleeding during infancy and rFVIIa was used for their treatment. After a period of unresponsiveness to rFVIIa, inhibitor was found in the level of 191 and 170 BU respectively.

We used Feiba for the older case and controlled his musculoskeletal bleedings and the titer of inhibitor gradually decreased to <20 BU. Furthermore we performed full genetic analysis and found their mutations.

To the best of our knowledge this is the first report of inhibitor against factor VII among patients with congenital FVII deficiency. Moreover we suggest a successful therapeutic management in these cases.

PB 4.42-6

Laboratory assessment of Hermansky-Pudlak Syndrome: a case report

Pilgrimm-Thorp AK, Pillitteri D, Scholz T, Krause M and Kirchmaier CM

Deutsche Klinik für Diagnostik, Wiesbaden, Germany

Hermansky-Pudlak Syndrome (HPS) is a rare, autosomal recessively inherited disorder that is divided into seven subtypes (HPS 1–7) that share the following three symptoms: oculocutaneous tyrosine positive albinism, ceroid lipofuscinosis and a platelet disorder due to a δ-Storage-Pool deficiency leading to spontaneous bleeding episodes, especially epistaxis and mucocutaneous bleedings at a normal platelet count. Pulmonary fibrosis is a major complication in some types of HPS.

An 11-year old Russian girl presented with facial haematoma, oculocutaneous albinism and severely impaired sight. The parents reported recurrent epistaxis and haematoma.

Routine parameters showed normal PTT, normal FVIII- and von-Willebrand-Factor (vWF) levels and a normal *in vitro* bleeding time. Platelet analysis showed a rather normal platelet aggregation with a slight desaggregation in response to collagen and no aggregation in response to TRAP.

Fibrinogen binding was normal in response to ADP but pathological in response to TRAP, Mepacrine staining was reduced and *in vivo* bleeding time was longer than 15 min.

FACS analysis of platelet granules using mabs CD62P and CD63 showed a total lack of dense bodies but normal alpha granule content. ATP determination test showed a total lack of ATP after platelet activation confirming the absence of dense bodies. Thrombin generation in platelet rich plasma showed a reduced ETP and Peak.

A DDAVP challenge test was conducted resulting in a normalized *in vivo* bleeding time. FVIII and vWF-levels were elevated approximately threefold.

We conclude that not all laboratory methods are able to reveal a complex haemorrhagic disorder like HPS. For example *in vitro* bleeding time is not a possible screening parameter in case of HPS. Here, it is necessary to evaluate platelet function using specialized tests such as granules determination, fibrinogen binding in response to various agonists or ATP-determination in order to reveal the platelet dysfunction.

PB4.43 – Von Willebrand disease: Clinical – V

PB 4.43-1

The effectiveness of screening of exon 28 in patients with Type 3 Von Willebrand disease

Ravanbod S, Enayat S, Rassoulzadegan M, Nasirnejad F, Rastegar Lari G, Chupan A, Baghaipour MR, Jazebi M and Ala F

Comprehensive Hemophilia Care Center, Tehran, Iran

Type 3 Von Willebrand disease is a severe autosomal recessive bleeding disorder with almost undetectable levels of VWF. Its molecular diagnosis is particularly complex due to the large size of the VWF gene, with 52 exons and the existence of a highly homologous (>96% homology) pseudogene. Presently, 1157 VWD patients are registered in this centre's database, of whom 508 (43.9%) have been tentatively diagnosed as type 3 or severe VWD. The high prevalence of this type of VWD is due to consanguineous marriages practiced in Iran. Although molecular diagnosis of type 3 VWD by direct sequencing of the entire VWF gene is now carried out in developed countries, in developing countries with limited resources such as Iran, this is not as yet feasible.

In this study we report the results of the investigation of 155 unrelated patients from the type 3 VWD patients on our database, sequencing only exon 28 of the VWF gene, as this exon is the first step to genetically investigate any patient with severe VWD.

In this group, we have identified 15 (9.6%) p.Arg1659X nonsense mutations, 10 of whom are of Arab ethnicity. Pseudogene conversion was found in 7 (4.5%) patients having a p.Gln1311X nonsense mutation. Finally, five previously unreported mutations, including, one c.4710C>A substitution leading to p.Tyr1570X; three frameshift mutations in position 4029 due to a T deletion; one A insertion in position 3968, one A deletion in position 4308 and the entire deletion of exon 28, causing VWF inhibitor formation in one patient.

With this limited approach, we have managed to identify 27(17.4%) genetic defects in our type 3 VWD patients. In addition to facilitating genetic counselling and carrier detection in these families, these findings could also help in better understanding of the correlation between genetic defects and bleeding symptoms.

PB 4.43-2

Four novel von Willebrand factor mutations in mild von Willebrand disease

Castaman G[1], Giacomelli S[1], Coppola A[2], Rodeghiero F[1] and Tosetto A[1]

[1]San Bortolo Hospital, Vicenza; [2]University Federico II, Napoli, Italy

Background: The likelihood to detect a causative von Willebrand factor (VWF) gene mutation in patients with von Willebrand disease (VWD) decreases significantly with increasing VWF levels >30 U/dL (Goodeve et al, 2007).

Aim of the study. We identified four novel VWF mutations in patients with mild VWF deficiency and a disproportionately significant bleeding tendency (bleeding score ³ 5).

Methods: The entire coding sequence and promoter region of VWF was screened by direct sequencing.

Results: One mutation occurred in the propeptide region (c. 430 G>A in exon 4 leading to G144S) in a patient with a type 2 N Normandy phenotype (FVIII:C 16 U/dL, VWF:Ag 47 and VWF:RCo 44 U/dL). Interestingly, desmopressin administration corrected VWF deficiency completely (VWF:Ag and VWF:RCo >130 U/dL), while FVIII:C remained below 50 U/dL, suggesting impaired VWF-FVIII binding. A second mutation (c.2878 C>T in exon 22 leading to R960W) occurred in the FVIII binding region of VWF. Basal FVIII:C was slightly

higher than VWF (FVIII:C 54 U/dL, VWF:Ag 40 and VWF:RCo 42 U/dL), but its survival after desmopressin was shorter. A third mutation (c.3583 G>T in exon 27 leading to E1195Y) occurred in the D3 domain and was associated with a type 2A/2M phenotype (FVIII: C 44 U/dL, VWF:Ag 55 and VWF:RCo 20 U/dL). The latter (c.5827 C>T in exon 34 leading to R1943C) occurred in the D4 domain and was associated with a true type 1 VWD phenotype (FVIII:C 54 U/dL, VWF:Ag 48 and VWF:RCo 44 U/dL), although the loss of cysteine could be implicated in abnormal multimerization.

Conclusions: This study confirms the wide heterogeneity of phenotypes in VWD accounted for by the importance of the domain in which the mutation is located. Furthermore, a causative VWF gene mutation could be often detected even in milder VWF deficiency with a significant bleeding history

PB 4.43-3

Atorvastatin ameliorates angiodysplasia-associated bleeding in von Willebrand Disease

Goodyear DM and Poon M-C

University of Calgary, Calgary, Canada

Background: The association between angiodysplasia and congenital/acquired von Willebrand Disease (vWD) has been well described and appears to be related to a loss of high molecular weight multimers or von Willebrand Factor (VWF)-mediated regulation of angiogenesis[1,2]. Management of angiodysplasia-associated bleeding in these patients consists of various therapies, including VWF replacement therapy, octreotide, hormone therapy, beta-blockers and anti-fibrinolytics. Recent case reports describe the successful use of anti-angiogenic therapies such as thalidomide or atorvastatin in these patients. Statins exhibit cholesterol-independent vascular effects and inhibit angiogenesis in high doses[3]. The availability and side effect profile of atorvastatin make it an attractive option to manage angiodysplasia-associated bleeding in patients with VWD.

Aim/Methods: Retrospective chart review and case report describing successful management of angiodysplasia-associated bleeding in two patients with VWD

Case 1: 73 year old female with Type 2B VWD (previously described as Montreal Platelet Syndrome) with recurrent angiodysplasia-associated bleeding and iron-deficiency anemia since 2008. Bleeding was controlled with VWF replacement therapy twice weekly (60 IU VWF:RCo/kg), octreotide, combination estrogen/progestin therapy and intermittent tranexamic acid. While on therapy in 2011, she had three hospital admissions for acute gastrointestinal bleeding requiring red blood cell (RBC) transfusions. Endoscopy confirmed bleeding from angiodysplasia in the small bowel. Despite alternate day VWF replacement therapy and addition of proton pump inhibitor, patient continued to have melena and needed intravenous iron replacement for chronic anemia.

Patient has had no GI bleeding since beginning atorvastatin in December 2011. Began 10 mg daily with dose titration every 4 weeks to maximum of 80 mg. No adverse side effects were experienced clinically or on monthly laboratory monitoring. Patient discontinued use of octreotide in February 2012 and hormone therapy in September 2012. Has not required tranexamic acid or iron infusions. Laboratory parameters have improved (December 2011: hemoglobin 111, MCV 79, ferritin 16 compared to December 2012: hemoglobin 144, MCV 90, ferritin 77). VWF replacement therapy was decreased to three times weekly in January 2013.

Case 2: 71 year old female with Type 2M VWD and multiple comorbidities including angiodysplasia-associated bleeding from the cecum confirmed on colonoscopy, dialysis-dependent renal failure and myelofibrosis – receiving VWF replacement therapy post-dialysis three times weekly (60 IU VWF:RCo/kg). Began to have hematochezia in May 2012 requiring RBC transfusions every 3–4 weeks. Started atorvastatin 10 mg daily with no further hematochezia and reduction in RBC transfusion requirements (every 6–8 weeks) after 6 months of therapy.

Conclusions: These cases illustrate that atorvastatin may be used to successfully control angiodysplasia-associated bleeding in patients with VWD, especially in those who have failed standard therapies. It may also result in an improvement in iron deficiency anemia with reduced iron and RBC transfusion needs. Atorvastatin is preferred because it is easily accessible and has a better side effect profile than thalidomide which is associated with venous thromboembolism.

Predictors of von Willebrand disease diagnosis in individuals with borderline von Willebrand factor plasma levels

Bucciarelli P[1], Siboni SM[1], Stufano F[1], Biguzzi E[1], Canciani MT[1], Mistretta C[1], Baronciani L[1], Lotta LA[2], Rosendaal FR[3] and Peyvandi F[1]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan; [2]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy; [3]Leiden University Medical Center, Leiden, The Netherlands

Background: Individuals with borderline von Willebrand factor (VWF) plasma levels represent a diagnostic challenge. Second level tests are required to confirm or exclude the diagnosis of von Willebrand disease (VWD). These tests are time-consuming and expensive. Advance knowledge which individual parameters can predict the diagnosis of VWD would allow performing second level tests only in a subset of individuals with borderline VWF.

Aims: To assess which individuals with borderline VWF plasma levels are likely to have VWD and should undergo second level tests.

Methods: Between 2007 and 2011, 950 individuals referred to our center after bleeding episodes or detection of abnormal coagulation tests were investigated with first screening tests (blood count, PT, APTT, factor VIII:C, VWF:RCo and VWF:Ag). In 95 of these patients [64 females and 31 males; median age: 28 years (IQR: 15–44)] borderline VWF plasma levels (i.e., VWF:RCo between 30 and 60 IU/dL) were found. All 95 patients underwent second level tests (VWF collagen binding, VWF multimeric analysis, ristocetin-induced platelet agglutination, and VWF intra-platelet analysis) to diagnose or exclude (and, if diagnosed, to characterize) VWD. In all of them the bleeding diathesis was evaluated by calculating the bleeding severity score (BSS). A positive family history was defined as having at least one first- or second-degree family member with hemorrhagic diathesis. Data of all the 95 individuals with borderline VWF were used to build a multivariable logistic regression model in which VWD (confirmed or excluded with second level tests) was the outcome and individual characteristics (e.g., sex, age, BSS, family history, VWF:RCo plasma levels, ABO blood group) were considered as predictors. This model was used to assess which variables were predictive of VWD. The predictive capability of the logistic model was measured as the area under the ROC curve (AUC).

Results: In 47 of the 95 individuals with borderline VWF (49%) the diagnosis of VWD was established with second level tests. Of them, 38 (81%) were type 1, 7 (15%) type 2 and 2 (4%) had an acquired von Willebrand syndrome. In the multivariable logistic model, a negative linear relationship between VWF:RCo plasma levels and risk of having VWD was present, most evident for individuals with non-0 blood group, in whom a 7-fold increased risk of a positive diagnosis was found for every 5 IU/dL decrease in VWF:RCo [adjusted odds ratio: 7.00 (95% CI: 1.48–33.11)]. The other variable clearly associated with VWD diagnosis was female sex [adjusted odds ratio: 5.86 (95% CI: 1.49–19.37)]. BSS, positive family history and age were poorly

associated with VWD diagnosis. The full logistic model explained about 60% of the outcome variance (R^2: 0.596) and its AUC was 0.89 (95% CI: 0.83–0.95).
Conclusion: Low VWF:RCo plasma levels and female sex are the two strongest predictors of VWD diagnosis in individuals with borderline VWF. The role of low VWF:RCo levels is mainly evident in individuals with non-0 blood group. This predictive model has a promising discriminative capability to identify patients with VWF borderline levels who are likely to have VWD.

PB 4.43-5
Significant improvement of live birth rate in VWD patients with repetitive reproductive failure treated with VWF concentrate

Von Depka Prondzinski M, Henkel-Klene A, Döpke S, Ekhlasi-Hundrieser M and Detering C
Werlhof-Institut, Hannover, Germany

Background: Women with von Willebrand Disease (VWD) are at risk of a variety of complications including miscarriage. Pregancy loss may occur pre-, peri- or post-implantation. Currently, there are limited data defining the exact risk of miscarriage and preventive therapeutic options.
Aim: The aim of this study was to improve the live birth rate in patients with von Willebrand disease and recurrent pregnancy losses. Here, we report data on their treatment with VWF concentrate.
Method: In total 55 pregnant patients (mean age: 31.4; 22–42) were included in this open-label, single-centre study (52 patients with VWD type 1 and 3 with type 2A). They received VWF concentrate (VWF-C) because of previous miscarriage associated with bleeding (78%), bleeding during pregnancy (13%) or other reason (9%). Prior pregnancy losses (in total 101 of 135 pregnancies, 75%) occurred in trimester 1 (t1: $n = 86$), t2 ($n = 10$) and in t3 ($n = 5$). Historical live birth rate (LBR) was 25.4%. Blood samples were collected up to 279 days of pregnancy to analyse FVIII:C, VWF antigen (VWF:Ag) and ristocetin cofactor activity (VWF:RCo). Furthermore, the median doses of factor concentrates/kg BW and the median total number of infusions were calculated. A total of 109 healthy pregnant women served as a control to establish pregnancy adopted reference ranges.
Results: Our data show an increase of mean FVIII:C (106–163 IU/dL), VWF:Ag (124–239 IU/dL) and VWF:RCo (108–183 IU/dL), resp., under replacement therapy throughout the whole pregnancy. In spite of replacement therapy FVIII:C, VWF:Ag and VWF:RCo stayed close to the lower limit of the controls. Mean total VWF concentrate administered per pregnancy was 163644 IU during 43.2 treatment days (range: 1–107) and life birth rate increased to 80% ($P < 0.0001$) with a relative risk reduction to 0.19 to develop pregnancy loss.
Conclusion: In bleeding patients with VWD and recurrent miscarriages we could demonstrate a dramatic increase of LBR from 25.4 to 80% and a risk reduction of miscarriage of 80% in women receiving VWF concentrate. The optimal treatment strategy remains to be clarified.

PB 4.43-6
Analysis of clinical phenotype and genotype in patients with VWD2B, in a single institution of Argentina

Woods AI[1], Bermejo IE[2], Sánchez-Luceros A[1], Kempfer AC[1], Calderazzo JC[1], Meschengieser S[2] and Lazzari MA[1]
[1]IMEX-CONICET-ANM; [2]National Academy of Medicine, CABA, Argentina

Background: Type 2B von Willebrand disease (VWD2B) is characterized by gain-of-function mutations in the A1 domain of von Willebrand factor (VWF) inducing a greater affinity for platelet GPIb, associated with the disappearance of large forms of multimers (HMWM), thrombocytopenia, positive ristocetin induced platelet aggregation (RIPA) at low concentrations, and VWF:RCo/VWF:Ag <0.6. An atypical form of VWD2B was also described, characterized by both normal platelet count (PC) and multimers, but positive RIPA at low concentrations (Casonato A, 2010). It is extremely important to determine the degree of severity of the disease, correlating in each patient the phenotype with genotype. This could help to decide for example, the input to the patient prophylactic treatment, prophylaxis of bleeding in a challenge as surgery, childbirth, etc.
Aims: We tried to find a relationship between the mutations identified, the BSS, PC, multimeric pattern, lower minimal aggregating ristocetin concentration, and propeptide/VWF:Ag ratio (VWFpp ratio) in 19 patients (pts) with VWD2B with candidate mutations.
Methods: The exon 28 was amplified and sequenced (ABI Prism310). BSS was calculated in each pts.
Pts were grouped according to their mutation.
Results: The following mutations were described in our pts:
p.R1304V ($n = 3$; females = 2); BSS = 4.3 ± 0.9; all pts with both normal PC, and multimers, and positive RIPA at 0.5 mg/mL. VWFpp ratio (normal value = 1.5 ± 0.5) = 2.5 ± 0.3.
p.R1306W ($n = 4$; females = 2); BSS = 6.3 ± 1.9; low PC and absence HMWM = all of pts; positive RIPA at 0.3 mg/mL = 25% of pts, at 0.5 mg/mL = 75% of pts. VWFpp ratio = 2.21 ± 0.4.
p.R1308C ($n = 4$; females = 4), BSS = 4.3 ± 1.8; low PC = 50% of pts; absence of HMWM = all pts; positive RIPA at 0.3 mg/mL = 25% of pts, at 0.7 mg/mL = 75% of pts. VWFpp ratio = 2.1 ± 0.5.
p.V1316M ($n = 8$; females = 5) was the most frequent mutation in our pts. BSS = 4.6 ± 1.0; low PC = 87.5% of pts; absence of HMWM = all of pts; positive RIPA at 0.3 mg/mL = 25% of pts, at 0.5 mg/mL = 62.5% of pts, at 0.6 mg/mL = 12.5% of pts. VWFpp ratio = 2.5 ± 0.4.
Conclusion: Phenotypic profile of p.R1304V revealed atypical VWD2B, given the presence of both normal PC and multimers in those pts.
Considering the other 16 pts with typical VWD 2B, all of them had absence of HMWM, and 81.25% had low PC.
Pts with p.R1306W had BSS higher than the other pts, although the difference was not statistically significant ($P = 0.158$); all those pts also had low PC and absence of HMWM. These findings could indicate a higher tendency to more severe clinical symptoms associated with this mutation. No differences were observed in the BSS with the other pts.
It is important to take into account that only 15.8% of our 19 pts showed positive RIPA at 0.7 mg/mL. In contrast, a 75% of pts with p.R1308C had positive RIPA at 0.7 mg/mL.
According to these results, we agree with the recommendations of using 0.5–0.7 mg/mL RIPA for diagnosing VWD2B (SSC, ISTH 2010).
VWFpp ratio was slightly high in all our pts with typical and atypical VWD2B, but unrelated to the different mutations, the BSS, the PC, and the lower aggregating concentrations of RIPA.

PB4.44 – Von Willebrand disease: Clinical – VI

Individually tailored prophylaxis in Type 3 von Willebrand Disease patients: efficacy and safety of a von Willebrand Factor concentrate with a low factor VIII content

Gouider E[1], Peerlinck K[2], Hermans C[3], Gadisseur A[4], Klukowska A[5], Knuchel N[6], Stevens W[6], Matysiak M[5], Meddeb B[1] and Henriet C[6]

[1]Hospital Aziza Othmana, Tunis, Tunisia; [2]Gasthuisberg Hospital, Leuven, Belgium; [3]Cliniques Universitaires Saint-Luc, Bruxelles, Belgium; [4]Antwerp University Hospital, Edegem, Belgium; [5]Medical University of Warsaw, Warsaw, Poland; [6]LFB, Les Ulis, France

Background: Patients with von Willebrand disease (VWD) have highly variable bleeding tendency including life-threatening and spontaneous/trauma-related bleeds. As two bleeding patterns mucosal and non-mucosal are identified for VWD, individualized prophylactic therapy was introduced in a clinical protocol in order to provide optimal treatment.

Aims: To evaluate, in a prospective multicentre study, the efficacy and safety of WILFACTIN (von Willebrand factor concentrate with low factor VIII content) in patients on long-term prophylaxis.

Methods: Prophylaxis regimen was defined according to the type of bleeding episodes to be prevented (mucosal or non-mucosal) and the patient's response to WILFACTIN (plasma levels at 48 h post-infusion of 60 IU VWF:RCo/kg). In patients with predisposition to mucosal bleeds and post-infusion VWF:RCo levels >10 IU/dL, the regimen was 60 IU/kg twice a week (if <10 IU/dL, three times a week). In patients with predisposition to non-mucosal bleeds and post-infusion FVIII:C levels >20 IU/dL, the regimen was 40 IU/kg twice a week (if FVIII:C < 20 IU/dL, three times a week).

The primary efficacy endpoints were the number of spontaneous bleeds and the annual frequency of bleeding episodes. Both treated and non-treated bleeds were taken into account. The secondary endpoint was the analysis of all bleeding symptoms.

Results: Analysis included seven patients with type 3 VWD. Patient median age at prophylaxis start was 16 years (11–45). The follow-up was at least 1 year. They had a history of recurrent bleeding episodes from musculoskeletal (3), gastrointestinal (GI) (1) or other mucosal (3) origin.

Median annual bleed rate was lower during prophylactic treatment compared to during the year prior to enrolment: reducing from 33 to 1.1 in 'musculoskeletal' group and from 52 to 4.2 in 'mucosal' group, excluding GI. No episode of GI bleeding occurred during the 31 months of follow-up in the patient included for this prevention. Individually, the annualized bleeding rate was reduced by more than 67% in six of the seven patients. Due to defective dentition at study entry, the seventh patient had an average of 58.2/year during prophylactic treatment. This patient had repeated traumatic gingivorrhagia (not treated) until his dental condition was corrected. Across all patients, the median reduction in bleeding rates was 81.9%. Two patients had no spontaneous bleeds during the first year. When analysing all bleeding symptoms, the patients experienced a total of 109 bleeding episodes over 206 patient-months or 4.35 bleeds per year per patient. Only 23 of 109 bleeds (21%) required a curative treatment and most of them (86%) were controlled by a single injection of WILFACTIN. No factor VIII concentrate was used. Five patients developed trauma-induced bleeds for a total of 85 (78%) bleeds. No patient presented thrombotic complications nor developed a neutralizing inhibitor to VWF.

Conclusion: Prophylactic treatment of VWD resulted in an obvious reduction in annual bleeding rate compared to episodic treatment. This study shows that individually tailored prophylaxis with WILFACTIN is safe and efficacious.

PB 4.44-2

Analysis of clinical severity of VWD2A and VWD2M patients, according to their candidate mutations, in a single institution of Argentina

Woods AI[1], Sánchez-Luceros A[1], Kempfer AC[1], Calderazzo JC[1], Meschengieser S[2] and Lazzari MA[1]

[1]IMEX-CONICET-ANM; [2]National Academy of Medicine, CABA, Argentina

Background: Type 2A and 2M Von Willebrand disease (VWD2A and VWD2M) are characterized by VWF:RCo/VWF:Ag <0.6, absent 1.2 mg/mL ristocetin induced platelet aggregation (RIPA). Type 2A shows absence of high and intermediate molecular weight multimers, whereas type 2M shows normal multimers. Given the variable bleeding tendency, it is extremely important to determine the degree of severity of the disease, correlating in each patient the phenotype with genotype. This could help to decide for example, the input to the patient prophylactic treatment, prophylaxis of bleeding in a challenge as surgery, childbirth, etc. At least two different pathophysiological mechanisms are known within VWD2A: mutations that impair multimerization (group I) and those with increased susceptibility of ADAMTS13 (group II), predominantly in the A2 domain.

Aims: We wanted to look for clinical parameters that would be significant to establish 'a priori' differences in clinical behavior of VWD2A and 2M pts. We analyzed the bleeding score system (BSS, ISTH) and the propeptide/VWF:Ag (VWFpp ratio: normal value = 1.5 ± 0.5) between VWD2A patients (pts) (n = 11), and VWD2M pts (n = 33) trying to find (if any) some differences in the severity of clinical symptoms in type 2A and 2M variants with candidate mutations.

Methods: The exon 28 was amplified and sequenced (ABI Prism310) in VWD2A and VWD2M pts previously diagnosed. Pts were grouped according to the VWD variant and their mutation. BSS, VWFpp ratio and mutation were analyzed in each VWD variant

Results: VWD2A:
All (n = 11): BSS = 6.18 ± 2.7; VWFpp ratio = 2.46 ± 0.76.
In the A1 domain: p.P1266Q (n = 1): BSS = 5; VWFpp ratio = 2.13;
p.C1272F (n = 2): BSS=8.0 ± 2.0; VWFpp ratio = 3.26 ± 0.12;
In the A2 domain: p.L1503P (n = 1): BSS = 4; VWFpp ratio = 1.6;
p.G1505R (n = 1): BSS = 10.0; VWFpp ratio = 2.56;
p.Y1542D (n = 1): BSS = 2; VWFpp ratio = 1.27;
p.R1597W (n = 3): BSS = 5.3 ± 1.9; VWFpp ratio = 2.8 ± 0.4;
p.I1628T (n = 1): BSS = 5; VWFpp ratio = 2.08;
VWD2M
All (n = 33): BSS = 4.5 ± 2.5; VWFpp ratio = 2.2 ± 0.74;
In the A1 domain: p.F1293C (n = 2); BSS = 4.5 ± 1.5; VWFpp ratio = 2.9 ± 0.6
p.R1315C (n = 6); BSS = 3.8 ± 1.7; VWFpp ratio = 2.0 ± 0.6
p.G1324S (n = 1): BSS=13; VWFpp ratio = 1.22
p.R1334Q (n = 1); BSS = 3; VWFpp ratio = 1.09
p.R1374C (n = 7); BSS = 3.0 ± 1.4; VWFpp ratio = 2.9 ± 0.56
p.A1437T (n = 2); BSS = 4.5 ± 0.5; VWFpp ratio = 2.76 ± 0.19
In the A2 domain: p.E1549K (n = 10); BSS = 4.1 ± 1.8; VWFpp ratio = 2.06 ± 0.4
p.R1564W (n = 1); BSS = 8; VWFpp ratio = 1.12
p.R1583W (n = 1); BSS = 4; VWFpp ratio = not done
p.I1628T (n = 3); BSS = 4.0 ± 2.9; VWFpp ratio = 1.79 ± 0.17

Conclusion: Globally considered, BSS were higher in VWD2A than in VWD2M variant, although the difference was not statistically significant (P = 0.065). There was no difference with the VWFpp ratio between VWD2A and 2M variants. No differences could be established on BSS and VWFpp ratio and the candidate mutations in each VWD variant; however, the number of pts with mutations is too small to draw conclusions. Given these results, it is possible to consider that

the presence of all multimers might be associated with a better clinical profile of VWD2M pts, despite the VWF:RCo/VWF:Ag <0.6 seen in these pts. Some other unknown conditions could be influencing the severity of the clinical profile observed in patients VWD2A.

PB 4.44-3

Evaluation of a commercial von Willebrands factor: factor VIII binding assay for the identification of von Willebrands disease Normandy variant

Needham J, Lewis H and Rangarajan S

Hampshire Hospitals NHS Foundation Trust, Basingstoke, UK

Background: von Willebrands disease (VWD) Normandy variant (type 2N) is a rare autosomal recessive sub-type of VWD resulting from a missence mutation that impairs the ability of von Willebrands factor (VWF) to bind factor VIII (FVIII) resulting in a reduced FVIII concentration and half-life in the circulation. If there is no informative family history and limited clinical features, patients with type 2N VWD can potentially be diagnosed with a mild or moderate haemophilia A phenotype in the case of males and possible haemophilia A carrier in the case of females, due to low levels of factor VIII and usually normal levels of VWF. Until recently only 'in-house' assays have been available for the assessment of VWF binding to FVIII. There is now a commercial assay available designed to identified patients homozygous or compound heterozygous for type 2N VWD which offers standardisation of reagents and calibration.

Aims: To evaluate the enzyme immunoassay (ELISA) based Stago Asserachrom VWF:FVIIIB assay in the differential diagnosis of suspected patients with type 2N VWD, mild or moderate haemophilia A or haemophilia A carrier and the suitability of assay method for automation.

Methods: VWF binding to FVIII using the Stago Asserachrom VWF:FVIIIB was measured using frozen citrated plasma samples from 40 patients with known type 2N VWD, type 1 VWD, mild or moderate haemophilia A and normal subjects. The assay was performed manually according to the manufactures instructions and an automated method established on the Triturus plate reader (Grifols). The patients VWF antigen (VWFAg) level must be known and for both methods the initial dilution of plasma samples to a standardised 10.0 IU/dL VWFAg concentration was performed manually.

Results: Patient and normal VWF:FVIIIB levels ranged from 10.0 to 145.0% and results correlated (r = 1.0) with patient clinical diagnosis based on phenotype and genotype results. VWF:FVIIIB levels <20.0% correlated known type 2N VWD patients. There was good correlation (r = 0.98) and no significant difference (P = 0.2) between manual and automated performance of assay.

Summary/Conclusions: The evaluation has demonstrated that the assay is suitable for manual or automated performance following primary dilution of sample and provides a standardised approach as an alternative to 'in-house' assays. However, the determination of individual patients VWFAg level and subsequent dilution of sample is critical to the accurate final measurement of VWF:FVIIIB levels. The Stago Asserachrom VWF:VIIIB assay was found to correlate 100% with patients previously diagnosed with homozygous or compound heterozygous for type 2N VWD or excluded. The availability of a commercial assay for VWF:FVIIIB should assist in the diagnosis and clinical management of patients presenting with reduced levels of circulating FVIII.

PB 4.44-4

Genetic analyses of two patients with von Willebrand disease (VWD) type2B: implication of type 2B in the differential diagnosis for thrombocytopenic patients

Sanda N[1], Tanaka R[2], Kishimoto M[3], Suzuki N[1], Kunishima S[4], Takatsu M[1], Matsumoto H[1], Nakamura S[3] and Matsushita T[1]

[1]Nagoya University Hospital, Nagoya; [2]Saitama Medical University, Iruma-gun; [3]Nagoya University Graduate School of Medicine, Nagoya; [4]National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background/Aim: Von Willebrand disease (VWD) is one of the most common inherited bleeding disorder characterized by quantitative and/or qualitative von Willebrand factor (VWF) abnormalities. In this study, we performed genetic analyses of the VWF gene from four Japanese patients from two unrelated families with thrombocytopenia, who had been diagnosed as idiopathic thrombocytopenic purpura (ITP).

Case 1: a 14-year-old man. His abdominal purpura was found at 1 year and 10 months old. He presented unexplained thrombocytopenia (17×10^9/L) with increased bone marrow megakaryopoiesis and had been diagnosed as ITP. He had no family history of bleeding tendency. Pulsed corticosteroid therapy or high dose intravenous γ-globulin administration had no effect on thrombocytopenia. Sustained easy bruising and epistaxis continued until he was referred to our institution. Factor VIII procoagulant activity (FVIII:C) was found to be decreased to 52% of normal and the plasma ristocetin cofactor activity of VWF (VWF:RCo) and the antigen (VWF:Ag) was 25% and 69%, respectively.

Case 2: The propositus is a 41 years old father of a family pedigree and had been diagnosed as chronic ITP. He and his two sons had moderate thrombocytopenia (57, 60, 32×10^9/L, respectively) and showed moderate bleeding symptoms of easy bruising and epistaxis. When they lived in US, he was diagnosed as VWD and his plasma VWF lacked higher molecular weight large multimers. FVIII:C, VWF:RCo, VWF:Ag was 30% and 13%, 28%, respectively.

In both patients, ristocetin-induced platelet aggregation was normal or enhanced in the presence of lower concentrations of ristocetin. In the peripheral blood smear of the both patients, giant platelets and large platelet aggregates were visible, suggesting that thrombocytopenia was due to uncontrolled platelet aggregation in the circulation.

Methods: We amplified the exon 28 including the exon/intron boundaries of the VWF gene by polymerase chain reaction using allele-specific primers, and analyzed DNA sequences of the patients.

Results: Direct sequencing showed that case 1 patient was heterozygous for a A1461D (c.4382C > A) substitution. Case 2 and his sons were heterozygous for a V1316M (c.3946G > A) substitution. These mutations are located in the VWF A1 domain and have been found in VWD type2B patients.

Conclusion: Patients presenting muco-cutaneous bleeding and thrombocytopenia are usually diagnosed as ITP when the bone marrow megakaryocytes are normal/increased. Especially case 1 had no relatives of VWD and the diagnosis of type 2B VWD was not performed unless plasma VWF concentrations were tested. We conclude and propose that type 2B VWD should be included in the differential diagnosis of thrombocytopenia and VWF:RCo or VWF:Ag is tested when other conditions are excluded causing thrombocytopenia.

PB 4.44-5

Analysis of von Willebrand Disease in the South Moravian population (Czech Republic): The BRNO-vWD Study; an update

Vangenechten I[1], Smejkal P[2], Zapletal O[2], Bouddount F[1], Zavrelova J[2], Blatny J[2], Penka M[2], Michiels JJ[1] and Gadisseur A[1]
[1]Antwerp University Hospital, Edegem, Belgium; [2]University Hospital Brno, Brno, Czech Republic

Von Willebrand Disease (VWD) is an autosomally inherited bleeding disorder caused by a quantitative or qualitative defect of von Willebrand factor (VWF). The current ISTH classification is based on measurement of VWF:Ag, VWF:RCo, Ristocetin Induced Platelet Aggregation (RIPA) and VWF multimers.

In a collaboration between the University Hospital Brno (Czech Republic) and the Antwerp University Hospital (Belgium) a family-based analysis of VWD in the Moravia area of the Czech Republic was performed. Blood samples were collected from patients with suspected or known VWD with one of the following characteristics: VWF:Ag <35%, VWF:RCo/VWF:Ag <0.7, VWF:CB/VWF:Ag <0.7, FVIII:c/VWF:A < 0.5, or positive low concentration RIPA, and grouped in families. From each family the proband was included in the study together with a at least one affected sibling or parent.

Blood was collected from 205 patients from 95 families with suspected VWD. FVIII:c, VWF:Ag, VWF:RCo, VWF:CB, VWFpp, VWF-FVIII binding (if indicated), VWF multimers and molecular analysis were performed at Antwerp University Hospital. Platelet Function Analyzer and RIPA testing were done locally.

Based on laboratory tests and VWF multimers distribution of different subtypes of VWD was as follows: VWD type 1 in 60/95 families (incl. 1 type 1 Vicenza family), and type 2 in 29/95 families (type 2A in 14/95, type 2B in 4/95, and type 2M in 8/95), with 6/95 still unconfirmed/unclassified. All cases of type 3 (6/205 patients) were based on the presence of (often asymptomatic) type 1 VWD in both parents. Diagnosis of VWD type 1 Vicenza was suggested by a high VWFpp/VWF:Ag ratio (4.87) and confirmed by the presence of the R1205H mutation. Molecular analysis is still ongoing with currently 41/95 families fully analysed and the remainder partially. Sofar, 28 Mutations in the VWF gene have been found in 55/95 families, of which 2 are new to the ISTH VWD database (http://www.vwf.group.shef.ac.uk/), and awaiting gene expression studies. In 12/95 families heterozygous type 2N mutations were detected.

This study is the first characterisation of VWD in the (South) Moravian population of the Czech Republic. These data are important for understanding of phenotype-genotype relationship in VWD. The full laboratory and multimeric analysis for all samples are finished. Further molecular analysis is ungoing.

PB 4.44-6

DDAVP use and cardiovascular outcomes in patients with bleeding disorders undergoing invasive procedures

Suryanarayan D, Goodyear DM and Poon M-C
University of Calgary, Calgary, Canada

Background: Desmopressin (1-deamino-8-D-arginine vasopressin, DDAVP) is commonly administered for surgical prophylaxis or treatment of acute bleeding in patients with hemophilia A, von Willebrand's disease (vWD) and various platelet disorders. There are anecdotal reports of myocardial infarction in adult patients treated with desmopressin. For this reason, it is used with caution in patients with cardiovascular disease and is considered contraindicated in patients with unstable coronary artery disease and poorly controlled hypertension. The Southern Alberta Rare Blood and Bleeding Disorders Clinic (RBBDC) in Calgary have used DDAVP regularly for surgical prophylaxis for patients with mild hemophilia A and von Willebrand disease who have been proven to have an increase in von Willebrand and Factor VIII levels after administration of DDAVP.

Aim: The objective of this study was to determine if DDAVP use in our patients with mild hemophilia A and von Willebrand disease, increases the risk of adverse cardiovascular events, including myocardial infarction, angina or atrial fibrillation. Secondary outcome of interest was the incidence of hyponatremia after DDAVP.

Study Design: Retrospective database and chart review.

Methods: Retrospective chart review and RBBDC database review was conducted on all patients with bleeding disorders who underwent surgical procedures requiring DDAVP prophylaxis/treatment between Jan 2008 and Feb 2012.

Results: A total of 289 patients with bleeding disorders underwent surgical procedures between Jan 2008 and Feb 2012. Out of these, DDAVP prophylaxis was used for 119 procedures (38 minor, 81 major) in 78 patients (M:F = 25:53, mean age 45 (range 17–71). Diagnosis included: 55(70%) VWD [6(10%) type 2, 49(89%) type 1], 16 (20%) mild hemophilia A and other bleeding disorders 7(9%). Cardiovascular comorbidities included: coronary artery disease 10 (13%), hypertension 19 (24%), diabetes 7(9%) and congestive heart failure 1 (1%). All the patients received DDAVP at mean dose of 19.8 ± 3.4 mcg. The mean number of treatments was 2.2 ± .5 (range 1–5) for major and 1.2 ± 0.7 (range 1–5) for minor procedures. Adjunctive therapies used included tranexamic acid in 21(27%), Kogenate FS® in 4(5%) and Humate P in 1(2%). Sixteen patients aged ≥60 years (mean age 66.4 ± 4.4) underwent a total of 24 procedures (major:15.62%; minor 9.37%). Of these, 8(50%) had comorbid coronary artery disease, 8(50%) had hypertension and 3(19%) had diabetes. The mean number of treatments for this group was 1.9 ± 1.3 (range 1–4) for major and 1 (range 1–3) for minor procedures. Adverse events were described in 2 (2%) patients within 1 month of DDAVP administration. A 60 year old female with undiagnosed bleeding disorder, hypertension, and coronary heart disease developed atrial fibrillation on Day 20 post DDAVP for transjugular liver biopsy. Postoperative hyponatremia noted in a 66 year old male with mild hemophilia A undergoing colonoscopy. There were no cases of myocardial infarction, angina or congestive heart failure reported.

Conclusion: Surgical prophylaxis/treatment with DDAVP was generally safe and well tolerated. There were few adverse cardiovascular outcomes in patients above 60 years of age

Factors predicting choice of anticoagulant treatment in elderly patients with VTE – findings from the RIETE registry

Sterpu R[1], Bertoletti L[2], Mahe I[3], Hennou S[3], Pinson M[3], Hernandez L[4], Schellong S[5], Garcia-Bragado F[6] and Monreal M[7]
[1]Hôpital Louis Mourier, Colombes, France; [2]Centre Hospitalier Universitaire, Saint Etienne, France; [3]Hôpital Louis Mourier – APHP, Colombes, France; [4]Hospital General Universitario de Alicante. Spain, Alicante, Spain; [5]Municipal Hospital of Dresden Friedrichstadt, Dresden, Germany; [6]Hospital de Girona Dr. Josep Trueta., Girona, Spain; [7]Hospital Universitari Germans Trias i Pujol, Barcelone, Spain

Background: The incidence of venous thromboembolism (VTE) increases significantly with age, and clinicians face multiple age-specific challenges in real life management of VTE.

Aims: We investigated factors influencing the choice of acute and long term anticoagulant treatment in an elderly, non-selected population diagnosed with VTE, with the aim of clarifying what treatment decisions clinicians are currently making for this population.

Methods: Using data collected in the RIETE registry (an international registry of consecutively enrolled patients with VTE), we analyzed clinical characteristics and therapy choices in 11,403 patients ≥75 years old. Acute treatment is defined as treatment administered in the first days (<10 days). Long term treatment is all anticoagulant treatment administered afterwards. Patients were treated according to standard practices. All patients were followed up for at least 3 months.
Results: Low molecular weight heparins (LMWH) were the initial treatment in 93.5% of patients over 75. Presence of severe renal insufficiency (estimated GFR <30 mL/min/m^2) was significantly associated with clinicians' use of unfractionated heparin (UFH) in the acute phase of treatment (OR 2.05, 95% CI 1.5–2.6).
For long term treatment, clinicians followed two major strategies: vitamin K antagonists (VKAs) were used in 8124 (71.2%) patients and LMWH used in 2879 (25.2%) patients. In long term treatment, the major determinant in choosing long term LMWH therapy over VKAs was the presence or not of cancer (OR 2.52, CI 2.2–2.76). Clinicians favoured long term LMWH treatment when anaemia was present (OR 2.07, 95% CI 1.9–2.27). Severe renal insufficiency (estimated GFR <30 mL/min/m^2) did not discourage practitioners from choosing long term LMWH therapy, as 405 patients (14.07%) treated with long term LMWH had a creatinine clearance <30 mL/min/m^2. Age, weight and laboratory abnormalities such as thrombopenia were other major influences on treatment choice.
A direct comparison between patients treated with VKA and those treated with long term LMWH revealed that the latter patients were more fragile, had lower body weights, had significantly more comorbidities (such as chronic lung disease, chronic renal disease, anaemia, and thrombopenia), were more prone to immobility, and had shorter durations of anticoagulant treatment. Amongst these patients, 946 (32.86%) had a concomitant diagnosis of cancer.
Conclusion: Real life assessment of VTE management shows that choosing anticoagulant treatment remains difficult in elderly patients. Overall, this choice was determined by parameters classically associated with the risk of bleeding. Unexpectedly, clinicians seemed to consider LMWH to be safer for chronic use in extremely fragile elderly patients, perhaps due to an overestimation of bleeding risks associated with VKA treatment. Our study highlights the need for controlled randomised studies with the aim of determining the best anticoagulation strategy to adopt in patients over 75 years old.

PB 4.45-2

Association between bleeding risk and persistence on warfarin therapy in patients with VTE in clinical practice

Kaatz S[1], Fu AC[2], AbuDagga A[2], LaMori JL[3], Bookhart BK[3], Damaraju CV[4], Tan H[2], Schein J[3] and Nutescu E[5]
[1]Hurley Medical Center, Flint, MI; [2]HealthCore Inc., Wilmington, DE; [3]Janssen Scientific Affairs, LLC, Raritan, NJ; [4]Janssen Research & Development, LLC, Raritan, NJ; [5]University of Illinois Hospital & Health Sciences System, Chicago, IL, USA

Background: It is unclear how healthcare providers weigh bleeding risk in patients with venous thromboembolism (VTE) and various levels of VTE recurrence risk who are treated with warfarin.
Aim: To examine the association between bleeding risk level and length of warfarin therapy among patients following a first observed VTE event.
Methods: Data from the HealthCore Integrated Research Database, representing 45 million members in 14 US commercial health plans, were used in this retrospective observational study. Patients meeting the following criteria between June 2007 and September 2011 were identified: (i) had a first observed VTE, designated as the index event; (ii) had no prior use of anticoagulants; (iii) were aged ≥18 years old; (iv) had ≥12 months continuous health plan eligibility before and after the index event; (v) had ≥1 anticoagulant prescription fill within 7 days after the index event and ≥1 warfarin fill during the post-index period; and (vi) had no mechanical valve replacements, atrial fibrillation, or rivaroxaban/dabigatran use during 12 months before the index event. Patients were categorized by bleeding risk level based on the Computerized Registry of Patients with Venous Thromboembolism bleeding risk scheme: high (score >4), intermediate (score 1–4), and low bleeding risk (score 0). Length of therapy was measured by continuous warfarin treatment, based on consecutive fills of warfarin with <90 days of allowable gap, unless there was an international normalized ratio test every 42 days. Survival analyses (Kaplan-Meier curves and Cox proportional hazard model) were used to estimate the effects of bleeding risk levels on length of therapy and were adjusted for baseline demographics and VTE recurrence risk levels (provoked VTE, cancer-related VTE, and unprovoked VTE).
Results: Of the 1868 patients who met inclusion criteria (mean age 57 ± 15 years, 47% female), 45% had low, 54% had intermediate, and 1% had high bleeding risk. The average length of warfarin therapy was 314 ± 266 days (mean follow-up period 733 ± 245 days). Patients with low bleeding risk had a mean of 277 ± 254 days of therapy, while patients with intermediate/high bleeding risk had a mean of 344 ± 273 days. Stratifying by VTE recurrence risk (provoked, cancer-related, and unprovoked VTE) showed that patients with intermediate/high bleeding risk were less likely to discontinue warfarin therapy than were those with low bleeding risk (all P values <0.001). After adjusting for demographics and VTE recurrence risk, patients with intermediate/high bleeding risk remained 25% less likely to discontinue warfarin therapy than those with low bleeding risk (hazard ratio 0.75, 95% CI: 0.64–0.87, $P < 0.001$).
Summary/Conclusion: VTE patients with intermediate/high bleeding risk were less likely to discontinue warfarin therapy than were those with low bleeding risk, which seems counterintuitive. Patients with high bleeding risk may also be perceived to have higher VTE recurrence risk; however, these patients were still less likely to stop warfarin therapy after statistical adjustment for VTE recurrence risk. Additional studies are needed to investigate whether clinical prediction rules for bleeding and recurrent VTE are associated with duration of warfarin therapy in real-world clinical practice.

PB 4.45-3

Differential effects of dabigatran etexilate and ticagrelor on bleeding as assessed by washed blood and shed blood tests in healthy subjects

Van Ryn J[1], Giessmann T[1], Gouya G[2], Wolzt M[2], Schurer J[1], Lobmeyer M[1] and Brueckmann M[1]
[1]Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany; [2]Medical University of Vienna, Vienna, Austria

Background & Aim: The most frequent side effect associated with long term anticoagulant and antiplatelet therapy is bleeding. It has been attempted with different methods to assess blood loss in healthy volunteers (HV). The purpose of this study was to examine the feasibility of two alternative methods for the assessment of bleeding due to anticoagulation with dabigatran etexilate (DE) vs. antiplatelet therapy with ticagrelor.
Methods: Washed blood and shed blood methods were tested in two groups of 12 HVs. DE (Pradaxa®, 220 mg, $n = 8$) or ticagrelor (Brilinta®180 mg, $n = 4$) was given as a single dose and bleeding methods were done at 0, 2, (3 only washed blood) and 6 h. Washed blood: a forearm skin incision with junior Surgicutt® was made and the wound area was washed with saline. Wash solution was collected and measured photometrically. AUC was recorded as blood loss, bleeding time as the first well with optical density (OD) <0.05. Shed blood: two incisions in the forearm using an adult Surgicutt® were made and blood emerging from the wound was collected over 4 min and placed in a protease inhibitor solution. Plasma was assayed by ELISA for ß-thromboglobulin (ß-TG), thrombin-antithrombin (TAT), prothrombin fragment

(F1 + 2), fibrinopeptide A (FPA). Venous blood was taken at the same time points.

Results: Study drugs were well tolerated. Blood loss (AUC) at predose was 70 ± 42 OD*sec and bleeding time was 3.6 ± 0.6 min. DE increased AUC 2–3-fold over baseline at 2, 3, and 6 h in washed blood test, but had no effect on bleeding time prolongation vs. control. Ticagrelor increased blood loss (AUC) >10-fold and prolonged bleeding time from 5.4 to >20 min. DE reduced ß-TG, FPA and slightly reduced TAT, but had no effect on F1 + 2 in shed blood. Ticagrelor reduced ß-TG, but had no effect on other parameters in shed blood. Parameters were unchanged in venous blood.

Conclusions: This study shows that quantification of bleeding with DE and ticagrelor is possible using the washed blood technique. Shed blood increases sensitivity of detecting the pharmacological activity of these compounds compared to venous blood. These two methods could serve as experimental models to sensitively assess blood loss and to also allow for the investigation of reversal agents.

PB 4.45-4

A randomized clinical trial for the effects of an anticoagulation clinic in heart disease patients at a Brazilian public hospital

Martins MAP, César C, Ribeiro D, Nobre VA, Oliveira JAC, Palhares DMF, Botelho GR, Rocha MO and Ribeiro ALP

Universidade Federal de Minas Gerais, Belo Horizonte-MG, Brazil

Background: Warfarin sodium is the oral anticoagulant most commonly prescribed in Brazil. The management of patients under warfarin therapy is challenging due to the drug's narrow therapeutic index, wide variability in dose response, and the need for frequent monitoring of the international normalized ratio (INR). Clinical evidence shows that better outcomes are achieved when anticoagulation therapy is managed by anticoagulation clinics rather than by the usual medical practice.

Aims: To determine the efficacy and safety of an anticoagulation clinic in heart disease patients.

Methods: A randomized clinical trial was performed including a calculated sample size of 280 heart disease outpatients recruited from 2009 to 2010 at a public hospital in Belo Horizonte, Brazil. The inclusion criteria were age of >18 years, definitive cardiopathy diagnosis and at least one indication for long-term oral anticoagulation. The exclusion criterion was treatment with warfarin for <30 days prior to recruitment. Data collection was performed during the patient admission process in an anticoagulation clinic recently established in this hospital. Of the 280 patients enrolled, 151 were randomly assigned to the control group and followed-up for 6 months while assisted by the usual medical practice and for additional 6 months after the intervention represented by the anticoagulation clinic. The variables analyzed were: sex, age, time in therapeutic range (TTR) and number of thromboembolic and bleeding events. Any type and severity of hemorrhage were considered as bleeding event (eg. hematoma, epistaxis, gastrointestinal or intracerebral hemorrhage). Thromboembolic events included arterial and venous thrombosis. INR results were used to calculate TTR by linear interpolation. Measurements of central tendency and variability were calculated. The comparison of TTR was performed by paired *t*-test. The analysis of complications was performed by nonparametric Willcoxon. The database was created by double entry in Epidata and statistical analyses were performed with SPSS, v. 18.0. The Ethics Committee of the Universidade Federal de Minas Gerais approved this research. All participating patients signed a written informed consent. The study was registered in ClinicalTrials.gov under the code NCT01006486.

Results: The mean age was 56.3 ± 13.9 years and 80 (53.0%) patients were female. In the first semester, the TTR was 55.5 ± 28.5% and there were 182 complications related to the use of warfarin (171 hemorrhagic and 11 thromboembolic events). In the second semester, the TTR was 62.1 ± 22.6% and there were 95 complications (93 hemorrhagic and 2 thromboembolic events). There was statistically significant difference in TTR between the two semesters ($P = 0.006$). Additionally, there was a statistically significant difference of adverse events between the two semesters ($P = 0.003$).

Summary/Conclusion: These results demonstrated that the anticoagulation clinic was associated with the improvement of TTR which is an important parameter of quality of the oral anticoagulation. There were fewer complications after assistance in the anticoagulation clinic. These findings suggest that the availability of this service as a supportive specialized care may represent a useful strategy to manage the risks associated with warfarin therapy. Moreover, it can help to improve the quality of care focused on heart disease patients assisted by the Brazilian Public Health System.

PB 4.45-5

Correctness of the identification by patients of colour of urine samples obtained a point of care test for dabigatran and rivaroxaban

Harenberg J[1], Du S[2], Krämer S[1] and Weiss C[3]

[1]Clinical Pharmacology; [2]Clinical Phramacology; [3]Biometry and Statistics, Mannheim, Germany

Background: In certain clinical situation such as for fibrinolytic therapy it may be necessary to know weather patients have a new oral anticoagulants (NOAC) on board or not. Otherwise it makes the decision for a medical intervention difficult. Also, it is important that patients are fully compliant with NOACs, more so than with warfarin, which has a longer half-life. NOACs are excreted between 25% and 80% into the urine and can be determined by point of care (POC) methods. The precision of the POC test is close to 100% for dabigatran (D) and 97% for rivaroxaban (R) when performed by trained medical personal.

Aim: We determined the precision of the reading of the colour of the POC tests by the naked eye of patients because the test will be performed by patients themselves.

Methods: Urine was obtained from 15 patients each during therapy with 110 mg bid or 150 mg bid D or 10 mg od R or no anticoagulation. The presence of NOACs were analysed by the POC tests. These are based on the development of specific colours within 15 min in the presence (positive, blue or clear colour) and absence (negative, green or yellow colour) of D and R, respectively. The colour of the total of 60 samples was identified by the naked eye of 30–32 patients.

Results: A total of 480 and 465 naked eye readings of the colours were available for D and R samples obtained by the POC tests were available for analysis. The results are given as mean and 95% confidence interval (CI), sensitivity, specificity, accuracy, positive (PPI) and negative predictive index (NPI, all%), and the Youden-Index (sensitivity + sensitivity – 100) for D and R. The sensitivity was 100% (99.2–100) and 96.6% (94.5–98.0) for D and R; the specificity was 99.2% (97.9–99.8) and 98.0% (96.1–99.1) for D and R; the accuracy was 99.6% (98.9–100) and 97.2% (95.9–98.2) for D and R; the PPI was 99.2% (97.9–99.8) and 98.3% (96.6–99.2) for D and R; the NPI was 100% (99.2–100) and 96.1% (94.2–98.0) for D and R; and the Youden Index was 0.99 for D and 0.95 for R, respectively.

Conclusion: Patients identify the colours of urine samples obtained by a POC method specific for D and R in urine from patients on treatment with high precision. Patients have to learn testing and identification of colour by expert personal. During this exercise patients with therapy of D with so far unknown very rare amblyopia for red-green colour are identified. For those few patients another person has to perform the POC test. Patients currently perform the test themselves using a prototype test system.

PB 4.45-6

Analysis of the preference of patients to choose conventional or new oral anticoagulants based on a short questionaire

Zolfaghari S[1], Kremer C[1], Abou-Ayash N[1], Frölich L, MD[2], Harenberg J and MD[1]

[1]Clinical Pharmacology; [2]Geriatric Psychiatry, Mannheim, Germany

Background: Heparins and vitamin K antagonists (VKA) are treatments of chose for prevention of embolism in atrial fibrillation, for prophylaxis of postoperative deep vein thrombosis following total hip- and knee replacement surgery and treatment of acute venous thromboembolism and of their recurrent events. Several new oral anticoagulants (NOAC) are available for these indications. Certain factors are now identified which patients with atrial fibrillation would benefit from NOAC compared to VKA. Personality traits are known to influence patient's decision to choose specific treatment options.

Aim: Aim of the project is to identify personality traits which influence the decision of patients to choose treatment with conventional or new oral anticoagulants.

Methods: In the first step, patients (n = 110) on stable treatment VKA for at least 3 months completed the validated personality inventory (Freiburger Persönlichkeitsinventar FPI-R) and a self-developed questionnaire on general attitudes regarding anticoagulant therapy with about 47 items. For evaluation of the results, patients were divided in two groups according to the reply to the question weather they would be willing to switch from VKA to a NOAC. Six items of the self developed questionaire and the introversion/extraversion scale of the FPI were identified by means of a logistic regression to discriminate patients willing or not willing to change VKA to NOAC therapy. This short questionnaire was completed by the same patients (n = 85) after 6 months to confirm the reproducibility of the regression analysis.

Results: Logistic regression analysis defined the following seven items of the long questionaire and of the FPI for their willingness to change the medication from VKA to NOAC with 98% probability: extraversion – introversion scale on the FPI-R, hope for a better quality of life with a NOAC, no scepticism for new drugs, wish of no routine monitoring for dose adjustment, relevance of the practitioner's opinion, thoughts in the past of alternatives for anticoagulation, and difficulty to adjust the prothrombin time. The short questionnaire identified with a probability of 85% of the same patients willing to change the anticoagulant therapy (chi square test $P < 0.0001$).

Conclusion: Seven items were identified for the identification of the preference of patients to perform oral anticoagulant with VKA or NOAC. These questions are now available in the internet to substantiate the results www.blutverduennung.uni-hd.de. The study compares the results of the replies of to the questions for patients on treatment with VKA, patients who changed anticoagulation from VKA to NOAC and patients without experience of VKA treatment and being on anticoagulant therapy with one of the NOACs from initiation of therapy.

Asian patients with splanchnic vein thrombosis: a sub-analysis from an international registry

Riva N[1], Bang S-M[2], Oh D[3], Lee JO[2], Schulman S[4], Sartori MT[5], Grandone E[6], Beyer-Westendorf J[7], Barillari G[8], Di Minno D[9], Duce R[10], Malato A[11], Santoro R[12], Dentali F[1] and Ageno W[1]

[1]Department of Clinical and Experimental Medicine, Insubria University, Varese, Italy; [2]Seoul National University, Seoul, South-Korea; [3]Pochon CHA University, Seoul, South-Korea; [4]McMaster University, Hamilton, Canada; [5]University of Padua, Padua, Italy; [6]IRCCS Casa Sollievo Della Sofferenza, S.Giovanni Rotondo, Italy; [7]Dresden University Clinic, Dresden, Germany; [8]Ospedale di Udine, Udine, Italy; [9]University of Naples, Naples, Italy; [10]Galliera Hospital, Genoa, Italy; [11]Cattedra ed UO di ematologia con trapianto, Palermo, Italy; [12]Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: Splanchnic vein thrombosis (SVT) is a manifestation of unusual site venous thromboembolism (VTE). Studies on patients with deep vein thrombosis and pulmonary embolism suggest that epidemiology, pathogenesis and management in Asian countries might be different from Western regions. However, whether these differences pertain also to SVT is unknown.

Aims: The aim of this analysis was to compare the characteristics of SVT in Asian and Western countries.

Methods: We enrolled in a prospective multicenter international registry, 613 consecutive patients with an objectively diagnosed SVT between May 2008 and January 2012. Information on clinical presentations, risk factors and therapeutic strategies was collected and analysed separately for Asian and non-Asian patients and then compared.

Results: 137 Asian patients were included. Asian patients were younger than non-Asian patients (51 vs. 54 years, P = 0.032), most commonly of male gender (70.1% vs. 60.5%, P = 0.052) and less likely to have a personal or family history of VTE (3.7% vs. 13.6%, P = 0.002, and 0.7% vs. 10.6%, P = 0.001, respectively).

Computed tomography was more frequently performed in Asian patients (96.4% vs. 63.9%, $P < 0.001$), while ultrasonography was more commonly used in non-Asian patients (2.2% vs. 28.1%, $P < 0.001$). According to the site of thrombosis, Budd-Chiari syndrome (BCS) was predominantly found in Asian patients (19.0% vs. 5.8%, $P < 0.001$), whereas portal vein thrombosis was more often diagnosed in non-Asian patients (67.9% vs. 79.7%, P = 0.005).

Among the 46 patients with BCS, Asian patients presented more frequently liver cirrhosis (45.8% vs. 14.3%, P = 0.050), but less haematological cancer (0% vs. 28.6%, P = 0.007). BCS was incidentally detected in more Asian patients (50.0% vs. 14.3%, P = 0.027); while abdominal pain (25.0% vs. 76.2%, P = 0.002), anorexia (0% vs. 23.8%, P = 0.017) and fever (0% vs. 19.0%, P = 0.040) were more commonly reported in non-Asian patients.

Among the 552 patients with spleno-porto-mesenteric (SPM) vein thrombosis, Asian patients were more likely to have underlying solid cancer (31.5% vs. 19.4%, P = 0.008) and less likely haematological cancer (1.8% vs. 10.3%, P = 0.008) or ongoing hormonal therapy (0% vs. 5.3%, P = 0.007). SPM thrombosis was more frequently unprovoked in Asian patients (36.9% vs. 24.7%, P = 0.013). No differences between the two groups emerged in the proportion of patients with incidentally detected SPM thrombosis.

Anticoagulant treatment was less utilized in Asian patients, since during the acute phase only 51.1% patients were started on anticoagulation, compared with 84.8% non-Asian patients ($P < 0.001$). Asian patients received more frequently unfractionated heparin (15.3% vs. 8.8%, P = 0.039) and less frequently low molecular weight heparin or fondaparinux (32.1% vs. 77.4%, $P < 0.001$), compared to non-Asian patients. No difference was found in the prescription of vitamin K

antagonists. Thrombolysis was more commonly performed in Asian patients (3.6% vs. 0.9%, $P = 0.032$).

Conclusions: The results of our analysis suggest that Asian patients with SVT may have specific characteristics. Differences in pathogenesis and clinical manifestations are possibly explained by ethnicity, while the diverse management approaches may also be due to the observational nature of our study.

PB 4.46-2

Vitamin K in oral solution or tablets: a cross-over study and randomized controlled trials to compare effects

Van Rein N, Willem LM, Gebuis EPA, Groeneveld E-J, Rosendaal FR and Van Der Meer JM

Leiden University Medical Center, Leiden, The Netherlands

Background: Vitamin K1 (VK1) is used to reverse effects of coumarins. The current formulation in the Netherlands is an oral solution in oil, but recently tablets have become available. Tablets have a longer shelf life and are easier to ingest. However, bioavailability of VK1 is higher in the presence of fatty substances, possibly resulting in different effects of the oily solution compared with the tablets.

Aims : To compare the bioavailability and the effect on the international normalized ratio (INR) of tablets and solutions of VK1 in healthy volunteers and anticoagulated patients.

Methods: The study consisted of three parts, all carried out with 5 mg of VK1. First, the bioavailability of the tablets and solution was assessed in a crossover study with healthy volunteers. The volunteers took the tablets or oral solution and crossed over to the other formulation after a wash-out period of 2 weeks. VK1 plasma levels were measured at $t = 0,2,4,6$ and 24 h. Primary outcomes were VK1 concentrations after 4 h and the area under the curve (AUC). Second, patients on phenprocoumon who had to undergo an invasive procedure and had to take VK1 were asked to participate. INRs were measured at $t = 0.24$ and 48 h to compare effects. These were considered similar when the percentage of patients with and INR <2.0 at 48 h did not differ more than 10% between both formulation groups. Third, patients using phenprocoumon with an indication for VK1 due to a high INR were asked to participate. INRs were measured at $t = 0.24$ and 48 h and VK1 levels were measured at $t = 0$ and 24 h. The primary outcome was the decrease in INR after 24 h and results of this part will be available at the ISTH. Informed consent was obtained from all subjects and the study was approved by the medical ethics committee of the LUMC.

Results: In the crossover study, concentrations of VK1 at 4 h were 96 nM for the tablet and 83 nM for the solution group, and were not different (mean difference 13 nM, 95% confidence interval [CI] = −44–69). The AUCs were 301 nmol/mL·h for the tablet and 282 nmol/mL·h for the solution group, and were not different (mean difference 19 nmol/mL·h, 95% CI = −126–164). In the second part, clinical characteristics of the two patient groups were similar. We excluded one patient because he was previously shown to be resistant to VK1. Two patients dropped out of the tablet group at day three (due to earlier admission to the hospital and a too high INR at 24 h [INR = 2.3]). The average INR decreased from 2.52 (95% CI 2.42–2.62) to 1.59 (95% CI 1.55–1.63) to 1.39 (95% CI 1.36–1.42) for the solution, and from 2.55 (95% CI 2.48–2.62) to 1.65 (95% CI 1.61–1.68) to 1.41 (95% CI 1.39–1.43) for the tablets at 0, 24 and 48 hours respectively. The patients with INRs under 2.0 were 36 (100%) in the solution compared to 33 (100%) in the tablet group.

Conclusions: Bioavailability and effects on the INRs of VK1 solution and tablets are similar.

PB 4.46-3

Efficacy and safety of dabigatran in over 75 years old patients with atrial fibrillation

Mavri A, Sinigoj P, Vene N, Vizintin-Cuderman T, Tratar G, Gubensek M, MIklic M and Ostasevski-Fernandez N

University Medical Centre, Ljubljana, Slovenia

Background: The use of dabigatran, an oral direct thrombin inhibitor, for the prevention of stroke is increasing in patients with atrial fibrillation and is being applied also to the elderly, who might be exposed to higher bleeding risk.

Aim: To assess efficacy and safety of dabigatran in patients with atrial fibrillation aged more than 75 years.

Methods: Patients attending our Anticoagulation clinic that started dabigatran, after its release in our country in September 2012, were included. Before starting the treatment renal and liver function and hemoglobin and platelets count were assessed and all patients completed an educational course on anticoagulant treatment.

Results: 290 patients on dabigatran were followed for mean 91 ± 58 days, 136 were aged >75 (80.1 ± 3.9) years and 154 < 75 (64.8 ± 8.6) years. The older group had higher $CHADS_2$ (2.7 ± 1.1 vs. 1.5 ± 1.1, $P < 0.001$) and HASBLED scores (1.3 ± 0.5 vs. 0.8 ± 0.7, $P < 0.001$). Majority of the elderly patients (93%) received 110 mg bid dose (D110), while the majority of the younger patients (75%) received 150 mg bid dose (D150).

There was no major bleeding in the older group. In the younger group two patients suffered major gastrointestinal bleeding, both on D150, and treatment was discontinued. There were 19 (14.0%) minor bleeding in the older and 26 (16.9%) in the younger group (RR = 0.83; 95% CI 0.48–1.43; $P = 0.59$), predominantly epistaxis, subconjunctival, gum bleeding, bruises and minor haematochezia, gynecological and urological bleeding. Only in nine cases of minor bleeding treatment was interrupted for a few days. There was no statistically significant difference in age, $CHADS_2$ or HASBLED score between patients that experienced minor bleeding and those that had no bleeding events, neither in the older, nor in the younger group. Due to gastrointestinal side effects treatment was discontinued in 10 patients (3.5%), in seven patients in the older (all on D110) and in three patients in the younger group (all on D150). None of the patients suffered a thromboembolic event.

Conclusion: In our population of patients older than 75 years, treatment with dabigatran was safe and effective using lower dose of dabigatran in majority of the old population.

PB 4.46-4

Assessment of apixaban on automated analyzers using a Liquid Anti-Xa assay

Cao Z, Kung C, Bottenus R and Triscott M

Instrumentation Laboratory, Orangeburg, New York, NY, USA

Background: Apixaban (ELIQUIS) is a direct factor Xa inhibitor anticoagulant indicated to prevent venous thromboembolism after elective hip or knee replacement and to reduce the risk of stroke and systemic embolism with nonvalvular atrial fibrillation. Although apixaban does not require regular monitoring, its assessment in certain situations is helpful.

Aims: HemosIL Liquid Anti-Xa assay (Instrumentation Laboratory, Bedford, MA, USA) is an automated chromogenic assay intended for the quantitative determination of unfractionated heparin (UFH) and low molecular weight heparin (LMWH) in human citrated plasma on IL Coagulation Systems. Here, we report its performance on ACL TOP Family analyzers to measure apixaban in plasma samples.

Methods: HemosIL Apixaban calibrators and controls were used to calibrate and quality control, respectively the HemosIL Liquid Anti-Xa assay on ACL TOP analyzers. Two levels of calibrators (0 and 500 ng/mL apixaban) and two levels of controls (150 and 300 ng/mL

apixaban) were prepared with known concentrations of apixaban spiked into normal plasma. The lyophilized calibrators and controls were reconstituted with 1 mL of water. A 5-point calibration curve was created and apixaban plasma values were assessed using the stored calibration curve. A similar method can be applied to other automated analyzers.

Results: The auto-dilution mode on the ACL TOP Family analyzers with the bilevel apixaban calibrators was used to create a 5-point calibration curve (0, 100, 200, 350 and 500 ng/mL apixaban). The test's nominal linearity range of 10–500 ng/mL can be extended to 1000 ng/mL with reflex testing. After reconstitution, the controls and calibrators have on-board stability of at least 8 h, closed-vial 2–8 °C storage stability of 10 days, and closed-vial −20 °C storage stability of at least 2 months. Precision studies showed overall CV% of 1.42, 2.07 and 2.24 for the 500 ng/mL calibrator, 150 ng/mL low control and 300 ng/mL high control, respectively. The test is interference free with bilirubin up to 25 mg/dL, hemoglobin up to 500 mg/dL and triglyceride up to 1000 mg/dL.

Summary/Conclusions: HemosIL Liquid Anti-Xa assay has been proven to be a robust assay for the detection of antithrombin-dependent anticoagulants. Here, we report its application for testing of the direct factor Xa inhibitor anticoagulant, apixaban. The apixaban test with HemosIL Liquid Anti-Xa can be easily implemented on ACL TOP analyzers. The test has good sensitivity in the low range to verify clearance of apixaban prior to surgery, as well as sensitivity in the clinical range and high range. The test has satisfactory calibrator/control stability, good sample precision, and minimum interference from pre-analytical variables.

PB 4.46-5

The influence of novel oral anticoagulants (NOAC) on routine coagulation assays

Byrne MB, Doyle M, White B, Ryan K, O'Donnell J and O'Connell N

St James's Hospital, Dublin, Ireland

Background: Novel oral anticoagulants licensed for use in Europe include the direct thrombin inhibitors (DTI) Dabigatran (Pradaxa®) and Argatroban (Argatra®, Arganova® or Novostan®) and the factor Xa inhibitor, Rivaroxaban (Xarelto®). These drugs are increasingly being prescribed as an alternative anticoagulant to Warfarin or Heparin. Evaluation of the effects of these anticoagulants on local coagulation assays is recommended.

Aims: The aim of this project was to assess the effect of the novel anticoagulants on routine coagulation assays including the Prothrombin Time (PT), Activated Partial Thromboplastin Time (APTT), Thrombin Time (TT) and the Fibrinogen assay.

Method: A series of reference plasmas were prepared with increasing doses of the relevant anticoagulant. The direct thrombin inhibitor plasma concentrations were assayed by a dilute thrombin time (Hemoclot Thrombin-Inhibitor assay, Hyphen BioMed). The Rivaroxaban® plasma concentrations were measured using an anti-Xa assay (HemosIL Test^{a} Heparin, Instrumentation Laboratory) with calibrators from Hyphen BioMed. The PT and APTT were measured using HemosIL® RecombiPlasTin 2G and SynthASil respectively, the TT using an in-house dilution of DIAGEN Bovine Thrombin and Fibrinogen by the Clauss method using two reagents, HemosIL® Fibrinogen-C and TriniCLOT[TRADEMARK] Fibrinogen. Plasma levels of anticoagulant were correlated with the PT, APTT, TT and Fibrinogen level.

Results: The Thrombin Time proved most sensitive to the DTIs showing prolongation above the reportable range of 60secs at 0.03 μg/mL Dabigatran and 0.27 μg/mL. Argatroban. However, the rapid prolongation of the TT means that while a normal TT indicates very low levels of DTI, a prolonged TT does not give an indication of drug concentrations. The PT and APTT showed a dose dependent increase for the DTIs ($R^2 > 0.98$) with the APTT effect being more pronounced. The most notable effect of the DTIs on routine assays was on the Fibrinogen assay using the HemosIL® Fibrinogen-C reagent. A decrease in measured Fibrinogen levels occurred with increasing concentration of both Argatroban and Dabigatran. This decrease was less apparent with TriniCLOT[TRADEMARK] reagent which has a higher thrombin concentration of approximately 75 NIH U/mL vs. 35 NIH U/mL for the HemosIL® Fibrinogen-C reagent. The reagent discrepancy for measured fibrinogen increased with increasing concentrations of DTI. The PT and APTT showed a dose dependant increase for Rivaroxaban and again the APTT effect was more pronounced.

Conclusion: Argatroban, Dabigatran and Rivaroxaban cause prolongation of the PT and APTT. Argatrobanand Dabigatran cause marked prolongation of the TT. Clauss Fibrinogen assays may give falsely reduced measured levels in the presence of a DTI but a more accurate estimation of Fibrinogen concentration is obtained if the concentration of thrombin is increased. The effect of the novel anticoagulants on routine coagulation assays may be difficult to interpret in the acutely ill or bleeding patient who may have concomitant dilutional or consumptive coagulopathy. In these situations, a specific assay is recommended for analysis of plasma drug concentrations but knowledge of the effects of the novel anticoagulants on local coagulation assays is also useful for clinicians.

PB 4.46-6

Moderate-intensity warfarin therapy in extended treatment of venous thromboembolic disease improve patient comfort, decreasing bleeding risk without increasing risk of relapse: a matched-paired study

Casals Sole FJ

Hospital Clinic, Barcelona, Spain

Background: Extended anticoagulant treatment is recommended for patients with venous thromboembolic disease (VTD) and cancer activity or a proximal non-provoked deep venous thrombosis with low bleeding risk. Low-intensity warfarin therapy (INR target range between 1.5 and 2) has been used for this situation; however a significant number of relapses occurred.

Aims: We suggest treating these patients with moderate-intensity of Vitamin-K antagonists (VKA) (INR target range 1.8–2.5).

Methods: All patients were followed in one Centre. Consecutive patients with VTD intended to be in extended anticoagulant treatment, taking VKA for more than 3 months in standard regimen (INR range 2–3) were switched to a new control range (INR range 1.8–2.5) after patient's consent. Intervals for INR testing were programmed following a previously designed algorithm. Time in Therapeutic Range (TTR) was computed by Rosendaal method. Annual Risk of Intracerebral Haemorrhage (ARICH) was computed by weighting each INR value-day for adjusted annually incidence of intracerebral haemorrhage reported by Hylek (2003) in warfarin treated patients. Paired-*t* test for small samples and Wilcoxon signed rank tests were used to evaluate differences. Discriminant and data analyses were performed using STATA12 statistical software.

Results: Starting in September 2003 this study was conducted to October 2012. In this period 22 patients were recruited mean age 64.6 ± 18.9 years (59% of men), treated previously with VKA at INR 2–3 therapeutic range for a median of 1.02 years, and then were treated for a median of 2.04 years with VKA at the new therapeutic range. No recurrences appear in a follow-up of 78.1 patients-years, two major bleeding episodes (one post-traumatism) were found, two patients died for an unrelated VTD episode. A significant reduction in therapeutic cost was attained (from 78–113 €/month to 52–63 €/months) consequence of reduction in monitoring frequency (from 17.9 to 12.8 of median tests/year, $P < 0.001$). From 1591 INR measurements, median INR value's was significantly decreased in patients treated with the proposed regimen (INR 2.42–2.27 $P < 0.005$). No statistically differences between both series were found in TTR (67.2 ± 11.2% in the INR standard range and 62.7 ± 15.4% in the new range), nor in

Percentage of Time Elapsed (PTE) at INR <1.5, but a significant difference is found between both series in PTE at INR >3.0, but this significance disappear when INR >3.5 was analyzed. The TTR computed between the INR extended to 1.8 and 3.2, was 83.06% and 89.45 for each series respectively. ARICH (0.4%) was significantly reduced with the proposed regimen ($P = 0.04$). But despite using this therapeutic regimen we identified 13.6% of unstable or/and unacceptable treatments, predisposing these patients to a bleeding and/or thrombotic risk and making them candidates to stop therapy or to switch to the news orals anticoagulants.
Conclusion: With moderate-intensity VKA treatments there are significant tendencies to ameliorate patient comfort, decreasing INR monitoring frequency and costs, without increasing adverse effects, supporting safety to reduce the lower INR limit to 1.8. But a more extensive study would avoid a type II error.

PB 4.47-1

The effect of venous thromboembolism treatment patterns and clinical outcomes in a real world population: the Q-VTE study cohort

Tagalakis V, Patenaude V, Kahn SR and Suissa S
Lady Davis Institute for Medical Research/Jewish General Hospital, Montreal, Canada

Background: Few studies have assessed treatment patterns of acute venous thromboembolism (VTE) and their effect on clinical outcomes in a real world population.
Aim: We aimed to identify determinants of anticoagulant treatment patterns for acute VTE, and the effects of these patterns on VTE death, recurrence, and bleeding in a real world setting.
Methods: We used the linked administrative healthcare databases of the province of Québec, Canada, including the hospitalization, universal healthcare services, out-patient prescription, and vital statistics databases. We identified all beneficiaries with an incident DVT or PE between 2000 and 2009 using diagnostic algorithms based on ICD-9-CM or ICD-10-CA diagnosis codes. Subjects who were not eligible for drug insurance coverage at the time of diagnosis were excluded. Subjects were followed until VTE recurrence, death, major bleeding, or end of study (December 31, 2009). Anticoagulant use was characterized by anticoagulant type and duration of treatment. Hazards ratio models were used to estimate the effect of treatment patterns as a function of patient characteristics, and to determine their effect on clinical outcomes.
Results: Among the 40,776 cases with VTE, 29,598 cases (73%) were dispensed a prescription for an anticoagulant, and most ($n = 26,247$; 89%) received a vitamin K antagonist (VKA). In all, 58% of cases discontinued VKA within 90 days of initiating warfarin. In a multivariable analysis, predictors of VKA initiation over time included a diagnosis of PE (Hazard Ratio (HR) 1.62, 95% Confidence Interval (CI) 1.58–1.66), older age groups, and patients hospitalized for VTE. Predictors of VKA discontinuation included a diagnosis of DVT (HR 1.18, 95% CI 1.15–1.22), younger age groups, and out-patient diagnosis and management of VTE. Short-term (<30 days) and long-term (>30 days) VKA use were associated with improved mortality compared to no VKA use (Rate Ratio (RR) 0.63, 95% CI 0.60–0.68 and RR 0.59, 95% CI 0.59–0.67; respectively). The mortality benefit was no longer observed following VKA discontinuation and there was excess mortality 15–70 days after discontinuation in the short-term (RR 1.26, 95% CI 1.15–1.37) and long-term (RR 1.53, 95% CI 1.36–1.73) users. Compared to no VKA use, short-term and long-term use were associated with a decreased recurrence rate (RR 0.71; 95% CI 0.62–0.82 and RR 0.60; 95% CI 0.50–0.71; respectively). The rate of recurrence increased after 15 days of discontinuation and at 1 year remained elevated in short-term (RR 2.10; 95% CI 1.64–2.68) and long-term (RR 2.49; 95% CI 1.87–3.33) users. The rate of major bleeding was increased with short-term (RR 1.34, 95% CI 1.22–1.48) and long-term VKA use (RR 1.50, 95% CI 1.36–1.66) and remained elevated until 70 days following discontinuation.
Conclusions: Our study provides useful information regarding predictors of treatment patterns for VTE in a real world setting. Moreover, irrespective of duration, anticoagulation therapy with VKA is associated with improved mortality, a decreased risk of recurrence, and an increased risk of major bleeding, and that following discontinuation, the mortality benefit is no longer seen, the rate of recurrence is significantly higher, and the risk of bleeding may persist.

PB 4.47-2

Alterations induced by Rivaroxaban on hemostasis can be reversed by different coagulation factor concentrates: *in vitro* experimental studies with steady and circulating human blood

Arellano-Rodrigo E[1], Galan AM[2], Sanz V[2], Molina P[2], Reverter JC[2], Tassies D[2], Díaz-Ricart M[2] and Escolar G[2]
[1]*Hospital Clinic;* [2]*Hospital Clinic, IDIBAPS, Barcelona, Spain*

Background: Rivaroxaban is a new oral anticoagulant with inhibitory action on FXa with a good efficacy and safety profile, but with no specific antidotes that could rapidly reverse its prohemorrhagic potential.
Aims: We explored the effects of rivaroxaban on hemostasis with special emphasis on possible interferences with platelet and coagulation mechanisms under flow conditions. We also investigated the potential action of different factor concentrates at reversing the antihemostatic action of rivaroxaban.
Methods: Concentrations of rivaroxaban equivalent to the Cmax reported at steady state after 20 mg rivaroxaban (230 ng/mL) were added *in vitro* to blood alliquots from healthy donors. A series of laboratory approaches were applied to explore modifications in hemostastic mechanism using technologies implying steady and flow conditions. Modifications in platelet reactivity towards surfaces were measured at elevated shear rates in a cone and plate analyzer (Impact R®). Effects on thrombin generation (TG) and on thromboelastometry parameters (TEM) were assessed. Modifications in platelet adhesive, aggregating and procoagulant activities were evaluated in studies with flowing blood maintained at a shear rate of 600-1. The potential reversal action of rFVIIa at final concentrations in blood equivalent to 270 μg/kg, activated prothrombin complex concentrates (aPCCs) at 75 IU/kg or non activated prothrombin complexes (PCCs) at 50 IU/kg, were assessed.
Results: Rivaroxaban did not affect the reactivity of platelets to a polymeric surface in the Impact R®. Rivaroxaban altered TG parameters as confirmed by a prolongation in the lag-phase and a reduction in the maximal thrombin peak. The previous alterations were significantly improved by rFVIIa, aPCCs and PCCs. The intensity of the effects of rivaroxaban and the efficacy of the concentrates to improve TG were highly dependent on the composition of the reagents used to trigger TG. Rivaroxaban prolonged clotting time (CT), clot formation time (CFT) and reduced maximal clot firmness (MCF) in TEM studies. Alterations in these parameters were corrected and occasionally overcompensated (MCF) by rFVIIa and aPCCs. Rivaroxaban quantitatively reduced platelet and fibrin interactions ($P < 0.05$ and $P < 0.01$, respectively) with damaged vascular surfaces in studies with flowing blood. These alterations were counteracted by the different concentrates, with platelet interactions showing a more pronounced correction with rFVIIa and aPCCs, and fibrin formation being variably compensated with efficacies following this quantitative order rFVIIa>aPCC>PCCs.
Conclusions: Rivaroxaban at 230 ng/mL added to blood from healthy volunteers caused evident alterations in hemostasis parameters related to its recognized anticoagulant action. Alterations in hemostasis induced by rivaroxaban were variably compensated or even reversed by the different factor concentrates. Studies with flowing blood under

conditions that more closely relate to the bleeding situation reveal that relatively high doses of rFVIIa, aPCCs or PCCs could be useful in the restoration of hemostasis in patients subjected to treatment with this new oral anticoagulant. Further studies should help establishing doses of these concentrates that can effectively and safely restore the alterations on hemostasis in to the different clinical settings. Grants: EC10-070, SAF2009-10365, SAF2011-28214, RedHERACLES RD06/0009/1003, FIS(CP04-00112, PS09/00664).

PB 4.47-3

Adherence to anticoagulant treatment with dabigatran in a real-world setting

Schulman S[1], Shortt B[2], Robinson M[1] and Eikelboom JW[1]
[1]*McMaster University, Hamilton;* [2]*University of Waterloo, Mississauga, Canada*

Background: In clinical trials the adherence to prescribed regimen with dabigatran was enhanced by frequent follow-up visits and pill counts. There is concern that in clinical practice without laboratory monitoring or pill counts the adherence to a twice-daily regimen will be reduced and the risk of thromboembolic events is thereby higher than in the trials.

Aims and Methods: In a cross-sectional cohort study we interviewed During July–September 2012 all patients who had been started on dabigatran by us or referred to our clinic, had remained on treatment for at least 3 months and are followed by our anticoagulant clinic. As part of routine clinical care all patients receive an initial teaching session, explaining the rationale for anticoagulation and careful instructions regarding the treatment. After a visit at 3 months we only see the patients every 12 months. We obtained information on the number of capsules of dabigatran dispensed by the pharmacy of each patient covering the entire treatment period, not including RE-LY and RELY-ABLE participation time. Adherence was calculated as daily doses dispensed divided by number of days between first and last refill minus days off dabigatran for invasive procedures or hospitalization, and was expressed as percent. In addition, information on bleeding, thromboembolic events and other adverse events, specifically dyspepsia, was captured from the interviews and medical records.

Results: We interviewed 103 patients and could not reach another four patients by telephone. Seventeen patients had participated in the RE-LY and RELY-ABLE trials and had been treated with dabigatran for a total of 62.8 (±15.6) months, of which 14.4 (±2.0) months after conclusion of those studies, and 86 patients were study-naïve with treatment for 13.0 (±5.5) months. The mean age was 75.5 (±8.5) years, 45% were females, and mean CHADS2 score was 2.5. Dispensation data was obtained for 99 patients and adherence was 99.7% (median; interquartile range 94.6% to 100%) with 10 patients showing <80% adherence. On the interview 40 patients (39%) acknowledged that they sometimes had missed taking the medication, ranging from 'twice in 6 years' to 'every day'. Eighteen patients (17%) reported bleeding complications, four of which required hospitalization; one patient had an ischemic stroke and 28 (27%) reported some degree of dyspepsia. There were no significant differences in the results between study-experienced and study-naïve patients.

Conclusion: In our clinical practice, adherence to the twice-daily dabigatran regimen was generally good, although 10% of the patients had a low adherence of <80%. Routine feedback from the pharmacies could inform the physician to improve the anticoagulant management. A limitation of our study is that we cannot validate that the patients actually ingested the capsules.

PB 4.47-4

Thrombelastometry monitoring of the anticoagulant effect of dabigatran etexilate

Stancheva AG
University Hospital Lozenetz, Sofia, Bulgaria

Introduction: Dabigatran etexilate is an oral, reversible, competitive direct thrombin inhibitor, affecting both thrombin generation and activity. While coagulation monitoring is not required with dabigatran etexilate in routine clinical practice, effects on various coagulation assays have been studied. Thrombin clotting time (TT), ecarin clotting time (ECT), TT determined by Hemocloth® thrombin inhibitor assay and plasma diluted thrombin time (PDTT) have been used to evaluate the anticoagulant effects of dabigatran. Lack of readily available method to determine the degree of dabigatran induced anticoagulation activity creates a major challenge.

Aim: Thrombelastometry assess and interpretation of the anticoagulant effects of direct thrombin inhibitor on patients undergoing dabigatran therapy.

Methods: The study includes 35 patients receiving dabigatran (110 mg twice daily), five of them undergoing elective hip replacement surgery and 26 patients with atrial fibrillation. Rotation Thrombelastometry analyses were performed on ROTEM® analyzer (Pentapharm GmbH, Munich, Germany) in citrated blood, based on reagent activation of the haemostatic processes with thromboplastin tissue factor (TF) for EXTEM test, and aprotinin for APTEM test. STA Compact (Diagnostica Stago-Roche) was used to determine TT. The assays were performed before starting dabigatran therapy, on the first and on the seventh day after the beginning of the therapy. Two patients passed sight bleeding esophageal incidents during this period. The same ROTEM® parameters were also assayed in citrated blood assays with consecutive increasing plasma concentrations of dabigatran.

Results: ROTEM® parameters EXTEM/CT (x = 160s ± 25s; ref. r. 38–79s) и INTEM/CT (x = 310s ±42s; ref. r. 100–240s) are significantly increased in patients with fixed therapeutic doses of dabigatran. These parameters express high linearity in consecutively increasing dabigatran plasma concentration (from 15 mkg/mL to 44 mkg/mL). The rest ROTEM® parameters providing information for clot formation function (EXTEM/CFT and INTEM/CFT), fibrin polymerization (FIBTEM), firmness of the clot (EXTEM/MCF and INTEM/MCF) and clot elasticity (MCE) remain in reference ranges and show no significant changes in consecutively increasing dabigatran plasma concentrations. The two patients with clinical manifestation of dabigatran overdoses expressed very high values of EXTEM/CT (230s; ref.r.38–79s) и INTEM/CT (448s ref.r. 100–240s).

Conclusion: Our investigations suggest that Rotation thrombelastomethry (ROTEM®)could be used as a possible method for monitoring the anticoagulant effect of dabigatran therapy .

PB 4.47-5

Large inter-individual variability of the response to new oral anticoagulants

Bloemen S[1], De Laat M[1], Ninivaggi M[1], Lenderink T[2], Leers MPG[2], De Laat B[1], Hemker CH[1] and Al Dieri R[1]
[1]*CARIM, Maastricht University, Maastricht;* [2]*Atrium Medical Centre, Heerlen, The Netherlands*

Background: New, direct inhibitors of thrombin and factor Xa (FXa) show more stable pharmacokinetics than vitamin K antagonists do. Before the conclusion can be drawn that this warrants standard dose treatment it should be ascertained that the pharmacodynamic characteristics of the agents are predictable as well.

Aims: To investigate the response of the plasma from healthy subjects and patients with atrial fibrillation (AF) to a fixed dose of conventional and new anticoagulants.

Methods: Thrombin generation (TG) was determined by calibrated automated thrombinography (CAT).
Platelet poor plasma (PPP) of 44 healthy subjects was spiked with otamixaban (direct FXa inhibitor), melagatran (direct thrombin inhibitor), unfractionated heparin, dermatan sulfate and pentasaccharide at concentrations around IC50. Thrombin generation was measured at 5 pM tissue factor and 4 μM phospholipids. The effect on TG of rivaroxaban (direct FXa inhibitor) in five patients with AF was assessed in whole blood, platelet rich plasma (PRP) and PPP before therapy and in the 1st and 2nd week of therapy, 3 h after ingestion of the drug.
Results: In the PPP of 44 healthy subjects the coefficients of variation (CV's) were 18% for the uninhibited endogenous thrombin potential (ETP) and 16% for the uninhibited peak height. A dose-dependent inhibition of all anticoagulants was observed in both ETP and peak height. The concentration of anticoagulant that inhibited ETP and peak around 50% was added to the individual plasmas. After inhibition the variation increased to 20–24% (ETP) and 24–43% (peak) for conventional and modern anticoagulants alike.
In the patients, both after 1 and 2 weeks of therapy, the ETP in PPP, PRP and whole blood decreased to a highly variable extent. The least variation was seen in PPP. The individual values of the response to rivaroxaban of the ETP were (1st week [%]/2nd week [%]): 21.9/29.3; 33.4/38.9; 9.1/11.3; 50.4/40.8 and 34.6/0.5. The values are to disparate and the number of patients too small to draw any quantitative conclusion, but it is obvious that the inter-individual variation is enormous. The differences in inhibition between the first and the second week in the same individual appear more similar than the inter-individual differences, which suggests that there may exist high and low responders.
Conclusions: This study indicates that the new anticoagulants cause quantitative changes in thrombin generation, that are as variable as those brought about by administration of vitamin K antagonists or by heparin treatment. The first results in patients suggest that, before relying on the effect of a fixed dose, the dose response in a patient should be determined.

PB 4.47-6

A single-centre prospective study on fluctuations in INR control for Singapore's Muslim patients on oral anticoagulation therapy with stable dosing over the months of Ramadan and Hari Raya Aidilfitri

Lai YF, McCheen HH, Lim SH, Yeo HIF, Nah SC, Kong MC, Mya HTD, Lee LH and Ng HJ
Singapore General Hospital, Singapore, Singapore

Background: Oral Vitamin K Antagonist (OVKA) is known to have its anticoagulant effects augmented by changes in dietary vitamin K intake and lifestyles. During the Muslim fasting month of Ramadan, where dietary habits and lifestyles are altered, such effects may surface.
Aims: To detect and study INR deviations and percentage time within therapeutic range (%TTR) before, during and after Ramadan in stable warfarinized patients, whom otherwise have steady INR control.
Methods: Potential study subjects were screened from hospital anticoagulation clinic (ACC) database, and pharmacy's warfarin dispensing records. Only stable warfarinized patients who met the inclusion criteria were shortlisted and contacted for recruitment. All recruited patients underwent weekly INR monitoring, with four readings per subject per month, using Coaguchek XS Point-of-care coagulometer throughout a 3-month study period from a month before Ramadan to a month after it. The warfarin doses for these patients were kept constant, and they were instructed to keep to their usual religious practices, eating habits and lifestyle as previous years. All readings were blinded to the subjects until the end of the study to minimize confounding factors.
Results: In the intention-to-treat analysis population (n = 32), the mean difference in INR during the Pre-Ramadan month and the Ramadan month was significant at 0.207 [P = 0.032, 95% CI 0.013–0.401]. In contrast, a greater mean difference in INR of −0.309 [P = 0.001, 95% CI −0.506-(−0.112)] was observed between the Ramadan and the Post-Ramadan months. No significant changes in INR were detected between the non-Ramadan months [P = 0.629, 95% CI 0.93-(−0.298)], thereby suggesting that these increases in INR during Ramadan could be attributed to fasting. In the per-protocol analysis population (n = 30), where study drop-outs and confounding results were excluded to increase sensitivity, the difference in INR between the Pre-Ramadan and Ramadan periods was 0.228 [P = 0.002, 95% CI 0.86–0.369]; and −0.256 [P = 0.002, −0.399] for Ramadan and post-Ramadan periods. Mean difference across non-Ramadan months was insignificant [P = 0.692, 95% CI −1.172–0.114]. These show that the INR readings had increased significantly during the fasting month in line with our postulation that a reduced vitamin K intake and changes in lifestyle could lead to an increase in INR. The percentage time within therapeutic range (TTR) also showed a dip to 69.56% compared to 80.99% before Ramadan and 70.80% after Ramadan. The secondary outcome of the study focused on the time taken to return to baseline INR after a fluctuation is observed during the Ramadan period. From the Kaplan-Meier survival analysis, on average, the first out-of-range INR can be seen 12.1 days [95% CI 9.0–15.1] after the start of fasting. Subsequently, an average of 10.8 days [95% CI 7.9–13.7] is required for the INR to return back to its therapeutic range after Ramadan ends.
Conclusion: The results of this study suggests possibility of significant INR fluctuation during Ramadan fasting. Additional caution or even pre-emptive dose reduction may be warranted especially for patients maintained at higher end of their target ranges, or for patients prescribed with narrower target ranges.

PB 4.48-1

Aptamer based thrombin inhibitors: efficacy and functional stability *in vitro*

Gribkova I[1], Spiridonova V[2], Gorbatenko A[1] and Sinauridze E[1]
[1]National Research Center for Hematology, Ministry of Health, Moscow; [2]Belozersky Institute of Physico-Chemical Biology at Lomonosov Moscow State Unive, Moscow, Russian Federation

Background: Thromboembolic diseases are a major cause of human mortality worldwide. Any strategy of anticoagulant therapy is essentially aimed at neutralizing excess thrombin production. A new approach in this field is development of enzyme inhibitors on the basis of single- or two-stranded DNA or RNA fragments (aptamers). The advantage of such type of inhibitor is possibility to create antidotes to them. Thrombin was the first protease to which an inhibitory aptamer (15TBA) was produced. Subsequent research with computer modeling provided a basis for engineering other aptamers (31TBA etc.). However the life span of these inhibitors in circulation *in vivo* was limited by a few minutes. It was assumed that the reason for such effect was destructive action of 3'-exonuclease.
Aims: Investigation *in vitro* of anticoagulant properties by a new global coagulation test of thrombodynamics and measurement of functional stability in human blood of two single-stranded DNA thrombin-inhibiting aptamers (15TBA and 31TBA).
Methods: Anticoagulant activity of 15TBA (5'-GGTTGGTGTGGTTGG-3') and 31TBA (5'-CACTGGTAGGTTGGTGTGGTTGGGGCCAGTG-3') was investigated by a new coagulation test of thrombodynamics, measuring the spatial clot growth rate in nonstirred plasma. The functional stability of aptamers during incubation in human blood was investigated *in vitro* by measuring APTT. Samples for analysis of coagulation were withdrawn after 1 h, 2 h, 3 h, 4 h of incubation.
Results: Both aptamers reduced the spatial clot growth rate (IC_{50} for clot growth rate decreasing are 9.5 мМ and 4.0 мМ for 15TBA and

31TBA, correspondingly). Thrombin-inhibiting aptamersretained their anticoagulant activity during incubation in human whole blood *in vitro* for at least 4 h.
Conclusions: Thrombodynamic test perfectly monitors anticoagulant conditions in human plasma. It was shown that 15TBA and 31TBA decrease clot growth rate, with 31TBA being a more active anticoagulant. The anticoagulant activity of both aptamers was stable in human whole blood *in vitro* for hours. So, the 3'-exonuclease could not be the reason for fast decrease of aptamers' functional activity *in vivo*. The main role in the removal of oligonucleotides from the circulation is played obviously by the liver.
The work was supported by RFBR grant N11-04-01530.

PB 4.48-2
Laboratory monitoring of novel oral anticoagulants rivaroxaban and dabigatran

Eerenberg ES[1], Kamphuisen PW[2], Sijpkens MK[1], Meijers JC[3], Büller HR[1] and Levi M[1]
[1]Academic Medical Center, Amsterdam; [2]University Medical Center Groningen, Groningen; [3]Academic Medical Center Amsterdam, Amsterdam, The Netherlands

Background: Rivaroxaban and dabigatran are new oral anticoagulants that both have been licensed worldwide for the treatment of atrial fibrillation and rivaroxaban also for venous thrombosis. Both drugs specifically inhibit one coagulation factor, factor Xa and thrombin, respectively, and both compounds have stable pharmacologic profiles, making regular monitoring as rewuired for Vitamin K antagonists unnecessary. However, in specific circumstances, such as in renal insufficiency, patients using these anticoagulant drugs may need laboratory monitoring and perhaps dose adjustments.
Aims : The aim of this study was to assess a proper monitoring method for both drugs.
Methods and Results: Samples were used from a cross-over study in healthy volunteers, originally designed to find a method of reversal for both anticoagulants (Eerenberg et al, Circulation, 2011). Twelve healthy male volunteers received rivaroxaban 20 mg twice daily, and dabigatran 150 mg twice daily for two and a half days, with a washout period of 11 days. Blood was drawn at the end of each treatment period. Following rivaroxaban treatment, the median plasma concentration was 273 μg/L, with an almost three fold difference in the interquartile range (158–393). Rivaroxaban significantly prolonged the anti-FXa assay and prothrombin time (PT), and both assays showed the best correlation with plasma concentrations (rho 0.63 for the anti-FXa assay and 0.47 for the PT). Dabigatran administration led to a median plasma concentration of 88 μg/L, with also a nearly three fold variability in the interquartile range (54–133). Dabigatran increased the activated partial thromboplastin time (aPTT), the Hemoclot and ecarin clotting time (ECT) significantly, and all assays correlated well with plasma concentrations (rho 0.99, 0.99 and 0.97, respectively).
Conclusions: Plasma concentrations of rivaroxaban and dabigatran in healthy volunteers show considerable variability. Coagulation assays that corresponded well with plasma concentrations are the anti-FXa and PT for rivaroxaban, and the aPTT, Hemoclot and ECT for dabigatran.

PB 4.48-3
Thrombin generation assay to monitor the reversal of anticoagulants by FEIBA

Turecek PL, Schrenk G, Schaedler M, Peyrer-Heimstaett S, Rottensteiner H and Scheiflinger F
Baxter Innovations GmbH, Vienna, Austria

Background: Rivaroxaban and dabigatran, direct inhibitors of factor Xa and factor IIa (thrombin) respectively, are new oral anticoagulants (NOACs) used in a large number of patients to prevent thromboembolic disease following orthopedic surgery and non-valvular atrial fibrillation. In the event of a major bleed, however, there is no specific way to reverse their anticoagulant effect.
Aims: The objective of the study was to evaluate and compare the effect of rivaroxaban and dabigatran on the thrombin generation (TG) potential of human normal plasma and to determine the potential of FEIBA, a marketed and clinically used activated prothrombin complex concentrate, to reverse the anticoagulant effect of these NOACs.
Methods: The effect of rivaroxaban and dabigatran on the TG of human normal plasma was assessed using the Technothrombin TG assay. TG was triggered by a tissue factor reagent containing a low concentration of phospholipid micelles. Plasma was spiked with up to 1900 ng/mL of NOACs and TG determined with or without addition of a concentration series of FEIBA. Prothromplex total, a marketed and clinically used 4-factor PCC (prothrombin complex concentrate), and Prothromplex, a marketed and clinically used 3-factor PCC, served as active control items.
Results: Both rivaroxaban and dabigatran inhibited TG in a concentration-dependent manner. In contrast to dabigatran which mainly delayed the initiation phase (lag time), rivaroxaban inhibited TG with respect to lag time and peak thrombin level even at low concentrations. FEIBA corrected the impaired TG parameters induced by both NOACs to the level of normal human plasma. 0.5 U/mL FEIBA completely restored TG of plasma spiked with 60 ng/mL rivaroxaban, and had a similar effect on dabigatran. The potential to reverse the anticoagulant effect of NOACs *in vitro* was less pronounced for Prothromplex and nonexistent for Prothromplex total. This lack of efficacy turned out to be associated with the presence of heparin in the formulation buffer of these drugs. While FEIBA showed a concentration-dependent increase of TG in human normal plasma, Prothromplex had no effect and Prothromplex total even had an anticoagulant effect on TG. Neutralization of heparin in Prothromplex total increased TG to a level similar to that obtained with FEIBA when added to human normal plasma.
Summary/Conclusions: Thrombin generation assay was demonstrated to be suitable for monitoring the effect of NOACs and determining the potential of FEIBA as a reversal agent. The mechanisms of rivaroxaban and dabigatran to inhibit TG in human normal plasma were shown to differ. Nonetheless, FEIBA effectively corrected the anticoagulant effect of each NOAC. By contrast, other coagulation factor complex concentrates containing heparin were not effective, and in case of Prothromplex total, even showed an anticoagulant effect.

PB 4.48-4
Small-molecule thrombin inhibitors based on derivatives of N-arylbenzamidines

Alekseeva P, Fedorova E and Kuvaeva E
Saint-Petersburg State Chemical Pharmaceutical Academy, Saint Petersburg, Russian Federation

Thrombin is an enzyme which belongs to the class of hydrolases from the group of serine proteases catalyzing the conversion of fibrinogen to fibrin in blood clotting. Searching for substances that can control the process of blood coagulation, particularly, by means of inhibition of thrombin is one of the main areas of medicinal chemistry.

At present argatroban is the only synthetic direct inhibitor of thrombin, used for intravenous introduction. Another medicine is dabigatran etexilate, a low molecular weight prodrug, which has been recently approved by the US Food and Drug Administration (FDA) for oral use. Thus, the development of new direct thrombin inhibitors is an urgent task.

In the present work on developing an oral drug with anticoagulant activity a molecular design of a series of *N*-arylbenzamidines containing strongly basic amidine functional group in their structure was conducted. Such groups are typical for many serine protease inhibitors.

Virtual screening was performed using the original docking program FlexX that enables docking of a low molecular weight organic compounds and calculating the energy of inhibitor-enzyme interaction.

The crystal structure of thrombin was used as a target for screening and docking (PDB code 1O2G; http://www.rcsb.org/pdb). Virtual screening was performed using our own library of ligands. The criteria for selection of potential thrombin inhibitors were the highest value scoring function (predicted binding energy, kcal/mol).

After computer simulation several compounds were selected for further chemical synthesis and experimental verification of their activity. Among the selected compounds *N*-phenylbenzamidine (**I**) and *N*-4-nitro-phenylbenzamidine (**II**) demonstrated similar values of binding energy.

However, despite the similarity of compounds' **I** and **II** chemical structure, the conformation and location of these compounds regarding the active site of the enzyme differed significantly.

Compound **II** showed a similar interaction with the active site of the enzyme due to binding to the hydrophobic side chains of residues Trp 60A, Trp 60D, and also forms hydrogen binding with Gly 216 of thrombin active center. In contrast, the interaction diagram of compound **I** with the enzyme did not contain all of the interactions for the known inhibitors. Analysis of the results allowed us to assume that compound **II**, in contrast to **I,** may demonstrate anticoagulant activity.

To confirm this, compounds **I** and **II** were synthesized and studied for potential anticoagulant activity.

The results of biological studies had demonstrated that only compound **II** exhibited anticoagulant activity. Moreover this compound is less toxic than the ligand **I**.

Thus, the virtual screening allowed the accurate identification of the anticoagulant effect of compound **II**. This effect has been manifested in increasing of the prothrombin time value among intact laboratory rats after repeated (5 days) administration of this compound.

Compound **II** exhibits anticoagulant activity in the intact animals, low toxicity (LD_{50} more than 2000 mg/kg intraperitoneal injection of laboratory mice), and is of practical interest. The patent on the structure of the corresponding potential inhibitor of coagulation is pending.

PB 4.48-5

Purification and characterization of fibrinogenolytic serine protease from Agkistrodon brevicadus venom

Byambasuren S[1] and Dashnyam P[2]

[1]Mongols Life Science Institutes; [2]Mongolian Academy of Science Institute of Botany, Ulaanbaatar, Mongolia

Complex mixtures of toxins from over 300 poisonous snakes found throughout the world have been widely used as sources for discovering drugs to dissolve blood clots and prevent strokes. Snake venoms contain a number of serine and metalloproteinases, included among these are the fibrinogenolytic serine proteanases[5]. Fibrinogenolytic enzymes act on fibrinogen, leading to defibrinogenation of blood and a consequent decrease in blood viscosity[6]. A Fibrinogenolytic serine protease was purified from the venom of *Agkistrodon brevicaduss*.

The purpose of our study was identification, purification and characterization of new fibrinogenolytic substance that can be a candidate for antithrombotic agent.

Fibrinogenolytic enzyme was purified by HPLC 3-columns procedure Blue Sepharose FF, Phenyl Sepharose HP and Source 15S column. Homogeneity, molecular weight, iso-electric focus, fibrinogenolytic activity of the purified protein was determined by 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) analysis with reducing and nonreducing condition. Modification on Bigs method was used to thrombin time determination. 0.2 mL of diluted plasma and sample were incubated for 3 min and added 1NIH thrombin and clotting time was recorded on MC1 coagulometer. Platelet-rich plasma (PRP) was prepared freshly from rabbit blood containing 3.8% sodium citrate by gentle centrifugation (100 rpm for 10 min). Platelet poor plasma (PPP) was prepared from remaining platelet solution by centrifugation. PRP was diluted to 200,000–250,000 platelets per microliter with PPP. PRP (350 μL) plus 100 μL of sample was incubated for 20–30 s in a Ap2110 'SOLAR' aggregometer and collagen (0.2%) was added to initiate platelet aggregation. The maximum aggregation response obtained from addition of inducer and working buffer instead of purified enzyme.

Two types of fibrinogenolytic enzyme (27 and 36 kDa) are contained in *Agkistrodon blomhoffii ussuriensis* venom. Purified fibrinogenolytic enzyme with 12 and 24 kDa molecular weight included in 36 kDa dimer serine protease. Fibrinogenolytic enzyme cleaved quickly β-chain and produced X-fragment. Fibrinogenolytic enzyme inhibited platelet aggregation in 25–50% induced by collagen.

The purified enzyme is postulated that the enzyme is capable of functioning in a cooperative manner to effectively remove fibrinogen and consequently to reduce the blood viscosity. Also some developments and more characterization studies need to be done with this enzyme.

PB 4.48-6

Interaction of defibrotide with dabigatran, rivaroxaban and apixaban in the whole blood, platelet rich plasma and platelet poor plasma studies

Fareed J[1], Hoppensteadt D[1], Jeske W[1], Iqbal O[1], Syed D[1], Kalodiki E[2] and Wahi R[1]

[1]Loyola University Medical Center, Maywood, IL, USA; [2]Imperial College, London, UK

Introduction: Defibrotide represents a single stranded mammalian DNA derived agent originally developed for anti-thrombotic and anti-ischemic indications. Defibrotide is currently used to treat or prevent a failure of normal blood flow (Veno-occlusive disease, VOD) in the liver of patients having had bone marrow transplants or received certain drugs such as oral estrogens and mercatopurine. Defibrotide is a polypharmocologic agent with multiple sites of actions, which include anti-inflammatory and vaso-facilitatory effects. The purpose of this investigation is to determine potential interactions of defibrotide and some of the newer oral anticoagulant drugs, such as dabigatran, apixaban and rivaroxaban.

Materials & Methods: Defibrotide (lot no. DV0601) was obtained in powder form from Gentium s.p.A (Villa Guardia, Italy). The active form of dabigatran was purchased from Selleckcham (Houston, TX). Apixaban and rivaroxaban were obtained commercially and were of synthetic origin. The effect of defibrotide and the new oral anticoagulant drugs, such as dabigatran, apixaban and rivaroxaban, on agonists (epinephrine, ADP, collagen, arachidonic acid and 2.5 U thrombin) was measured using platelet aggregation technique. The platelet rich plasma collected from normal healthy donors (n = 15) were also supplemented with each of the individual anticoagulant drugs, alone in a range of 0–1000 ng/mL and in combination with defibrotide at 100 μg/mL. Such clotting times as the PT, aPTT and Heptest and thrombin generation studies were carried out. In addition, whole blood activated clotting time (celite) studies were carried out by supplementing each of the individual oral anticoagulant agents at 1 μg/mL, alone and with defibrotide at 100 μg/mL.

Results: Neither defibrotide nor the newer anticoagulants produced any effects on the epinephrine, ADP, collagen and arachidonic acid induced aggregation of PRP ($P > 0.05$). However, dabigatran at concentrations of >62.5 ng/mL produced inhibition of thrombin induced aggregation, all of the other agents did not have any effect on thrombin. Defibrotide at a concentration 100 μg/mL did not alter the aggregation profile in anticoagulant supplemented PRP. In both the plasma and whole blood anticoagulant assays, dabigatran produced stronger anticoagulant effects (306 + 30 s) than both apixaban (145 + 12 s) and rivaroxaban(160 + 15 s). Defibrotide exhibited minimal effects (135 + 10 s). Defibrotide in combination with dabigatran produced modest augmentation of the anticoagulant responses (360 + 42 s), however, it had much weaker effects on rivaroxaban (168 + 18 s) and apixaban(152 + 14 s). All of the anticoagulants in the TGA produced varying degrees of inhibition of thrombin generation in the following order; dabigatran > rivaroxaban > apixaban. Defibrotide did not produce any effects at concentrations of 100 μg/mL. When combined with oral anticoagulants, it did not show any augmentation of rivaroxaban and apixaban; however, it enhanced dabigatrans inhibitory effects.
Conclusions: These results suggest that defibrotide itself has weak or negligible anticoagulant effects in the plasma and whole blood assays. It does not produce any inhibitory effects on platelet function, moreover, it does not have any modulatory effects on the new anticoagulant mediated platelet aggregation responses. While defibrotide does not show any interactions with apixaban and rivaroxaban, it has some effect on the anticoagulant responses of dabigatran. These studies demonstrate that unlike heparins, defibrotide exhibits minimal interactions with newer oral anticoagulant drugs.

PB4.49 – Intrinsic pathway of coagulation

PB 4.49-1

The Alzheimer's disease-related peptide beta-amyloid accelerates thrombin generation and clot formation in plasma in a factor XII-dependent manner

Zamolodchikov D[1], Renné T[2] and Strickland S[1]
[1]*Rockefeller University, New York, NY, USA;* [2]*Karolinska Institutet, Stockholm, Sweden*

Background: There is strong evidence that the beta-amyloid peptide (Aβ) plays a key role in Alzheimer's disease (AD). This disease is characterized by cerebrovascular abnormalities, and numerous vascular risk factors have been linked to AD development and progression. Epidemiological and experimental data also suggest the existence of a prothrombotic state in AD, manifested as elevated plasma levels of thrombin generation markers, increased levels of activated platelets, and improvement in memory and pathology following anticoagulant therapy. Such a hypercoagulable state could contribute to cognitive decline by causing cerebral hypoperfusion and inflammation, leading to neuronal dysfunction. Aβ, which is cleared from the brain into the circulation, may contribute to the prothrombotic state in AD by enhancing the activity of coagulation factors.
Aims: Here, we investigated whether Aβ can potentiate coagulation factor activity and promote thrombin generation and clot formation in plasma.
Methods and Results: Clot formation in human plasma, monitored by turbidity assay, was accelerated in the presence of Aβ. To determine if accelerated clotting was a result of Aβ's enhancement of one or more coagulation factors, thrombin generation in platelet rich and platelet poor plasma was monitored by calibrated automated thrombogram. Lag time to thrombin generation was decreased and thrombin peak height was increased by Aβ in a dose-dependent manner. This effect was abolished when coagulation factor XII (FXII) was inhibited and when $FXII^{-/-}$ mouse plasma was used, but not when the extrinsic coagulation pathway was blocked. Chromogenic substrate assays and Western blotting showed that Aβ can activate FXII and lead to factor XI activation, suggesting that Aβ may accelerate thrombin generation via activation of the intrinsic coagulation pathway.
Conclusion: These findings, combined with our previous results demonstrating Aβ-mediated impaired fibrinolysis, provide a possible mechanistic role for Aβ in the procoagulant state observed in AD.

PB 4.49-2

Activation of the intrinsic pathway of coagulation without kinin generation in factor XII-deficient chicken plasma

Prezoto BC[1], Lui MS[1] and Da Motta G[2]
[1]*Butantan Institute;* [2]*Federal University of São Paulo, São Paulo, Brazil*

Background: After binding to negatively charged materials *in vitro*, mammalian activated factor XII (FXIIa) triggers both the intrinsic pathway of coagulation and plasma kallikrein-kinin system (KKS), respectively through its natural substrates factor XI (FXI) and plasma prekallikrein (PPK). However, it is unclear how these two systems are activated *in vivo* and whether they are activated simultaneously. In mammals, high molecular weight dextran sulfate (DXS, ~500 kDa) can activate factor XII (FXII), leading to plasma kallikrein formation, and generation of bradykinin, inducing to a transient depressor response. A single gene corresponding to the predecessor of both FXI and PPK is present in chicken genome, but that corresponding to FXII is missing. The contact system activator ellagic acid-based reagent (EA) can reduce the clotting time (CT) of recalcified chicken whole blood (WB) samples despite the lack of FXII.
Aims: We investigated in chickens whether both fibrin formation and KKS can be activated by negatively charged materials *in vitro* and *in vivo*, respectively.
Methods: WB samplesfrom rats and chickens ($n = 6$ each) collected in the presence of sodium citrate (0.38%)were recalcified after pretreatment with EA (¼ of the dose used in aPTT assay)and theCT measured by rotational thrombelastometry (final volume 340 μL). Possible activation of the KKS was tested by measuring mean arterial pressure (MAP) changes after i.v. injection of DXS (150 μg/kg) into the jugular veins of anesthetized, non-heparinized, rats and chickens ($n = 6$ each) (sodium pentobarbital, 60 mg/kg, i.p., and 100 mg/kg, i.m., respectively). The responses to DXS injection were measured either in the presence or absence of the bradykinin-potentiating peptide Captopril (0.1 mg/kg).
Results: Exposure to EA reduced CT of chicken and rat WB samples from 1013 ± 156 to 375 ± 62 s, and from 248 ± 32 to 98 ± 07 s, respectively (mean ± SEM). The FXII inhibitor, corn trypsin inhibitor (CTI, 100 μg/mL), did not prevent the stimulation of clotting by EA in chicken WB (375 ± 62 s), although it completely blocked this effect of EA in rat WB (235 ± 29 s). However, the stimulation of clotting by EA in chicken WB was blocked by the FXI inhibitor, aprotinin (500 UI/mL) (1097 ± 187 s). Chicken WB clotting induced by the factor X activator, Russel's viper venom (10 ng/mL) (456 ± 56 s) was not inhibited in the presence of the same dose of aprotinin (472 ± 47 s). In rats DXS caused a transient fall in MAP (from 85 ± 5 to 42 ± 4 mmHg, performing 120 s to return to basal level) andduration of the hypotension was prolongedby Captopril (from 92 ± 8 to 48 ± 6 mmHg, performing316 s to return to basal level). The same dose of DXS failed to affect basal values of MAP (88 ± 9 mmHg) in chickens either in the presence or absence of Captopril.
Summary/Conclusions: Our data suggest that the chicken intrinsic pathway can be activated in the absence of FXII, leading to fibrin formation through activation of FXI, without activation of the KKS. We propose this clotting system as useful for studying regulatory molecular mechanisms for FXI and KKS activation *in vivo*.

PB 4.49-3

Inhibiting the activation of the intrinsic pathway with a FXII-targeting RNA aptamer

Woodruff BS, Layzer J and Sullenger B
Duke University, Durham, NC, USA

Background: Understanding the differences between thrombosis and hemostasis in the vascular system is critical to developing safe and effective anticoagulants, as this depends on striking the correct balance between inhibiting thrombus formation (efficacy) and reducing the risk of severe bleeding (safety). To this end, constituents of the intrinsic pathway of coagulation, namely factor XII, appear to be involved in pathological thrombus formation, but are not required for hemostasis. Exposure of the plasma protein factor XII to an anionic surface generates activated factor XII that not only triggers the intrinsic pathway of blood coagulation through the activation of factor XI, but also mediates various other vascular responses through activation of the plasma contact system. While deficiencies of factor XII are not associated with excessive bleeding, thrombosis models in animals deficient in factor XII have suggested that this protease contributes to stable clot formation. Therefore, factor XII has emerged as an attractive therapeutic target to treat or prevent pathological thrombosis formation without increasing the risk for hemorrhage.
Aims: Using an *in vitro* directed evolution and chemical biology approach, we sought to isolate a nuclease resistant RNA aptamer that binds specifically to factor XII and directly inhibits factor XII coagulant function.
Methods and Results: Utilizing convergent systematic evolution of ligands by exponential enrichment (SELEX), we first selected for an enriched pool of aptamers that bound to the plasma proteome. We then used this 'focused' pool to isolate a nuclease resistant RNA aptamer that binds to FXII and FXIIa with high affinity and specificity. This aptamer dose dependently prolongs fibrin clot formation in an aPTT, while having no effect in a PT. Biochemical assays employed to determine the method of anticoagulation found that while this aptamer does not inhibit the active site of FXIIa, it does inhibit the autoactivation of factor XII by various substances. In addition, this aptamer inhibits factor XI activation, while not affecting the ability of FXIIa to activate prekallikrein.
Conclusions: Thus, using the aptamer platform, we have characterized a potent and effective anticoagulant, which offers targeted inhibition of discrete macromolecular interactions involved in the activation of the intrinsic pathway of blood coagulation. We believe that we have isolated a powerful tool which can be utilized to further elucidate the role of FXII in hemostasis and thrombus formation, as well as identified a promising therapeutic agent that might prove to be an effective and safe means of controlling coagulation.

PB 4.49-4

Cycling induces a hypercoagulable state via contact activation

Posthuma J[1], Loeffen R[1], Van Oerle R[1], Henskens YMC[2], Ten Cate H[1], Spronk HMH[1] and Van Der Meijden PEJ[1]
[1]*Cardiovascular Research Institute Maastricht, Maastricht University Medical Cent, Maastricht;* [2]*Maastricht University Medical Center, Maastricht, The Netherlands*

Background: Although a clear association between exercise and activation of coagulation has been demonstrated, evidence is fragmented and the trigger remains unknown. Given the protease activated receptor (PAR) activation by coagulation proteases and the subsequent cellular effects such as inflammation, migration and apoptosis, haemostatic changes during exercise may contribute to the development of endofibrosis in cyclists. This pathology is characterized by intimal thickening of the iliacal artery, with reduced blood flow as a consequence.
Aim: In this proof-of-principle study the overall changes in the haemostatic and haematological profile of young (semi)-professional cyclists after long-term strenuous exercise was investigated.
Methods: Venous blood was collected from 17 male cyclists before and after 4 h of cycling (≈120 km). The coagulation system was assessed by thromboelastometry (ROTEM; NaTem), thrombin generation (TG: CAT method), FXIa concentration using a modified CAT based assay, and Thrombin-Antithrombin (TAT) levels. Platelet reactivity was measured by impedance aggregometry (Multiplate). Von Willebrand factor (vWf) levels, tissue plasminogen activator (tPA) activity, and D-dimer levels were measured for evaluation of endothelial function and fibrinolytic activity.
Results: Hematocrit and hemoglobin levels remained constant during exercise. Compared to baseline, white blood cell count was significantly elevated, predominantly caused by a 1.2 fold increase in monocytes and a 2.7 fold increase in neutrophils, which were related to a significant increase in cortisol (375 ± 81 vs. 440 ± 106 nM). Likewise, the vWf level was increased (110 ± 44 vs. 193 ± 72%). An increased coagulation activity after exercise was shown by a significant elevation in TAT levels (1.9 ± 0.6 vs. 2.5 ± 0.8 ng/mL). Furthermore, non-triggered ROTEM clot formation was significantly accelerated (CT 1109 ± 188 vs. 918 ± 82 s) with increased clot strength (MCF 44.0 ± 3.6 vs. 49.1 ± 5.3), suggesting the presence of an endogenous coagulation trigger. These results were supported by a two fold increased thrombin generating potential in the absence of a tissue factor trigger, as well as by 1 pM tissue factor triggered TG. The enhancement of TG was not influenced by inhibition of the extrinsic pathway through active site inhibited factor VII, suggesting the contribution of the intrinsic pathway of coagulation. This finding was supported by a 2 fold increase in FXIa level. The procoagulant state was accompanied by enhanced platelet aggregation in response to ADP, arachidonic acid and TRAP. The fibrinolytic activity was increased, as indicated by elevated tPA activity (0.6 ± 0.3 vs. 1.9 ± 1.1 U/mL) and D-dimer levels (210 ± 66 vs. 246 ± 119 ng/mL).
Conclusions: Cycling induces a hypercoagulable state through both increased platelet reactivity and contact dependent activation of coagulation. Furthermore, cycling leads to increased fibrinolytic activity and endothelial dysfunction. Although this procoagulant response in cyclists may primarily reflect a physiological response to physical stress, it may eventually contribute to abnormal vascular responses including the development of endofibrosis.

PB 4.49-5

Genetic characterization of seven patients affected by FXI deficiency

Castaman G[1], Giacomelli S[1], Giuffrida A[2], Dragani A[3] and Biasoli C[4]
[1]*San Bortolo Hospital, Vicenza;* [2]*Immunohaematology and Transfusion Medicine, Haemophilia Center, Verona Hospital, Verona;* [3]*Haemophilia Center, University of Pescara, Pescara;* [4]*Bufalini General Hospital, Cesena, Italy*

Background: FXI deficiency is a rare bleeding autosomal disorder characterized by a heterogeneous bleeding tendency, often unrelated to the levels of circulating FXI. More than 150 mutations have been reported in FXI gene and two are most frequent in the Jewish Ashkenazi population (Glu117X and Phe283Leu).
Aim: In this study we report the genetic analysis of nine Italian patients (five with severe and four with mild FXI deficiency).
Results: One asymptomatic patient (FXI:C = 0.3%) has two known heterozygous mutations (Glu117X/c.908DelG). The other four patients with a severe deficiency (FIX:C = 1–5%) have four different homozygous mutations: two novel, Gln-13X (in the propeptide) and Trp407Arg (in the active site), one known splice site mutation in intron 6 (c.595 + 3A>G) and one Gly578Cys (in the active site), already described by our group. The latter two patients have a mild bleeding

history. Both missense variations are in the Apple 3 domain of the protein. In position 407 a substitution of the amin oacid Tryptophan with a Cysteine has been already described. The substitution of an aromatic and hydrophobic amino acid (Trp) with a linear and basic one (Arg) possibly interferes with the polar bond with the Ile403 and Gly404 residues causing protein instability.
Two patients with mild deficiency but with a significant bleeding history show the heterozygous variation Trp228Cys. Another mild patient with post-surgery bleeding has a heterozygous Cys122Tyr substitution. Finally, the last asymptomatic patient with mild FXI deficiency is heterozygous for a Arg184Gly mutation.
Conclusions: This study confirms the wide genetic heterogeneity in Italian patients of non-Jewish origin affected by FXI deficiency. Furthermore we confirm the lack of correlation between levels of circulating FXI and the manifestation of bleeding symptoms.

PB 4.49-6
Novel coumarins with improved solubility as FXIIa inhibitors

Bouckaert C, Vancraeynest C, Dolusic E, Frédérick R and Pochet L
University of Namur, Namur, Belgium

Background: Thrombotic diseases remain a major cause of death in industrialised countries. Anticoagulants have proven their efficacy to address these disorders. However severe bleeding complications are still reported even with the use of recently marketed drugs. Novel and safe antithrombotics are thus required.
In this perspective, coagulation factor XIIa (FXIIa), a serine protease implicated in the contact phase of coagulation cascade, recently emerged as a promising target in the development of such agents. Indeed, it was demonstrated that FXII deficiency or inhibition protects against thrombosis without causing spontaneous bleeding in mice.
Aim: Based on these considerations, the goal of our project is to develop novel selective FXIIa inhibitors to detail the exact role of this enzyme in thrombotic diseases. These compounds could also be a good starting point for the development of new antithrombotic drugs.
The 3-carboxamide coumarins are to date the only nonpetidic and selective inhibitors of FXIIa described in literature (COU294). However, their low solubility and poor pharmacokinetics resulted in a lack of activity in *in vivo* models of thrombosis. As a consequence, we aim to improve these characteristics while keeping the selectivity and potency towards FXIIa.
Methods: Twenty-five compounds were synthesized. Their solubility was investigated in pH 7.9 TRIS-imidazole. Inhibition potency on FXIIa was screened at several concentrations according to the maximum of solubility.
Results: A new series of coumarins with an amino group at position 3 or 6 of the carboxamide coumarin scaffold was first synthesized. While solubility was largely increased the inhibition potency on FXIIa remained relatively low.
Conclusion: A new series of 3-carboxamide derivatives was synthesized to selectively inhibit FXIIa and with the aim of improving their solubility. Pharmacomodulations will be fully discussed.

PB4.50 – Blood coagulation system – V

PB 4.50-1
Protein C inhibitor and the ambivalent regulation of apoptotic cell removal

Rieger D, Sokolokova B and Geiger M
Medical University of Vienna, Vienna, Austria

Background: Protein C inhibitor (PCI) is a secreted serine protease inhibitor, first ascribed to inhibit activated protein C, but it also inactivates other clotting factors and fibrinolytic enzymes, suggesting a regulatory role in hemostasis. Glycosaminoglycans and certain negatively charged phospholipids, like phosphatidylserine (PS) and phosphatidylethanolamine (PE), bind to PCI and stimulate its activity. PS is best known as a phagocytosis marker, exposed on the surface of apoptotic cells, serving as phagocytosis signal. Deranged apoptotic cell removal by phagocytes can lead to tissue damage and chronic inflammation, which is a risk factor for the development of vascular disease.
Aims: It is the aim of this study to determine binding of PCI to cell membranes with different lipid surface exposure (e.g.: live and apoptotic cells) and to determine the influence of PCI on the process of apoptotic cell removal.
Methods: To investigate the influence of PCI on phagocytosis we used a dual color Flow Cytometry based study design, and apoptotic Jurkat cells as 'meal' for phorbol ester differentiated U937 cells, that show macrophage like functions. To study the binding of PCI to different cell membranes PCI was directly coupled with a fluorophore. Different cell types and -stages were incubated with PCI-Cy3 together with the apoptosis marker Annexin V-FITC, and analysed by confocal microscopy, fluorescence resonance energy transfer (FRET) microscopy, and Flow Cytometry .
Results: Our results indicate that exogenously added PCI inhibits the phagocytosis of apoptotic cells. PCI bound primarily to apoptotic cells and only to a small extent to U937 cells. The amount of PCI-binding U937 cells increased with differentiation, probably due to a higher degree of PS exposure on the surface of macrophages involved in phagocytosis. Interestingly, the expression of PCI increased with the time of phorbol ester induced differentiation, resulting in enhanced phagocytosis. Data obtained by FRET analysis suggest an interaction of PCI and PS on the surface of apoptotic cells, probably leading to coverage of the phagocytosis marker PS, preventing recognition by phagocytes.
Conclusion: On the one hand this study underlines the importance of PCI for the function of mature macrophages, but on the other hand uncovering secreted PCI as a negative regulator of apoptotic cell removal. Further studies are needed to clarify this ambivalence of one protein performing differently in the process of apoptotic cell phagocytosis and its relevance for vascular disease.

PB 4.50-2
Hemostasis in acute respiratory viral infections in often sick children with gene's polymorphism (asp299gly) toll-4 and (ser 249 pro) toll-6 receptors

Malezhik L, Karpova N and Malezhik M
Chita state medical academy, Chita, Russian Federation

We were interested in hemostasis in acute respiratory viral infections in often ill children, which were carriers of genetic defects in the Toll-4 (Asp299Gly) and Toll-6 (Ser249Pro) receptors. Purpose: To examine the state of the hemostatic system with SARS in sick children in the presence of polymorphism of Toll-4 (Asp299Gly) and Toll-6 (Ser249-Pro) receptors.
Materials and Methods: 190 children from 1 to 3 years often ill with acute respiratory infections were examined. The control group consisted of healthy children from 1 to 3 years with the number of episodes of SARS not more than four cases per year. Of 190 patients 90 children were carriers of the gene polymorphism (Asp299Gly) Toll-4 receptor, and 100-were carriers of mutations in the gene (Ser249Pro) Toll-6 receptor. Blood sampling was performed at admission to hospital; coagulation and fibrinolytic activity was determined by conventional methods in children with ARI.
Results: It was established that acute respiratory viral infection was developed during the following hypercoagulability in often ill children. It was expressed by the shortening of plasma recalcification time, increasing concentration of the fibrinogen and the number of fibrin monomer complexes. Fibrin was depressed by fibrinolysis due to rapid formation. The main cause of hypercoagulability in ARI was antigenic

activation of immune cells and destruction of affected tissues. The expression occurred on the cell surface of tissue factor, which was initiated by the formation of prothrombinase on the external mechanism by activation of cells involved in inflammation. The degree of expression was higher in sick children than in healthy ones, which could be one of the causes of hypercoagulability in blood flow in respiratory infections. The expression of tissue factor was marked greater in genetic defects in membrane receptors (Toll-4) than in similar cells with normal structure of signaling receptors. Besides, the level of fibrin monomer complexes was higher in holders of polymorphic variants of the gene Toll-4 receptor concentration of fibrinogen than that of similar ill children with normal allele 299 Asp. Fibrinolysis was slowed due to rapid formation of fibrin especially in carriers of mutant heterozygote (Asp299Gly) and homozygote with the replacement of allele (299Gly). Such changes in findings of hemostasis were revealed in sick children with polymorphisms Toll-6 (Ser249Pro) receptor. They had high blood concentrations of fibrinogen, fibrin monomer complexes. Euglobulin fibrinolysis was lengthened in heterozygotes (Ser249Pro) to 12.5% in comparison with carriers of the normal homozygotes and by 32% for the holders of the mutant homozygotes with allele 249Pro. Tissue factor expression on cells with the genetic defect in the Toll-6 receptor was more marked than in healthy children.

Conclusion: Consequently, hypercoagulability in children with ARI was more marked in the polymorphism of genes Toll-4 and Toll-6 receptor than those of the same children, but without the genetic mutations in the signaling receptor.

PB 4.50-3

Developmental haemostasis: the quantity of haemostatic proteins change with age

Attard C[1], Van der Straaten T[1], Vasiliki K[1], Monagle P[2] and Vera I[1]

[1]Murdoch Childrens Research Institute, Parkville; [2]University of Melbourne, Melbourne, Australia

Background: Developmental haemostasis recognises the physiological differences in the haemostatic system of neonates and children compared to adults. Compared to the knowledge of haemostatic system physiology in adults, our understanding in neonates and children remains inadequate.

Routine clinical coagulation testing most commonly measures functional parameters of the haemostatic system once it has been activated. While many studies have demonstrated age-specific differences in functional haemostatic assays, very few studies have measured age-specific quantitative levels of haemostatic proteins.

The majority of studies in the paediatric setting use the term 'quantity' when in fact they are referring to a functional measurement rather than the direct measurement of a specific protein.

An understanding of the normal fluctuations in the quantity of haemostatic proteins is vital in the prevention, diagnosis, and treatment of haemostatic problems during infancy and childhood. This is especially important in the setting of novel anticoagulants that target specific proteins of the coagulation system.

Aim: To develop age-specific, quantitative reference ranges for a comprehensive number of haemostatic proteins.

Methods: Plasma samples were obtained from 120 healthy individuals from the following age groups: neonates (Day 1 and Day 3), 28 days to 1 year, 1–5 years, 6–10 years, 11–16 years and adults. Each age-group consisted of 20 individuals.

Factors II, V, VII, VIII, IX, X, XI, XII, and XIII, Plasminogen, Protein C as well as total and free Protein S were quantified using commercially available sandwich ELISA assays (Diagnositica Stago and Affinity Biologicals).

Reference ranges were determined for each protein and age-group by encompassing 95% (between the 2.5th and 97.5th centiles) of the population. Neonatal and paediatric results were compared to adult results using an independent *t*-test, where a P value of <0.05 was considered statistically significant. The Levene's Test for Equality of Variance was used to determine the variance. Where unequal variance was detected, an Aspin-Welch test was used. Correction for multiple testing was conducted using the Monte-Carlo approach based on 10,000 samples. All analyses were performed using NCSS 2007, Version 07.1.12.

Results: The concentration of the majority of coagulation proteins was found to vary significantly with age. Of the proteins measured, 10 were significantly different between neonates and adults and these differences persisted throughout childhood for most of these proteins. Factor XIII and Factor VIII were the only proteins that did not change with age.

Conclusion: The results of this study confirm for the first time that the quantity of most coagulation proteins changes significantly with age. Further research is required to investigate how the quantity of haemostatic proteins influences functional assays. Furthermore, it is imperative that we investigate how the differences in the quantity of these proteins contributes to the effect of anticoagulants, especially when considering the use of novel anticoagulants that target specific proteins of the coagulation system.

PB 4.50-4

Effects of rVIIa in thrombocytopenic cord blood derived plasma

Haidl H, Grangl G, Schlagenhauf A, Leschnik B, Schweintzger S and Muntean W

Medical University of Graz, Graz, Austria

Background: Primary haemostasis of newborns is excellent in normal conditions, although neonatal platelets show impaired function in aggregation measurements. Thrombocytopenia is a well known problem in neonatal care, and poses a significant risk for bleeding, particularly intracranial haemorrhage.

RVIIa, developed and licensed for bleedings of haemophiliacs with inhibitors, has almost become an universal haemostatic agent in different bleeding events including thrombocytopenic bleeding. In cases of life-threatening bleedings, rVIIa also has been applied for newborns.

Aim: Aim of our study was to assess *in vitro* data about the effects of rVIIa on thrombin generation in normal and thrombocytopenic neonatal plasma in comparison to adults.

Methods: Cord blood and adult blood was collected (n = 5 each), PRP was prepared by centrifugation at 250 ***g*** and different concentrations of platelets (100,000/μL, 75,000/μL, 50,000/μL, 10,000/μL and PPP) were created by diluting with autologous PPP. Thrombin generation with PRP reagent was measured using Calibrated Automated Thrombography (CAT) with rVIIa (1.5 μg/mL and 3 μg/mL final concentration) and without.

Results: Addition of rVIIa leads to a shortening of lag time. This effect is more pronounced in cord blood. Time-to-peak is slightly shortened in cord blood, but not in adult blood, velocity index is decreased only in cord blood. Total ETP and peak levels are not markedly influenced by rVIIa. These effects are comparable in all tested platelet concentrations. There is no difference in the effects of 3.0 μg/mL or 1.5 μg/mL.

Conclusion: Data show that platelets in cord blood derived plasma can create enough surface for rVIIa to accelerate initiation phase of coagulation even in thrombocytopenic plasma. This implicates that rVIIa has similar effects in neonatal plasma even under conditions of thrombocytopenia compared to adult controls. As controlled studies on use of rFVII in neonatal patients are rare, our in-vitro measurements shed light into the procoagulatory efficacy in this particular patient group. The right dosage in neonates remains a point of discussion.

PB 4.50-5

Thrombin generation testing to monitor warfarin anticoagulation in thrombotic antiphospholipid syndrome patients

Efthymiou M[1], Lawrie AS[1], Mackie IJ[1], Machin SJ[1] and Cohen H[2]
[1]University College of London; [2]University College London Hospitals NHS Foundation Trust, London, UK

Background: Warfarin monitoring in patients with antiphospholipid antibodies (aPL) can be complicated due to the variable responsiveness of thromboplastin reagents to lupus anticoagulants (LA), which may in turn potentially influence the validity of the prothrombin time (PT)-International Normalised Ratio (INR) in monitoring anticoagulation treatment in thrombotic antiphospholipid syndrome (APS).
Aim: To evaluate thrombin generation potential in thrombotic patients with and without APS treated with warfarin anticoagulation and to compare the INR values obtained using two commonly used PT/INR reagents, which have differing sensitivity to LA.
Methods: Eighty thrombotic patients with (n = 35) and without (n = 45) APS receiving warfarin anticoagulation were studied (32 out of 35 of the APS patients were LA positive). Thrombin generation test (TGT) was performed using the calibrated automated thrombinogram with the PPP reagent (5 pM tissue factor, 4 μM phospholipid, Diagnostica Stago). Three parameters were derived from the thrombin generation curves: lag time, peak, and endogenous thrombin potential (ETP). PT in all samples was measured with the Innovin (Siemens) and the PT Fib HS Plus (IL) thromboplastin reagents using the Sysmex CS-5100i and the IL TOP500, respectively. INR was calculated using instrument-specific assigned ISI values. Thrombin generation parameters were correlated with INR values and compared between the patient groups. Amidolytic Factor X (FX) levels were measured using a commercial kit (Biophen, Hyphen). Unless otherwise indicated, results are expressed as median and observed range.
Results: INR with Innovin and PT Fib HS Plus were 2.93 (1.55–5.93) and 3.03 (I.58–5.17) respectively for the APS patients and 2.48 (0.98–5.85) and 2.45 (0.95–4.79) respectively for the non-APS patients. Seven patients (4 APS) showed >0.5 INR unit difference between reagents; five of these seven patients had an INR >4.5. There was an inverse correlation between the INR and the normalised endogenous thrombin potential (ETP%) in both patient groups: Innovin and PT Fib HS Plus vs. ETP in APS patients: rs = −0.84 and rs = −0.80 respectively ($P < 0.0001$) (ETP% 20.7 [8.9–49.2]); and in non-APS patients: rs = −0.83 and rs = −0.73 respectively ($P < 0.0001$) (ETP% 29.9 [5.8–95.6]). Similar relationships were observed with normalised peak thrombin values. The normalised ETP and peak thrombin were significantly decreased and lag times significantly increased in the APS compared with the non-APS patients ($P < 0.001$, 0.007 and 0.0001 respectively), which may reflect the higher INR values in the APS patients. Amidolytic FX levels (19.7 (12.7–34) APS, 20.9 (12.7–131.5) non-APS) correlated well with the INR with both thromboplastins and with the ETP.
Conclusion: These data suggest that anticoagulant intensity on warfarin determined using Innovin and PT Fib HS Plus, with instrument-specific ISI values, concurs with that measured by the TGT which provides a good assessment of anticoagulant intensity in APS as well as non-APS patients. ETP evaluation combined with PT-INR may give a better indication of the intensity of anticoagulation in both thrombotic APS and non APS patients.

PB 4.50-6

Evaluation of a new chromogenic protein C assay (DG-Chrom PC) on the Q Hemostasis Analyzer (Grifols)

Hickey KP, Cooper P and Kitchen S
Sheffield Haemophilia and Thrombosis Centre, Sheffield, UK

Background: Protein C (PC) assays need to demonstrate strong precision, linearity, and specificity to be suitable techniques for PC estimation. Grifols (Spain) have developed a new chromogenic PC (DG-Chrom PC) assay for their Q Hemostasis Analyzer.
Aim: Evaluate the performance characteristics of Grifols DG-Chrom PC assay with comparison to an established PC technique.
Method: All blood samples were taken into 0.109 M citrate tubes and centrifuged at 2000 ***g*** for 10 min prior to freezing aliquots at −70 °C. The DG-Chrom PC (Q-PC) assay on the Q Hemostasis Analyzer utilises reconstituted lyophilised snake venom PC activator (Protac) and chromogenic substrate. The reference PC method was an in house assay performed on ACL TOP analyser (Instrumentation laboratory, UK) utilising Protac (Pentapharm, Switzerland) and chromogenic substrate, S-2366 (Quadratech, UK).
Results: All calibration curves (n = 11) generated r^2 values >0.999 with Q-PC assay. Three levels of precision (n = 40) were performed for Q-PC; normal pool (99 IU/dL) returned CV of 1.7%, abnormal pool (48 IU/dL), CV 2.5% and low abnormal pool (12 IU/dL), CV 5.3%. PC assays can suffer from cleavage of chromogenic substrate by targets other than PC e.g. kallikrein. Replacing Protac activator with buffer and testing normal (n = 10) and abnormal plasmas (n = 10) established that no non-specific cleavage of chromogenic substrate was detected. Q-PC estimations performed on PC deficient plasma (Technoclone, UK) generated undetectable PC levels (n = 10).
Pooled plasma with PC of 130 IU/dL demonstrated good linearity between 0 and 130 IU/dL (n = 5), mean r^2 of 0.998 with Q-PC assay. Accuracy of Q-PC assay was evaluated (n = 5) using 3rd SSC analysed at four dilutions. Undiluted plasma (89 IU/dL) generated mean estimate of PC 90.1 IU/dL, at 44.5 IU/dL dilution, mean PC of 46.4 IU/dL, at 22.2 IU/dL dilution, mean PC of 24.1 IU/dL, and at 11.1 IU/dL dilution, mean PC of 11.3 IU/dL. The limit of sensitivity of this assay was evaluated using 3rd SSC diluted in buffer (n = 5). Q-PC accurately measured PC level of a 5.6 IU/dL dilution, estimates of PC level ranged from 4.3 to 5.2 IU/dL.
For method comparison residual plasmas stored at −70 °C were utilised. Study groups included low PC (congenital and acquired, n = 54), healthy normals (n = 57), heparinised (n = 11) and liver disease (n = 13) samples. Linear regression analysis of all samples calculated weighted r value of 0.984 (n = 143), within test groups correlation (r^2) ranged between 0.782 and 0.977. There were statistically significant differences between PC assay results obtained in individual test groups and in the combined group, however the differences were small and in no group was this difference large enough to be considered clinically relevant.
Conclusion: The new Grifols PC assay (DG-Chrom PC) demonstrates good precision and excellent linearity. Q-PC limit of sensitivity was measured at 5.6 IU/dL using 3rd SSC and the assay appears suitable for diagnosis of hereditary homozygous PC deficiency. No significant optical density was observed for Q-PC assay when blank assessment was performed, suggests PC blank estimation is not routinely required. Q-PC compared well with the established in house assay when pathological and healthy normal patient samples were tested.

PB4.51 – Blood coagulation tests – XV

PB 4.51-1

Evidence that low protein C is a crucial determinant of the pro-coagulant imbalance in cirrhosis

Chantarangkul V[1], Tripodi A[2], Primignani M[1], Lemma L[1], Clerici M[1] and Peyvandi F[3]
[1]IRCCS Cà Granda Maggiore Hospital Foundation; [2]Università degli Studi di Milano; [3]Universita degli Studi di Milano, Milano, Italy

Background & Aims: Cirrhosis is associated with a plasmatic pro-coagulant imbalance detected by thrombin generation tests performed in the presence-vs.-absence of such activators of protein C as

thrombomodulin or Protac®. This imbalance is thought to be due to decreased protein C and increased factor VIII. To test this hypothesis we analyzed plasma from 50 patients with cirrhosis before and after *in vitro* addition of purified protein C meant to restore normal levels.

Methods: Results for two thrombin generation assays were expressed as ratios of endogenous thrombin potential (ETP) with-to-without-thrombomodulin or as Protac®-induced coagulation inhibition (PICI %). By definition, high ETP ratios or low PICI% reflect a pro-coagulant imbalance.

Results: The median (range) protein C level before addition was 40% (4–101%) and increased to 156% (110–305) after addition ($P < 0.001$). The pro-coagulant imbalance, which was high before protein C addition [ETP-ratio = 0.83 (0.44–1.00)] was reduced after addition [ETP-ratio = 0.60 (0.14–0.84)], $P < 0.001$. ETP-ratios were inversely correlated with protein C activity (rho = −0.46, $P < 0.001$). Similar results were obtained with the Protac®-assay.

Conclusions: The results provide direct evidence that the pro-coagulant imbalance observed in plasma from patients with cirrhosis is due to reduced protein C and can be reversed by increasing its levels. The findings may have clinical implications for the treatment or prophylaxis of thrombosis in these patients.

PB 4.51-2

Effekt of recombinant Factor VIIa BAY 86-6150 on clot formation kinetics

Siegemund T[1], Adam N[2], Schobess R[2], Scholz U[2] and Siegemund A[2]

[1]The Scripps Research Institute, La Jolla, CA, USA; [2]MVZ Labor Dr. Reising-Ackermann und Partner, Leipzig, Germany

Background: BAY 86-6150 is a new recombinant FVIIa preparation with increased half-life and improved potency by enhanced binding to activated platelet surfaces. In hemophilia A and B the onset of blood coagulation is delayed and the clot formation is diminished. Clot waveform analysis is a fast and affordable method to investigate fibrin generation by analyzing the kinetic properties of fibrin formation after activation of the intrinsic coagulation cascade.

Aim: Clot waveform analysis is used to demonstrate the capability of BAY 86-6150 to correct a hypocoagulable state and is compared to thrombin generation (TG) and thrombelastography.

Method: All patients were from the centre of blood coagulation and had a history of bleeding disorders. Healthy subjects from our lab served as controls. Blood drawings and subsequent experiments where performed after informed consents were obtained in accordance to the Declaration of Helsinki. The measurements were performed in whole blood, in platelet-rich and platelet-poor plasma. BAY 86-6150 was added *in vitro* and coagulation was tested using clot waveform analysis (ACL TOP, activator Synthasil, Instrumentation Laboratory, Kirchheim, Germany), ROTEM (Tem International, Munich, Germany), CAT (Thrombinoscope, Maastricht, The Netherlands) and Technothrombin TGA (Technoclone, Vienna, Austria). For clot waveform analysis the time-dependent change of absorbance was analyzed as well the first three derivatives of the curve.

Result: All used methods showed a dose-dependent correction of delayed and diminished coagulation in hemophilia by BAY 86-6150. TG showed a complete normalization as well as thrombelastography. In clot waveform analysis, independent of tissue factor activation, BAY 86-6150 normalized the delay and total fibrin formation; fibrin formation velocity remained slightly slowed down. The procoagulant effect of BAY 86-6150 was strong in severe hemophilia and diminished in healthy controls.

Conclusion: Recombinant FVIIa BAY 86-6150 showed a dose-dependent normalization of coagulation in severe hemophilia. Onset and velocity of clot formation was improved significantly. BAY 86-6150 did not lead to a procoagulant state in healthy controls. Clot waveform analysis is an affordable, extremely fast and convenient method to investigate different aspects of clot formation and may pose as an alternative to thrombin generation and thrombelastography.

PB 4.51-3

Design and establishment of a biobank for a multicenter and interdisciplinary prospective cohort enrolling elderly patients with venous thromboembolism (SWITCO65+)

Méan M[1], Aujesky D[1], Laemmle B[1], Gerschheimer C[2], Trelle S[3] and Angelillo-Scherrer A[4]

[1]Inselpital, Bern; [2]CHUV, Lausanne; [3]Bern University Hospital, Bern; [4]University Hospital of Lausanne (CHUV), Lausanne, Switzerland

Background: In the field of haemostasis, many preanalytical variables influence the results of coagulation assays and may affect the quality of the subsequent results. Therefore, methods to limit these results variations should be foreseen when building a biobank in the field of haemostasis. A biobank of biological material from venous thromboembolism (VTE) patients is essential for translational research aiming to better characterize VTE at several levels ranging from diagnostic and prognostic classification to prediction of response to therapy.

Aim: Our detailed description of the biobank of the Swiss Cohort of Elderly Patients with Venous Thromboembolism (SWITCO65+) is thus intended to facilitate set-up of other biobanks in the field of hemostasis and to contribute substantively to the discussion of Good Practice and Standard Operating Procedure.

Methods: SWITCO65+ is a multicentre interdisciplinary cohort that prospectively enrolled consecutive patients aged ≥65 years with VTE at nine Swiss hospitals from September 2009 to March 2012. The patients will be followed up until December 2013. The cohort includes a large biobank with biological material from each participant taken at baseline and after 12 months of follow-up. Whole blood from all participants was assayed with a standard haematology panel, for which fresh samples are required. Two buffy coat cryovials, one PAXgene Blood RNA System tube and one whole blood sample were also collected at baseline and will be used for RNA/DNA extraction. Blood samples were processed and cryovialed within 1 h of collection for special assays, and transported in batches by commercial courier to a central laboratory where they were stored in ultra-low temperature archives. Use of barcoding and electronic databases ensured efficient management of the biobank. All analyses of the same type were performed in the same laboratory in batches. Using multiple core laboratories increased the speed of sample analyses and reduced storage time.

Results: Among the 1003 patients who agreed to participate in the cohort study, 905/1003 (90.2%) had a blood collection at baseline. The SWITCO65+ DNA and RNA depository was designed to permit both genome wide association and-replication studies, with the single limitation that 99.8% of the study patients were Caucasians. Only a small minority of those 905 patients refused to provide blood samples for genetic analyses (6.5%). By October 16th, 2012, after an average follow-up time of 512 days, 799 (80.1%) patients were still actively participating, 150 (15.0%) had died, and 1 (0.1%) was lost to follow-up. Forty-seven out of 1003 (4.7%) patients had withdrawn their consent, but only 6 (0.6%) did not allow us the use of their data and blood samples for analysis. By November 2012, 20,802 vials were stored in the central SWITCO65+ biobank and 7852 vials had already been sent for subsequent analyses in one of the four participating laboratories (Lausanne, Zürich, Bern, Geneva).

Discussion: After recruiting, processing and analyzing the blood of 905 study participants, we determined that the adopted methods and technologies were fit-for-purpose and robust.

PB 4.51-4

A simple screening method for the identification of the presence of FVIII and FIX inhibitors by determining the steepness of the routine aPTT reaction curves

Coen Herak D, Milos M and Zadro R

Zagreb University Hospital Center, Zagreb, Croatia

Background: The majority of modern coagulation analyzers have the feature to continously monitor the changes in light transmittance or absorbance during the performance of routine aPTT. Consequently, every aPTT measurement is recorded as a reaction curve characterized by the specific shape and slope that depends on coagulation acceleration associated with the formation of fibrin. Besides the routine evaluation mode, some analyzers check the plausibility of a kinetic curve by using additional checking methods in order to protect from false aPTT results. If kinetics does not meet the criteria, the result is flagged with a question mark, meaning that the result is questionable and that the kinetic curve should be visualy inspected. We have observed that in plasma samples with FVIII and FIX inhibitors flagged aPTT results were obtained due to the doubtful onset of coagulation because kinetic curve did not reach the predefined angle.

Aims: This prompted us to investigate the possibility to detect the presence of FVIII and FIX inhibitors by analyzing flagged aPTT results after visual inspection and manual measurement of angle that determines the steepness of reaction curve.

Methods: The study included 61 patient plasma samples with request for the determination of FVIII or FIX inhibitors. Routine aPTT measurement was performed using Actin FS on the BCS-XP coagulation analyzer (Siemens Medical Solutions Diagnostics, Germany) at 405 nm with the manufacturer's proposed evaluation method DRIFTING BASELINE (DB) and checking method ANGLE DB with predefined minimal angle of 30 degrees. Each aPTT result with angle lower than 30 degrees was flagged and the measurement continued at 570 nm (checking method ANGLE DB with predefined minimal angle of 15 degrees), followed by the visual inspection of the kinetic curve. Additionally, for each aPTT result manual measurement of reaction curve angle at 405 nm was performed. FVIII and FIX activities were measured by one-stage clotting assay. Inhibitor screens were performed and inhibitor titers determined by the Nijmegen modified Bethesda assay. Patients were divided into two groups according to the absence (group I, $n = 38$) or presence (group II, $n = 23$) of FVIII ($n = 21$) and FIX ($n = 2$) inhibitors.

Results: A flagged aPTT result at 405 nm was recorded in all patients with inhibitors, and in three patients without inhibitors. When measurement continued at 570 nm, no flagged aPTT result was obtained. For all tested samples an excellent correlation between FVIII activities (range: 1–91 U/dL; median: 7.0 U/dL) and measured angle (range: 25.5–78.0 degrees; mean angle ±SD: 49.2 ± 19.4 degrees) was obtained ($r = 0.928$; $P < 0.001$). Statistically significant difference ($P < 0.001$) for measured angle was identified between group I (range: 29.5–78.0 degrees; mean angle ±SD: 62.1 ± 12.6 degrees) and group II (range: 25.5–29.5 degrees; mean angle ±SD: 28.0 ± 1.3 degrees). ROC curve analysis revealed that the predefined minimal angle of 30 degrees distinguishes between patients with and without inhibitors with 100% sensitivity and 92.1% specificity.

Summary/Conclusions: Based on obtained results, ANGLE DB checking method together with visual inspection of aPTT reaction curve and angle measurement, provides a simple and reliable tool as a screening method for the presence of FVIII and FIX inhibitors.

PB 4.51-5

Laboratory estimation of expanded uncertainty of D dimer measurement by ELISA.

Martinuzzo ME[1], Carbone RJ[1], Barrera HL[1], Ujhelly C[2], D' Adamo MA[1], Otaso JC[1], Gimenez IM[1] and Oyhamburu J[1]

[1]Hospital Italiano de Buenos Aires-Grupo Bioquímico; [2]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

D dimer (DD) is a useful biomarker of thrombin and plasmin effect that is widely used by Haemostasis and Thrombosis laboratories. There is a lot of discrepancy of results obtained by different methods, but ELISA one has been recognized as the most sensitive with the higher negative predictive value for the exclusion of venous thromboembolism. The cut off value for exclussion of venous thromboembolism widely used by this method is 500 ng/mL FEU. The aim of the present study was to estimate the uncertainty of the measurement of DD in our laboratory. We did it by using the data of the Internal Quality Control provided by the manufacturer and those from the results of the last five CGL Surveys of College of American Pathologist. We calculated the extended uncertainty of DD measured by an ELISA (Vidas D-Dimer Exclusion) following the Nordtest Handbook formula: Internal Quality Control + Interlaboratory comparison results.

Formulas used were:

Combined standard uncertainty (μ_c) $= \sqrt{(cv^2 + m\ bias^2)}$

cv = cv Internal Quality Control

m bias $= \sqrt{(RMS\ b)^2 + \mu\ (Cref)^2}$

RMS b: $\sqrt{\Sigma\ bias^2/n}$ (total DD surveys results)

μ (Cref): RMS of cv interlaboratory/$\sqrt{N}$ (number of participant laboratories of CGL)

Expanded uncertainty (U) $= 2 \times \mu_c$ (95% of confidence Interval)

We calculated U for the two levels of control provided by the manufacturer: one around 500 ng/mL FEU and the other around 5000 ng/mL FEU. Each lot of the reagent provides different lot of both controls (low and high), we performed an ANOVA analysis to make sure that their values were statistically comparable.

U results obtained were 15.57% for the lower level of control (500 ng/mL FEU) and 16.76% for the higher (5000 ng/mL FEU). The results were similar for the two levels of control, and both were acceptable considering that U should not be >⅔ of the allowed total error (TEA), Gella Tomás et al, Documents of SEQC 2009: 27–29. In our laboratory we chose TEA of 30%, requirement informed by The American Association of Bioanalysts.

U values expressed as quantity of analyte were 78 and 838 ng/mL FEU for the lower and the higher level, respectively, being the possible report for patients' plasma results 500 ± 78 and 5000 ± 838 ng/mL FEU.

Conclusion: The expanded uncertainty estimation is a useful tool to assess the quality of results produced by the laboratory. The U of DD measurement by ELISA estimated in our laboratory was acceptable, but its value should be considered and it could be very important when clinical decisions are taken, particularly at 500 ng/mL FEU level.

PB 4.51-6

Validation of rivaroxaban anti-Xa activity measurement

Rathbun S, Tafur AJ, Mauer K, Gausman J and Marlar RA

University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA

Background: New oral anticoagulants are increasingly being used. Specifically, rivaroxaban has been approved for use without routine monitoring, but the lack of a predictable drug level measurement may complicate management of anticoagulated patients. Drug level measurement is instrumental in monitoring compliance, potential medication failure, safety for interventional procedures, and for the care of the chronically anticoagulated patient and pediatric, pregnant, renal disease patients. Activated partial thromboplastin time, and

prothrombin time have been evaluated as surrogate measurements for rivaroxaban and found to have poor correlation. Alternatively, high-performance liquid chromatography-tandem mass spectrometry [HPLC-MS/MS] can be used to measure rivaroxaban levels between 0.50 and 500 μg/L with excellent inter-assay accuracy, but the timely clinical availability is limited. To overcome these limitations, an anti-factor Xa based assay using rivaroxaban calibrators is currently under investigation as a method to monitor rivaroxaban.

Aims: The aims of the project are to correlate the STA®-Liquid Anti-Xa using the STA®-Rivaroxaban Calibrators (Diagnositica Stago) with the serum drug levels via HPLC-MS/MS in patients currently receiving rivaroxaban, and secondly, to correlate the PT/PTT, thrombin generation (CAT assay) and Thromboelastograph (TEG) with the anti-Xa activity and HPLC-MS/MS rivaroxaban level.

Methods: This is a prospective validation cohort study including 20 adult patients receiving rivaroxaban and 10 healthy control subjects. Recruited patients receiving rivaroxaban have a total of three blood samples taken at specific time points at least 2 h apart. Plasma is divided into four aliquots of 0.5 mL for measurement of PT/PTT, anti-factor Xa rivaroxaban assay, rivaroxaban HPCL-MS/MS, and thrombin generation. TEG activity is measured at one random time point for each patient. Correlation and linear regression evaluations are performed on each of the clotting based tests including both TEG and LC/MS/MS values. All tests are centrally measured except for the independent measurements of HPLC-MS/MS. A rho2 of >0.9 will be considered acceptable for clinical use.

Results: To date, all 10 healthy controls and 4 of 20 identified patients receiving rivaroxaban have been completed including TEG analysis. Upon completion of sample collection, statistical and clinical analysis will be completed. Based on our preliminary evaluation, the anti-factor Xa assay with rivaroxaban calibrators and controls will have a positive correlation with serum measurements by HPLC-MS/MS and a good correlation with the PT/PTT. To date, the TEG results are intriguing in their response to clot formation and structure. The thrombin generation assay will provide additional information regarding the level of anticoagulation and rivaroxaban induced variation.

Summary: We anticipate that the results of this study will validate a viable rivaroxaban-specific quantitative assay using rivaroxaban calibrators in a standard anti-factor Xa activity for the measurement of rivaroxaban that is applicable for patient monitoring when medication compliance or peri-procedural evaluation is required.

PB 4.52-1

Dilute Russell Viper Venom Time: a useful assay for the monitoring of direct oral anticoagulants in patients?

Douxfils J[1], Classen J-F[2], Baudar J[2], Walbrecq S[2], Chatelain C[2], Chatelain B[2], Mullier F[2] and Dogné J-M[1]

[1]University of Namur, Namur; [2]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: Direct oral anticoagulants (DOACs) include anti-IIa agent (dabigatran etexilate: DE) and anti-Xa agents (rivaroxaban, apixaban and edoxaban). DOACs do not require monitoring nor frequent dose adjustment. However, searching for the optimal response at the individual patient level may be useful in some situations. Activated partial thromboplastin time, Hemoclot Thrombin Inhibitor® (HTI) and ecarin clotting time have been proposed to monitor dabigatran whereas anti-Xa chromogenic assays are preferable to monitor anti-Xa agents. However, there is still a need for a global test easily implementable and widely available that may be used for all DOACs. Recent studies showed that the dilute Russell Viper Venom Time (DRVV-T) could be used for the monitoring of DOACs but these results have not been performed on clinical samples.

Aim: To analyse and compare the results obtained with STA®-DRVV Screen and Confirm with the clinical plasma drug levels estimated with Hemoclot Thrombin Inhibitor® (HTI) for DE samples and Biophen Direct FXa Inhibitor® (DiXaI) for rivaroxaban samples.

Materials: Three patients under DE (150 mg *bid*) and three patients under rivaroxaban (20 mg *od*) were included in this study. Blood samples were taken at 2 h and 3 h after drug administration, and just before the next scheduled intake of the drug (C_{trough}: 12 h for DE and 24 h for rivaroxaban). The following tests were performed at each time-point:

Estimation of plasma drug concentrations: The HTI® (Hyphen Biomed) assays and the Biophen DiXaI® (Hyphen Biomed) were performed to estimate plasma drug concentration for DE and rivaroxaban samples, respectively. These tests have been shown to highly correlate with the HPLC-MS/MS reference measurement.

Dilute Russell Viper Venom Time: STA®-DRVV Screen and Confirm (Stago Diagnostica) were performed according with the recommendations of the manufacturer. Normal pooled plasma used as reference for the ratio was obtained from 42 healthy individuals.

Results: The estimated plasma range concentration was from 0 to 308 ng/mL for DE and 0 to 388 ng/mL for rivaroxaban. STA®-DRVV and the estimated plasma dabigatran concentration highly correlates (r^2 = 0.90 and 0.95 for Confirm and Screen, respectively) but showed a plateau at 100 and 200 ng/mL for Confirm and Screen, respectively. The correlation between STA®-DRVV and the estimated rivaroxaban concentrations depends on the reagent (r^2 = 0.95 and 0.78 for Confirm and Screen, respectively). The relation was linear on the range of concentration encountered in this study. The use of ratio did not improve the correlation parameters.

Conclusion: STA®-DRVV Confirm and Screen should not be used to evaluate DE therapy since concentrations above 100 and 200 ng/mL could not correctly be discriminated. STA®-DRVV Confirm could be used as a screening test to estimate rivaroxaban plasma levels thanks to the high correlation and the good sensitivity on the whole therapeutic range. Further investigations are required to propose normal range value at different sampling time.

PB 4.52-2

Validation of an assay for determination of anti-xa activity of Rivaroxaban

Delavenne X[1], Meuley R[1], Baylot D[2] and Mismetti P[1]

[1]University Hospital of Saint-Etienne; [2]Clinique Mutualiste, Saint-Etienne, France

Aim: Rivaroxaban (Xarelto®) is a new oral direct factor Xa inhibitor. The purpose of this study was to evaluate the performance of STA® – Liquid anti-Xa reagent (Diagnostica Stago), for the ex vivo measurement of rivaroxaban anti-Xa activity. Accuracy of this assay was evaluated by comparison of results with HPLC/MS method, across a wide range of concentrations.

Method: Samples were tested with STA® – Liquid Anti-Xa reagent used with a dedicated set-up on STA-R® analyzer in combination with STA® – Rivaraxaban Calibrator and STA® – Rivaroxaban Control. A second aliquot of each plasma sample was tested in HPLC/MS following a protocol previously validated.

109 samples from two different studies were included in the method comparison.

- 74 plasma samples obtained from patients receiving rivaroxaban therapy (10 mg OD) for prevention of venous thromboembolic risk in hip/knee replacement.
- 35 plasmas obtained from seven healthy young male volunteers drawn: 2 h, 3 h, 4 h, 6 h and 10 h after ingestion of a 80 mg single dose of rivaroxaban. Besides, samples withdrawn at T0 h were tested only with STA® – Liquid Anti-Xa to verify the residual anti-Xa activity (in the absence of the molecule).

Both studies were conducted in accordance to ethical rules and had received ethical committee and health agency approvals.

Correlation was analyzed through linear regression and differences were plotted in Bland & Altman graph.

Results: Analysis of QC results shows good inter-day precision: CV = 2% with STA® – Liquid Anti-Xa based on results in ng/mL, for both levels of concentration.
Results obtained in ex vivo plasma samples ranged from 25 to 370 ng/mL.
The correlations between STA® – Liquid Anti-Xa and HPLC/MS demonstrated results equivalence.
Linear regression equation: y = 1.09x + 13.10 (r = 0.990)
Results obtained for samples withdrawn at T0 h were all inferior to the detection limit of the assay (25 ng/mL).
Conclusion: The combination of STA® – Rivaroxaban Calibrator and Control with STA® – Liquid Anti-Xa gives consistent results with the reference method, the HPLC/MS, and is suitable for the daily activity of any laboratory.

PB 4.52-3

Point of care heparin monitoring: combined use of clot rate and clot time

MacDonald SG[1], Luddington R[1], Sharples L[2] and Besser M[2]
[1]*Cambridge University Hospitals NHS Foundation Trust;* [2]*Papworth Hospital NHS Foundation Trust, Cambridge, UK*

Background: The Sonoclot® analyser (Sienco Inc., Denver, Colorado) assesses the viscoelastic properties of whole blood using resistance to motion imparted on a vertically oscillating tubular probe allows assessment of plasma coagulation, platelet function, clot retraction and fibrinolysis, in combination and independently.
Heparin dosing with the kaolin activated clotting time (ACT) is used in Cardiopulmonary bypass and cardiology interventions but not in ICU where aPTT is preferred. There is an unmet need for a point of care analyser that allows reliable heparin dosing between 0.3 and 1.0 U/mL in ICU patients.
The Sonoclot ® allows the measurement of an ACT equivalent reaction time to clot formation alongside kinetic measurements of clot formation, the clot rate (CR).
We investigated the Sonoclot to determine whether the values generated by this technology could give a more accurate and therefore clinically useful heparin estimate in patients receiving heparin therapy.
Aims: To assess whether a combination of Activated Clotting Time (ACT) and Clot Rate (CR) provides a better prediction of Heparin Anti-Xa level than each parameter separately using the Sonoclot analyser.
Methods: Samples from nine volunteers were collected into 3 mL S-Monvette collection tubes containing 0.106 mol trisodium citrate. These were pooled within 15 min of collection and were spiked to heparin spike levels of 0, 0.2, 0.4, 0.6 and 0.8 U/mL using unfractionated heparin (LEO Laboratories Ltd, Risborough, UK). Actual Anti-Xa levels were determined using the HaemosiL liquid heparin assay (IL UK, Ltd.)
Routine ACT measurements (Haemochron) were compared to the aPTT assay on the Sonoclot analyser. Results for ACT and CR were assessed for utility in predicting heparin level.
Statistical analysis: Data summaries based on comparative plots were constructed to assess the relationship between heparin levels and viscoelastic parameters provided by the Sonoclot analyser. Thereafter, equations were made to model the relationships in order to calculate the dose of heparin from individual and combined parameters.
Results: Using the Sonoclot analyser, there is a strong linear relationship between heparin Anti-Xa level and ACT, and strong non-linear relationship with clot rate; using log (CR) this relationship was linear. ACT alone explains 91% of the variation in heparin, log(CR) 95% and a combination of the two 96% of the variation.
Summary/Conclusions: Statistically, ACT and CR are very highly correlated and when combined in a single model compete against each other to explain the effect of heparin rather that contributing separately to the anticoagulant effect. However, when ACT and log(CR) are combined the predicted heparin level is expected to be within ±0.18 of the true heparin value 95% of the time compared to within ±0.30 (ACT alone) and ±0.22 (log(CR) alone).
These results suggest a model incorporating both the heparin dependant increase in clot formation time as well as the decreased rate of clot formation will provide a more accurate estimate of the true level of heparin in a patient than traditional time based heparin estimates as is the case for aPTT and ACT.

PB 4.52-4

Effects of rFVIIa and vatreptacog alfa on clot formation and thrombin generation in blood from patients with haemophilia

Fernandez-Bello I[1], Lind V[2], Butta Coll NV[1], Jiménez Yuste V[1], Stenmo C[2] and Ezban M[2]
[1]*Hospital Universitario La Paz, Madrid, Spain;* [2]*Novo Nordisk S/A, Copenhagen, Denmark*

Background: Monitoring the effectiveness of bypassing agents remains a challenging issue in the treatment of haemophilia patients with inhibitors as no validated assays are yet available. Thromboelastography (TEG) and thrombin generation test (TGT) are currently being evaluated to assess the clinical efficacy of by-passing agent such as activated recombinant factor VII (rFVIIa). These analytical procedures are subjected to large variability and no standardized protocol exists which makes clinical application difficult. In order to obtain more insight into the mechanism of action of rFVIIa and vatreptacog alfa (a potent rFVIIa analogue), and to define linking of TEG/TGT variables to clinical outcome after treatment with these agents, we evaluated the effect of both drugs on TEG and TGT.
Aims: To study the effect of vatreptacog alfa and rFVIIa on TEG and TGT throughout application of several assay conditions.
Methods: Whole blood from 11 patients with severe haemophilia (one patient with inhibitor against FIX) and 15 healthy donors was collected in citrate tube and citrate tube containing 50 μg/mL corn trypsin inhibitor (CTI)(HTI). Whole blood, platelet poor plasma (PPP) and platelet rich plasma (PRP; 100,000 platelets/μL) from patients with haemophilia were spiked with concentrations of rFVIIa and vatreptacog alfa representing the expected *in vivo* concentration after i.v. administration of 90 μg/kg (rFVIIa) and 80 μg/kg (vatreptacog alfa). Normal range for TEG and TGT was established based on healthy controls with no addition of drugs. Conditions for TEG analysis included addition of three final concentrations of tissue plasminogen activator (tPA, 1.2–1.5–1.8 nM) and two final dilutions of Innovin (1:30,000 or 1:50,000) as source of tissue factor (TF). Conditions for TGT included coagulant activation by addition of Reagent PPP-Low (Thrombinoscope) for PPP, and preactivation with convulxin/TRAP (Bachem) for PRP samples.
Results: In PPP-TGT tests, CTI produce an anticoagulant effect in all TGT variables in both controls and untreated plasma of patients with haemophilia. Both rFVIIa and vatreptacog alfa shortened lagtime and time-to-peak significantly. Both compounds showed significant difference from untreated patient samples. The response of vatreptacog alfa was, as expected, more pronounced on time-to peak, ETP and peak. Influence of CTI in PRP-TGT tests was stronger than observed in the PPP-tests. In the TEG test, final dilution 1:50,000 of Innovin (0.1 pM TF) produced the largest difference between rFVIIa and vatreptacog alfa for all parameters, in particular in the MA. Inclusion of CTI induced a strong anticoagulant effect in all parameters but improved differentiation between the effect of rFVIIa and vatreptacog alfa.
Conclusions: Addition of CTI to blood prior analysis by TGT and TEG dampens the response in both haemophilia and normal blood. TGT in PRP without CTI was the best condition to evaluate effect of rFVIIa and vatreptacog alfa. In the TEG test, a dilution of 1:50,000 Innovin is useful for monitoring effect of rFVIIa and vatreptacog alfa. Addition of 1.5 nM tPA further allows to study effect on clot strength (MA). All results are based on experimental *in vitro* assays, the clinical response requires further studies in the future.

PB 4.52-5

Evaluation of the Silica Clotting time (SCT) test as a secondary test for the detection of Lupus Anticoagulant

Gandhi T, Chowdary P and Riddell A
Royal Free Hospital, London, UK

Background: Anti-phospholipid antibodies are a large heterogenous family that are commonly detected as Lupus Anticoagulant (LA), anti-cardiolipin antibodies (aCL) or anti-ß2 Glycoprotein1 antibodies. LAs are antibodies which inhibit in-vitro phospholipid dependent coagulation assays and are not specific to any coagulation factor. Published guidelines for lupus testing require laboratories to use two screening tests of different principles to test for LA. The latest guidelines published by Keeling *et al*. 2012 specify that the first test should be the DRVVT and the second 'will usually be an aPTT using a reagent with proven LA sensitivity or a modified aPTT' with the addition of a confirmatory step to demonstrate phospholipid dependence.
Aims: Our current practice involves performing a DRVVT and aPTT 50:50 mix. Our aim was to evaluate the Instrumentation Laboratory (IL) SCT assay to be used as a secondary screening test for LA. The SCT is a lupus sensitive aPTT based test which includes a confirmatory step to demonstrate phospholipid dependence.
Methods: Initial screening tests including PT, INR, aPTT, TT and aPTT 50:50 mix were analysed using IL reagents, DRVVT was analysed using American Diagnostica Lupus reagents and SCT was analysed using the IL SCT kits on an ACL TOP (IL UK). In total, double spun plasma from149 patients were analysed. aCL and anti-ß2 Glycoprotein1 levels were included in the evaluation. 35 normal plasma controls were also tested for the SCT to establish a local reference range.
Results: Both the SCT-Screen and SCT-Confirm assays showed good intra and inter assay coefficient of variation (CV) of 2.9% and 2.8% respectively and the establishment of the 99th percentile (Pengo *et al*., SSC 2009) from 35 normal controls indicated a cut-off value of 1.16. Both the DRVVT and SCT ratio demonstrated good agreement in 79% of patient samples. A total of 30 (20%) positive LA's were picked up using both tests. The DRVVT test alone detected 18/30 (60%) and the SCT alone detected 28/30 (93%). Of the samples positive for LA, 12/30 (40%) were not detected by the DRVVT test. Anti-ß2 Glycoprotein1 antibodies were requested in only 61/149 patients in which four were positive. Three out of four tested positive with both DRVVT and SCT and one was negative with both. aCL antibodies were requested in 104/149 patients with eight having a raised IgG level. Three were positive with DRVVT and SCT and a further two were only positive with the SCT. Three patients tested negative with both.
Conclusion: Anti-phospholipid antibodies are very heterogenous. There is no single test or reagent available to detect all positive LA's. Our results demonstrate the value of investing in a secondary test which can make testing for LA more sensitive. Being an aPTT based test, the SCT will also show a prolongation with both the screen and confirmatory steps in presence of clotting factor deficiencies. SCT is a very useful secondary test that compliments the DRVVT and meets the current guidelines.

PB 4.52-6

Hemocompatibility of manufactured nanoparticles: guidelines proposal

Laloy J
University of Namur, Namur, Belgium

Background: Nanosciences and nanotechnologies are in constant evolution. Development of new therapeutic and diagnostic agents using nanotechnologies for reach their pharmaceutical target require the knowledge of biocompatibility of nanoparticles with the blood compounds. Hemostasis is the ensemble of physiological phenomena which prevent and lead to stop bleeding; it maintains the vascular integrity. A dysfunction of the hemostasis can lead to slow down or even to completely stop the circulation of the blood. It is therefore primordial to know what NPs can have an effect on coagulation.
Aims: The aim of this study is the evaluation of the biocompatibility of manufactured nanoparticles (NPs) on erythrocytes integrity, on platelets aggregation and on coagulation cascade.
Methods: Five types of NPs were studied: carbon nanotubes, fullerenes, silicon dioxide, copper oxide and silicon carbide. Various techniques assessing activation and aggregation of the platelets or the impact of NPs on coagulation cascade were investigated. An approach in transmission and in scanning electron microscopy was also accomplished.
Results: The Impact-R® with scanning electron microscopy support and the calibration thrombin generation tests were the reference method to investigate the potential impact of NPs on platelet function and the procoagulant activity of NPs, respectively.
Conclusions: Guidelines for testing NP hemocompatibility were suggested which responds to a request of scientific community due to lack of recommendations for the evaluation of nanomaterial hemocompatibility.

PB4.53 – Blood coagulation tests – XVII

PB 4.53-1

Clot waveform analysis in patients with thrombophilia

Siegemund T[1], Scholz U[2] and Siegemund A[2]
[1]The Scripps Research Institute, La Jolla, CA, USA; [2]MVZ Labor Dr. Reising-Ackermann und Partner, Leipzig, Germany

Background: Clot waveform analysis derives additional information from the fibrin formation process in an aPTT or PT measurement beyond the usual clotting time. Using an optical detection system, alteration of absorbance during clot formation is mathematically processed to obtain data regarding fibrin formation (measured curve), thrombin activity (first derivative), prothrombinase activity (second derivative) and tenase activity (third derivative).
The only available global assay to detect hypercoagulability is the cost- and labor-intensive thrombin generation assay; an actual hypercoagulable state can be detected by the determination of D-dimer or prothrombin fragments f1 + 2.
Aim: The majority of known procoagulant alterations of the coagulation cascade are located in the vicinity of thrombin and factor Xa formation. Therefore, using clot waveform analysis is a promising tool to investigate patients with thrombophilia. The study is aimed to show the feasibility of clot waveform analysis for screening and monitoring patients with inherited or acquired thrombophilia. The results are compared to established thrombophilia markers, including thrombin generation, D-dimer and prothrombin fragments f1 + 2.
Methods: Clot waveform analysis is measured using an ACL TOP (Instrumentation Laboratory, Kirchheim, Germany), using a Synthasil-activated aPTT assay (Instrumentation Laboratory). Measured optical data were processed using the Savitzky-Golay algorithm. D-dimer and prothrombin fragments f1 + 2 (Siemens Healthcare Diagnostics, Marburg, Germany) were determined, as well as thrombin generation using the ETP assay (Siemens Healthcare Diagnostics) or Technothrombin TGA (Technoclone, Vienna, Austria).
Only patients with a clearly defined diagnosis and a complete thrombophilia screening were included. Pregnant women were observed from the first trimester till 6 weeks post partum. From each subject an informed consent was obtained.
Results: Patients with thrombophilia showed significantly higher thrombin generation than healthy controls or patients without thrombophilia. Clot waveform analysis showed significant differences between these groups in all investigated parameters.

D-dimer, prothrombin fragments f1 + 2 and thrombin generation increase through pregnancy from first to third trimester and normalize post partum. The same tendency was observed with all parameters calculated from clot waveform analysis. Pregnant women with LMWH (measured at trough level) have higher prothrombotic markers than patients without therapy.

Conclusions: Clot waveform analysis is an inexpensive, easy and fast method to screen and monitor patients with thrombophilia and can be done without any additional measurements beside a standard aPTT. Clot waveform analysis also reflects the physiological and unphysiological changes occurring in uncomplicated or complicated pregnancy, respectively. The method can be easily adapted to other optical detection systems.

PB 4.53-2

Measurement of dabigatran concentrations by calibrated thrombin clotting time in comparison to LC-MS/MS in human volunteers on dialysis

Stangier J, Schmohl M, Gansser D, Moschetti V, Ley L and Formella S

Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany

Background: Dabigatran etexilate is an oral direct thrombin inhibitor approved for prophylaxis of venous thromboembolism following surgical total knee or hip replacement and for stroke prevention in patients with non-valvular atrial fibrillation in more than 80 countries worldwide. Although clinical monitoring of dabigatran etexilate is not required, a simple and precise laboratory method to measure dabigatran concentrations in patient plasma may be useful in certain clinical circumstances, e.g. emergency situations.

Aims: In a PK/PD study in generally healthy end stage renal disease (ESRD) human volunteers, dabigatran pharmacokinetics and -dynamics were investigated. Ethics committee approval and patients' informed consent were obtained. Serial plasma samples were collected for analysis of dabigatran plasma concentrations by LC-MS/MS, and by the quantitative Hemoclot® direct thrombin inhibitors (dTT) assay. Assay precision and accuracy, and comparability of dabigatran concentrations determined by the dTT assay with those determined by an LC-MS/MS reference method, were investigated.

Methods: Samples were obtained from seven ESRD human volunteers without atrial fibrillation in steady state conditions of dabigatran in a Phase I clinical trial for measurement of dabigatran by dTT (citrated plasma samples) and by a validated LC-MS/MS reference method (EDTA plasma samples). Plasma concentrations were not corrected for dilution by citrate solution in sampling tubes. The dTT assay was calibrated with commercially available dabigatran standards (Hyphen BioMed, France). Agreement of dabigatran concentrations determined by the dTT assay and the reference LC-MS/MS method was assessed by regression analysis and Altman-Bland difference plots. Mean bias and limits of agreement were calculated.

Results: Prolongation of dTT paralleled the dabigatran plasma concentration-time profile in these healthy volunteers and displayed a linear correlation with dabigatran plasma concentrations. The mean R^2, slope and intercept of the regression line were 0.93, 0.146 s/(ng/mL) and 32 s (baseline dTT), respectively. The Hemoclot assay showed excellent assay precision with coefficients of variation (CV) below 5% for total, within-day and between-day imprecision. Accuracy determined by analysis of quality control samples (QC) at 122 and 297 ng/mL dabigatran was 90% and 111%, respectively. Between-day imprecision (CV) of QC analyses was 5% at 297 ng/mL and 9% CV at 122 ng/mL dabigatran. Dabigatran concentrations in study samples were between 7 and 440 ng/mL. In total, 304 paired data points were included in the method comparability study. Correlation of dabigatran concentrations determined by dTT and LC-MS/MS were assessed by regression analysis. The R^2 of the linear regression line was 0.96 with a slope of 1.013 which is within the acceptance limits of 0.85–1.15. The mean concentration ratio of the LC-MS/MS and dTT was 0.955.

Conclusion: The Hemoclot® thrombin inhibitor assay is a simple method to measure dabigatran plasma concentrations in otherwise healthy human volunteers undergoing regular haemodialysis. Agreement between dabigatran concentrations determined by the dTT assay and the LC-MS/MS reference method met pre-specified acceptance criteria.

PB 4.53-3

Thromboelastometry in liver transplantation of end-stage liver disease and familial amyloidotic polyneuropathy patients

Leite F[1], Magalhães R[2], Chumakova A[2], Siva C[2] and Cruz E[2]

[1]Santo António's Hospital -Centro Hospitalar do Porto; [2]Santo António's Hospital -Centro Hospitalar do Porto, Porto, Portugal

Background: Bleeding is a serious intraoperative complication of orthotopic liver transplantation (OLT) compromising graft and patient survival. Thromboelastometry (TE) is a point-of-care test that monitors haemostasis in a cell-based model, providing different information from plasmatic standard laboratory tests (SLT), namely platelet function and fibrinolysis. In our center TE was used to diagnose and manage haemostasis disorders in OLT, performed at surgery theater by hematologists. In contrast to most candidates to OLT with end-stage liver disease (ELD), familial amyloidotic polyneuropathy (FAP) patients have normal liver function (1). Clinical data results are contradictory concerning TE cost/effectiveness analysis. We evaluated the consumption of blood and blood products in OLT performed in ELD and FAP groups of patients.

Methods: From 59 OLT, 42 were performed in ELD and 17 in FAP groups. SLT data [fibrinogen concentration, prothrombin time (PT), international normalized ratio (INR), platelet count (PC) and activated partial thromboplastin time (APTT)], hematocrit, haemoglobin, and TE using ROTEM® technology have been recorded at basal, hepatectomy, anhepatic, reperfusion and final phases of OLT surgery. The severity of disease has been evaluated by the Model for End-Stage Liver Disease (MELD) *United Network for Organ Sharing* modification score for patients with hepatic failure. We compared the number of units of blood components [red blood cells (RBC), plasma and platelets)] transfused between groups of patients who underwent OLT with TE (+TE) with the control group without TE monitoring (-TE) presenting similar severity of liver disease [ELD + TE (n = 23) vs. ELD-TE (n = 19) and FAP + TE (n = 10) vs. FAP-TE (n = 7)]. This evaluation included the blood and blood components transfused during surgery till 48 h after OLT. Student-t test was used to assess differences between groups ($P < 0.05$).

Results: There were no differences in MELD score between ELD + TE and ELD-TE groups (15.1 ± 1.6 vs. 12.9 ± 1.6; P = 0.36). Basal hematocrit (%), hemoglobin level (g/dL) and PC (x10^3/mL) were not different between ELD + TE and ELD-TE groups [(32.8 ± 1.1 vs. 30.3 ± 1.5; P = 0.24); (10.9 ± 0.4 vs. 10.4 ± 0.6; P = 0.48); (128.7 ± 8.9 vs. 119.5 ± 16.3; P = 0.61) respectively]. We did not find significant differences in the number of RBC, platelets nor plasma between ELD groups (+TE vs -TE) [(5.9 ± 1.3 vs. 4.3 ± 1.2; P = 0.39); (1.0 ± 0.6 vs. 1.6 ± 0.8; P = 0.52); (4.0 ± 1.1 vs. 2.1 ± 0.9; P = 0.19) respectively]. In FAP group, 48 h after surgery the TE+ group showed higher RBC consumption (1.22 ± 0.4 vs. 0.29 ± 0.2; P = 0.02) despite higher basal PC (246.7 × 10^3/mL ± 16.3 vs. 181.8 × 10^3/μL ±25.7; P = 0.04) and lower PT and INR at hepatectomy (12.4 ± 0.36 vs. 13.8 ± 0.26; P = 0.02 and 1.1 ± 0.03 vs. 1.3 ± 0.03; P = 0.045, respectively). No significant differences were found in the other parameters.

Conclusions: In our center, thromboelastometry use in liver transplantation was not associated with lower blood transfusion in patients with or without hepatic failure. This result may be due to the fact that a

hematologist in the operating theater made transfusion decisions putting together TE and SLT results with clinical judgment in accordance with validated transfusion algorithms.

(1)-LismanT, PittauG, LeiteF *etal*. (2012) The circulating platelet count is not dictated by the liver, but may be determined in part by the bone marrow: analyses from human liver and stem cell transplantations. *J Thromb Haemost*; 10:1624–30.

PB 4.53-4

Impact of apixaban on haemostasis diagnosis assays: practical recommendations

Douxfils J[1], Classen J-F[2], Baudar J[2], Walbrecq S[2], Chatelain C[2], Chatelain B[2], Mullier F[2] and Dogné J-M[1]

[1]University of Namur, Namur; [2]CHU UCL Mont-Godinne-Dinant, Yvoir, Belgium

Background: As other anticoagulant drugs, apixaban may affect the results of a series of coagulation assays routinely used in case of thrombophilia or in the exploration of a haemorrhagic event. There is a need for the clinician and the biologist to know whether these tests are influenced by apixaban.

Aim: We aim at providing good laboratory recommendations for the accurate interpretation of haemostasis routine laboratory assays that may be influenced in patients treated with apixaban.

Materials: Apixaban is spiked at increasing concentration (0–500 ng/mL) in normal citrated human platelet-poor plasma to assess the Thrombin Time (TT), Ecarin Clotting Time (ECT), Reptilase Time (RT), testing for lupus anticoagulant (dilute Russell Viper Venom Time (dRVVT), PTT-LA® and Staclot-LA®), Activated Protein C Resistance (APC-R), measurement of clotting factors (XII; XI; IX; VIII; VII; V; X and II), antithrombin measurement (with thrombin and factor-Xa based assay), fibrinogen measurement (Clauss and PT-derived method) and Protein-C and free Protein-S (immunological and clotting method). All methodologies were performed according to the recommendations of the manufacturer.

Results: *Thrombin time, ecarin clotting time and reptilase time*

Both of these tests are not influenced by apixaban.

Determination of lupus anticoagulant

The PTT-LA® and the Staclot-LA® are both prolonged in a concentration dependent manner in presence of apixaban. DRVV-T (screen and confirm) is also prolonged dose dependently. For PTT-LA® and Staclot-LA® (with buffer or phospholipids)the relation is exponential and the concentration needed to double the clotting time (2xCT) is 52 ng/mL, 23 ng/mL and 32 ng/mL, respectively. For DRVV-T (screen and confirm) the relation is linear and the 2xCT is 205 ng/mL and 230 ng/mL, respectively.

Activated protein C resistance, clotting factor measurement, protein-C and protein-S measurement

Apixaban mainly influences the aPTT-based clotting factor measurement (FVIII, FIX, FXI and FXII). This may be explained by the relatively low sensitivity of Innovin® (the PT-reagent used for the PT-based determination of clotting factor II, V, VII, X) in comparison with the CKPrest®. The protein-C measurement is not affected by apixaban as well as the measurement of free protein-S using the immunological method. The measurement of free protein-S using the chronometric method is affected by apixaban (increase of 13% by 100 ng/mL of apixaban). The APC-R ratio is only affected at high concentration (447 ng/mL) of apixaban.

Antithrombin measurement

Apixaban influences the measurement of antithrombin using factor Xa-based chromogenic assay (12% per 100 ng/mL). Thrombin-based chromogenic assay is not affected by the presence of apixaban.

Fibrinogen measurement (Clauss and PT-derived methods)

The measurement of fibrinogen is not influenced by apixaban using the Clauss method. For the PT-derived method, the variability is greater with an overestimation of the fibrinogen rate at higher concentrations (>200 ng/mL) in apixaban.

Conclusions: We show that immunological assays are not influenced by apixaban. When applicable, these tests should be recommended. Apixaban mainly interferes with chronometric or chromogenic assays that involve FXa or upstream coagulation factors. When these tests are used, it is mandatory to take into account the inter-reagent variability as well as the delay between the last intake of the drug and the blood sampling.

PB 4.53-5

Multimodal microscopy for real time imaging of thrombus formation

Kalchenko V[1], Kuznetsov Y[1], Meglinski I[2] and Harmelin A[1]

[1]The Weizmann Institute of Science, Rehovot, Israel; [2]University of Otago, Dunedin, New Zealand

Background: The use of multimodal optical diagnostic approach has a great potential in biomedical research and It can significantly expand the capabilities of vascular diagnostics.

Objective: To evaluate a multimodal approach for simultaneous *in vivo* imaging of laser induced thrombus formation.

Methods: In the present study we combined time domain Laser Speckle Imaging (tLSI) technique with Digital Fluorescence Intravital Microscopy (dFIM).

Results: tLSI approach has been used for rendering blood vessels structure and monitoring blood flow in the mouse ear *in vivo*, with high spatial resolution, whereas dFIM provides visualization of thrombus formation and changes in the vascular permeability, assisted by application of various fluorescent contrast agents (Fluoroscein, FITC, Rhodamin 6G).

Conclusion: The combined application of tLSI and dFIM approaches provides efficient *in vivo* imaging method of laser induced thrombus formation along with changes in blood flow velocity within all vessels in the region of interest.

PB 4.53-6

Evaluation of a new liquid recombinant human thromboplastin reagent for the determination of prothrombin time (PT) in an optical coagulometer

Miranda M and Montanini V

Diagnostic Grifols, Parets del Vallès, Spain

Background: A new liquid recombinant human thromboplastin reagent (DG-PT L Rec) for the determination of prothrombin time (PT) was evaluated by Grifols prior to its launch. This reagent is intended mainly for screening of the extrinsic coagulation pathway and monitoring oral anticoagulant therapy (OAT).

Aims: The aim of this study was to evaluate the performance of the reagent in Q Hemostasis Analyzer (Grifols) with normal and OAT samples, by comparing it to an established similar reagent, as well as assessing its precision with commercial control plasma.

Additionally, performance of the reagent in PT-derived fibrinogen assay (PT-DF) was evaluated by comparing it to fibrinogen Clauss assay, and assessing its precision with commercial control plasma.

Methods: Precision was determined according to CLSI EP5 guidelines in normal (DG-C1) and abnormal (DG-C2) lyophilised control plasma and in a commercial pool of normal plasma (PNP).

DG-PT L Rec performance was compared to an established recombinant human thromboplastin (Innovin, Siemens). Method comparison was performed by analysing 105 fresh platelet poor plasma (PPP) from patients under OAT therapy and apparently healthy individuals.

Comparison of PT-DF assay and fibrinogen Clauss assay (DG-FIB L Human, Grifols) was performed by analyzing 35 fresh PPP from apparently healthy individuals.

Results: Within-run precision (CV_{wr}) in seconds and ratio was lower than 3% in normal and abnormal level. Within-device precision

(CV_{wd}) in seconds and ratio was within 4% in normal and abnormal level.
Least-square linear regression of the results obtained by DG-PT L Rec and Innovin achieved a correlation coefficient (r) higher than 0.990. DG-PT L Rec obtained longer clotting times in OAT samples, being thus highly sensitive for these kind of samples. There was no clinically significant difference neither in ratio for normal samples nor in INR for OAT samples in the therapeutic range.
For PT-DF assay, CV_{wr} and CV_{wd} in mg/dL were lower than 6% and 8%, respectively, in normal and abnormal level.
Least-square linear regression of the results obtained by PT-DF assay and DG-FIB L Human achieved a correlation coefficient (r) higher than 0.970. There was no clinically significant difference in normal fibrinogen values.
Conclusion: DG-PT L Rec is a liquid recombinant human thromboplastin reagent suitable for screening of the extrinsic coagulation pathway and monitoring oral anticoagulant therapy in Q Hemostasis Analyzer, obtaining precise and reliable results.
DG-PT L Rec is adequate for PT-DF assay in Q Hemostasis Analyzer, achieving precise results and being comparable to Clauss fibrinogen assay results for normal samples.

PB4.54 – Blood coagulation tests – XVIII

PB 4.54-1
Influence of FIX and FVIII PEGYLATION on FIX and FVIII activity based on APTT assays

Lochu A[1], Romari N[1], Beltran J[1], Magdelaine A[1], Ezban M[2] and Hermit MB[2]
[1]Diagnostica Stago, Gennevilliers, France; [2]Novo Nordisk, Måløv, Denmark

Background : N9-GP is a 40kD PEGylated recombinant human FIX derivate and N8-GP is a 40kD PEGylated recombinant human FVIII derivate in development at NOVO NORDISK. It is a new class of molecules for the treatment of haemophilia, characterized by a prolonged half-life. It has been shown that PEGylation of proteins could influence the clotting times in certain APTT based assays.
Aim : The aim of this study is to evaluate the impact of PEGylation of FIX (N9-GP) and FVIII (N8-GP) on respectively FIX and FVIII activity using the one stage clotting assay with a wide range of APTT reagents (Diagnostica Stago and TCoag) on the STA-R® analyser (mechanical clot detection, Diagnostica Stago) and chromogenic assays (Hyphen).
Methods : FIX deficient plasmas were spiked with FIX preparations: BeneFIX® (Pfizer) or N9-GP (Novo Nordisk). FVIII deficient plasmas were spiked with FVIII preparations: Advate® (Baxter) or N8-GP (Novo Nordisk). These preparations were tested both in one-stage clotting assays using different APTT reagents from Stago and TCoag, on the STA-R®, and with chromogenic assays. WHO International Standards, BeneFIX® or Advate® and N9-GP or N8-GP preparations were used as calibrators.
Results : The results of this study for N9-GP showed a wide variability of the FIX activity using non-PEGylated molecules as calibrators, depending on the APTT reagent used. Levels of FIX were underestimated with a Kaolin based APTT reagent (STA® - CK Prest®), overestimated with Silica based APTT reagents (STA® - PTT A, TriniCLOT Automated aPTT, TriniCLOT aPTT HS and TriniCLOT aPTT S), slightly underestimated with an Ellagic Acid based APTT reagent (STA® - Cephascreen ®) and in the normal range with a FIX chromogenic assay.
Using the N9-GP molecule as calibrator, FIX levels were all in the normal range, whatever the APTT reagents.
Concerning FVIII activity, using non-PEGylated molecules as calibrators, levels of FVIII were underestimated with Silica based APTT reagents (STA® - PTT A, TriniCLOT Automated aPTT, TriniCLOT aPTT HS and TriniCLOT aPTT S) and in the normal range with a Kaolin based APTT reagent (STA® - CK Prest®), with an ellagic acid based APTT reagent (STA® - Cephascreen®) and with a FVIII chromogenic assay.
Using the N8-GP molecule as calibrator, FVIII levels were all in the normal range, whatever the APTT reagents.
Conclusions : The study confirmed the impact of PEGylation of FIX and FVIII on FIX and FVIII activity APTT based assays, respectively. Some reagents provided activity in the normal range while other APTT reagents showed a wide variability. Further investigations are needed to understand the biochemical mechanisms involved in these interactions and to try to normalise the results by different means such as the use of a specific calibrator or assigning an assay specific conversion factor to obtain results comparable to those obtained with chromogenic assays.

PB 4.54-2
Influence of time delays in sample processing on protein S assays

Hickey KP, Cooper P, Kitchen S and Makris M
Sheffield Haemophilia and Thrombosis Centre, Sheffield, UK

Background: There is increasing centralisation of coagulation services with requirement to transport samples to central sites for testing. Plasma may be frozen for transport but the cheaper option, transportation of blood samples at ambient temperature may sometimes be considered. Preanalytical variables such as time delay in sample processing can adversely influence coagulation tests.
Aims: To investigate the effect of storing citrated whole blood at room temperature for 24 h, on different activity and antigenic assays of free protein S (FPS).
Method: Five samples were drawn from healthy donors (n = 10) into Becton Dickinson (BD) citrated (0.109 M) vacutainer tubes. One sample was centrifuged (2000 g for 10 mins) and plasma aliquots frozen at −70 °C within 30 min of venepuncture (time 0). The remaining samples were stored at 20–25 °C for 4, 8, 12 and 24 h and plasma frozen at −70 °C. FPS antigen was measured by; automated immunoassay (FPS-IL) (Instrumentation Laboratory, UK), Liatest FPS (Stago, France), Innovance FPS (Siemens, UK), and ELISA (Woodhams method). Samples were also tested with PS activity assays; Clot S (Precision Biologic, Canada), Pro S (IL, UK), Protein S Ac (Siemens, UK) and StaClot (Stago, France).
Results: There was no statistically significant change over 24 h in FPS levels when tested by Liatest, Innovance or ELISA assay ($P \geq 0.05$) The Liatest and Innovance FPS antigen assays showed a mean 3% fall in FPS at 24 h and the FPS ELISA, a mean 2% fall in FPS at 24 h. With FPS-IL statistically significant change was observed at 8 h ($P \leq 0.05$), with a mean 11% fall (range −8 to −14%) in FPS at 24 h. Statistically significant change in StaClot PS activity occurred at 12 h ($P \leq 0.01$), however diagnostically significant changes were observed in individual samples by 4 h. The other activity assays showed statistically and diagnostically significant change in PS activity at 8 h ($P \leq 0.05$). Overall falls in PS activity at 24 h; Clot C (mean −15%, range −9% to −29%), Pro S (mean −17%, range −12 to −26%), Protein S Ac (mean −14%, range −7 to −24%), StaClot (mean −14%, range +10 to −32%).
Conclusion: FPS antigen demonstrates differing stability in samples stored as whole blood depending on methodology employed for analysis. Liatest and Innovance FPS methods employ two monoclonal antibody and share similar stability to ELISA technique utilising polyclonal antibody. Increasing loss of measurable FPS is observed in the FPS-IL assay which incorporates an initial stage of binding FPS to a C4b-binding protein latex reagent prior to the addition of a monoclonal antibody latex reagent. Whole blood samples stored at room temperature are stable for FPS measurement for 24 h if analysed using Liatest, Innovance or ELISA FPS assays, but <8 h if using FPS-IL.

We have previously shown that FPS can be reliably measured by ELISA (polyclonal antibodies) up to 72 h, whilst FPS-IL demonstrated increasing instability with statistically significant change at 48 and 72 h ($P \leq 0.001$).

PB 4.54-3

Time-and space-resolved imaging of coagulation as a method for monitoring the effectiveness of LMWH therapy after total hip replacement

Serebriyskiy I[1], Taranenko IA[2], Vuimo TA[1], Surov S[1], Ovsepyan RA[1], Ataullakhanov F[1] and Momot AP[2]
[1]HemaCore, Moscow; [2]Altay branch of Research centre for Hematology, Ministry of Health, Barnaul, Russian Federation

Background: In the postoperative period after total hip replacement patients assigned LMWH. Anticoagulant therapy in some patients can be ineffective. The aim of this study was to investigate the possibility of a new global coagulation assay to control effect of enoxaparin.
Methods: *In vitro* study – plasma samples frome nine patients after total hip replacement with the addition of increasing concentrations of enoxaparin 0.0, 0.03, 0.06, 0.12, 0.25, 0.5, 1.0, 2.5 anti-Xa IU/mL. The clinical study included 44 patients before and after total hip replacement. Enoxaparin 40 mg opd, 1–10 day after surgery. Plasma samples were collected before surgery, after surgery before the start of enoxaparin, after 5 days of enoxaparine treatment, after 10 days of enoxaparine treatment, after 30 days postop, after 90 days postop. Time-and space-resolved imaging of coagulation (Thrombodynamics, HemaCore LLC, Russia) – a new global coagulation assay based on videomicroscopy of a fibrin clot growing from an imitated damaged vessel wall (surfaces with immobilized tissue factor), the growth rate of the fibrin clot in space V was measured (norm 20–30 μm/min).
Data are presented as Median (25th percentile; 75th percentile), * - $P < 0.05$.
Results : *In vitro* experiments V were: 0.0 IU/mL – 34.7(33.7;35.8), 0.03 IU/mL – 30.9(27.1;31.0)($P = 0.008$ vs. 0.0 IU/mL), 0.06 IU/mL – 23.(21.6;24.2) ($P = 0.008$ vs. 0.03 IU/mL), 0.12 IU/mL – 14.1 (13.8;15.5)($P = 0.008$ vs. 0.06 IU/mL), 0.25 IU/mL – 10.0 (9.5;10.1) ($P = 0.008$ vs. 0.12 IU/mL), 0.5 IU/mL – 5.5(5.0;8.3)($P = 0.008$ vs. 0.25 IU/mL), 1 IU/mL – 4.9(3.0;5.3($P = 0.01$ vs. 0.5 IU/mL), 2.5 IU/mL – 2.0(1.6;2.5($P = 0.008$ vs. 1.0 IU/mL).
In clinical study V in patients plasma samples were: before surgery – 28.1(26.1; 31.1), after surgery – 41.9 (34.6; 46.2)(* vs. preop.), on the 5th day – 26.9(20.6;30.8)(* vs. postop.), 10 day – 26.5(21.3;29.7), 30 day – 28.5(26.0;33.4)(* vs. 10 day), day 90 – 36.0(32.3;42.3)(* vs. 30 day).
Conclusion: Growth rate of the fibrin clot in space V can be use for detecting of enoxaparin anticoagulant effect. In pts after HIP replacement V can detect enoxaparin anticoagulant effect and can detect some pts with return postop. condition after end of enoxaparin treatment

PB 4.54-4

Evaluation of TEG® and ROTEM® inter-changeability

Campello E, Luca S, Claudia RM, Sara M, Elena P and Paolo S
Department of Cardiologic, Throcacic and Vascular Science, University of Padua, Padova, Italy

Background: The principle behind Viscoelastic Haemostatic Assays is based on the tendency of blood to increase its viscosity and elasticity through the process of coagulation. The clot changes over time are visualized as an evolving trace where the time to initiation of clot formation, the rate of clot formation and the maximum strength of the clot are among the most commonly utilized variables. The greatest use has been the application of VHAs-guided transfusion of blood components in hepatic and more widely in cardiac surgery. Recent years have seen a renewed interest in this technology with applications for both pharmaceutical monitoring and patient screening. Two frequently used VHA devices are TEG® and ROTEM®. They differ markedly in terms of function and user interface, and it is not clear whether this affects their performance in a clinical setting. Only a few studies have previously compared the interchangeability of TEG® and ROTEM®. In particular, studies performed within cardiac surgery and liver transplantation procedures concluded that the assays may be inter-changeable. Conversely, inter-changeability seemed to be limited in the trauma setting.
Aim: The aim of our study was to compare the results of the TEG® and ROTEM® analyses in a cohort of patients with different pro-hemorrhage conditions and to assess the inter-changeability of the two devices.
Methods: We measured blood samples from 18 consecutive patients referred to our Unit for a pro-hemorrhagic condition. The TEG® and ROTEM® assays were performed simultaneously. In the TEG® system, we performed three measurements: the kaolin TEG® (kaoTEG), the rapid TEG® (r-TEG), and the functional fibrinogen (FF-TEG). In the ROTEM® system three measurements were also performed: INTEM, EXTEM and FIBTEM. We compared three widely used variables from the VHA trace: the reaction time from initiation of the assay to the first detectable coagulation, denoted R-time for TEG® and clotting time (CT) for ROTEM®; the time from start of coagulation to clot amplitude of 20 mm, called the K-time in TEG® and clot formation time (CFT) in ROTEM®; lastly, the maximum amplitude (MA) for TEG®, which corresponds to the maximum clot firmness (MCF) for the ROTEM® device. Correlations were calculated using Sperman's rank correlation coefficient.
Results: Patients enrolled were bleeding during bi-ventricular assistance (4), during liver transplantation (3), cardiovascular surgery (5), trauma (2), pediatric patients under L-Asparagenase induction therapy for acute lymphatic leukemia (4). We found a good correlation between: (a) MCF and MA in the three tests considered (INTEM vs. kaoTEG $r = 0.77$, $P < 0.01$; EXTEM vs. r-TEG 0.76, $P = 0.01$; FIBTEM vs. FF-TEG $r = 0.69$, $P < 0.01$); (b) CT and R-time in INTEM vs. kaoTEG ($r = 0.57$, $P = 0.002$) and in EXTEM vs. r-TEG ($r = 0.51$, $P = 0.01$); (c) CFT and K-time in INTEM vs. kaoTEG ($r = 0.27$, $P = 0.04$) and in EXTEM vs. r-TEG ($r = 0.31$, $P = 0.03$).
Conclusions: According to these observations inter-changeability between TEG® and ROTEM® is confirmed in different clinical settings. The search for a 'global' assay of haemostasis continues and the TEG®/ROTEM® or a derivative of this technology may provide the answer, or part of the answer, to that question.

PB 4.54-5

Unravelling the thrombin generation assay

Dunster JL[1], Byrne H[2], Franks S[3], Gibbins JM[1] and King J[4]
[1]University of Reading, Reading; [2]University of Oxford, Oxford; [3]Health and Safety Laboratory, Buxton; [4]University of Nottingham, Nottingham, UK

Background: The enzyme thrombin is central to blood coagulation, being the end product of a complicated protein cascade with multiple feedbacks that operates over multiple time scales to ensure thrombin is delivered to the right place at the right time. The propensity for a patient's blood to clot may be determined by the thrombin generation assay. A typical profile of thrombin generation over time is characterised by an initial lag phase followed by a rapid increase that is subsequently inhibited. Recent improvements in, and commercialisation of, the thrombin generation assay mean that there are an expanding number of studies utilising it.
Aims: By modelling and mathematical analysis of the reactions within the thrombin generation assay we hope to enhance our understanding of the sequence of reactions within this complicated network providing simplified approximations and network diagrams that clearly indicate which reactions dominate at each point in time. Comparison of model

simulations to experimental data in principle allows us to determine if current biological knowledge of the thrombin generation cascade is sufficient to explain experimental results.
Method: We present a mathematical model for the early steps in the generation of thrombin. We have analysed this model using the method of matched asymptotic expansions to derive a sequence of simplified models in time that characterise the key reactions within the cascade.
We have then extend our initial model to represent the coagulation cascade as it would occur in the environment of the thrombin generation assay. The resulting system of ordinary differential equations is used to generate numerical simulations that we compare to some of the experimental data now being generated from the commercial assay under a variety of disease conditions.
Results: The mathematical analysis breaks down the complicated network of reactions into a series of much simpler mathematical approximations in time. Two of the simplified models found provide an excellent substitute for the full model, capturing the exposive growth in thrombin generated and then its decay. We also derive simple mathematical expressions for the key parameters of time-lag, peak concentration and ETP (area under the curve) that describe the thrombin generation assays trace in time.
Numerical simulations of our full model, without any modification in parameter values obtained from literature, show a close fit to published experimental data.
Conclusion/Summary: By applying the method of matched asymptotic expansions to this complicated network of reactions we have produceda series of simple mathematical snapshots at distinct points in the time scale over which thrombin is generated. This allows us to understand the dependenceof eachtime-point on protein levels and rate parameters. Fromthis we are able to derive simple mathematical expressions for the key markers of thrombin generation(e.g. peak concentration and ETP) allowingamuch simpler interpretation of them in terms of the kinetic parameters. Approximations such as these could be used to connect experimentally derived biological markers to the underlying mechanisms that cause them to vary.

PB 4.54-6
Validation of a new liquid fibrinogen assay

Berthier A[1], Blanc M[2], Foissaud V[3] and Khoury E[4]
[1]Stago, Asnieres-Sur-Seine; [2]Emile Roux Hospital, Le Puy-en-Velay; [3]Military Hospital, Percy; [4]General Hospital, Le Raincy – Montfermeil, France

Background: The Clauss method for fibrinogen testing appears to be the most reliable method for general use in clinical laboratories.
Aim: STA® – Liquid Fib is a new liquid fibrinogen assay for the quantitative determination of fibrinogen levels in plasma which is based on the Clauss clotting method.
The aim of this study was to evaluate STA® – Liquid Fib performances through a method comparison conducted in three different laboratories: Le Puy en Velay, Montfermeil and Percy;France.
Method: Patients were tested with STA® – Liquid Fib and the reference method: STA® – Fibrinogen 5 on STA-R® or STA® Compact analyzers using precalibrated test setups.
673 patients referred to the laboratory for fibrinogen testing and were included in the study.
45 samples had fibrinogen levels under 1.5 g/L and 47 samples had fibrinogen levels above 8 g/L. Samples were spread along the working range (0.4–12 g/L).
Correlations were analyzed through linear regressions (STA® – Liquid Fib vs. STA® – Fibrinogen 5) and Bland Altman Graph.
Results: Results obtained with the new reagent STA® – Liquid Fib vs. the current reagent STA® – Fibrinogen 5 are well correlated:
- Puy en Velay: y = 1.00x – 0.13 (r = 0.99)
- Montfermeil: y = 1.00x −0.01 (r = 1.00)
- Percy: y = 1.03x −0.12 (r = 0.99)

A Bland Altman Graph shows that more than 95% of samples are within the acceptable ranges.
Conclusion: Results show good consistency between STA® – Liquid Fib and STA® – Fibrinogen 5. In addition, STA® – Liquid Fib improves workability by its ready to use liquid format.

PB4.55 – Coagulation factor VIII

PB 4.55-1
Detection of non-human sialic acid *N*-glycolylneuraminic acid in Factor VIII products by ultra-performance liquid chromatography with fluorescent labeling

Lu Q, Mei B and Peters RT
Biogen Idec Hemophilia, Waltham, MA, USA

Background: Glycosylation is a common posttranslational modification found on mammalian proteins, and these glycan structures often terminate with a sialic acid. Human glycans terminate with a specific form, *N*-acetylneuraminic acid (NANA). However, recombinant glycoprotein therapeutics produced in animal cell lines and/or with animal serum often contain *N*-glycolylneuraminic acid (NGNA), a derivative of NANA, which is not normally found in humans. It has been reported that all humans possess anti-NGNA antibodies and sometimes at high level approaching 0.1–0.2% of circulating IgG. As a result, NGNA is potentially immunogenic and needs to be monitored.
Aims: The aim of the study is to determine NGNA levels in recombinant FVIII Fc fusion protein (rFVIIIFc), which is expressed in a human cell line, HEK 293, and compare to NGNA levels in other recombinant FVIII products that are produced in animal cell lines, by using a sensitive ultra-performance liquid chromatography (UPLC) method with fluorescence detection after 1,2-diamino-4,5-methylenedioxybenzene (DMB) labeling.
Methods: FVIII samples were incubated with 50 mM sulfuric acid at 80 °C for an hour, and the released NGNA was then derivatized with DMB at 50 °C for 3 h covered by aluminium foil. The DMB derivatized sample was analyzed by UPLC fluorometric detection using a C18 column (1.7 μm particle size). The NGNA standards were prepared the same way as protein samples to obtain the calibration curve. The NGNA levels in FVIII molecules were determined based on the obtained calibration curve. The percentage mole NGNA per mole of protein was calculated for all the tested FVIII products.
Results: The method showed very good linearity for NGNA from 2.5 fmol to 6.2 pmol. The limit of detection (LOD) and limit of quantitation (LOQ) for NGNA were estimated to be 2.5 fmol and 4.5 fmol, respectively. No detectable NGNA was found in rFVIIIFc that was produced with human cell line HEK293, whereas different levels of NGNA (mole percentage) were detected in the marketed recombinant B-domain deleted FVIII (20.31 ± 0.73%) and two marketed full length recombinant FVIII (1.33 ± 0.14% and 5.99 ± 0.32%, respectively) which are all produced with animal cell lines, CHO or BHK.
Conclusions: A very sensitive and robust UPLC method with fluorescence detection was developed for the detection of NGNA after DMB labeling. No NGNA was found in rFVIIIFc by this method as expected, whereas all the other recombinant FVIII products tested contained levels of NGNA significantly above the LOD of the assay. Although the impact of the presence of these potentially immunogenic non-human modifications are not known for FVIII, recombinant expression using a human cell line grown in chemically defined media ensures that the glycan structures are fully human.

PB 4.55-2

Molecular characterization of nine F8 splicing mutations in RNA isolated from patient's leukocytes. Evaluation of in silico prediction tools accuracy

Martorell L[1], Corrales I[2], Parra R[3], Raya A[4], Barquinero J[5] and Vidal F[2]

[1]Institute for Bioengineering of Catalonia (IBEC), Barcelona; [2]Banc de Sang i Teixits, Barcelona; [3]Banc de Sang i Teixits, Hospital Universitari Vall d'Hebron, Barcelona; [4]Inst. Bioengineering Catalonia (IBEC, CIBER ICREA), Barcelona; [5]Institut de Recerca Hospital Vall d'Hebrón (VHRI-UAB), Barcelona, Spain

Background: The inherited deficiency Haemophilia A (HA) is caused by a broad spectrum of defects in the FVIII gene (*F8*). Mutations affecting mRNA splicing comprise approximately 8% of the reported HA cases in the *F8* mutation database. However, only a few of them have been fully characterized by mRNA analysis.

It is known that correct mRNA splicing involves four different signals to recognize exon-intron boundaries: 5' and 3' splice junctions of the intron, branch sites and a polypyrimidine tract. In addition, exon recognition can be affected by several cis-acting elements within the exons and introns. *In silico* prediction analysis can provide a valuable means to predict the molecular effect of splice site mutations, however it only displays score variations, which difficult the interpretation regarding the exact biological consequences.

Aim: To systematically characterize the phenotypic effect of potential splice site mutations (PSSM) and to understand the correlation with FVIII levels and disease severity.

Methods: Eight pairs of primers were designed for full-length *F8* cDNA amplification by single-step RT-PCR in RNA isolated from leukocytes. This procedure was used to study nine (six of them hitherto unreported) PSSM, previously identified at genomic level in the routine molecular diagnostic of HA patients. The effect of PSSM in the *F8* mRNA expression and processing was studied using samples from healthy donors as a control. The concordance of *in silico* predictions and experimental data was then assessed.

Results: The mRNA analysis in the HA index cases demonstrate diverse molecular mechanism: c.601 + 1delG produces either the exon 4 or 4 plus 5 skipping; c.602-11T>G results in the exon 5 skipping; c.671-3C>G where either exon 6 or 5 and 6 were lost; c.6115 + 9C>G that skipped exon 19; and c.6016-1G>A where the exon 20 was skipped. Both c.1009 + 1G>A and c.1009 + 3A>C mutations resulted in the activation of a cryptic donor splicing site skipping the last 121 bp and 135 bp respectively of exon 7; and finally, intron retention was showed in cases: c266-3delC that result in the activation of a cryptic acceptor splicing site (ASS) 57 bp within the intron 2 and c.5587-1G>A that presented a cryptic ASS 44 bp within intron 16. The experimental results obtained were compatible with observed phenotypes. Although, *in silico* analyses were unable to predict the splicing effect of several mutations, combination of distinct *in silico* tools running distinct algorithms is sensitive and accurate predicting in many cases whether an effect on splicing is expected and can be used prudently as a decision-making guide.

Conclusion: The method developed can be extended to study the pathogenic effects of any PSSM along *F8*. Our results also demonstrated the presence of ectopic aberrant transcripts in leukocytes from HA patients and from control samples, that could hinder the interpretation of results. Hence, the study of *F8* mRNA from leukocytes has to be considered carefully but it is still a useful tool to determine the mechanisms by which PSSM contributes to the phenotype in HA patients.

Funding: HEMO-iPSC (FIS PI11/03024-PI11/03029)

PB 4.55-3

Heat-sensitization allows the detection of anti-FVIII antibodies in patients with acquired hemophilia, who have a negative Bethesda assay

Bodo I[1], Szederjesi A[1], Galgoczi J[1], Kael K[1], Nagy E[2], Pap K[1], Szabo K[1], Varkonyi A[1], Vilimi B[1] and Masszi T[1]

[1]St. Istvan & St. Laszlo Hospital; [2]National Rheumatology Institute, Budapest, Hungary

Background: The Bethesda assay is the standard way to detect anti-FVIII antibodies (Abs) in both hereditary hemophilia A (HA) with inhibitors, and acquired hemophilia A (AHA). Unfortunately, the Bethesda assay is insensitive. A recent modification reported that heat treatment sensitized the traditional Bethesda assay in patients with HA who had presumed inhibitors based on the fact that they had shortened *in vivo* FVIII survival. There is no available data so far with the modified assay in AHA. AHA antibodies are different from the inhibitors found in hereditary HA in many ways. Thus, it is not trivial that the modification should also work in AHA. Also, the setting of treated AHA offers a much more convenient way of detecting the *in vivo* effect of the inhibitor, because endogenous FVIII levels rise gradually with treatment and there is no need to measure exogenous FVIII half life.

Aims: To prove the concept of heat-sensitization for the classic Bethesda assay, and to see if heat treatment will also render the Bethesda assay more sensitive in detecting antibodies in AHA patients.

Methods: To prove the concept, we tested the sensitized assay in a cohort of 15 AHA patients followed at our institution. We identified samples stored between October 2011 and January 2013. We identified 14 samples with FVIII <70%, and a traditional Bethesda assay result of <5 BU for testing with the heat sensitized method1. As a negative control, we also tested 24 samples from the same patients with FVIII>70% (i.e. samples from patients in complete remission).

Results: Of 15 consecutive patients with AHA, we identified seven patients who had samples with FVIII levels <70%. Of these seven patients, five had at least one sample that tested negative with the traditional Bethesda assay, while positive with the modified heat-sensitized assay. Of 14 samples with FVIII <70% and negative traditional Bethesda assay, eight tested positive with the modified heat-sensitized assay. In four patients, where the false-negative FVIII zone with the traditional Bethesda assay could be determined (i.e. the zone where only the sensitized assay detects anti-FVIII ABs), the zone fell between 42% and 67% FVIII. All samples that tested positive with the classic assay were also positive with the modified assay. None of the 24 patient samples with >70% FVIII levels had positive antibody tests with either of the assays.

Conclusion: We conclude that the heat-sensitized modified Bethesda assay allows detection of previously undetected anti-FVIII Abs in a large proportion of acquired hemophilia A patients. This proves the concept of the heat treatment making the assay more sensitive while preserving specificity.

Identification of structurally permissive regions in coagulation factor VIII suitable for the insertion of exogenous peptidyl elements

John K[1], Liu T[1], Chang P-YB[2], Ding S[2], Patarroyo-White S[1], Goodman A[1], Kumar S[1], Wang D[3], Seth Chhabra E[1], Mezo A[1], Pierce JR[4], Haiyan J[5], Baisong M[6], Schellenberger V[7] and Robert P[6]

[1]Biogen Idec Hemophilia, Waltham, MA; [2]Amunix Inc., Mountain View, CA; [3]Biogen Idec, Cambridge, MA; [4]Biogen Idec, Cambridge, MA; [5]Biogen Idec Hemophilia, Waltham, MA; [6]Biogen Idec Hemophilia, Waltham, MA; [7]Amunix Inc, Mountain View, CA, USA

Background: Several strategies for extending the half-life of human factor VIII (FVIII) have resulted in the development of variants that achieve up to a 1.6-fold half-life increase in humans compared to unmodified FVIII. The intra-domain insertion of unstructured hydrophilic polypeptides of defined amino acid composition and low immunogenic potential (XTENs) is a promising alternative approach for generating FVIII variants with improved pharmacokinetic properties. The impact on the clearance and function of FVIII may be optimized by varying the location, composition, length and number of XTEN insertions by entirely recombinant methods. This work provides the first example of a systematic effort to identify sites within FVIII that can structurally accommodate the insertion of exogenous peptidyl elements, including XTEN, without the loss of FVIII activity.

Aim: To evaluate the amenability of FVIII to intra-domain polypeptide insertion and to lay the groundwork for the development of multiple XTEN-containing FVIII molecules with improved pharmacokinetic properties.

Methods: Insertion sites within FVIII were selected on the basis of the following criteria: (i) significant inter-species protein sequence variability, (ii) high calculated accessible surface area, (iii) exclusion of sites within defined secondary structural elements, (iv) moderate to high intrinsic flexibility predicted by molecular dynamics simulation, and (v) exclusion of sites proximal to known hemophilia A missense mutations. A 42 residue XTEN element (XTEN-42) was inserted at sites that satisfied these criteria, as well as at selected sites that did not, and the resulting FVIII activity in conditioned medium of transfected HEK293 cells was measured. Next, XTEN-144 was substituted at sites that had yielded activity with XTEN-42 insertion and inserted at several additional sites, including those determined to be structurally analogous by spatial alignment of FVIII domains, and activity was similarly measured. Several different non-XTEN peptidyl elements were also substituted at positions determined to be permissive for insertion.

Results: Based on the criteria described above, a total of 59 sites in FVIII were evaluated with XTEN-42 and/or XTEN-144 insertion. Of these, 37 sites, designated 'permissive sites', accommodated the insertion of either XTEN-42 or XTEN-144, or both, as determined by FVIII chromogenic assay. No permissive sites for XTEN-144 insertion were identified in the C domains of FVIII. Rather, permissive sites clustered within two distinct surface loops, designated 'permissive loops', in each of the three A domains. These permissive loops occupy structurally analogous positions in the A domains of FVIII and correspond spatially to sodium binding elements on the surface of ceruloplasmin, a copper-binding paralog of FVIII and FV. Tolerability to insertion was not XTEN-specific, as FVIII accommodated diverse polypeptides including GFP, a 27 kDa protein with a defined tertiary structure, at these sites without abrogation of cofactor activity.

Conclusions: The permissive sites identified in FVIII are located within particular regions that tolerate insertion of peptidyl elements without loss of FVIII activity. These results set the stage for combinatorial approaches to evaluate the effect of multiple XTEN insertions on the activity and pharmacokinetic properties of FVIII.

PB 4.55-5

Factor VIII assessment using one-stage clot and chromogenic assay in trials investigating pharmacokinetics of different FVIII products

Tiede A[1], Ezban M[2], Krogh-Meibom T[3], Saugstrup T[2] and Møss J[2]

[1]Hannover Medical School, Hannover, Germany; [2]Novo Nordisk A/S, Søborg, Denmark; [3]Aarhus University, Tjele, Denmark

Background: Two assays are widely used for assessment of FVIII:C activity in plasma, the one-stage clot assay (OS) and the two-stage chromogenic substrate (CS) assay. The CS assay is mainly used for potency labelling of FVIII concentrates, in particular inEuropeaccording to EMA guidelines. Outside Europe, FVIII concentrates are often labelled according to the OS assay, which is also more widely used to monitor treatment in clinical practice. Discrepancies between these two assays have been reported and attributed to specific products, assay conditions, or the standard used.

Aims: To assess the impact of OS vs. CS assay discrepancy on pharmacokinetic parameters that are typically reported in clinical trials.

Methods: Clinical samples: Samples were derived from clinical trials in adult previously treated patients (ED>150) with severe haemophilia A (FVIII <1%) after a washout period of at least 4 days. A single intravenous dose of different FVIII products (recombinant or plasma-derived) was administered at a dose of 25, 50 or 75 IU/kg. Blood samples were collected before dosing, (15 min), 30 min, 1, 4, 8, 12, 24, 30 and 48 h post dose. Spiked plasma: Haemophilia A plasma was spiked with FVIII concentrates (target concentration: 0.03, 0.2, 0.6 and 0.9 IU/mL). Products: Three recombinant products (Advate® Baxter, Kogenate® Bayer, and turoctocog alfa, Novo Nordisk) and three plasma-derived FVIII products (Hemofil M® Baxter, Emoclot® Kedrion, and Fandhi® Grifols). Assays: OS assay using the SynthASil (Instrumentation Laboratory) aPTT reagent and CS assay based on the Coamatic® kit (Chromogenix). All measurements were done against commercial standard human plasma (Siemens) for the clinical samples and the 6th WHO FVIII plasma standard for the spiked samples.

Results: All recombinant products showed a discrepancy between results from OS and CS assay. The FVIII activity measured with the CS assay was higher than when measured with the OS assay (mean CS/OS ratios: Kogenate 1.65, Advate 1.22, turoctocog alfa 1.26). Plasma-derived products showed either no or very low discrepancies (mean CS/OS ratios: Hemophil 1.11, Emoclot 0.97, Fandhi 1.11). Similar results were obtained with spiked plasma samples. The discrepancy was consistently observed across the whole range of activities tested in clinical samples (0.01–1.5 IU/mL) and spiked plasma (0.03–0.9 IU/mL). The assay discrepancy affected most PK parameters (AUC, CL and $C_{30\ min}$), but had less impact on the terminal half-life.

Conclusion: The discrepancy between the two types of FVIII assay affects all recombinant products regardless of the length of the B-domain. The discrepancy affects parameters reported in clinical trials as well as routine monitoring. This should be taken into account when comparing trials and products. The consistent use of CS assay for labelling and monitoring of products or the use of product specific standards may eliminate discrepancies.

PB 4.55-6

Pre-clinical pharmacokinetic and pharmacodynamic (PK/PD) characteristics of rVIII-SingleChain, a novel recombinant single-chain FVIII

Zollner S, Raquet E, Feussner A, Müller-Cohrs J, Metzner H, Weimer T, Pragst I, Dickneite G and Schulte S

CSL Behring GmbH, Marburg, Germany

Background: rVIII-SingleChain, a novel recombinant coagulation factor VIII, produced and formulated without added animal- or human-derived materials, is under development at CSL Behring in the clinical trial program AFFINITY.

Aim: The present nonclinical studies were conducted in animals to gather knowledge about the PK/PD characteristics and as a result may enable a more precise estimate of the haemodynamic efficacy of rVIII-SingleChain for future clinical use in haemophilia A patients.

Methods: The PK behaviour of rVIII-SingleChain was assessed in different preclinical animal species. Doses ranging between 50 and 250 IU/kg of rVIII-SingleChain or licensed full-length FVIII concentrates were given to animals as a single intravenous administration. Plasma samples were drawn at various time-points following drug administration and systemic FVIII levels were determined by means of FVIII activity or FVIII antigen measurements. For investigation of the PD activity, escalating doses of rVIII-SingleChain and comparators, comprising either B domain deleted or full length FVIII, were administered to haemophilia A mice. Following drug treatment total blood loss was monitored as a primary endpoint after tail clip and a subsequent 30 min observation period. Furthermore, procoagulant activity was measured as occlusion rate in a $FeCl_3$-induced arterial thrombosis model *in vivo* and by recording thrombin generation activity *ex vivo*, both after administration of rVIII-SingleChain or full-length FVIII to haemophilia A mice at dose levels of 200–250 IU/kg.

Results: Overall, treatment with rVIII-SingleChain resulted in slightly, but consistently improved pharmacokinetic properties compared to full-length rFVIII when measuring plasmatic FVIII concentrations. In all animal species systemic availability, mean residence time and terminal half life were increased between 1.6 and 2 fold, while clearance rates were decreased two fold for rVIII-SingleChain compared to full-length rFVIII. Whereas, other variables like *in vivo* recovery and volume of distribution of rVIII-SingleChain were comparable to full-length rFVIII. Under acute bleeding conditions as present in the tail clip model, the pharmacodynamic efficacy of rVIII-SingleChain was found to be indistinguishable from all licensed rFVIII products tested. Furthermore, consistent with the favourable pharmacokinetic characteristics, equal doses of rVIII-SingleChain showed increased thrombin generation vs. full-length rFVIII: For advanced time points between 2 and 6 days thrombin peak levels of 50–250 nM were sustained after treatment with rVIII-SingleChain indicating an average extension of PD effects by 20 h. Similarly, prolonged procoagulant activity of rVIII-SingleChain compared to full-length rFVIII was observed in haemophilic mice over 64 h after treatment following $FeCl_3$-induced arterial thrombosis as a consequence of endothelial damage.

Summary/Conclusion: In conclusion, the nonclinical studies presented interesting PK/PD properties of rVIII-SingleChain in animals, since pivotal characteristics required for sustained haemostatic efficacy appear favourable. Results obtained from this investigations support the evidence necessary for proceeding with clinical trials and to explore whether such favourable nonclinical properties of rVIII-SingleChain may translate into clinical benefits for the treatment of haemophilia A patients.

PB4.56 – Angiogenesis and Arterial Vascular Disorders

PB 4.56-1

A Novel Technetate-99 m labeled anti-intergin peptide dimer useful for tumor imaging

JI S[1], Zheng Y[2], Ruan C[3] and Liu S[2]

[1]Jiangsu Institute of Hematology, Suzhou, China; [2]Purdue University, West Lafayettte, IN, USA; [3]Jiangsu Institute of Hematology First Affiliated Hospital of Soochow University, Suzhou, China

Background: Integrin a_vb_3 plays a significant role in tumor angiogenesis and metastasis, is expressed at very low levels on quiescent epithelial cells and mature endothelial cells, but it is overexpressed on activated endothelial cells of neovasculature and some tumor cells. Therefore, integrin a_vb_3 is considered as an interesting molecular target for early cancer detection. Cyclic RGD peptides are potent integrin a_vb_3 receptor antagonists.

Aims: Evaluation of ^{99m}Tc-HYNIC-6D-RGD_2as a new radiotracer for tumor imaging.

Methods: HYNIC-6D-RGD_2 was evaluated for its integrin $\alpha_v\beta_3$ binding affinity against ^{125}I-echistatin bound to U87MG cells in a whole-cell displacement assay. After radiolabeling, ^{99m}Tc-HYNIC-6D-$RGD_2$was analyzed by radio-HPLC. Female athymic *nu*/*nu* mice (4–5 weeks) were inoculated subcutaneously with 5×10^6 of U87MG cells into the shoulder flank of each animal. Three weeks after inoculation, the animals were used for biodistribution and imaging studies. The tumor-bearing mice (20–25 g) were randomly selected, and each animal was administered with ~0.1 MBq of ^{99m}Tc-6D-RGD_2 by tail vein injection. Animals (5–8) were sacrificed by sodium pentobarbital overdose (~200 mg/kg) at 5, 30, 60 and 120 min post-injection (p.i.). Blood, tumors and normal organs (brain, eyes, heart, spleen, lungs, liver, kidneys, muscle and intestine) were harvested, weighed, and counted on a Perkin Elmer Wizard – 1480 g-counter. The organ uptake was calculated as the percentage of injected dose per gram of wet tissue (%ID/g). The blocking experiment was performed using RGD_2 as the blocking agent in six animals.

Results: The IC_{50} value for HYNIC-6D-RGD_2 was calculated to be 66.68 ± 0.19 nM. ^{99m}Tc-6D-RGD_2 was prepared in very high specific activity and high radiochemical purity (>95%), and was able to remain stable in solution for >24 h post-labeling. The tumor uptake of ^{99m}Tc-6D-RGD_2 was 4.20 ± 0.42, 3.13 ± 0.47, 2.45 ± 0.90 and 0.30 ± 0.01%ID/g at 5, 30, 60 and 120 min post-injection, respectively. The blocking experiment clearly showed that the tumor uptake of ^{99m}Tc-6D-RGD_2 is integrin a_vb_3-specific.

Conclusion: Considering its high uptake in the xenografted U87MG glioma tumors, fast clearance from normal organs and high metabolic stability, it was concluded that ^{99m}Tc-6D-RGD_2 is may be a useful tool for imaging integrin a_vb_3-positive tumors.

PB 4.56-2

Optimal antithrombotic strategy in patients undergoing carotid endarterectomy

Gamzatov T and Svetlikov A

Sokolov Clinical Hospital 122, Saint Petersburg, Russian Federation

Background: Over the last decades carotid endarterectomy (CEA) has become one of the most common surgical procedures. The aim of CEA is to prevent stroke or transient ischemic attack (TIA) in patients with carotid artery diseas (CAS). Although protective, this procedure may be associated with minor and major neurological complications including stroke and TIA. Some of these complications are due to

improper surgical technique, inadequate neurological control or underestimation of collateral blood flow at the time of surgery. However, improper regimen of antithrombotic treatment during and after carotid endarterectomy is known to be important factor contributing to the development of neurological deficits in this group of patients.
International guidelines on the surgical management of carotid artery disease advocate for the routine use of low-dose aspirin (50–325 mg daily) before, during and after surgical procedure in order to prevent intraoperative and postoperative arterial thromboembolic complications. However, no algorithm has been proposed with regard to patients with aspirin-resistance as well as those, who are at a high risk for venous thromboembolism (VTE).
Aim: To optimize existing guidelines on the surgical management of carotid artery disease by suggesting the differentiated antithrombotic strategy for patients with aspirin resistance and those at high risk of venous thromboembolism.
Methods: 60 patients with carotid artery disease have been consecutively operated with conventional endarterectomy technique involving synthetic patch angioplasty. All patients were split in two groups according to their aspirin-resistance test. Group A (n = 12) was formed from the patients with aspirin-resistance and Group B (n = 48) without it. All patients received standard regimen of preoperative antiplatelet treatment with aspirin 75–150 mg daily. However, patients from group A (n = 12), have been put on clopidogrel 75 mg daily immediately after surgery provided that they didn't have documented clopidogrel-resistance. Patients from group B (n = 48) have been left on aspirin after surgical procedure. Those patients with high venous thromboembolism risk score (four patients in all, one from group A and three from group B) have been managed with prophylactic doses of low-molecular-weight heparins in addition to their antiplatelet treatment.
Results: Mean age of the study individuals was 68.5 ± 5.4 years for all enrolled subjects and did not vary considerably between two groups. Both groups were uniformly sex-matched. There have been no strokes or transient ischemic attacks in either group after surgery. Postoperative wound hematoma was diagnosed in two patients (4.2%) from group B, one of which required repeated surgical intervention.
Conclusions: In light of commonly encountered aspirin resistance, differentiated antithrombotic strategy is essential when considering optimal antithrombotic treatment in patients undergoing CEA. However, larger studies will be needed to confirm clinical efficacy of this approach.

PB 4.56-3
VEGF-A, sVEGFR-1, sVEGFR-2 in myeloproliferative neoplasms

Drela E, Rosc D, Gadomska G, Stankowska K, Boinska J, Slusarz R and Michalska M
Nicolaus Copernicus University in Torun, Collegium Medicum in Bydgoszcz, Poland, Bydgoszcz, Poland

Background: The most important and effective angiogenic factor is vascular endothelial growth factor (VEGF), responsible for differentiation, migration and survival of endothelial cells. VEGF works by binding with specific tyrosine kinase receptors: VEGFR1, VEGFR-2 and VEGFR-3. Currently, there are known two soluble forms of the VEGF receptors (sVEGFR): sVEGFR-1 and sVEGFR-2, which may act as inhibitors of angiogenesis. The results of studies conducted in many diseases and pathological conditions indicate a significant role of VEGF in tumor angiogenesis. There is an ongoing search for non-invasive, effective research methods to assess the intensity of angiogenesis in the course of many diseases, including those in myeloproliferative neoplasms.
Aims: The aim of this study was to evaluate the concentration of VEGF-A, sVEGFR-1 and sVEGFR-2 in patients with MPNs.
Methods: The study involved 79 patients with myeloproliferative neoplasms (mean age 61.42), hospitalized and diagnosed at the Clinical Ward of Hematology of the Dr. J. Biziel University Hospital No. 2 in Bydgoszcz, Poland. These patients were enrolled in the study at the time of the diagnosis of MPNs and prior to the implementation of appropriate treatment. The study group included 46 patients with essential thrombocythaemia (ET), 19 with polycythemia vera (PV), seven with chronic myeloid leukemia (CML) and seven with the primary myelofibrosis (PMF). The control group consisted of 39 healthy volunteers to correspond to the age (the mean age of 60) and gender to the study group. In blood samples were determined VEGF-A, sVEGFR-1 and sVEGFR-2 using ELISA tests (R&D Systems, USA). The study was approved by the Bioethics Committee of Collegium Medicum in Bydgoszcz, the Nicolaus Copernicus University in Torun, Poland.
Results: In the present study, there was a significantly higher concentration of VEGF-A in all patients with MPNs, as compared to the control group (Me = 96.00 pg/mL vs. 18.82 pg/mL, $P < 0.000001$). There were also demonstrated significantly lower levels of sVEGFR-1 and sVEGFR-2 in patients with myeloproliferative neoplasms compared to the control group ($P = 0.004001$ and $P < 0.000001$, respectively). Furthermore, we made a detailed analysis of the results in respective subgroups of patients with myeloproliferative neoplasms, as compared to the control group. The concentration of VEGF-A was significantly higher in all subgroups: ET (Me = 105.74 pg/mL), PV (Me = 71.72 pg/mL), PMF (Me = 64.80 pg/mL) and CML (Me = 553.84 pg/mL) compared to the control group (Me = 18.82 pg/mL). It was also found significantly lower levels of sVEGFR-1 in patients with PV (Me = 87.66 pg/mL) and ET (Me = 87.44 pg/mL), as compared to the control group (Me = 133.70 pg/mL) ($P = 0.021815$ and $P = 0.009522$, respectively). SVEGFR-2 concentration was significantly lower in all subgroups of patients with MPNs, as compared to the control group.
Conclusion: Increased levels of VEGF-A indicate the increased angiogenesis in patients with myeloproliferative neoplasms.

PB 4.56-4
Evaluation of arterial stiffness in β-thalassemia/Hb E patients

Satitthummanid S[1], Uaprasert N[2], Sutcharitchan P[2], Puwanant S[2], Srimahachota S[1] and Boonyaratavej Songmuang S[2]
[1]King Chulalongkorn Memorial Hospital; [2]Chulalongkorn University, Bangkok, Thailand

Background: The common disease-related complications of thalassemia intermedia (TI) are venous thromboembolism and pulmonary arterial hypertension leading to right-sided heart failure. β-thalassemia/Hb E has TI phenotypes and is more prevalent in South East Asia. However, systemic arterial complications have been less studied. Non-invasive and blood pressure independent arterial stiffness measurement of Cardio-Ankle Vascular Index (CAVI) has been used and able to predict outcomes in general population.
Aims: To assess arterial stiffness using CAVI method in β-thalassemia/Hb E compared to normal population.
Methods: Age and sex matched cases of 43 β-thalassemia/Hb E and 43 normal subjects were examined with CAVI, echocardiography, ferritin, CBC and blood chemistry.
Results: CAVI values in β-thelassemia/Hb E patients were significantly higher than controls (7.79 vs. 7.26, $P = 0.002$), and significantly correlated with pulmonary pressure, PASP ($r = 0.39$, $P = 0.012$) and PADP ($r = 0.47$, $P = 0.002$), heart rate ($r = 0.36$, $P = 0.02$), MCV ($r = 0.31$, $P = 0.045$) and MCH ($r = 0.32$, $P = 0.039$). In addition, β-thalassemia/Hb E patients had significantly higher heart rate, pulmonary pressure, BUN, triglyceride levels and peak tricuspid annular systolic velocity (RV S') but significantly lower BMI, diastolic blood pressure, Hb, MCV, MCH, Cholesterol, HDL and LDL levels than controls. Subgroup analysis revealed post splenectomy has higher PADP than controls but has no correlation with CAVI values.

Conclusions: Systemic arterial stiffness using CAVI method was significantly increased in β-thalassemia/Hb E patients and correlated with increased pulmonary arterial pressure. Therefore, CAVI might be considered as a surrogate marker of atherosclerosis as well as cardiovascular morbidities in TI patients. A prospective study in a large population of patients is warranted.

PB 4.56-5

HDL cholesterol, apolipoprotein A-I, and HDL subfractions predict severity of coronary artery disease

Gurbel PA[1], Kevin BP[1], Tantry US[1], Gesheff M[1], Singla A[1], Franzese C[1] and Toth P[2]

[1]*Sinai Center for Thrombosis Research, Baltimore, MA;* [2]*University of Illinois College of Medicine, Peoria, IL, USA*

Background: Observational studies demonstrated an inverse relation between HDL cholesterol and risk for developing coronary artery disease (CAD) and its clinical sequelae including MI, death, and need for revascularization. HDL2 (large) is protective, HDL3 (small) is associated with increased risk for disease. More recent studies suggest that HDL2 and HDL3 are equally beneficial. We evaluated the relationship between HDL-C, apo A-I, and HDL subfractions and severity of CAD.

Methods: Patients (n = 353) with suspected CAD with or without statins therapy, were enrolled. Lipids and lipoproteins were measured by a vertical density gradient, ultracentrifugation technique in blood samples collected prior to coronary angiography (CA). The severity of CAD was defined as minimal stenosis (<25%), intermediate stenosis (25–75%), and severe stenosis (>75%) of any major coronary vessel as indicated by CA.

Results: The severity of atherosclerotic lesions inversely correlated with HDL-C and apo A-I irrespective of statin therapy. Among patients not receiving statin therapy, both HDL 2 and 3 correlated inversely with severity of atherosclerotic disease. For patients on statin therapy, the relationship between disease severity and HDL3 was significant.

Conclusions: In the MAGMA study, serum levels of HDL-C, apoA-I, and HDL3 have an inverse and significant relationship to severity of CAD. These results support accruing evidence that higher levels of HDL2 and HDL3 are associated with less severe CAD.

PB 4.56-6

Releasate of PAR1-activated platelets enhances capillary formation of endothelial progenitor cells

Huang Z, Zhu L, Miao X, Ander C, Hjemdahl P and Li N

Karolinska Institute, Stockholm, Sweden

Background: Endothelial progenitor cells (EPCs) contribute importantly to endothelial regeneration and new vessel formation. Platelets contain both pro- and anti-angiogenic regulators, and release them differently upon different stimuli. Thrombin receptor PAR1 stimulation is known to induce selective release of pro-angiogenic regulators.

Aims: To investigate if the releasates of PAR1-activating peptide (PAR1-AP) stimulated platelets can enhance the angiogenic properties of EPCs.

Methods: Venous blood was collected from healthy subjects for Ficoll isolation of mononuclear cells. The cells were cultured in an endothelial conditioning medium (ECM: EBM-2 Single Quots medium plus 10% FBS) during 4 weeks, with culture media changed every third day. Autologuous washed platelets (2×10^9/mL) were stimulated by PAR1-AP (10 μM), and the releasate was collected after centrifugation. EPC proliferation was monitored using a [^{3}H]-thymidine incorporation assay. EPC migration was assessed using a modified Boyden chamber, and an *in vitro* tube formation assay was performed on Matrigel-covered culture plates.

Results: EPC colonies usually appeared after 3 weeks culture, with 1–2 colonies per 60 mL blood. EPC colonies generated from adherent peripheral mononuclear cells displayed a cobblestone morphology. Supplementation with PAR1-AP releasate (10% ECM volume) approximately doubled the migration of EPCs in modified Boyden chambers (n = 3). Moreover, PAR1-AP releasate enhanced EPC tube formation on Matrigel[TRADEMARK] Matrix. Thus, as compared to ECM alone, EPC cultures with PAR1-AP releasates developed denser capillary network, with increased numbers of branch points (by approximately 55%). Surprisingly, the releasate did not promote but rather attenuated EPC proliferation as evidenced by a 30% reduction of thymidine incorporation in EPC cultures with PAR1-AP releasates.

Conclusions: Releasates from PAR1-AP-stimulated platelets enhance the capillary forming capacity of EPCs. Inhibitory effect of the releasate on EPC proliferation is probably due to the fact that PAR1 stimulation can still induce a considerable release of anti-angiogenic factors.

PB4.57 – Fibrinogen/Fibrin – V

PB 4.57-1

Combination of haemostatic agents reduces blood loss and enhances survival in a two-hit model of blunt liver injury

Zentai C[1], Rossaint R[1], Ten Cate H[2], Spronk HMH[2] and Grottke O[1]

[1]*RWTH Aachen University Hospital, Aachen, Germany;* [2]*Maastricht University Medical Center, Maastricht, The Netherlands*

Background: In the treatment of trauma-induced coagulopathy there has been a shift from an empirical treatment with FFP to a targeted therapy with coagulation factors concentrates and other haemostatic agents in recent years. Tranexamic acid (TX) is increasingly used as first line therapy for traumatised patients. Prospective studies investigating the combination of TX with other haemostatic agents are missing.

Aims: In a two-hit pig model with two blunt liver injuries and haemorrhagic shock we explored the effects of a combined therapy with TX, fibrinogen, and prothrombin complex concentrate (PCC) on blood loss and coagulation variables.

Methods: After local ethical approval trauma was induced in 36 anaesthetised pigs. A second hit standardised blunt liver injury grade III was induced using a custom made instrument. After the first injury phase with severe haemorrhagic shock over 30 min, animals were resuscitated with crystalloids to maintain nadir blood pressure. Ten minutes after the following second liver injury animals were re-transfused with washed erythrocytes and randomised to receive either normal saline (control), TX (15 mg/kg, TX group), TX and fibrinogen (90 mg/kg, TXF group) or TX, fibrinogen and PCC (20 U/kg, TXFP group).

Thromboelastometry (ROTEM), including a modified method for fibrinolysis ('tPA-ROTEM') and global coagulation parameters were monitored over 4 h and blood loss was measured. Statistical analysis was performed using ANOVA with Tukey *post hoc*. The significance was defined as $P < 0.05$.

Results: Coagulation was severely impaired after the infliction of injuries and haemorrhagic shock. Prothrombin time (PT: 15 ± 2 s) and clot formation (CFT: 81 ± 14 s) prolonged over time. Correspondingly, concentrations of fibrinogen (49 ± 10 mg/dL) and clot strength (MCF: 53 ± 4 mm) were severely reduced. Infusion of fibrinogen restored CFT, MCF and increased concentrations of fibrinogen significantly. An additional impact on global coagulation variables after the infusion of PCC could not be observed. In contrast, coagulation in the control group was increasingly impaired over time. TX-treated animals showed an inhibition of tPA induced fibrinolysis with no impact neither on MCF nor CFT.

The total blood loss as the primary endpoint of this study was lowest in the TXF (1012 ± 86 mL) and TXFP (1037 ± 118 mL) groups, followed by the TX (1579 ± 306 mL) and control group (2376 ± 478 mL; $P < 0.05$. Accordingly, all animals of TXF and TXFP groups survived, whereas five of nine animals (55%) and two out of nine animals (22%) died in the control and TX groups, respectively ($P < 0.05$). Clinically and macroscopically no adverse events were observed.

Conclusions: The early application of TX and fibrinogen significantly reduced blood loss and enhanced coagulation variables in a highly lethal model with blunt liver injuries and prolonged haemorrhagic shock. The additional use of PCC showed no further effects in this specific animal model, which is most likely attributed to a lack of impaired thrombin generation. Thus, the early use of a combined treatment with coagulation factors and TX is a reasonable and safe approach to reduce the need for the transfusion of FFP and red blood cells.

PB 4.57-2
Detection, localisation and quantification of intracellular phosphorylated human fibrinogen by proximity ligation: a novel approach for the characterisation of fibrinogen phosphorylation

Cooke EJ, Cordell PA, Pease RJ, Grant PJ and Smith KA
University of Leeds, Leeds, UK

Background: Human fibrinogen is secreted from hepatocytes in its phosphorylated form, with 20–25% of circulating fibrinogen phosphorylated exclusively at Aα chain Serine 3 (Ser3) and Serine 345 (Ser345). Elevated levels of phosphorylated fibrinogen have been observed in foetal fibrinogen, ovarian cancer patients, venous thromboembolism and acute phase responses; however, the cause of this increase and the effect of fibrinogen phosphorylation on clot structure and function remain undetermined. The latter has previously been investigated *in vitro* using several potential kinases but the results have proved inconsistent, failing to clarify the role of these phosphorylation sites. Similarly, this post-translational modification has yet to be explored at a cellular level.

Aims: The aim of the current investigation was to develop a method for the detection of intracellular phosphorylated human fibrinogen Aα chains and determine the subcellular location of fibrinogen phosphorylation.

Methods: We have carried out a proximity ligation assay (PLA) using commercially available reagents to detect and quantify phosphorylated fibrinogen in two cell lines: i) human hepatocytes (HepG2 cells), and ii) Chinese hamster ovary cells expressing recombinant human fibrinogen. The cells were fixed, permeabilised and blocked for non-specific binding before probing with anti-fibrinogen Aα chain and anti-phosphoserine primary antibodies. Hybridisation of secondary PLA probes in close proximity results in the generation of a DNA template, which is amplified and detected with fluorescently-labelled oligonucleotides. Markers for endoplasmic reticulum, Golgi apparatus and nucleus detection were incorporated to reveal the site of fibrinogen phosphorylation. Finally, cells were mounted and imaged using confocal microscopy.

Results: Using this technique we have visualised, for the first time, phosphorylated fibrinogen within HepG2 and CHO cells. Preliminary data suggests phosphorylation of fibrinogen takes place in the endoplasmic reticulum, as indicated by the distribution of signal and minimal co-localisation with the Golgi apparatus. In contrast, control cells expressing the Bβ and γ chains of fibrinogen contained negligible signal of random distribution, highlighting the specificity of this method.

Conclusion: This novel approach will facilitate identification of the protein kinase(s) responsible for this modification *in vivo*, providing a valuable tool for the characterisation of Ser3 and Ser345 phosphorylation. Furthermore, it will be used to determine whether elevated levels of fibrinogen phosphorylation accompanying the acute phase response result from increased synthesis of high molecular weight fibrinogen, or an up-regulation of fibrinogen kinase activity in response to extracellular stimuli. Elucidating the mechanism of cellular fibrinogen phosphorylation and its contribution to haemostatic and thrombotic processes could aid the diagnosis and management of associated pathologies.

PB 4.57-3
Functional aspects of platelets and factor XIII in hereditary afibrinogenaemia

Hoffmann T, Bomke B, Seidel H, Strathmann K, Alatsaki A, Dücker C and Scharf RE
Heinrich Heine University Medical Center, Duesseldorf, Germany

The clinical phenotype of hereditary afibrinogenaemia (HAF) is heterogeneous. Thus, even profound deficiency of fibronogen (Fg) and, consequently, in fibrin (Fn) formation may not be associated with a hemorrhagic phenotype. We now studied a patient with HAF and examined platelet and FXIII function with regard to Fg/Fn parameters.

Patient: The proposita is a 30-year-old woman in whom afibrinogenaemia resulting from a mutation in the *FGA* gene (c.510 + 1_510 + 4delGTAAinsCCAAAA) was diagnosed after gastrointestinal hemorrhage at birth. During childhood and adolescence, the patient suffered from easy bruising only. In 2012, ankle joint bleeding for the first time necessitated replacement therapy with a fibrinogen concentrate (FgC, Haemocomplettan® CSL Behring).

Methods: Coagulation screening was performed by prothrombin time (PT)(Thromborel S®, Siemens), activated partial thromboplastin time (aPTT) (Pathrombin SL®, Siemens) and thrombin time (TT)(BC Thrombin®, Siemens). For fibrinogen assessment, the Clauss method (Multifibren®, Siemens) and nephelometric determination of the antigen concentration (Sigma®) were used. FXIII activity was measured with the Berichrom FXIII® test (Siemens), FXIII antigen concentration was assessed using an ELISA test (Haemochrom®). Platelet function was screened with PFA-100® (Siemens) and platelet aggregation studies were performed by light transmission with a DiaSysGreiner® instrument. For thrombelastometry ROTEM®(tem international) was used. To assess dysfunctional fibrinogen, the ratio of Fg (Clauss) and Fg concentration was used (Fg-R, normal >0.9). Likewise, FXIII dysfunction was estimated by the ratio of FXIII activity and FXIII antigen concentration (FXIII-R, normal >0.9). All tests were performed before as well as after hemotherapy with FgC.

Results: Prior to substitution, none of the coagulation tests (PT, PTT, TT, TEM) revealed any detectable clot formation. Platelet function appeared intact upon PFA screening and aggregation testing in response to high-dose arachidonic acid and collagen. By contrast, platelet aggregation with 'weak agonists' was strongly reduced (epinephrine 5%, normal >70%; ADP 46%, normal >70%). FXIII levels were reduced to 22% in activity (normal >80%) and to 58% in concentration (normal >70%). Hemotherapy with FgC led to an increase of Fg levels (Clauss) in a dose- and time-dependent manner. Consequently, the results of the hemostasis tests, including TEM, improved or normalized, which was also true for platelet aggregation in response to weak agonists. Moreover, FXIII activity increased. This increase was strongly correlated to Fg levels (Clauss) ($r = 0.98$). Of note, despite the uniform increases both in Fg and FXIII activity, the Fg ratio (0.62) as well as the FXIII ratio (0.54) remained abnormal.

Conclusion: This case report illustrates that impaired platelet function in HAF may be restricted to reduced aggregation upon stimulation with weak agonists. Substitution of fibrinogen can restore normal platelet aggregation. FXIII function in HAF appears to be compromised due to reduced concentration and reduced function. Even though fibrinogen substitution leads to strongly correlated increases of Fg levels (Clauss) and FXIII activity, functional deficiencies of Fg/Fn and FXIII may persist. Our observations warrant extended assessment of platelet function and FXIII function in patients with fibrinogen disorders.

PB 4.57-4

Fibrinogen clottable protein assays (Clauss assay vs. CLOTr methods): the effects of fibrinogen & thrombin concentrations on clot formation, structure and clot turbidity

Raut S

National Institute For Biological Standards and Control, Potters Bar, UK

Background: Following the establishment of the WHO 3rd International Standard (IS) for Fibrinogen Plasma (09/264) and more recently the WHO 2nd IS Fibrinogen Concentrate (09/242), it was evident that, although Clauss assays were found to be suitable for assaying fibrinogen clottable protein in plasma [low inter-laboratory variability, GCV = 3.2%; $n = 22$ with good agreement (<4% difference) with CLOTr (assays following clot removal) methods], they were not found to be suitable for assaying fibrinogen concentrates [high inter-laboratory variability, GCV = 17.2–26.8%; $n = 17$–24 with poor agreement (18–81% higher potency) with CLOTr methods]. Studies were carried out to investigate this discrepancy.

Aim: To investigate the influence of fibrinogen and thrombin concentrations on assays used to determine thrombin clottable protein in fibrinogen concentrates.

Methods: Clot turbidity (as measured by absorbance at 405 nm) measurements were carried out at varying fibrinogen and thrombin concentrations to assess their effects on clot structure and function. SDS-PAGE analysis and Transmission Electron Microscopy (TEM) were also carried out to assess the structure of the clot, and fibre & protofibril formation respectively.

Results: At physiological concentrations of fibrinogen (1–4 mg/mL), an increase in low levels of thrombin concentration (from 0.03 to 0.6 IU/mL) leads to a proportional increase in turbidity (absorbance) of the clot. However, higher thrombin levels (from 0.6 to 20 IU/mL) lead to a reduction in turbidity. Furthermore, at supra-physiological concentrations of fibrinogen (e.g. @ 10 mg/mL), this reduction in turbidity is observed at a much lower thrombin concentrations (from 0.3 to 5 IU/mL). At low thrombin concentrations, it is thought that fibrinopeptide cleavage is slower (as observed by slower rate of absorbance) so that protofibrils are formed more slowly and shorter protofibrils aggregate as they are formed, resulting in thicker fibres. But at higher thrombin concentrations, the maximum rate of assembly is greater and the maximum turbidity is consequently lower. The lower turbidity with an increase in fibrinogen concentration can be similarly explained. These results are further confirmed by SDS-Page gels and TEM scans.

Conclusions: Results from these studies indicate that clotting can be influenced by thrombin and fibrinogen concentrations. Small differences between the concentrations of these analytes can have a significant effect on the turbidity & opacity of fibrinogen clot being formed and this may explain the high variability observed in Clauss assays, where both mechanical and photometric clot detection systems are employed and where significantly higher thrombin concentrations are used (100–200 IU/mL). These differences are less apparent with the CLOTr method where clot is initially formed, removed and washed prior to protein analysis. For assays of thrombin clottable protein in fibrinogen concentrates, optimal concentrations of fibrinogen and thrombin concentrations are found to be 1–4 mg/mL and 1–5 IU/mL respectively. For Clauss assays further validation is likely to be required. These finding are to be proposed for the EP monograph revision for this method.

PB 4.57-5

New liquid quality controls for D-Dimer assays with extended stability

Robert M, Vial T, Aiello L, Ashwell T, Langlet S and Grimaux M

Stago, GENNEVILLIERS, France

Background: Due to evolutions in quality assessment programs undertaken by medical laboratories, Stago has developed the STA® – D-Di Control. The kit comprises of two levels of liquid controls, which are dedicated for use with D-Dimer assays, when performed on Stago analyzers. These controls can be used in conjunction with STA® – Liatest® D-Di or STA® – Liatest® D-Di PLUS. The levels of these controls are targeted to have a D-Dimer concentration of around 0.75 μg/mL and 2.30 μg/mL.

Aim: The aim of this study is to demonstrate the performance of the STA® – D-Di Control kit, in terms of analyzer on board stability and after opening.

Methods: STA® – D-Di Control 1 and 2 were opened and placed on board:- the STA-R® and STA Compact® analyzers for 72 h- the STA Satellite® for 48 h. The controls were then assayed with STA® – Liatest® D-Di. The controls were also assayed after the opening of the vials, which were then recapped and stored at 2–8 °C for 30 days.

Results: The on board stability results show that the absolute variations tested on a lot

- after 72 h on the STA-R® and the STA Compact® is 0.05 μg/mL and 0.02 μg/mL for Control 1 and 0.13 μg/mL and 0.04 μg/mL for Control 2, respectively
- after 48 h on the STA Satellite® is 0.00 μg/mL for Control 1 and 0.08 μg/mL for Control 2.

Stability after the opening of the vial and storage at 2–8 °C for 30 days shows that the absolute variations observed for a lot does not exceed 0.00 μg/mL for Control 1 and 0.05 μg/mL for Control 2.

Conclusion: STA® – DDi Control is stable over time, allowing the use of Quality Controls on board the analyzer over a period of 72 h on the STA-R® and STA Compact® or 48 h on the STA Satellite®. In addition, STA® – DDi Control when stored at 2–8 °C in its original recapped vial, is stable for 30 days. With this extended stability, the STA® – D-Di Control allows laboratories to adapt the frequency of quality control in an optimized way. The liquid formulation also allows better practicality and the reduction in handling errorsSTA® – D-Di Control can be used with the STA® – Liatest® D-Di or STA® – Liatest® D-Di PLUS for D-Dimer Assays.

PB 4.57-6

Purification and characterization of a new fibrinogen concentrate: results at laboratory scale

Guglielmone H, Farias F, Lombardi R, Bernardi M and Vitali M

Universidad Nacional de Córdoba, Córdoba, Argentina

Background: Fibrinogen (Fg) replacement therapy is mandatory during the hemorrhagic episodes in congenital and acquired fibrinogen deficiencies, the latter being associated with liver failure, disseminated intravascular coagulation, massive transfusion and cardiac surgery. At present, only a few Fg concentrates are available worldwide.

Aims: The objective of this study is to show the results achieved, in a laboratory scale, of a new Fg concentrate obtained from discarded material produced during the process of purification of Factor VIII.

Methods: After the dissolution of the cryoprecipitate, aluminum hydroxide treatment, viral inactivation process, adjustment of pH and ionic strength, this protein mixture is loaded on an ion exchange column. Under these conditions, the unbound protein material eluted is used as a source for isolation of Fg. After adjusting the pH and conductivity, this eluate is mixed with heparin-Sepharose in a ratio near 1:1 and washed with buffer of equilibrium (sodium citrate, sodium chloride, glycine and lysine) until absorbance near to 0. Fg is eluted with the same buffer but containing more high concentration of

glycine and lysine in a sharp peak. Next, the product obtained is concentrated for ultra-filtration and lyophilized.
Results: In total 20 chromatographic runs were made starting from different eluates which contained an average of 246 mg/dL of immunologic Fg (range 180–306 mg/dL). The concentration of functional and immunological Fg obtained in the peaks after elution were 319 ± 48 mg/dL and 340 ± 58 mg/dL, respectively and the total protein concentration was 351 ± 65 mg/dL. The ratio between Fg functional/immunologic was 0.94 and Fg functional/protein concentration was 0.91. The electrophoresis in polyacrylamide gels and Western blots analysis revealed the presence of a single band representing >90% of total protein content in the zone of Fg.
Summary: The results allow us to conclude that using a fast and inexpensive method starting from an eluate of proteins, which in our working conditions were discarded; we can isolate and purify a concentrate of Fg with a high degree of purity and coagulability judging by the protein analysis.

PB4.58 – Other coagulation factors – IV

PB 4.58-1
Spectroscopic evidence of intrinsic disorder in the activation peptide of coagulation factor X

Persson E[1], Kaas Hansen MJ[1] and Kragelund B[2]
[1]Novo Nordisk A/S, Måløv; [2]University of Copenhagen, Copenhagen, Denmark

Background: The vitamin K-dependent coagulation factors (F) VII, IX, X and protein C share the same domain organisation, with the exception of an activation peptide missing in FVII. FX possesses the longest half-life and activation peptide, where two N-linked glycans (N39 and N49) are key determinants. Upon activation of the zymogens, the activation peptide is released and the circulatory half-life drops dramatically. The half-life of the zymogen and activated forms of FVII are similar. A half-life prolonging effect of the activation peptides has been shown when these were inserted in FVII. Altogether, this indicates that the activation peptides play a fundamental role in the retention and clearance mechanisms of the coagulation factors. Recently, the N-linked glycans in the activation peptide of FX were found to be important for localisation to macrophages protecting it from rapid clearance. The influence of the N-linked glycans on the structure of FX and that of the activation peptide is unknown. In order to gain more knowledge about the life cycle of vitamin K-dependent coagulation factors structural information about the activation peptides would be valuable.
Aims: To investigate the structure of the activation peptide of FX alone and in the context of zymogen FX and the influence of the N-linked glycans on the structure.
Methods: Structural characterisation of the human FX activation peptide, expressed in *E. coli*, was performed using multidimensional heteronuclear nuclear magnetic resonance (NMR) spectroscopy. Plasma-derived human FX, N-deglycosylated FX and FXa were studied using circular dichroism (CD) and fluorescence spectroscopy.
Results: The NMR studies of the glycan-free FX activation peptide showed that it is intrinsically disordered without a defined fold. However, determination of residual secondary structure, from backbone carbon chemical shifts using a urea-denatured sample as the internal reference, revealed a transient α-helix located between residues 32 and 39 in the activation peptide. Far-UV CD spectroscopy of FX, N-deglycosylated FX and FXa indicated that FX and N-deglycosylated FX have indistinguishable secondary structure contents, whereas FXa appeared to be less disordered. Near-UV CD studies indicated only minor differences between the tertiary structures of FX, N-deglycosylated FX and FXa. Fluorescence spectroscopy experiments revealed no differences in the emission intensity or in wavelength of emission maximum between FX and N-deglycosylated FX, whereas the emission maximum for FXa was blue-shifted indicating a lesser degree of structural disorder.
Summary/Conclusions: The isolated activation peptide of FX is intrinsically disordered with a transient, low-populated α-helix. Our data strongly indicates that the structural disorder persists when the activation peptide is in the context of the parent protein, and that the N-linked glycans do not influence the structure of FX.

PB 4.58-2
Pseudonaja textilis venom FXa is poorly inhibited by human antithrombin

Johnson DJ and Huntington JA
University of Cambridge, Cambridge, UK

The venom of the Common Brown Snake (*Pseudonaja textilis*) contains an analogue of the mammalian prothrombinase complex consisting of factor Va (fVa) and factor Xa (fXa) orthologues with identity to the human versions of 54% and 49% respectively. Evolutionary modifications of its own plasma fX and fV, such as the removal of the membrane dependency of the complex and improved affinity of venom fVa for fXa, led to the venom having powerful systemic procoagulant activity resulting in the conversion of its prey's prothrombin to thrombin. This leads to consumptive coagulopathy of the victim, causing severe fibrinogen depletion, early hypotension and spontaneous bleeding and pulmonary thromboembolism. The use of heparin to prevent the catastrophic coagulation as a result of envenomation by *P. textilis* has been investigated, however one study suggested that pre-treatment with heparin can prevent the coagulant effects of the venom, while another showed that treatment with heparin 15 min after envenomation had no effect.
Here our aim is to investigate the inhibition of *P. textilis* fXa by human antithrombin and to determine if inhibition is affected by heparin pentasaccharide. Rates of inhibition of recombinant *P. textilis* fXa were measured in the presence and absence of pentasaccharide by measuring depletion of uncomplexed fXa over time on SDS PAGE. In the absence of pentasaccharide human antithrombin inhibited *P. textilis* fXa poorly with a k_{app} of 7.1 M/s, at least 500 fold slower than human fXa. Inhibition was enhanced by pentasaccharide by around 1000 fold (similar to the enhancement seen for human fXa). The poor inhibition rates, both in the presence and absence of pentasaccharide, can be explained by differences in the 36 loop and the autolysis loop that contribute to recognition of antithrombin, including the critical arginine150 (chymotrypsin numbering) residue in human fXa which is a proline in *P. textilis*. Evolutionary changes in *P. textilis* venom fXa have therefore resulted in a molecule that is poorly inhibited in mammalian blood, thus enhancing the potency of the venom.

PB 4.58-3
Real-life use of activated recombinant Factor VII (rFVIIa) in elderly patients with haemophilia with inhibitors – data from the UK National Haemophilia Database

Dolan G[1], Bjerre J[2] and Hay CRM[3]
[1]Queens Medical Centre, Nottingham, UK; [2]Novo Nordisk, Bagsværd, Denmark; [3]Manchester Royal Infirmary, Manchester, UK

Background: Improved management has led to greater life expectancy and a growing population of elderly patients with haemophilia. Activated recombinant Factor VII (rFVIIa) has been approved globally for the treatment of bleeds in patients with haemophilia with inhibitors. It is important to assess the safety of rFVIIa from post-marketing reports in elderly patients, who are at increased risk of thromboembolism, and for whom data have previously been scarce.

Aims: To assess the real-world use and safety of rFVIIa in elderly patients (≥65 years old) in a post-marketing surveillance study requested by EMA when licensing the higher (270 μg/kg) rFVIIa dose, and conducted on behalf of Novo Nordisk by the UK National Haemophilia Database between 1/1/08 and 30/6/11.
Methods: The National Haemophilia Database (NHD) collects data from all UK haemophilia centres on all patients with bleeding disorders, collecting treatment data quarterly and adverse event death and diagnostic data as it arises. Data on rFVIIa dosing and safety, including adverse drug reactions, were collected prospectively. The study was conducted in accordance with the Data Protection Act and the Declaration of Helsinki.
Results: Overall, 139 patients were treated with rFVIIa for a total of 1356 bleeding episodes (episodes/patient: median 3.0; mean 9.76; range 1–124). Of these, 29 (20.9%) were elderly patients (>65 years old) (median age 70.6 years; mean 73.1 years, range 65.2–94.9 years), who were treated for 130 treatment episodes (episodes/patient: median 2.0; mean 4.48; range 1–59). Most (79/130 [61%]) of these episodes were in patients with haemophilia A, with lower proportions in acquired haemophilia (33%) and FVII-deficiency (6%). Elderly patients received a lower initial rFVIIa dose compared with the rest (mean 106.8 vs. 152.7 μg/kg; median 90.2 vs. 112.2 μg/kg), a higher number of rFVIIa doses (mean 5.7 vs. 4.4; median 3.0 vs. 1.0) and had a longer median duration of treatment (7.0 vs. 2.6 h). In addition, elderly patients received a higher accumulated rFVIIa dose than the total population (mean 590.0 vs. 548.8 μg/kg; median 273.0 vs. 253.4 μg/kg). Initial rFVIIa dose administered was between 10.6 and 285.7 μg/kg and 24-h dose range was 35.1–938.7 μg/kg in elderly patients. Single-dose regimens (i.e., a dose spaced >26 h from previous and following doses) were administered to 48.3% of elderly patients for treatment of 21/130 (16.2%) episodes; this is substantially lower than the proportion of patients and episodes treated with single-dose regimens in the total population (71.9% and 51.3%, respectively). No adverse drug reactions, including thromboembolic events, disseminated intravascular coagulation or anti-rFVIIa antibody formation occurred in patients of any age.
Conclusions: This study documents the extensive use of rFVIIa in elderly patients with haemophilia with inhibitors. Importantly, no safety concerns have been raised for this population, including no reports of thromboembolic events. Single-dose regimens were less frequent in the elderly population and the total accumulated dose per treatment episodes was higher. The data suggest that higher initial dosing may shorten treatment duration in the elderly, but this requires further study.

PB 4.58-4

Ribavirin effects on expression of coagulation factors in HepG2 cells

Ando Y[1], Suzuki A[1], Okuyama E[1], Murata M[1], Kato I[1], Takagi Y[1], Takagi A[1], Murate T[1], Saito H[2] and Kojima T[1]

[1]Nagoya University Graduate School of Medicine; [2]National Hospital Organization-Nagoya Medical Center, Nagoya, Japan

Background and Aims: Previously, Yamamoto et al. reported significant decreases in doses of clotting factors used for hemostatic therapy and increased activities of clotting FVII in henophiliacs during administration of anti-HCV agent, ribavirin. They also showed that ribavirin upregulated FVII mRNA in cultured human normal hepatocytes as well as hepatoma cell line (HepG2). Although the action of ribavirin was evaluated, its complete effects were not yet elucidated. In this study, we investigated molecular mechanisms of FVII upregulation by ribavirin. Furthermore, we also focused on the other coagulation factors and analyzed ribavirin effects on their mRNA expressions in HepG2 cells.
Methods: We treated HepG2 cells with ribavirin (100 μg/mL) or mycophenolic acid (MPA; 100 μM) for 24 h, and added guanosine at a final concentration of 100 μM if necessary. We isolated total RNA from the cells and subjected to quantitative RT-PCR to determine mRNA levels of prothrombin, FV, FVII, FX, FXI, FXII, and HPRT1. HPRT1 was used as ribavirin-insensitive control.
Results: First, we verified that FVII mRNA was increased by ribavirin treatment. Ribavirin metabolite, ribavirin-monophosphate, is an inhibitor of IMP dehydrogenase (IMPDH), which is a rate-limiting enzyme for the *de novo* purine nucleoside synthesis. We tested another IMPDH inhibitor, mycophenolic acid (MPA), and found MPA treatment also upregulated FVII gene expression. Thus, we hypothesized IMPDH inhibition was critical for FVII mRNA increase. We used guanosine together with ribavirin to confirm our hypothesis, because intracellular GTP depletion induced by IMPDH inhibition could be reversed by addition of guanosine. As a result, we found that the FVII upregulation was completely diminished by guanosine supplementation. Meanwhile, we analyzed expression levels of the other coagulation factors, and found that ribavirin upregulated expression levels of several coagulation factors such as prothrombin, FV, FX, FXI, and FXII. While the increase levels differed individually, prothrombin, FX, and FXII mRNAs were increased only slightly; FV mRNA was upregulated to the same extent as FVII mRNA and FXI mRNA much more abundantly. We also analyzed FIX mRNA; however, HepG2 cells did not express FIX mRNA in a detectable level. MPA also upregulated these coagulation factors similarly. All of these upregulations were retracted by addition of guanosine.
Summary/Conclusions: Herein, we demonstrated that FVII was upregulated by ribavirin treatment. The FVII mRNA increase was induced in response to the intracellular GTP depletion following IMPDH inhibition. We also observed that ribavirin as well as MPA upregulated the other coagulation factor expressions, which were cancelled by addition of guanosine. Taken together, intracellular GTP reduction induced by ribavirin or MPA resulted in the significant mRNA upregulations of FV, FVII, and FXI. Although not all coagulation factor expressions were evaluated, the effect of ribavirin on these genes might attenuate hemorrhagic episodes *in vivo*.

PB 4.58-5

Elimination capacity of transmissible spongiform encephalopathy (TSE) model agents by the production process of therapeutic antithrombin

Figueras FJ, Otegui M, Belda JF, Vinent A, Caballero S, Diez JM, Gajardo R and Jorquera J

Instituto Grifols, S.A., Parets del Valles, Spain

Background: The variant Creutzfeldt-Jakob disease (vCJD) is a transmissible spongiform encephalopathy (TSE) mainly present in UK (UK) that peaked in the year 2000 with 28 cases. From 1995 (1st case) to December 2012, 227 cases have been reported across the world, 176 of them in the UK and 27 in France. Worldwide, it can be observed a downward trend in deaths and new cases, and no new cases of vCJD have been reported in UK since October 2011. The vCJD agent is mainly located in the Central Nervous System. However it can be found in the lymphatic system and non-neural tissues at much lower concentration. It has never been biochemically detected in human plasma suggesting that the concentration may be lower than in the above mentioned tissues. Nevertheless, as a precautionary measure, UK plasma is not used for the production of plasma derivates. Furthermore, even in the current absence of vCJD prevalence in the general population, Grifols studies the manufacturing processes to evaluate their capacity of removing prions in case they were present. In that sense, spiking and endogenous infectivity experiments have shown that different plasma protein manufacturing steps are very effective removing TSE model agents. Aims:Laboratory studies were conducted to establish the capacity of Grifols' antithrombin (Anbinex®) production process, to remove a spiked TSE-model agent.

Methods: For this purpose, two different brain-derived materials of Scrapie affected hamsters (strain 263K), clarified brain homogenate and detergent treated brain homogenate, were deliberately spiked into intermediate process solutions. Prion protein (PrP^{Sc}) was detected by Western Blot assay (WB) for protease-resistant prion protein. TSE infectivity was measured using a hamster bioassay. Three production steps were assessed: Fraction I and Fraction II + III precipitations and Nanofiltration through 15 nm filters (Planova™ 15N).
Results: The studied manufacturing steps showed a high capacity to remove the TSE model agent. Reduction Factors for the different TSE preparations (clarified brain and detergent treated brain homogenates, respectively) were 1.02 and 1.32 $\log_{10}$ WBU for Fraction I precipitation step, 3.83 and 2.39 $\log_{10}$ WBU for Fraction II + III precipitation step and ≥3.59 and ≥3.76 $\log_{10}$ WBU for the nanofiltration step. These results obtained by Western blot were in good agreement with bioassay data (Reduction Factors of 1.02 and 3.33 $\log_{10}$ ID_{50} for Fraction I and Fraction II + III precipitations).
Conclusion: Anbinex® manufacturing process effectively removes TSE model agents used as a model of vCJD, indicating that the production process has a high potential to eliminate TSE agents, in the unlikely event of a donor with vCJD.

PB 4.58-6

A prospective, open-label, randomized, parallel study with AICC to evaluate the efficacy and safety of prophylactic vs. on-demand treatment in hemophilia A or B subjects with inhibitors

Antunes S[1], Tangada S[2], Stasyshyn O[3], Mamonov V[4], Phillips J[5], Guzmán-Becerra N[2], Grigorian A[2], Schroth Ph[2], Ewenstein BM[2] and Wong WY[2]
[1]UNIFESP, São Paulo, Brazil; [2]Baxter Healthcare Corporation, Bioscience, Westlake Village, CA, USA; [3]Ukrainian National Academy of Medical Science, Lviv, Ukraine; [4]Hematology Research Center of the Russian Academy of Medical Sciences, Moscow, Russian Federation; [5]Wellington Hospital, Wellington South, New Zealand

Background: Treatment with FEIBA NF (AICC) is a key therapeutic option for controlling acute and difficult to treat hemorrhages in hemophilia A or B patients with inhibitors. Severe and recurrent episodes of joint, muscle, and soft tissue bleeds lead to significant joint damage and morbidity. Prevention of hemorrhages with prophylactic therapy reduces morbidity and improves quality of life. This clinical study evaluated the safety and efficacy of prophylaxis with AICC compared to on-demand treatment.
Aims: To demonstrate reduction of annualized bleed rate (ABR) in subjects using AICC prophylactically compared to on-demand therapy
To evaluate the safety of prophylactic AICC treatment compared to on-demand treatment.
Methods: This prospective, randomized study was designed with two arms: prophylaxis and on-demand regimens over 12 months ± 14 days. Thirty-six hemophilia A or B subjects with inhibitors refractory to FVIII or FIX treatment were enrolled across 17 sites globally. Seventeen subjects randomized to the prophylaxis arm, received AICC at a dose of 85 ± 15 U/kg every other day. Nineteen subjects randomized to the on-demand arm received AICC for control of acute bleeding episodes at dosages per their treating physician. Median age of the subjects was 23.5 years. The study was approved by each institutional ethics committee and all subjects signed informed consent.
Results: The median ABR for subjects in the prophylaxis arm (7.9) was significantly lower than subjects in the on-demand arm (28.7). For both intent-to-treat (ITT) and per-protocol (PP) efficacy analysis sets, the differences in mean transformed ABRs between prophylaxis and on-demand were statistically significant ($P = 0.0003$ and $P = 0.0006$, respectively). Occurrence of new target joints was substantially lower in the prophylaxis arm (7 in 5/17 subjects) compared to the on-demand arm (23 in 11/19 subjects). Median ABR for new target joints was higher in the on-demand arm (5.9) than in the prophylaxis arm (0); the difference is statistically significant ($P = 0.027$). A majority of the bleeding episodes were treated with a single infusion (both regimens 56.5%) and rated as excellent or good (on-demand 90.2%; prophylaxis 75.7%).
Of the 104 AEs reported, 30 were serious and 74 non-serious. Twenty-seven AEs (26.0%) in 8 (22.2%) subjects were deemed related to FEIBA; of these three were serious. Thirteen of the 36 subjects treated with AICC did not report any AEs. There was one unrelated death and one subject discontinued the study due to a non-serious hypersensitivity reaction. There were no thromboembolic events reported.
Conclusion: AICC was safe and efficacious in controlling acute and difficult to treat bleeding episodes in both prophylaxis and on-demand regimens
Significant reduction (72.5%) in ABRs for all bleeds was achieved with prophylactic use of AICC compared to on-demand therapy
Zero bleeding episodes was achieved on prophylaxis in 3/17 (17.6%) and 1/13 (7.7%) subjects in ITT and PP analysis sets respectively
Prophylaxis with recurrent dosing of AICC was safe without any clinical thromboembolic events or laboratory signals of thrombogenicity

PB4.59 – Regulation of coagulation and fibrinolysis – IV

PB 4.59-1

Applying phage display to screen a library of a1-protease inhibitor mutants for thrombin inhibitory activity

Sheffield WP, Scott BM and Gierczak RF
McMaster University, Hamilton, Canada

Background: Proteases of the coagulation system are primarily regulated by serine protease inhibitors (serpins) such as antithrombin (AT) and heparin cofactor II (HCII). Alpha-1-proteinase inhibitor (α_1-PI) is the most abundant serpin in plasma. The α_1-PI M358R ('Pittsburgh') mutant exhibits greatly increased rates of thrombin inhibition compared to wild-type α_1-PI, which predominantly regulates neutrophil elastase. M358 (P1) lies at the reactive centre (P1-P1') bond of the reactive centre loop (RCL) of α_1-PI, cleaved by cognate proteases as they become trapped in the serpin-type inhibitory complex. The relationship between RCL structure and serpin inhibitor function is incompletely understood and has not been subjected to saturation mutagenesis. α_1-PI M358R is a less potent inhibitor of thrombin than AT or HCII maximally activated by glycosaminoglycans, suggesting that it could be further engineered into a more potent thrombin-inhibitory serpin.
Aims: To apply phage display as a tool for the directed evolution of more active and/or more specific thrombin inhibitors based on the α_1-PI scaffold.
Methods: The T7Select 10-3b (Novagen) phage display system was used to express α_1-PI M358R on the bacteriophage surface, fused C-terminally to the first 348 residues of the T7 10B capsid protein. The T7Select 10-3b system was then used to express a library of α_1-PI mutant proteins with all possible codon combinations at positions P2 (P357) and P1 (M358) (441 possible mutants). The library was biopanned using a biotinylated sheep anti-human thrombin affinity-purified IgG and streptavidin- coated magnetic beads, in order to select the α_1-PI P2P1 mutants capable of forming stable complexes with thrombin. All sequences retrieved after five rounds of biopanning were inserted into arabinose-inducible *E. coli* expression vectors, and the recombinant α_1-PI P2P1 mutants were expressed in soluble form and screened for thrombin inhibitory activity.
Results: Following incubation of purified phage displaying only α_1-PI M358R with thrombin, denaturation-resistant α_1-PI M358R fusion

protein-thrombin complexes were detected by immunoblotting of solubilized phage, validating the approach. After biopanning of the α_1-PI P2P1 mutant phage library, the α_1-PI P357/M358R sequence appeared with a 50% frequency in randomly selected phage plaques, with the remaining candidates expressing a variety of novel mutant sequences. The α_1-PI P357/M358R sequence did not appear in phage plaques from the sample library mock-biopanned for five rounds without the addition of thrombin. When expressed in *E. coli*, the α_1-PI P357/M358R protein was the only P2P1 mutant capable of forming a stable complex with thrombin.

Summary/Conclusions: α_1-PI serpin maintained its inhibitory function when fused to T7 10B capsid protein on the surface of bacteriophage. Only one other serpin (plasminogen activator inhibitor 1) has been previously expressed in this manner. The number of mutants generated and screened in this study was over five times greater than the total number of α_1-PI mutants previously described in the literature. These findings suggest that the α_1-PI M358R protein has the optimal P2P1 sequence for thrombin inhibition, and constitute proof-of-principle for the application of this system to screen libraries of up to 10 million mutants in order to discover novel thrombin inhibitors of potential therapeutic value.

PB 4.59-2

Factors IXa and XIa promote uncontrolled clot growth under static conditions

Parunov LA[1], Jha K[1], Andersen JF[2], Tucker I[3], Ataullakhanov F[4], Lee TK[1] and Ovanesov MV[1]

[1]US Food and Drug Administration, Bethesda, MD; [2]National Institutes of Health, Bethesda, MD; [3]Oregon Health and Science University School of Medicine, Portland, OR, USA; [4]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russian Federation

Background: The fibrin clot stabilizes aggregated platelets and contributes to thrombogenesis by recruiting cells and proteins from circulating blood. However, the role of coagulation cascade reactions in the growth of the thrombus edge remains poorly understood.

Aims: In this study we evaluated three pathways of fibrin clot elongation under stagnant plasma conditions: passive diffusion of activated coagulation factors (F) IIa, IXa, Xa and XIa from the clot base to its edge, generation of activated factors inside the clot, and activation of coagulation by pre-activated FIXa and FXIa that may be present in circulation outside the growing clot.

Methods: A thin layer of recalcified human plasma was embedded in a low temperature melting point agarose gel and brought in contact with the immobilized tissue factor (TF) or a chamber with mixtures of activated coagulation factors and TF. Videomicroscopy of clot growth – thrombodynamics – was used to continuously monitor propagation of the clot edge into unclotted plasma. Small molecule coagulation factor inhibitors, inhibitory antibodies and single or double factor deficient plasmas (DP) were used to block individual steps of the coagulation cascade.

Results: In FIX-DP, immobilized TF, liquid TF and diffusion of FXa and FIXa induced dose-dependent but short (2–10 min) initial phases of rapid (up to 100 μm/min) growth rates resulting in small dense clots (0.2–2 mm in length) at the plasma/activator interface. These clots continued to grow further at a slow but almost steady rate (5–20 μm/min) for the duration of experiment (up to 120 min).

Addition of FIX in the absence of FXI(a) produced an intermediate phase of moderate clot growth rates for up to 40 min, at which time the clot growth rate declined steadily. Addition of FXI in the absence of activation by FXIIa reversed the decline, i.e., the rate of clot growth became quasi-steady. The quasi-steady clot growth was independent of FXI activation by FXIa; however, it was regulated by levels of FIX and FXI, and it could be reduced by blocking activation of FXI by thrombin and activation of FIX by FXIa. This quasi-steady clot growth could be induced by contact with TF, beta-thrombin or FXIa. Premixing FIX-DP with picomolar amounts of FIXa or FXI-DP with sub-picomolar FXIa (i.e., at concentrations that do not activate clotting independently of TF) resulted in fast and steady clot growth that was independent of the starting concentration of immobilized TF but proportional to FIXa or FXIa.

Conclusions: Diffusion and activation of coagulation factors inside the clot can support propagation of thrombus edge in the absence of blood flow. The effect is limited by the availability of TF at the site of injury, the distance from the site of TF exposure, and FXI activation inside the clot. Presence of FIXa and FXIa in circulation removes these limitations and supports uncontrolled clot growth. These results suggest that control of FIXa activity and its generation by FXIa could limit growth of intravascular thrombi.

PB 4.59-4

Peritoneal mesothelium expresses functionally active thrombomodulin

Morser J, Shao Z and Leung L

Stanford School of Medicine, Stanford, CA, USA

Background: The thrombin-thrombomodulin (TM) complex activates protein C (PC) and procarboxypeptidase B 2 (proCPB2 aka TAFI) that play anti-coagulant and anti-inflammatory roles within the vasculature. Extravascular expression of TM, however, has not been well studied. We hypothesized that TM is expressed on peritoneal mesothelial cells and leukocytes and thus facilitates PC and proCPB2 activation by thrombin within the peritoneal cavity

Methods: Mouse peritoneal macrophages were collected by lavage with PBS. Following PBS lavage, peritoneal mesothelial cells were detached from the peritoneum by intra-peritoneal trypsinization and lavage. Isolated MCs were maintained in culture for up to 4–5 passages. The phenotype of peritoneal macrophages and mesothelial cells was determined by immunofluorescence labeling in single cell suspension and in frozen abdominal tissue sections. PC and proCPB2 activation assays were performed in a 24-well culture plates on top of a single layer of mesothelial cells in culture. Levels of activated PC and CPB2 were measured using chromogenic substrates.

Results: Freshly isolated peritoneal mesothelial cells expressed high levels of TM while residential macrophages express TM weakly on their surface as detected by immunofluorescent staining and flow cytometry. Immunofluorescence studies of frozen sections of mouse abdominal wall, omentum, and intestine showed TM expression on the cells lining the peritoneum. Primary peritoneal mesothelial cells were adherent and displayed a typical polygonal, cobblestone-like morphology in culture. These cells expressed TM and endothelial protein C receptor (EPCR) on their surface, and the epithelial cell markers, calretinin, and cytokeratin intracellularly. Unlike endothelial cells, mesothelial cells were negative for the endothelial markers P-selectin (CD62p) and PECAM-1 (CD31). Thrombin activates PC and proCPB2 in the presence of cultured primary mouse peritoneal mesothelial cells. This activity is blocked by pre-treatment of mesothelial cells with a neutralizing anti-TM polyclonal antibody showing that thrombin activation of PC and proCPB2 on mesothelial cells is dependent on the presence of TM.

Conclusion: TM is expressed on peritoneal mesothelial cells and is functional, serving as thrombin's cofactor for protein C and proCPB2 activation. In the setting of peritoneal inflammation, thrombin generated locally will bind to mesothelial TM, leading to generation of activated PC and CPB2 and thus is actively involved in regulation of inflammation, fibrin clot formation and fibrinolysis within the peritoneal cavity.

PB 4.59-5

Role of platelets in the regulation of the spatial propagation of fibrin clot

Budkova V[1], Balandina A[2], Zapariy A[3], Ataullakhanov F[3] and Panteleev MA[2]

[1]Lomonosov Moscow State University, Khimki; [2]Center for Theoretical Problems of Physicochemical Pharmacology RAS, Moscow; [3]HemaCore LLC, Moscow, Russian Federation

Background: Activated platelets affect blood coagulation by secreting contents of their granules and exposing phosphatidylserine on the outer leaflet of the cell membrane.
Aims: We investigated the influence of platelets on the process of spatial fibrin clot growth in the reaction-diffusion *in vitro* experimental model (Thrombodynamics assay).
Methods: Spatial clot growth was monitored by light scattering in recalcified platelet-rich plasma (PRP) or in platelet-free plasma (PFP) of healthy subjects following activation with immobilized tissue factor (TF) at either high or low density (80 or 8 pmole/m^2, respectively).
Results: When coagulation was initiated by high TF density, platelets only moderately increased spatial clot growth velocity (V) from 25.7 ± 1.9 to 38.7 ± 8.3 μm/min ($n = 3$, $P = 0.08$); a similar effect was achieved with artificial phosphatidylserine microvesicles (V = 38.1 ± 1.4 μm/min).
On the contrary, in experiments with low TF density activation, platelets greatly increased V (from 6.5 ± 2.3 μm/min in PFP to 42.6 ± 10.6 μm/min in PRP; $n = 4$, $P < 0.05$). In heparin-supplemented plasma (0.09 ME/mL) activated with high TF density V was 12.2 ± 2.3 μm/min in PFP and 27.3 ± 6.2 μm/min in PRP ($n = 9$, $P < 0.05$). Addition of prostaglandin E1 (platelet activation inhibitor) in heparinized PRP decreased V in 1.5 ± 0.4 times ($n = 3$, $P = 0.1$). Apyrase and wortmannin did not show any effect on the spatial clot growth.
Conclusion: Clot growth rate in a reaction-diffusion system is insignificantly affected by platelets in normal conditions (physiological TF density and inhibitors concentration). Nevertheless the physiological concentration of the platelets in the plasma decrease the influence of clotting factors such as TF density decrease or heparin presence making system less sensitive to clotting conditions.

PB 4.59-6

Coleus forskohlii extract attenuates the anti-coagulation activity of warfarin

Chiba T[1], Yokotani K[1], Yamazaki Y[2], Shimura F[2], Yamada S[3], Shinozuka K[4], Sato Y[1] and Umegaki K[1]

[1]National Institute of Health and Nutrition, Tokyo; [2]Jumonji University, Saitama; [3]University of Shizuoka, Shizuoka; [4]Mukogawa Women's University, Hyogo, Japan

Background: *Coleus forskohlii* root extract (CFE) is a popular herbal ingredient in commercial dietary weight-loss supplements. The CFE used for such supplements has been standardized as 10% (w/w) active component forskolin. However, the safety of CFE remains unclear.
Aims: We studied the effects of CFE on cytochrome P450 (CYP) expression in the liver and its interaction with warfarin, which is a widely used anticoagulant.
Methods: ICR mice (male, 5 weeks old) were fed AIN93G-based diets containing various doses of CFE (dried roots of *C. forskohlii* obtained from Bangalore in southern India, extracted and standardized as 10% forskolin) or pure forskolin (Biomol, Plymouth Meeting, PA, USA). Plasma levels of aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase (ALP) were determined by enzymatic methods. Total cytochrome P450 content in liver microsomes was determined by optical density method, and activities of CYP subtypes were determined by high-performance liquid chromatography. CYP subtypes mRNA and protein levels in the liver were measured by real-time polymer chain reaction and Western blot analysis, respectively. Anti-coagulation activity was determined by prothrombin time, activated partial thromboplastin time, and thrombo test.
Results: When mice were fed various doses (0, 0.005, 0.05, 0.5, and 5%) of CFE for 3 weeks, the higher doses (0.5, 5%) of CFE decreased body weight and increased the relative liver weight, and significantly increased plasma levels of AST, ALT, and ALP. In addition, a high dose (0.5%) CFE significantly prolonged activated partial thromboplastin time. These data suggest that excess intake of CFE could induce hepatotoxicity and may inhibit coagulation. On the other hand, lower doses (0.005, 0.05%), which are comparable to doses taken in dietary weight-loss supplements in humans, did not change body weight, relative liver weight, or plasma levels of AST, ALT, or ALP. These data suggest that low-dose CFE does not induce hepatotoxicity. However, increased total content of hepatic CYP and activities of CYP2B, 2C, and 3A were observed with a lower dose (0.05%). Consistent with these findings, CFE increased CYP2B, 2C, and 3A mRNA expressions in the liver. CFE also increased CYP2C and 3A, but not 2B, proteins in the liver. Unlike the CFE, pure forskolin had little effect on CYP induction, indicating that an unknown factor is involved. When mice fed 0.05% CFE for 1 week were challenged with warfarin by gavage on the last 2 days of the treatment regimen, warfarin-induced anticoagulation was attenuated by CFE in parallel with induction of CYP, especially S-warfarin 7-hydroxylase.
Summary/Conclusions: These results indicate that intake of CFE, but not its active component forskolin, induces hepatic expression of CYPs and might affect efficacy of other drugs, including warfarin. To be safe, patients who take medicines should avoid using CFE, even though its effects might depend on the source of CFE or personal conditions.

Biomarker profiling of bladder cancer patients undergoing radical cystectomy. Relevance of thrombotic and inflammatory processes

Hoppensteadt D, Clark M, Quek M, Iqbal O, Kahn D, Cunanan J and Fareed J

Loyola University Medical Center, Maywood, IL, USA

Introduction: Inflammation and hemostatic activation may contribute to postsurgical thrombosis in patients with bladder cancer. This study profiled antiphospholipid antibody (APA), procoagulant microparticle (MP) and antiglycosaminoglycan antibody (AGA) levels and the thrombin generation profile in bladder cancer patients.
Materials and Methods: 134 serum samples collected from patients undergoing radical cystectomy and samples collected from healthy male and female individuals ($n = 50$) were analyzed. APA were measured with by ELISA (American Diagnostica, Stamford CT). MP were measured using a functional procoagulant assay (Hyphen Biomedical, ParisFrance). AGA were measured with a commercially available assay from GTI (Madison, WI). Thrombin generation was measured using a fluormetric method (Technoclone, Vienna, Austria). The proteomic profile was analyzed by SELDI-TOF mass spectrometry.
Results: A higher prevalence of elevated biomarkers was seen in the cancer group compared to normals. The average MP value was 3.1 + 5.8 nM (range 0.1–34.6 nM) with 26 of 134 samples were above the normal values of 2.8 ± 1.1. The average APA value was 6.7 ± 11 (range 4–65 nM) with 32 above normal. The average AGA value was 0.22 ± 0.09 (range .01–.8O) with 10 above normal. SELDI analysis showed unique biomarkers in the area of 11–12 kDa, 15.1–15.4 kDa, and 15.8–16.2 kDa which were absent in the normal group. Higher thrombin generation was observed in the cancer group.
Conclusion: This data suggests that bladder cancer patients have subclinical activation of thrombotic and inflammatory processes. The MP may be generated by cellular damage whereas the APA and AGA suggest vascular endothelial damage and activation. The unique proteo-

mic biomarkers in these patients suggest endogenous protease activation. A clinical correlation in the subset with higher markers may provide insight into the biomarker role in prognosis, risk stratification and treatment of bladder cancer.

PB 4.60-2

Prevalence of unexpected pulmonary embolism at contrast-enhanced CT scan performed for cancer staging in patients with advanced lung cancer

Verso M[1], Franco L[1], Mosca S[2], Fischer M[2], Chiari R[3], Marconi V[2], Paglialuca L[4] and Agnelli G[1]

[1]Division of Internal and Cardiovascular Medicine-Stroke Unit; [2]Radiology Department, Santa Maria della Misericordia Hospital; [3]Division of Medical Oncology, Santa Maria della Misericordia Hospital; [4]Division of Medical Oncology, Santa Maria della Misericordia Hospital, Perugia, Italy

Background: Patients with advanced lung cancer have been reported to be at high risk for venous thromboembolism (VTE). In patients with cancer, a rate of unexpected pulmonary embolism (UPE) of about 1.5% has been reported.
Aims: The aim of the study was to determine the prevalence of UPE in patients with stage IIIB or IV NSCLC or extensive SCLC who underwent CT scans for cancer staging.
Methods: We reviewed the contrast-enhanced CT scans of the chest performed for routine cancer staging in consecutive patients with advanced lung cancer (stage IIIB or IV NSCLC or extensive SCLC) referred to the Division of Medical Oncology at thePerugia hospital between 2008 and 2012. All CT scans were reviewed by an ad hoc panel composed by three radiologists. PE was defined as unexpected when a filling defect in central, lobar, segmental or sub-segmental pulmonary arteries were observed in absence of clinical suspicion of PE.
Results: Overall, 223 patients were included in the analysis: 180 patients with IV-NSCLC, 24 patients with IIIB-NSCLC, and 19 patients with extensive SCLC. A total of 899 CT scans were reviewed. The prevalence of UPE was 19.7% (44/223): 34 (77.3%) in patients with IV-NSCLC, 7 (15.9%) in patients with IIIB-NSCLC, and 3 (6.8%) in patients with advanced SCLC. Patients with UPE were 26 males and 18 females and had a mean age of 58 years (range 24–78). UPE was monolateral in 30 patients and bilateral in 14 patients. UPE involved central pulmonary arteries in six patients, lobar arteries in 16 patients and segmental arteries in 19 patients. Three patients had an isolated sub-segmental UPE. The mean time between cancer diagnosis and UPE was 11.8 months. 27% of cancer patients with UPE had the positive CT scan at diagnosis and 50% within 3 months. A recurrence of UPE was observed in one patient.
Conclusions: Patients with IIIB or IV NSCLC or extensive SCLC have a high rate of UPE at CT scan performed for cancer staging. UPE was bilateral in about one third of patients. A minority of UPE involved isolated sub-segmental arteries.

PB 4.60-3

Impact of chronic kidney disease and treatment with LMWH on the risk of major bleeding in patients with cancer-associated venous thromboembolism

Kooiman J[1], Den Exter PL[1], Cannegieter SC[1], Le Cessie S[1], Del Toro J[2], Sahuquillo JC[3], Pedrajas JM[4] and Huisman MV[1]

[1]Leiden University Medical Center, Leiden, The Netherlands; [2]Hospital General Universitario Gregorio Marañón, Madrid; [3]Hospital Municipal de Badalona, Barcelona; [4]Hospital Clínico San Carlos, Madrid, Spain

Background: Information on the risks of recurrent venous thromboembolic events (VTE) and major bleeding during anti-coagulant treatment in patients with cancer-associated VTE and chronic kidney disease (CKD) is scarce.
Aim: We analyzed these risks in CKD patients with cancer-associated VTE and compared their risk with those of non-CKD patients.
Methods: 1684 patients diagnosed with cancer-associated VTE between 2001 and 2011 were followed for 180 days after VTE diagnosis. Patients were treated mainly with low molecular weight heparin (LMWH) or vitamin-K antagonists. Primary outcomes were recurrent VTE and major bleeding. Secondary outcome was fatal bleeding.
Results: Recurrent VTE occurred in 62/994 (6.2%), 29/548 (5.3%), and 3/142 (2.1%) patients without CKD (eGFR >60 mL/min), with moderate (eGFR 30–60 mL/min), or severe CKD (eGFR <30 mL/min), respectively. Hazard Ratios (HRs) for recurrent VTE in moderate and severe CKD compared with non-CKD patients were 1.1 (95% CI 0.7–1.8) and 0.5 (95% CI 0.2–1.7), respectively. Major bleeding occurred in 45/994 (4.5%), 32/548 (5.8%), and 17/142 (12.0%) patients without, with moderate or severe CKD, respectively. HR for major bleeding in patients with moderate and severe CKD compared with non-CKD patients were 1.6 (95% CI 1.0–2.6) and 3.7 (95% CI 2.0–6.7) and for fatal bleeding 3.6 (95% CI 1.2–11.4) and 12.5 (95% CI 3.7–45.1), respectively. These increased bleeding risks in CKD patients were mainly observed in patients treated with LMWH.
Conclusions: The risks of major and fatal bleeding were increased in CKD patients, with VTE and cancer, which was most prominent in those treated with LMWH. These results highlight that LMWH should be used with caution in this specific population.

PB 4.60-4

Von Willebrand factor, ADAMTS13 levels and prediction of venous thromboembolism in patients with cancer

Pepin M[1], Kleinjan A[2], Hajage D[3], Büller HR[2], DiNisio M[2], Kamphuisen PW[4], Mahe I[1] and Stepanian A[1]

[1]APHP – Hopital Louis Mourier, Colombes, France; [2]Academic Medical Center, Amsterdam, The Netherlands; [3]APHP – Hopital Bichat, Paris, France; [4]University Medical Center Groningen, Amsterdam, The Netherlands

Background: Cancer patients are at high risk for venous thromboembolism (VTE). However, thromboprophylaxis in these patients is associated with an increased hemorrhagic risk. The Khorana score is a risk scoring model for prediction of VTE that includes clinical and laboratory parameters. It has been expanded by incorporating two biomarkers, soluble P-selectin (P-sel), and D-Dimer. Other laboratory markers like prothrombin fragment 1 + 2 (F1 + 2) have also been reported to predict VTE in cancer patients. von Willebrand factor (VWF) is a mutimeric protein that promotes platelet adhesion and aggregation in high shear stress conditions; it is also implicated in venous thrombosis. ADAMTS13 (a desintegrin-like and métalloprotéase thrombospondin type 1 motif) specifically cleaves VWF multimers and subsequently regulates its activity; previous studies displayed decreased levels of ADAMTS13 in cancer patients when compared to patients without cancer.
Aims: (i) to search for an association between VWF and ADAMTS13 levels and VTE in cancer patients; (ii) to compare Khorana score and expanded Khorana score before and after addition of VWF and ADAMTS13 levels.
Methods: multicenter case-control study. Subjects were ambulatory patients receiving chemotherapy for stage III or IV cancer, prospectively followed for 6 months for the development of VTE. Each case (patient who developed VTE) was matched with seven controls (patients who did not develop VTE) for age, sex, type of cancer and stage. The Khorana score and the expanded score were calculated. ADAMTS13 activity was measured using a fluorescence resonance energy transfer assay; VWF, ADAMTS13 antigen, P-sel, D-Dimer and F1 + 2 levels were measured using ELISA methods. Univariate

and multivariate analysis were performed to compare the levels between cases and controls. Logistic models were used to test whether VWF and ADAMTS13 levels would add significant prognostic information to Khorana and expanded Khorana score. Results are expressed as odds ratios (OR) and their 95% CIs.

Results: We studied 20 cases and 140 controls. VWF levels were significantly higher in cases when compared to controls (326 ± 185% vs. 242 ± 158%; $P = 0.02$), whereas ADAMTS13 levels were not significantly different (activity 87 ± 18.9% vs. 81.5 ± 18.9; antigen 579 ± 108 ng/mL vs. 564 ± 137 ng/mL). VWF and ADAMTS13 levels were not correlated ($r = -0.06$ Pearson). VWF levels significantly increased with increasing stage of cancer ($P = 0.03$) whereas ADAMTS13 activity levels only tended to decrease ($P = 0.06$). The addition of VWF levels significantly improved the Khorana score (OR = 3.5 [1.2–10.2]). ADAMTS13 activity levels significantly improved the Khorana and the expanded Khorana scores (OR = 5 [1.4–23.5]) and 5.8 [1.4–28.2], respectively).

Summary/Conclusions: Prospective studies are needed to confirm our results and determine if VWF and ADAMTS13 can be used as predictive markers of VTE in stage III/IV cancer patients. Our results also highlight a role of VWF and ADAMTS13 in the pathophysiology of VTE in cancer.

PB 4.60-5

Thrombotic events in children with malignancies in relation to treatment components of chemotherapy

Russo A[1], Wingerter A[1], Dudda JL[1], Feketeova J[1], Scharrer I[2] and Faber J[1]

[1]University Childrens Hospital Mainz; [2]University of Mainz, Mainz, Germany

Background: Thrombotic events are an important factor for morbidity and mortality in pediatric patients with hematological malignancies and solid tumors. The pathogenesis of these complications is most often multifactorial and either related to the underlying malignancy, the use of central venous catheters (CVC), certain antineoplastic treatment elements and/or genetic risk factors.

Aims: To retrospectively analyze thrombotic events and underlying pathogenetic factors in a single center pediatric cohort treated for malignant disease.

Methods: Overall 498 patients with childhood cancer (age 2–17 year) diagnosed between 2002 and 2012 were studied with regard to occurrence of thrombotic events, their association with antineoplastic therapy and hereditary thrombophilia.

Results: We recorded a total of 30 thrombotic events in 22 children among our patient population comprising 10 deep vein thromboses (DVT), 2 pulmonary embolisms (PE), 3 cerebral sinus venous thromboses (CSVT), 2 cerebral infarction, 3 venoocclusive diseases (VOD) and 10 CVC occlusions. In exception of one patient, thrombotic events occurred closely associated with antineoplastic polychemotherapy regimes including asparaginase, anthracyclines, high dose mtx, actinomycin and glucosteroids. Screening for genetic risk factors was possible in 15/22 children. 7/15 revealed a hereditary procoagulative abnormality.

Conclusion: Thrombotic events can occur in children with various malignancies and chemotherapy regimen. Screening for genetic risk factors as well as careful management and supportive treatment is therefore essential for prevention of thrombosis in these patients supplemented by anticoagulative therapy.

PB 4.60-6

Impact of haemophilia on cancer detection and management: a retrospective study

Biron-Andreani C[1], De Moerloose Ph[2], D'Oiron R[3], Chambost H[4], Schved J-F[1] and Hermans C[5]

[1]University Hospital, Montpellier, France; [2]University Hospital and Faculty of Medicine, Geneva, Switzerland; [3]Bicêtre APHP University Hospital, Paris- Le Kremlin Bicêtre, France; [4]La Timone Hospital AP-HM, Aix Marseille University, Marseille, France; [5]St-Luc University Hospital, Brussels, Belgium

Background: Lymphoma or hepatocarcinoma secondary to blood-borne transmitted diseases are well known malignancies in persons with haemophilia (PWH). However with increasing life expectancy more PWH are facing other malignancies such as prostate or colorectal cancers, requiring a close collaboration between oncologist and the haemophilia specialist.

Aims: The aim of present study was to analyze the impact of haemophilia on cancer detection and its management in five European haemophilia treatment centers (Brussels, Geneva, Marseille, Montpellier and Paris-Bicêtre) from three countries.

Methods: We collected retrospectively in the last 10 year-period, clinical data on cases of cancer that occurred in PWH.

Results: A total of 46 malignancies occurred in 1267 PWH during the observation period. Eighteen tumors were fatal (39%). The most common types of malignancy were hepatocellular carcinoma (12/46) and urogenital tract tumors (9/46). A change in bleeding pattern revealed cancer in four patients only. No bleeding was associated with chemotherapy or radiotherapy. Few bleeding complications occurred with surgical procedures because of insufficient haemostatic coverage for some cases and in spite of adequate clotting factor substitution for others. After cancer diagnosis, five patients had to be switched from on demand to prophylaxis substitution. In the majority of cases the treatment protocol of cancer was not modified because of hemophilia.

Conclusion: Our study emphasizes that in adults PWH a change in bleeding pattern should raise the suspicion of malignancy and also that a PWH should benefit from the same oncologic treatment as other persons with cancer but no hemophilia.

Recombinant thrombomodulin reduces the elevation of some biomarkers after allogeneic hematopoietic stem cell transplantation

Nomura S, Ish Kii, Fujita S, Yoshimura H, Hotta M, Nakanishi T and Ito T

Kansai Medical University, Moriguchi, Osaka, Japan

Background: Levels of cytokines, chemokines and soluble molecules fluctuate after allogeneic hematopoietic stem cell transplantation (HSCT). They can be influenced by various post-transplant complications, as well as by existing basal diseases, types of transplantation, and the conditioning regimen used.

Aims: In the present study, we investigated the effects of recombinant thrombomodulin (rTM) on levels of the cytokines, chemokines, and soluble factors registered in the 'SIGHT' research.

Methods: The subjects were 116 patients who underwent allogeneic HSCT (bone marrow = 69, peripheral blood stem cells = 20, cord blood = 37). Blood samples were collected before and after transplantation. Levels of cytokines (interleukin-6, tumor necrosis factor-α, high-mobility group box (HMGB) 1), chemokines (monocyte chemotactic protein (MCP)-1, RANTES), and soluble molecules (soluble vascular cell adhesion molecule (VCAM)-1, soluble E-selectin, plas-

minogen activator inhibitor-1, platelet-derived microparticles [PDMP]) were measured by enzyme-linked immunosorbent assay. The rTM was administered as a therapy for transplantation-associated coagulopathy (TAC). This protocol was completed in day 4–14 after HSCT and consisted of day doses of 380 unit/kg with every days. Control group was also used heparin or no anti-coagulation therapy.

Results : MCP-1, IL-6, and TNF-a exhibited more significant elevations on days 7–14 after HSCT. In contrast, the levels of HMGB1, sE-selectin, sVCAM-1, PAI-1 and PDMP exhibited significant changes on days 14-28. There were significant improvements in TNF-a, sE-selectin, sVCAM-1, HMGB1, PAI-1 and PDMP after rTM treatment, but not after heparin treatment.

Summary/Conclusion: We believe one of causes for TAC is pro-inflammatory cytokine including HMGB1. For this reason, it is thought that the direct anti-inflammatory effect of rTM's lectin domein plays an important role in therapeutic mechanism for TAC. The present findings suggest the possibility that rTM can play a therapeutic role for TAC after allogeneic HSCT.

PB 4.61-2

Peak factor Xa generation as a candidate biomarker for bevacizumab-induced thrombotic and bleeding events

Lakoski SG[1], Brummel-Ziedins K[1], Connolly G[2], Bravo MC[1], Cushman M[1] and Khorana A[2]

[1]University of Vermont, Colchester, VT; [2]University of Rochester, Rochester, MN, USA

Background: Bevacizumab, an anti- vascular endothelial growth factor monoclonal antibody, is an important component of regimens against colorectal and other cancers but is associated with a high risk of both thrombotic and bleeding events. The mechanisms underlying this are incompletely understood.

Aims: We evaluated the impact of bevacizumab therapy on Factor (F) Xa, a critical enzyme in blood coagulation, in a prospective pilot cohort study.

Methods: We prospectively enrolled patients initiating systemic treatment with a bevacizumab-containing regimen for metastatic colorectal, renal, breast, or lung cancer or lymphoma. At baseline and after 1 month of therapy we measured individual concentrations of plasma factors II, V, VII, VIII, IX, X, antithrombin and tissue factor pathway inhibitor and estimated tissue factor-initiated peak FXa generation using a mathematical model. Simple *t*-tests were used to assess statistical differences between groups.

Results: The cohort comprised 40 patients including 45% women, with a mean age of 59 (12) years. We ascertained six venous thromboembolism (VTE) events (15%) and seven bleeding events (17%). Peak FXa generation at baseline was 2.0 nM ± 0.16 (SE). Over a 1 month period on bevacizumab, there was a −3% ±7 change in FXa generation, −6% ±8 for patients who did not develop VTE and 16% ± 18 among those with a VTE ($P = 0.29$). D-dimer also changed during therapy among those developing VTE (5% ± 8) compared to those without a VTE (−3% ± 3 respectively, $P > 0.05$). Among those with hemorrhage, there was a −22% ± 12 change in FXa compared to −2% ± 9 among those without hemorrhage ($P = 0.30$), with similar trends for D-dimer (−7% ± 8 vs. −2% ± 4, $P > 0.05$, respectively).

Conclusion: In this pilot study, total active FXa generation increased (albeit not statistically significantly) after 1 month of treatment with bevacizumab among those who developed a VTE; conversely, FXa generation decreased among those who developed minor or major bleeding. We propose that FXa generation is a candidate biomarker of bleeding and thrombosis risk during bevacizumab therapy and further studies to investigate this are warranted.

PB 4.61-3

Anticoagulant treatment of cancer patients with pulmonary embolism in the real world

Kleinjan A[1], Hutten B[1], Di Nisio M[2], Kamphuisen PW[3] and Büller HR[1]

[1]Academic Medical Center, Amsterdam, The Netherlands; [2]G.D'Annunzio University, Chieti, Italy; [3]University Medical Center Groningen, Groningen, The Netherlands

Background: Since 2004, international guidelines provide specific recommendations for patients with cancer and pulmonary embolism (PE), namely long-term treatment with low molecular weight heparin (LMWH). However, recent studies indicate that the use of LMWH mono-therapy might be far from optimal. Another important area of uncertainty is the duration of the anticoagulant treatment.

Aims: Therefore, we evaluated the real world clinical practice of type and duration of anticoagulant therapy in cancer patients with PE over a period of 10 years.

Methods: This was a retrospective cohort study based on data from the Dutch Pharmo database, which contains hospitalisation and pharmacy data of over 4 million patients. PE patients with or without cancer were identified according to the International Classification of Diseases Ninth Revision (ICD9 CM), based on at least one hospitalization for cancer within 2 years prior to and 1 year after the PE. Thereafter, every subject with PE and cancer was matched to two subjects with PE without cancer, for age, sex and year of diagnosis of PE. The primary objective was to assess the type and duration of outpatient anticoagulant treatment for PE. The secondary objective was to evaluate the incidence of hospitalizations for bleeding during follow-up, which were expressed as incidence rate per 1000 patient years.

Results: Between January 1998 and August 2008, 600 cancer patients with PE and 1200 patients with PE without cancer were identified. Overall, long-term LMWH was prescribed in 82 (13.7%) of the cancer patients and in 8 (0.7%) of the cancer free patients ($P < 0.001$). From 1998 to 2008, there was an increase in the use of long-term LMWH in cancer patients, but not in controls ($P < 0.001$ and $P = 0.76$, respectively). In patients with cancer and PE in 2007/2008, LMWH was prescribed in 42 (32%) cases, compared to 1 (1.7%) of the cancer patients with PE in 1998/1999. Median duration of treatment was 5.8 months (interquartile range (IQR) 3.1–8.8) in cancer patients, compared to 7.0 months (4.9–11) in patients without cancer ($P < 0.001$). Cancer patients on long-term LMWH were treated for a median duration of 5.1 months (IQR 3.4–9.7), compared to 5.9 months (IQR 3.0–8.7; $P = 0.36$) in the cancer patients on VKA. In the group of cancer patients, 22 hospitalizations for bleeding per 1000 patient-years of follow-up were counted, compared to 11 hospitalizations per 1000 patient-years in the non-cancer patients (OR 1.9; 95% CI 1.2–3.1).

Summary/Conclusions: Although the use of LMWH in patients with cancer and PE is increasing, in 2008, patients are still mostly treated with VKA, and not with LMWH as recommended by guidelines. Future studies should focus on reasons for this underuse and on the impact of long-term LMWH use on the quality of life of cancer patients. Additionally, most cancer patients with PE are not treated indefinitely, instead receive anticoagulants for 6 months or shorter.

PB 4.61-4

L-asparaginase induced laboratory and clinical hemostasis impairments and use of replacement therapy in children treated from acute lymphoblastic leukemia – single center experience

M. Jovic, D. Micic, M. Kuzmanovic, O. Serbic-Nonkovic and A. Jovanovic

Mother and Child Health Care Institute of Serbia, Dr. Vukan Cupic, Belgrade, Serbia

L-asparaginase is an essential component of regimens used to treat patients with acute lymphoblastic leukemia (ALL). Reduced synthesis of proteins such as antithrombin, fibrinogen and other coagulation factors causes both thrombotic and hemorrhagic complications associated with L-asparaginase.

This was retrospective analysis of 42 children with acute lymphoblastic leukemia treated according the protocol ALLIC-BFM 2009 from the 1st of April 2010 up to 31st of December 2012 in our Institute. All 42 patients have received protocol IA, 13 patients have received protocol IB Augmented and 32 patients up to now have finished protocol IIB.

At the diagnosis the median value of prothrombin time was 80%, median value of activated partial thromboplastin time (aPTT) 26.5 s, median fibrinogen level was 3.4 g/L, and the median platelet count was 70×10^9/L. At that time there was no need for transfusions with fresh frozen plasma, cryoprecipitate or antithrombin concentrate. Several children received platelet transfusions, and there were neither thromboembolic nor major hemorrhagic complications.

During the first part of induction treatment (protocol IA), median values of PT and aPTT were almost the same as the values at the diagnosis (88.1% and 25.15 s), median fibrinogen value has dropped up to 1.1 g/L, antithrombin ranged from 23.2 up to 146% (median 66.3%), and D-dimers from 104 up to 8283 ng/mL (median 441 ng/mL). The median platelet count was 132×10^9/L. Fourteen children received different types of replacement therapy once, three, four, five or six times (10 single infusion of antithrombin, 17 single infusion of cryoprecipitate and four simultaneous infusion of antithrombin and cryoprecipitate, 31 infusions in total). One patient has developed partial sagittal sinus venous thrombosis, and sever hypoproteinemia with edema of the lower extremities was noticed in three patients.

During the second part of induction treatment (protocol IB Aug), median PT value was slight diminished (69.5%) and median aPTT was prolonged (32.15 s), median fibrinogen value has gradual increased up to 2 g/L. Antithrombin ranged from 28 up to 141.3% (median 44.3%), but the median value of D-dimers significantly dropped up to 156.5 ng/mL. Median value of platelet count was 98.75×10^9/L. Seven patients have received replacement therapy once, twice or three times (8 single infusion of antithrombin, 1 single infusion of cryoprecipitate and 1 simultaneous infusion of antithrombin and cryoprecipitate, 10 infusions in total).

During the first part of reinduction therapy (protocol IIA), median values of PT (110.2%), aPTT (24.8 s), antithrombin (88.6%), D-dimers (146 ng/mL) and platelet count (276×10^9/L) was in normal ranges. We only registered lowering of fibrinogen levels (median 0.9 g/L). Replacement therapy with cryoprecipitate received six patients during this part of treatment.

During augmentation and reinduction course there were no clinical manifestations of hemostasis impairment.

In conclusion, the most frequent and most sever impairments of hemostasis due to L-asparaginase were noticed during the first part of the induction period, so it is therefore clear that during this part of treatment there were the greatest need for replacement therapy. The rarest disorders of hemostasis (exclusively hypofibrinogenemia) were recorded during the reinduction phase

PB 4.61-5

Thrombotic events in acute promyelocytic leukemia – Single center experience

Mirjana M, Suvajdzic N, Elezovic I, Bogdanovic A, Djunic I, Colovic NR, Virijevic M, Vidovic A and Tomin D

Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Acute promyelocytic leukemia (APL) is a distinct subset of acute myeloid leukemia characterized by severe coagulopathy at presentation. As a part of the clotting activation, thrombosis either at diagnosis or during the treatment is a less recognized and probably underestimated life-threatening manifestation of APL

Aim: To report trombotic events in 60 de novo APL patients and to identify factors predictive for thrombosis development.

Method: We retrospectively analyzed data on ED in 60 newly diagnosed, *t*(15;17)(q22;q12) or PML-RARA positive APL patients (median age 44 years, range 19–78; 31/29 female/male) managed at the Clinic of Hematology from 2004 to 2012 with all-trans retinoic acid combined with anthracyclines. The diagnosis of deep vein thrombosis (DVT) was established by Color Doppler ultrasonography. The diagnosis of cardiac ischemic condition was based on electrocardiographic and cardiac enzymatic modifications. Budd-Chiari syndrome was diagnosed by CT scan and central retinal vein occlusion by ophthalmoscopy and fundus angiography.

Results: Thrombotic events (TE) were registered in 10/60 (16.7%) APL patients: five with DVT, (catheter-related in two patients), two with cerebral infarction and one by one patient with acute myocardial infarction, Budd-Chiari syndrome and central retinal vein occlusion. The timing of TE was as follows: one patient exhibited TE before therapy initiation, seven during induction, one patient during II consolidation and one during maintenance therapy. Only 2/10 (20%) patients displayed coagulation impairment at the time of thrombosis. One patient with TE (cerebral infarction) died during induction.

The main clinical and biological characteristics of 10 APL patients with thrombosis were: median age 47.5 years (range 31–64); 3/9 female/male; median WBC count 5.6×10^9/L (range: 1.1–88); median platelet count 46×10^9/L (range: 18–93); Sanz' s risk stratification: high 3/11 (27.5%), intermediate 3/11 (27.5%), low 5/11 (45%); Disseminated intravascular coagulation (DIC) was confirmed in 8/11 (72.7%) patients, median ISTH DIC score (International Society of Thrombosis and Hemostasis Scoring System for disseminated intravascular coagulation) was 5.4 (range: 2–7); variant form of APL displayed in 1/11 (9.1%) patients; seven patients disclosed aberrant immunophenotypic features: expression of CD2 in five and CD15 in two patients; additional cytogenetic abnormalities 2/10 (20%) patients; FLT3-ITD was documented in 2/10 (20%) cases; differentiation syndrome in 2/10 (20%).

Patients with TE displayed significantly higher median WBC count (5.6×10^9/L vs. 3.6×10^9/L, $P = 0.04$), higer median platelet count (46×10^9/L vs. 29×10^9/L, $P = 0.006$) and more frequent CD2 expression (50% vs. 24%, $P = 0.002$). No correlation was found with age, French-American-British subtype, laboratory coagulation parameters (fibrinogen, prothrombin time, activated prothrombin time, D-dimer), ISTH DIC score, CD15 expression, additional cytogenetic abnormalities, FLT3-ITD and differentiation syndrome.

Conclusion: TE rate of 16.7% in our APL cohort showes that TE rate in APL is frequent, especially during induction treatment. This result emphasizes significance of D-dimmer monitoring after coagulopathy resolution. Besides, our study suggests the possible relationship between TE occurrence on one side and laboratory findings (WBC and platelet count; CD2 expression) on the other.

PB 4.61-6

Thrombotic complications in hematological malignancies

Mishra P[1], Mahapatra M[2] and Seth T[2]

[1]All India Institute of Medical Sciences, New Delhi; [2]AIIMS, Delhi, India

Background: Patients with haematological malignancies have both a procoagulant state and an increased risk of thrombosis because of therapy. Population based surveys have identified haematological malignancies as a leading cause of thrombosis.

Aim: To evaluate the prevalence and outcome of patients with thrombotic complications in hematological malignancies.

Method: We identified patients with thrombosis from the case records of 636 indoor admissions with haematological malignancies from January 2010 to December 2011. We performed plasma homocysteine levels, factor V leiden, immunological markers including ACLA, ANA, and flow cytometric analysis for CD55 or CD 59 deficiency in all patients who had a thrombus. Proteins C, S and Antithrombin were analysed after patients were asymptomatic and off anticoagulation.

Results: Thirteen patients suffered a thrombosis. There were eight venous, six arterial thrombi including one patient who had both. Six patients had thrombus as presenting feature. Arterial thrombi involved brain in four and lung in two patients. Venous thrombi involved lower limbs in 4, sagittal sinus in two and renal vein in one patient who also had lower limb DVT. One patient each with waldenstrom's macroglobulinemeia (WM) and follicular lymphoma(FL) presented with leg DVT. However the patient with WM also had concurrent renal cell carcinoma and the patient with FL had liver cirrhosis. Among the remaining patients, seven had acute lymphoblastic leukemia(ALL) and four had acute myeloid leukemia(AML). Two patients with ALL had thrombus at presentation-one leg DVT and one anterior cerebral artery thrombus respectively. Remaining five patients with ALL suffered a thrombotic episode after starting chemotherapy. One of these patients had a pulmonary embolus and all the remaining four had intracerebral thrombi. The patient with ALL who had a pulmonary embolus was Philadelphia positive on Imatinib and had not received any L-asparaginase(L-ASP) prior to the thrombotic episode. All other ALL patients had received L-ASP. L-ASP was successfully continued in all patients under cover of heparin or warfarin except for one patient who suffered another episode of intracerebal thrombus despite anticoagulation. Two patients with AML had a thrombus at presentation of whom one presented with a parietal lobe infarct and the other, a young male of 28 years, had prior myocardial infarction and a documented factorV Leiden mutation. Of the other two AML patients who presented after chemotherapy, one patient was in induction phase and the other had started consolidation with high dose cytarabine at the time of thrombotic episode. Both these thrombotic episodes involved the upper limb (1 subclavian and 1 brachial) and were perhaps associated with the PICC line. No patient died because of thrombotic complications. Only one patient with ALL required a discontinuation of L-asparahinase. None of hese patients except for the one AML patient with Factor V Leiden mutation had a prior thrombotic episode.

Conclusions: An overt thrombotic episode was uncommon in our cohort of patients. There were predictive factors in none but one patient. L-ASP was most likely association in patients with ALL. L-ASP can be successfully continued under anticoagulant cover. A thrombotic episode had no bearing on outcome after chemotherapy.

PB4.62 – Antiphospholipid – V

PB 4.62-1

Variability in exposure of epitope G40-R43 of domain I in commercial anti-β2-glycoprotein I IgG ELISAs influences the diagnosis of the antiphospholipid syndrome

Pelkmans L[1], Kelchtermans H[2], De Groot PG[3], Zuily S[4], Regnault V[4], Wahl D[4], Pengo V[5] and De Laat B[2]

[1]Cardiovascular Research Institute Maastricht, Maastricht, The Netherlands; [2]Synapse BV, Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, The Netherlands; [3]University Medical Centre Utrecht, Utrecht, The Netherlands; [4]Regional Competence Centre for Rare Vascular Diseases, Nancy University Hospital, Nancy, France; [5]Thrombosis Centre, University of Padua, Padua, Italy

Background: Diagnosis of the antiphospholipid syndrome (APS) depends on the detection of autoantibodies against β_2-glycoprotein I (β_2GPI), the most prominent antigen in APS. A main problem is the high variability between commercially available anti-β_2GPI assays. Anti-β_2GPI antibodies constitute a heterogeneous population, but predominantly antibodies reacting to a cryptic epitope Glycine40-Arginine43 (G40-R43) in domain I of β_2GPI are associated with thrombosis. b_2GPI is present in blood in a native conformation. After interaction with anionic surfaces it opens up, resulting in exposure of G40-R43. Therefore, in diagnostic assays b_2GPI should be presented in the open conformation enabling antibodies to react with G40-R43.

Aims: We hypothesize that the high variability between commercial anti-b_2GPI ELISA assays arises from variation in exposure of epitope G40-R43.

Methods: Two patient-derived monoclonal antibodies P2-6 and P1-117 were tested for their reactivity towards β_2GPI. Using both antibodies, we compared exposure of epitope G40-R43 on β_2GPI in commercial anti-β_2GPI IgG assays (A-E). Ten G40-R43-reactive and 10 negative patient samples were tested in assays A and B. Additionally, samples of 176 SLE patients, possibly suffering from APS, were tested for reactivity towards domain I of b_2GPI and for positivity in assays A and B.

Results: Using neutral vs. anionic ELISA plates, we have shown that antibody P1-117 specifically reacts with epitope G40-R43, exposed only in the open conformation, while antibody P2-6 recognizes β_2GPI irrespective of its conformation. In assay A, both antibodies showed equal reactivity towards β_2GPI, indicating that all the coated β_2GPI exposes epitope G40-R43. In other assays P1-117 displayed lower reactivity towards β_2GPI than P2-6, demonstrating a reduced exposure of G40-R43. To rule out that other assay features account for the observed differences in reactivity, we have re-examined the reactivity of both antibodies on coated plates of assay A and B using the protocol and reagents from each assay. In all combinations, reactivity of both antibodies on a plate was comparable to the results obtained with its own protocol and reagents. This suggests that the coating, rather than any other component of the assays, is responsible for the differences between the assays. Interestingly, all 10 G40-R43-reactive patients tested positive in assay A, vs. only three in assay B. 24 of the 176 SLE patient samples were found positive for reactivity against domain I of b_2GPI by ELISA. Of these 24, 23 tested positive in assay A, vs. only 19 in assay B. Decreasing the cut-off value of assay B did not ameliorate test results, suggesting that the differences in correct patient classification between the assays is not simply the result from different cut-off settings.

Conclusions: Exposure of epitope G40-R43 on β_2GPI is highly variable in commercial anti-β_2GPI assays. By testing patient samples we have indications that patients may be falsely assigned negative in assays characterized by a reduced exposure of G40-R43. Our results have major implications for the diagnosis of APS. Antibodies P2-6 and

P1-117 can serve as controls to ensure sufficient exposure of G40-R43. Alternatively, we encourage the development of alternative assays coating only domain I of β_2GPI.

PB 4.62-2

Elevated levels of endothelial cell microparticles in patients with antiphospholipid antibodies correlate with levels of anti-beta2-glycoprotein I antibodies

McCrae KR and Chaturvedi S

Cleveland Clinic, Cleveland, OH, USA

Background: The antiphospholipid syndrome (APS) is characterized by venous or arterial thrombosis and/or recurrent fetal loss in the presence of circulating anti-phospholipid antibodies. It has been shown that these antibodies can cause activation of endothelial cells that leads to shedding of microparticles (MP). These MP have been ascribed procoagulant properties and increased MP levels have been observed in several disease states that share a phenotype of vascular dysfunction, inflammation and thrombosis such as cardiovascular disease, venous thrombosis and cancer.

Aims: The aim of this study was to characterize the levels of endothelial cell, monocyte, and platelet derived as well as tissue factor bearing MP in patients with APS. A secondary aim was to study whether MP levels correlate with titers of anticardiolipin antibodies and anti-β2 glycoprotein I antibodies.

Methods: Citrated whole blood from 47 patients with APS and 144 healthy controls were centrifuged at 1500 ***g*** for 15 min and the supernatant was centrifuged at 13,000 ***g*** for 2 min to obtain platelet free plasma (PFP). To detect MP and their origin, PFP was incubated with the following fluorochrome conjugated monoclonal antibodies and analyzed by flow cytometry (LSRII BD biosciences): Annexin V-APC, CD105-PE and CD144-PE (endothelial cells); CD41-PECy4 (platelets); CD14-PE (monocytes); and anti-Tissue Factor mAb-Alexa Fluor647. MP measurements were left skewed so a log 10 transformation was performed before comparing them with a *t*-test or running correlation analyses. $P < 0.05$ was considered significant for all analyses.

Results: Females comprised 52% of patients and 55% controls. The median age of patients and controls was 43 years and 29 years, respectively; however there was no association between age and MP numbers. Thirteen patients had APS along with SLE, 29 had a history of venous thrombosis, 12 had had strokes, and 5 of 21 female patients had a history of pregnancy loss.

Levels of Annexin-V, CD105 and CD144 (endothelial derived), CD41 (platelet derived) and TF positive MP were higher in patients ($47{,}000 \pm 7900$, $10{,}140 \pm 2164$, $46{,}690 \pm 8783$, $127{,}200 \pm 28{,}050$, and 7270 ± 2810 MP/mL respectively) vs. controls ($17{,}000 \pm 1800$, 3824 ± 374, $17{,}320 \pm 2636$, $54{,}910 \pm 7132$ and 2537 ± 747 MP/mL respectively). These differences were highly statistically significant (all $P < 0.02$). In contrast, there was no difference between CD14 positive MP levels (1035 ± 167 vs. 1409 ± 465, $P = 0.66$).

There was no significant association between age or clinical features (thrombosis, strokes, pregnancy loss) and MP levels. Interestingly, MP positive for Annexin V, CD105 and CD144 (endothelial markers) showed a positive correlation with IgG anti-beta 2- glycoprotein I (anti- β 2GPI) ($R = 0.60$, $P = 0.006$) and IgM anti- β 2GPI ($R = 0.58$, $P = 0.006$). These did not correlate with CD14 or CD41 positive MP levels and there was no association between MP levels and anti-cardiolipin antibodies.

Conclusions: Plasma of APS patients contains higher levels of endothelial cell and platelet derived microparticles and these correlate with anti- β 2GPI titers. This suggests that there is a chronic state of endothelial cell and platelet activation in these patients even in the absence of thrombosis and that anti-phospholipid antibodies likely play an important pathologic role in thrombosis.

PB 4.62-3

False positive results of Lupus Anticoagulant in plasmas of patients receiving LMWH or the new oral anticoagulants

Martinuzzo ME, Barrera HL, D'Adamo MA, Otaso JC, I Gimenez M and Oyhamburu J

Hospital Italiano de Buenos Aires-Grupo Bioquímico, Buenos Aires, Argentina

In the new guidelines for lupus anticoagulant (LA) diagnosis it is established not to study patients receiving unfractioned heparin, dicumarinic oral anticoagulants with INR >3.00 and to discontinue LMWH at least 12 h before searching a LA. In the last 2 years, oral direct thrombin and oral direct Xa inhibitors have been worldwide distributed for prevention and treatment of venous thromboembolism (VTE) and atrial Fibrillation (AF). So, it seems important to recognize the effect of these anticoagulants on results of LA tests. The aim of the present study was to describe the rate of false positive results of screening, mixing and confirmatory tests for LA in plasmas of patients that previously have normal coagulation tests results (LA-) and were receiving LMWH in therapeutic doses, Dabigatran etexilate (DAB) 220 mg/day because of an AF or Rivaroxaban (RIV) 10 mg/day for prophylaxis of VTE in elective hip replacement or 15 mg/day for AF. In patients with LMWH blood was taken at 4 h post dose, and for DAB and RIV between 1.5 and 4 h post dose. Tests evaluated were PT, APTT, ICA for APTT mixing study, DRVVT screen, ICA for DRVVT mixing study, normalized ratio (NR) for DRVVT screen/confirm, and NR for silica clotting time (SCT) screen/confirm. All tests were performed in a photo optical coagulometer (ACL TOP). The cut off points of tests and indexes were calculated according to guidelines as the 99th percentile of 50 plasmas from healthy donors. Plasmas from patients receiving LMWH ($n = 15$, anti Xa activity 0.5–1.6 U) presented: 26.6% PT activity <70%, 53.3% prolonged APTT and 62.5% of them did not correct with normal plasma (NP), 60% prolonged SCT screen, but only 10% positive NR SCT screen/confirm, 66.6% prolonged DRVVT screen, 50% of them without correction with NP, and 70% positive NR for confirmatory. Plasmas from patients taking DAB ($n = 15$) presented: 93.3% PT <70%, 100% prolonged APTT without correction with NP, 100% thrombin time very prolonged, 100% DRVVT very prolonged without correction with NP, and 80% of them with a positive NR DRVVT confirm, 100% of SCT screen prolonged but only 6.7% of positive NR SCT confirm. Among those receiving RIV at 15 mg/day ($n = 4$) all presented PT prolonged, DRVVT screen very prolonged without correction with NP and positive NR confirm, 75% presented slightly prolonged the APTT (<1.5 times), all SCT screen prolonged, but none positive NR for confirmatory test. Finally, plasmas from patients taking RIV 10 mg/day ($n = 20$), 75% presented PT <70%, only 10% prolonged APTT, 75% DRVVT screen prolonged, 80% of them did not correct with NP, and 73.3% with NR confirm positive, 20% of SCT screen prolonged but none of them with NR for SCT confirm positive. In conclusion, LMWH at therapeutic dose, DAB and RIV greatly affect recommended tests for LA testing not only in the screening and mixing studies, but also in confirmatory tests. It is mandatory to clearly access to the list of medications that patients are taken, and discontinue these anticoagulants before searching a LA to avoid false positive results.

PB 4.62-4

Anticoagulation for patients with antiphospholipid antibodies undergoing cardiopulmonary bypass – a novel strategy for optimisation of heparin anticoagulation

Ryan K[1], Goodyer M[1], O'Connell N[1], Gilmore R[1], Ni Ainle F[1], Jenkins V[1], Fagan P[2], Young V[2] and O'Donnell J[1]
[1]NCHCD, Dublin 8; [2]St. James's Hospital, Dublin, Ireland

Introduction: Cardiopulmonary Bypass (CPB), an essential component of many cardiothoracic surgical procedures, requires extremely high plasma heparin concentrations to prevent thrombosis within the extra-corporeal circuit, which may be life-threatening or result in significant morbidity. Consequently, heparin concentrations in the range of 3–4 IU/mL are required for CPB, which contrasts with the target of approximately 0.6 IU/mL used in the treatment of venous thrombosis. CPB surgery is also associated with a significant risk of major haemorrhage, particularly if excessive heparin is administered. Therefore, unfractionated heparin (UFH) and protamine doses are carefully monitored and titrated during CPB using near patient Activated Clotting Time (ACT) testing. It is recognised that Lupus Anticoagulants (LA) may influence this test. Thus, heparin monitoring in LA patients undergoing CPB surgery constitutes a common clinical problem.

Aims: No consensus exists on heparin monitoring in LA patients requiring CPB surgery. As LAs are heterogenous, their effect on the ACT is unpredictable. We wished to establish an appropriate ACT range for such patients by adopting an individualised approach and testing the response of the ACT to increasing heparin concentrations in such patients.

Methods: To elucidate the relationship between heparin concentration and ACT, we performed pre-operative ex-vivo spiking studies in seven patients with LA and prolonged APTTs who were planned to undergo CPB. In brief, whole blood was collected and spiked with increasing heparin concentrations (0–7 IU/mL). At each concentration, both ACT and anti-Xa levels were determined. In addition, peri-operative haemostasis was assessed in a prospective manner.

Results: Four patients has baseline prolonged ACTs. One patient demonstrated a non-linear response between increasing heparin concentrations and ACT, precluding this test's use as a means of determining intra-operative heparin concentrations and necessitating the use of anti-Xa monitoring. Four patients has flattening of their ACT curves, such that a standard ACT target of 400–480 s would have resulted in heparin concentrations significantly outside the desired 3–4 IU/mL range.

Conclusion: Cumulatively, these novel data demonstrate definitely that ex-vivo spiking studies are critical in order to optimise heparin dosing for LA patients undergoing CPB surgery. We propose that this methodology should be adopted as gold-standard practice.

PB 4.62-5

Anti-β2 Glycoprotein I autoantibodies and atherosclerosis in patients with ischemic stroke

Ben Said M[1], Sfar I[1], Younes S[1], Chaker F[1], Bannour I[2], Boughamoura L[3], Ben Abdallah T[1], Guermazi S[1] and Gorgi Y[1]
[1]Hôpital Charles Nicolle de Tunis, Tunis; [2]Faculté de Médecine de Monastir, Monastir; [3]Hôpital Tahar Sfar de Mahdia, Mahdia, Tunisia

Background: β2-Glycoprotein I (β2GPI) is a major antigenic target of antiphospholipid antibodies, with natural anticoagulant properties. IgG and IgM anti β2GPI are biological markers of the antiphospholipid syndrome (APS) and are strongly associated with thrombosis. The possible relationship between anti-β2GPI (aβ2GPI) antibodies and atherosclerosis is interesting because β2GPI has been found in atherosclerotic lesions. Anti-β2GPI could be implicated in the onset and/or progression of vascular parietal lesions and consequently in the pathogenesis of stroke.

Some authors have described an association between IgA aβ2GPI antibodies and diseases related to atherosclerosis but studies are still few. The aim of the present study is to evaluate a possible association between aβ2GPI of IgG, IgM, IgA isotypes and atherosclerosis in a group of patients with ischemic stroke

Patients & Methods: A total of 41 patients (20 male, 21 females) aged 26–84 years (mean 56 years), with ischemic stroke proved by CT-scan were included in our study. All patients were investigated with Doppler carotid to detect significant atherosclerotic changes (vascular stenosis with luminal reduction ≥50%). The control group consisted of 80 healthy subjects. We evaluated aβ2GPI (IgG, IgM and IgA isotypes) in plasmas of patients and normal controls by an enzyme-linked immunosorbent assay (Orgentec).

Results: Positivity for aβ2GPI antibodies of was seen in 18 cases (44%) of patients and none of the plasmas from the healthy control group ($P < 0.001$). The most frequent isotype was IgA ($n = 14$, 34.1%), followed by IgM ($n = 10$, 24.4%) and IgG ($n = 7$, 17%). Among the 18 patients positive for aβ2GPI, 8 (45%) are positive for only one isotype: IgA in four cases (22%), IgG in three cases (17%), and IgM in one case (6%). All patients with IgM aβ2GPI were negative for rheumatoid factor. The combination of three isotypes was seen in three cases (17%) and two isotypes in seven cases (39%). There was a correlation between IgM and IgA aβ2GPI ($P < 0.001$) but not between IgG and IgA aβ2GPI or IgG and IgM aβ2GPI.

Atherosclerotic plaque was detected in carotid Doppler in 31 patients (75%). Positivity of IgA or IgM aβ2GPI are significantly associated with atherosclerosis ($P < 0.01$ and $P < 0.05$ respectively).

All patients without atherosclerosis are negative for IgA and/or IgM aβ2GPI. Positivity of IgG aβ2GPI is not associated with atherosclerosis.

Discussion: Our results corroborate those of other studies which demonstrate a significant prevalence of aβ2GPI in unselected patients with stroke. Our data showed a strong correlation between IgA and IgM aβ2GPI in this disease. This study suggests that elevated IgM and/or IgA aβ2GPI could be risk factors for atherosclerosis and might contribute to the occurrence of ischemic stroke. IgG aβ2GPI directed against domain I are implicated in the occurrence of thrombosis but not in atherosclerosis. Does IgA and IgM aβ2GPI recognize domain I or others domains of the molecule involved in the protective role against atherosclerosis ?

PB 4.62-6

Antiphospholipid and antinuclear antibodies in schizophrenic patients during antipsychotic treatment: findings from the ANTRE study

Malý R, Masopust J, Andrýs C, Baant J, Krejsková V and Hosák L
University Hospital, Hradec Králové, Czech Republic

Background: Psychiatric disorders themselves and treatment with first or second generation of antipsychotic medications have been associated with increased risk of venous thromboembolism (VTE). Significantly higher levels of antiphospholipid (APA) and antinuclear antibodies (ANA) were repeatedly found in schizophrenic patients. Antiphospholipid antibodies (anticardiolipin antibodies – ACLA, antibody to beta2-glycoprotein I – beta2 GPI and lupus anticoagulat – LA) are among the most important risk factors of venous and arterial thrombosis.

Methods: This case-control prospective ANTRE (ANtipsychotics ThRombosis Embolism) study evaluates a possible association between APA (ACLA, beta2 GPI, LA) and antinuclear antibodies (ANA) and increased risk of thrombosis in patients with psychosis. IgG, IgM beta2 GPI, ACLA antibodies, LA and total ANA were assessed in 46 antipsychotic-naive patient with acute psychosis

(27.7 ± 8.0 years, range 18–52) and compared to 46 healthy controls matched for age and gender. In the patient group, we measured all the above parameters again after 3 months, one and 2 years of antipsychotic treatment.

Results: Prior to the initiation of antipsychotic treatment, there was significant difference in the plasma levels of ANA, ACLA and beta2 GPI IgG between patients and healthy controls. Elevated ANA was significantly higher ($P < 0.05$) than in the controls at the baseline as well during the 2 years of follow up. The plasma levels of beta2 GPI (IgG and IgM) and ACLA IgG increased significantly ($P = 0.047$; $P = 0.013$ resp. $P = 0.007$) in the course of 2-years antipsychotic treatment. Values of ANA did not change during follow- up.

Conclusions: These results point towards the existence of an autoimmune mechanisms in the pathophysiology of schizophrenia. On the other hand the pathological mechanisms of VTE in schizophrenia patients could be possibly explained by the increased titres of APA especially IgG isotype. We suppose an influence of the antipsychotic treatment on the rise in the levels of the APA.

PB 4.63-1

High specificity of Silica clotting time confirm/screen normalized ratio for LA diagnosis

Martinuzzo ME, Barrera HL, D'Adamo MA, Otaso JC, Gimenez IM and Oyhamburu J

Hospital Italiano de Buenos Aires-Grupo Bioquímico, Buenos Aires, Argentina

The new guidelines for the diagnosis of lupus anticoagulant (LA) stressed the importance of avoid false positive results for LA, trying to improve specificity. Reagents for silica clotting time (SCT) has been introduced in our country last year, a test describe as a combined Screen/confirm duet, Silica based, as was recommended to reach the diagnosis of LA. The aim of the present study was to evaluate the specificity of this test for the presence of LA. We included samples from patients referred to our laboratory for LA searching: 250 which tested positive for LA with our standard tests (DRVVT and APTT) and 84 samples which tested LA negative. As control groups we also tested: 25 samples from patients previously LA negative taken coumarin anticoagulants (ACO), 18 samples from cirrhotic patients, six from patients with DIC, 28 from patients with congenital deficiencies (2 Factor V, 2 Factor X, 7 haemophilia A, 5 haemophilia B, 5 Factor XI, 4 Factor XII and 3 patients with vWD), 10 samples from patients receiving LMWH at therapeutic dose, 6 samples from those receiving UFH, 15 Dabigatran etexilate 220 mg/day, and 7 Rivaroxaban 15 mg/day which presented SCT screen prolonged. SCT screen/confirm normalized ratio (NR) was calculated for each sample and results were evaluated using the cut off point (1.19) obtained according the guidelines as the 99th percentile of 60 plasmas from healthy donors. From the 250 LA positive samples SCT was positive in 72% of LA clearly positive ($n = 204$) and 22% of weak LA ($n = 46$). Among samples which tested LA negative ($n = 84$). 7 (8.3%) tested positive for SCT (five of them with NR close to the cut off point). From these six patients presented APTT and/or DRVVT slightly prolonged but not fulfilling mixing or confirmatory results to be considered as positive LA. Considering all control samples ($n = 115$) we observed only three positive SCT NR: one sample from a patient receiving LMWH, one receiving dabigatran and one with ACO. The specificity of the test was really high 97.4%, particularly taking into account we evaluated a wide spectre of samples which presented acquired or congenital abnormalities of blood coagulation.

Conclusion: We showed that SCT expressed as SCT screen/confirm NR with a cut off properly calculated is a very useful tool to improve specificity of LA testing, because it helps to differentiate the p

PB 4.63-2

Erythrocyte and platelet microparticles are associated with thrombotic complications of antiphospholipid syndrome

Wahl G[1], Merhi-Soussi F[2], Zuily S[1], Devignes J[1], Lecompte TP[3] and Latger-Cannard V[1]

[1]CHU de Nancy; [2]Universite de Lorraine, Vandoeuvre, France; [3]Hopitaux Universitaires de Genève, Geneva, Switzerland

Background: Microparticles (MP) derived from endothelial cells, leucocytes and platelets are increased in patients with antiphospholipid antibodies. It is currently unknown whether erythrocyte MP are increased in patients with antiphospholipid antibodies.

Aims: Thus the aim of our study was to quantitate circulating microparticules (MP) from endothelial cells, leucocytes, platelets and erythrocytes to establish their clinical correlation in patients with antiphospholipid antibodies with or without thombosis.

Methods: The patient population consisted of 33 patients with antiphospholipid antibodies, 23 of which had thrombotic antiphospholipid syndrome. Controls were 25 normal healthy subjects. All gave informed consent. In this study, we evaluated the number of MPs present in plasma from endothelial (EMP), platelet (PMP), leucocytes (LMP), and erythrocyte (ErMP) origin in healthy subjects in comparaison with two antiphospholipid patient group, thrombotic (APS patients) and non thrombotic (aPL patients). Data were acquired and analysed using a FACSCalibur flow cytometer with appropriate software (BD Biosciences, CA, USA).

Results: We compared the number EMP, PMP, LMP, and ErMP in two antiphospholipid patient groups, thrombotic (23 APS patients) and non thrombotic (10 aPL patients) both of which were all positive for aPL in comparaison with 25 healthy subjects. Levels of MP of various cellular origins in patients were compared with controls. EMP (pannel A) and LMP (pannel B) were increased in all patients with aPL (APS patients and patients without vascular thrombosis), $P = 0.04$ and $P = 0.0063$ respectively. On the contrary PMP (pannel C) and ErMP (pannel D) were similar to controls in thrombosis-free aPL patients ($P = 0.31$) while they were significantly increased in patients with APS and thrombosis, $P = 0.0063$ and $P = 0.042$ respectively.

Summary/Conclusion: Altogether our data show that circulating LMP and EMP levels are increased in patients with aPL without thrombosis but not PMP and ErMP. Circulating PMP and ErMP are only increased in APS patients. These results suggest that PMP and ErMP contribute to thrombosis in patients with antiphospholipid antibodies.

PB 4.63-3

Antibody titers and clinical outcomes in patients with single-double or triple positivity antiphospholipid antibodies

DeSancho MT, Bamme J, Chapin J, Christos P, Nguyen M and Roshal M

Weill Cornell Medical Center, New York, NY, USA

Background: Antiphospholipid Syndrome (APS) is a clinico-pathologic diagnosis characterized by the presence of thrombosis; pregnancy complications; and persistent (>12 weeks apart) presence of antiphospholipid antibodies (aPLs): anticardiolipin antibodies (aCL), anti-beta 2 GP1 antibodies (anti-b2GPI), and a clot-based dilute Russell viper venom test (DRVVT). Prior studies suggest that having three positive tests (triple positivity) in previously asymptomatic patients leads to higher risk of clinical manifestations. The role of the DRVVT ratio in these groups is uncertain.

Aims: To compare the incidence of clinical manifestations and DRVVT ratios among patients with one or two positive tests and those with triple positivity.

Methods: Retrospective chart review from January 1, 2002 to December 31, 2012 of patients ages 18–95 who were tested for aPLs at New York

Presbyterian Hospital. Demographics, presence of autoimmune diseases and cardiovascular risk factors including coronary artery disease, hypertension, hyperlipidemia, smoking status, and diabetes mellitus was collected. We reviewed the clinical manifestations defined as thrombosis: myocardial infarction (MI), cerebrovascular accident (CVA), pulmonary embolism (PE), deep vein thrombosis (DVT) and pregnancy complications. Titers of aCL and anti-b2GPI IgG and IgM isotypes were considered to be positive if >20 GPL or MPL and >99th percentile respectively. We calculated average antibody titers for aCL and anti-b2GPI in the two groups. We also calculated DRVVT ratios for both groups, as (clot time without phospholipid excess)/(clot time with phospholipid excess). A ratio of 1.2 or greater was considered positive.

Results: We had 55 patients with single or double-positive aPLs, and 23 patients with triple positive aPLs. The two groups were similar in gender (65% vs. 61%), history of autoimmune diseases (16% vs. 13%) and cardiovascular risk factors. There was no statistically significant difference in the incidence of CVAs (14.5% vs. 17.4%), MIs (3.6% vs. 13%), PEs (12.7% vs. 21.7%), DVTs (31% vs. 39%), or other VTE events (3.6% vs. 13.04%). Similarly, we did not identify a difference between pregnancy losses in the first trimester (13.8% vs. 28.6%), second trimester (13.9% vs. 14.3%), or third trimester (0% in both groups). All aPL antibody titer levels were significantly elevated in the triple positive group compared to the single/double positive group. The titers were aCL IgG = 17.6 vs. 95.9, aCL IgM = 20.8 vs. 47.5, anti-b2GPI IgG = 10.7 vs. 73.5, anti-b2GPI IgM = 28.5 vs. 56.7, $P \leq 0.001$ for all four aPLs). The DRVVT ratios were higher in the triple positive group compared to the single and double positive group (1.654 vs. 1.383; $P = 0.01$).

Conclusions: While not statistically significant, there was a trend toward more MI, PE and first trimester pregnancy losses in the triple positivity group compared to the single and double positive aPL. All aPL titers were significantly higher in patients with triple positivity aPL including DRVVT ratios than in patients with single-double positivity. Larger prospective multicenter studies are needed to determine the set of antibodies and the role of DRVVT ratio in predicting clinical outcomes in patients with aPLs.

PB 4.63-4

Circulating endothelial cells are increased in patients with antiphospholipid syndrome

Wahl G[1], Zuily S[1], Heymonet M[1], Massin F[1] and Faure GC[2]
[1]CHU de Nancy; [2]Universite de Lorraine, Vandoeuvre, France

Background: Circulating endothelial cells (CECs) are markers of endothelium damage and have been reported in antiphospholipid syndrome (APS). However it is unknown whether CECs are associated with thrombotic complications *in vivo*.

Aims: To determine whether CECs are increased in patients with antiphospholipid antibodies (aPL) in particular according to their thromboembolic history and underlying disease.

Methods: Clinical and laboratory variables were recorded from a prospective cohort. CECs were assessed by CellSearch®, Veridex; CECs phenotype: CD146+, CD105+, DAPI+, CD45- in patients with aPL and/or SLE. We determined clinical and laboratory variables significantly associated with a high rate of CECs (>20/mL). Informed consent was obtained from each patient.

Results: Forty-six patients were included (mean age 44 ± 15 years, 37 women). Twenty patients had SLE and aPL and 26 only aPL. Forty-two patients had a history of one or several thrombotic/obstetrical manifestations. The presence of a elevated CECs was associated with history of myocardial infarction (29.7 ± 28.1 vs. 10.6 ± 18; OR = 8.75[CI 95%; 1.2–63.9], $P = 0.04$), pulmonary embolism (21.3 ± 22.3 vs. 10.3 ± 18.7; OR = 8[CI 95%; 1.6–40.3], $P = 0.01$).

Summary/Conclusions: In patients with aPL, history of pulmonary embolism and myocardial infarction are significantly associated with endothelial perturbation evaluated by the number of CECs.

PB 4.63-5

Prevalence of antiphospholipid antibodies in psychiatric patients users and non-users of antipsychotics

Delluc A[1], Rousseau A[2], Le Galudec M[3], Canceil O[4], Woodhams B[2], Etienne S[4], Walter M[3], Mottier D[5], Van Dreden P[2] and Lacut K[5]
[1]EA 3878 GETBO, Brest; [2]Diagnostica Stago, Gennevilliers; [3]Université de Bretagne Occidentale, Brest; [4]Université Paris Descartes, Paris; [5]Inserm, CIC 0502, Brest, France

Background: Past reports have suggested that antiphospholipid (aPL) antibodies may emerge as a response to antipsychotics treatment, since a high prevalence of aPL antibodies in antipsychotics users has been observed. However, no control group of non-medicated psychiatric patients was included in these reports.

Aims: We aimed to determine the prevalence of aPL antibodies in psychiatric inpatients users and non-users of antipsychotics in order to assess a potential association between aPL antibodies and antipsychotics

Methods: In a cross sectional study we determined the prevalence of aPL antibodies in 333 psychiatric inpatients. We compared the proportions of positive aPL antibodies tests between users and non-users of antipsychotics with adjustments for potential confounders (age and psychiatric diagnosis). To detect the presence of lupus anticoagulant (LA) in the plasma, two coagulation tests were performed: dilute Russell viper venom time (STA-Staclot dRVV Screen/Confirm, Diagnostica Stago), and LA sensitive partial thromboplastin time (PTT-LA Diagnostica Stago). IgG and IgM antiβ2GP-1 were detected by ELISA with Asserachrom anti β2GP1, and anticardiolipin antibodies IgG and IgM were detected by ELISA with Asserachrom APA (all from Diagnostica Stago)

The protocol was approved by our hospital's Ethics Committee. After complete description of the study to the subjects, written informed consent was obtained from all patients, their relatives, or their guardian before inclusion.

Results: Patients' mean age was 57.3 ± 18.1 years (range 19–93 years), 153 (45.9%) were male. Of these 333 patients, 59 (17.7%) were diagnosed as having organic mental disorder (ICD-10 codes F0), 86 patients (25.8%) had schizophrenia (ICD-10 codes F2 and F8), 110 (33.0%) had mood disorder (ICD-10 codes F3), and 78 patients (23.4%) had another psychiatric diagnosis (ICD-10 codes F1 + F4 + F5 + F6 + F7). At admission, 185 patients (55.6%) were receiving at least one antipsychotic medication. The proportion of antipsychotics users carrying at least one aPL antibody was 27.0% (50/185) compared with 27.2% (40/148) in non-users ($P = 0.24$). The prevalence of each subgroup of aPL antibodies (LA, IgM and IgG anti-β2GP-I antibodies, IgM and IgG anti-cardiolipin antibodies) was not different between users and non users of antipsychotics (22.2% vs. 23.6%, $P = 0.62$, 3.8% vs. 2.0%, $P = 0.75$, 0.0% vs. 0.0%, P = NA, 1.1 vs. 1.4%, $P = 0.91$, 2.7% vs. 3.4%, $P = 0.71$ respectively with adjustments for age and psychiatric diagnosis). In each subgroup of psychiatric disorders, the proportion of patients with aPL antibodies was not different between users and non-users of antipsychotics except in patients with mood affective disorder. In this category, 14.9% of the 47 antipsychotics users and 33.3% of the 63 non-users had a positive test for at least one aPL antibody ($P = 0.04$). This difference was due to the presence of LA, which was detected in 10.6% of antipsychotics users and 30.2% of non-users ($P = 0.03$).

Conclusions: aPL antibodies were frequently found in patients with psychiatric diseases and no significant increase in the prevalence of aPL antibodies was observed in antipsychotics users. Long term prospective epidemiologic cohort studies are needed to establish the possible pathogenic implications of persistent aPL antibodies in psychiatric patients.

PB 4.63-6

Hypoprothrombinaemic Lupus Anticoagulant Syndrome masquerading as Acquired Haemophilia in a 5-year-old child

Sivaprakasam P[1], Tunstall O[2], Reilly-Stitt C[3], Marshall J[4] and Hamilton M[5]

[1]Bristol Royal Hospital for Children, Bristol; [2]Consultant Haematologist, Bristol Royal Hospital for Children, Bristol; [3]Bristol Royal Infirmary, Bristol; [4]Royal Devon and Exeter Hospital, Exeter; [5]Consultant Haematologist, Devon, UK

Background: Hypoprothrombinaemic lupus anticoagulant syndrome (HLAS) is a rare phenomenon caused by acquired hypoprothrombinaemia in the presence of lupus antibodies (LA). They pose both bleeding and thrombotic risk. It can be associated with systemic lupus erythematosus or rarely in children due to infections, medications or other causes producing antibodies

Aim: We describe a previously healthy child who presented with bleeding symptoms, later diagnosed with HLAS and responded to appropriate therapy

Methods: We describe a previously healthy 5-year-old child who presented to her local hospital with the new onset of bruising and ecchymoses, 2 days after a viral illness. Initial investigations revealed a prolonged prothrombin time (PT) (INR 2.3) and activated partial thromboplastin time (APTT) (APTTr 3.0). Factor assays using a reagent with intermediate lupus sensitivity showed a Factor VIIIC of 6%, Factor IX of <1% and Factor XI of 4% with otherwise normal levels. LA screen was positive. She was given a tentative diagnosis of Acquired Haemophilia and transferred to our hospital for further investigation and management.

Results: Initial investigations showed normal full blood count including platelet count (280 × 10*9/L) but prolonged PT (17.3 s) and APTT (61 s). A 50/50 mix study gave an APTT of 37.2 s and PT 12.8 s. Fibrinogen and D-dimer were normal. LA screen was positive, however autoimmune screen was negative. Factor analysis revealed Factor II 8.3%; Factor V 140%; Factor VII 79%; Factor X 84%. APTT dependent factor levels using an agent with low lupus sensitivity, Actin FS, were normal or near-normal but with markedly non-parallel curves.

She was diagnosed with post-viral Hypoprothrombinaemic Lupus Anticoagulant Syndrome. Short-course corticosteroid therapy was initiated; there was no recurrence of the bleeding and she showed consistent improvement in Factor II -levels 1 week and 6 weeks post therapy: 38.8% and 91% respectively. LA screen remained positive.

Summary: Hypoprothrombinaemic Lupus Anticoagulant Syndrome is a rare but previously reported condition in childhood. In this case, the presentation was with large bruises and ecchymoses and apparently low FVIIIC and FIX levels giving the apparent clinical syndrome of acquired haemophilia. It was only with repeat testing using reagents less sensitive to lupus anticoagulants that the diagnosis became clear and even then assays were difficult to interpret due to marked inhibition.

PB4.64 – Arterial Vascular Disorders – V

PB 4.64-1

Increased fibrinogen rises thrombin generation and fibrin clot formation in obese Zucker rats

Regnault V[1], Lagrange J[1], Louis H[1], Max JP[1], Thornton SN[1], Wahl D[1], Feve B[2], Benetos A[1] and Lacolley P[1]

[1]Inserm U1116, Vandoeuvre-les-Nancy; [2]Inserm U938, Paris, France

Background: The metabolic syndrome (MetS), a cluster of risk factor including abdominal fat, hypertension, dyslipidemia and disturbed glucose and insulin metabolism is associated with modifications in the arterial wall such as endothelial dysfunction and atherothrombosis. Enhanced platelet reactivity and coagulation and decreased fibrinolysis have been proposed as potential mechanisms but the determinants linking MetS and hemostasis remains unknown in particular in age-dependent arterial wall stiffening.

Aims: The main objective was to determine the triggering mechanisms and the substratum of the prothrombotic state in MetS.

Methods: We have characterized the hemostasis phenotype of lean and obese Zucker rats, aged 25 (adult) and 80 weeks (very old). Platelet reactivity was assessed by aggregation studies with platelet-rich plasma (PRP) and washed platelets and by using ADP and collagen as agonists. Thrombin generation was monitored in PRP and platelet-poor plasma (PPP) using calibrated automated thrombography (CAT). The *in vitro* reactivity of the coagulation system was estimated by the endogenous thrombin potential (ETP). Fibrinolysis was measured by a classical clot lysis assay in which thrombomodulin was added.

Results: Prothrombin fragment F1 + 2 and thrombin/antithrombin (TAT) complexes were increased in obese rats at 25 weeks of age. Platelet count was increased in obese rats at both ages (789 ± 34 vs. 574 ± 37 10^9/L at 25 week-old and 834 ± 63 vs. 633 ± 29 10^9/L at 80 week-old rats) without change in platelet response to ADP or collagen. ETP in PPP was higher in 25 week-old obese rats than in lean rats of the same age (428 ± 29 vs. 328 ± 27 nM/min) and still higher at 80 weeks compared with age-matched group (422 ± 30 vs. 306 ± 11 nM/min). Similar differences were observed wit PRP. Plasma prothrombin and tissue factor levels were increased in obese rats whatever the age whereas antithrombin was unchanged. The most striking result in obese rats was the increase in ETP without increase in thrombin peak but with a delay in thrombin inhibition. Fibrinogen was increased in obese rats (4.0 ± 0.2 vs. 2.8 ± 0.1 g/L at 25 week-old and 4.9 ± 0.2 vs. 3.1 ± 0.1 g/L at 80 week-old rats). Addition of purified fibrinogen in lean rats resulted in an increase in ETP and delayed thrombin inhibition. Half-lysis time was prolonged in obese rats at 25 weeks (46.5 ± 1.2 vs. 41.5 ± 0.7 min) and increased with age (54.1 ± 1.1 vs. 49.3 ± 1.8 min in 80 week-old obese and lean rats respectively). A cytokine array showed an increase in pro-inflammatory cytokines in obsess rats whatever the age.

Summary/Conclusion: To conclude, we have shown that thrombin generation increased in obese adult and very old Zucker rats without change in platelet activation. Increased inflammation and related fibrinogen level and subsequent decreased fibrinolysis may account for this hypercoagulable state in obese rats.

PB 4.64-2

Impact of venous thromboembolism on future risk of atrial fibrillation – the Tromsø study

Enga KF, Mathiesen EH, Løchen ML, Mathiesen EB, Njølstad I, Wilsgaard T, Braekkan SK and Hansen JB

University of Tromsø, Tromsø, Norway

Background: It has been widely accepted that pulmonary embolism may precipitate cardiac dysrhythmias although the degree of evidence is low. Pulmonary embolism may increase the right atrium pressure with subsequent atrial dilatation, eliciting stretch injuries that can in turn trigger atrial fibrillation (AF). Venous thromboembolism (VTE) is a common term for deep vein thrombosis and pulmonary embolism, since clinically silent pulmonary embolism often occur in the presence of a deep vein thrombosis. To our knowledge, the association between venous thromboembolism, including pulmonary embolism and deep vein thrombosis, and subsequent atrial fibrillation has not yet been explored in a prospective cohort study.

Aims: We wanted to investigate the impact of incident venous thromboembolism on future risk of atrial fibrillation in a prospective cohort study recruited from the general population.

Methods: The study included 29 774 subjects who attended at least one survey of the Tromsø study (1994–95, 2001–02, 2007–08). Baseline

information was obtained by questionnaires, blood samples and a physical examination. Incident events of VTE and AF were registered and validated from date of study inclusion to the end of follow-up, December 31, 2010. Cox proportional hazard regression using age as time-scale and VTE as a time-dependent variable was performed to estimate crude and multivariable hazard ratios (HR) with 95% confidence intervals (CI). Sex, body mass index, smoking, physical activity, total cholesterol, self-reported cardiovascular disease and diabetes were potential confounders included in the multivariable analyses. The study was approved by the regional committee for research ethics, and all participants gave their informed written consent to participate.

Results: Of the study participants, 540 (1.8%) had an incident VTE event, of which 50 (9.3%, age-adjusted incidence rate (IR) of atrial fibrillation per 1000 person-years: 17.76, 95% CI: 13.44–23.47) suffered from subsequent atrial fibrillation during a median follow-up of 15.6 years. There were 1619 subjects that had an atrial fibrillation without a prior VTE event during follow-up (5.8%, age-adjusted IR: 12.65, 95% CI: 12.05–13.29). Subjects with VTE had 64% higher risk of AF compared to subjects without VTE (multivariable adjusted HR: 1.64, 95% CI: 1.23–2.19). The risk estimates for atrial fibrillation were higher after pulmonary embolism (HR: 1.84, 95% CI: 1.17–2.90) than after deep vein thrombosis (HR: 1.50, 95% CI: 1.04–2.17). The incidence of atrial fibrillation was highest during the first 6 months after the VTE event (IR: 24.38, 95% CI: 12.31–48.26).

Conclusion: We found that incident venous thromboembolism was associated with future risk of atrial fibrillation. Our findings support the concept that overt and silent pulmonary embolism may lead to cardiac dysfunctions that, in turn, can trigger atrial fibrillation.

PB 4.64-3

Different role of hypercoagulability in myocardial infarction and ischemic stroke: a systematic review

Maino A[1], Siegerink B[2], Algra A[3], Peyvandi F[4] and Rosendaal FR[2]

[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milano, Italy; [2]LUMC, Leiden, The Netherlands; [3]UMCU, Utrecht; [4]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center University of Milan, Milano, Italy

Background: Hypercoagulability increases the risk of arterial thrombosis. However, there is emerging evidence that this effect may differ between various manifestations of arterial disease.

Aims: To compare the effect of coagulation factors as measures of hypercoagulability on the risk of ischemic stroke (IS) and myocardial infarction (MI).

Methods: We performed a systematic review of the literature searching for papers reporting on prothrombotic measures as risk factors for IS and MI. The effect of a risk factor on IS (relative risk for IS, RR_{IS}) was compared with the effect on MI (relative risk MI, RR_{MI}) by calculating their ratio ($RRR = RR_{IS}/RR_{MI}$) with corresponding 95% confidence interval (CI). To increase the validity of our analysis, we only included studies that reported risks for both MI and IS. When a risk factor has a similar effect (either increasing, decreasing or no effect) on MI and IS, the RRR equals 1, whereas a RRR >1 indicates a greater effect on IS risk than on MI, and vice versa. Prespecified subgroups were based on age, sex, stroke aetiology, study type and population baseline risk.

Results: We selected 70 papers, describing results from 32 study cohorts, accounting for 351 markers of hypercoagulability. 205 of these markers involved pro-coagulant factors, 46 anti-coagulant factors, 63 markers of fibrinolysis and 37 markers of platelet function and other pathways. 135 out of 351 markers (38%) had an RRR between 0.9 and 1.1, thus likely affecting the risk of IS and MI equally. In contrast, 136 out of 351 (39%) had an RRR >1.1, indicating a larger effect on IS risk than MI risk. Of these, 45/136 (33%) had an RRR >1.5 and 20/136 (15%) >2. The RRR of 80/351 (23%) markers of hypercoagulability was <0.9. Pro-coagulant factors contributed for the greatest part of the difference between RRRs (RRR >1.1, RRR <0.9: pro-coagulant 84/205 [41%], 44/205 [21%]; anti-coagulant 11/46 [24%], 10/46 [22%]; fibrinolysis 21/63 [33%], 15/63 [24%]; others 20/37 [54%], 11/37 [30%]). Within pro-coagulant factors the largest RRRs were observed for F5 Leiden mutation (RRR 3.42, 95% CI 0.11–104), a variant of FVIII (F8 rs6655259, RRR 4.72, 95% CI 0.62–35.73), presence of lupus anticoagulant (RRR 8.13, 95% CI 0.61–108.76) and three variants of FXIII (F13A1 V34L, RRR 4.66, 95% CI 0.44–49.10; F13A1 T204P, RRR 11.1, 95% CI 5.64–21.82 and F13A1 rs3024462, RRR 3.71, 95% CI 0.62–22.35). A substantial part of the studies (15 studies, 216 factors) combined haemorrhagic and ischaemic stroke as a single outcome. When restricted to those that excluded haemorrhagic stroke, 71 out of 135 markers (53%) had a RRR >1.1 (RRR >1.5: 33/84 [39%] and RRR >2: 16/84 [19%]). Larger RRRs were also found in young study populations (RRR >1.1: 27/44 (61%); RRR >1.5: 21/29 (72%) and RRR >2: 14/29 (48%); five studies).

Conclusions: These results suggest that the effect of various markers of hypercoagulability on the risk of IS is larger than that on MI, particularly in the young.

PB 4.64-4

A novel and selective proteasome inhibitor modulate expression of molecules linked to coagulation and angiogenesis independent of NF-kB activation in tumor cells

Chudzinski-Tavassi AM, Pacheco MTF, Berra CM, Moraes KLP, Sciani J, Bosch RV and Onuki J

Biochemistry and Biophysics Laboratory, São Paulo, Brazil

Amblyomin-X is a Kunitz-like recombinant protein which has shown inhibitory properties on factor Xa and tenase complex and also inhibits proteasome in human tumor cell lines but not in normal human fibroblasts. Proteasome inhibition generates aggresomes transported by dynein in which K48 and K63-linkage of ubiquitin signaling is involved. This signaling is also important to NF-κB pathway and studies have been reported that recruitment of dynein translocate p65/p50 heterodimer to act as an activator of a large number of genes like tissue factor (TF), TFPI and VEGF. The p50 subunit is generated by its precursor molecule p105 that is processed by the proteasome. TFPI not only inhibits thrombin generation by inhibiting FXa which then inactivates TF/FVIIa complex but also can act as adhesive ligand for cancer cells to extracellular matrices. Additionally, TF can enhance tumor metastasis and VEGF contributes to angiogenesis. The present study intends to evaluate the pathway that links coagulation and cancer in the antitumoral mechanism of action of Amblyomin-X. Cell culture: Normal human fibroblasts, Mia-PaCa-2 and SK-Mel-28 tumor cell lines. Real-Time PCR: SYBR® green based reaction. Aggresome formation: Commercial kit for flow cytometry and fluorescence microscopy. Ubiquitin signaling: Flow cytometry with specific K63 and K48 antibodies. Western blotting: Cell lysis and immunoblotting after SDS-PAGE with specific antibodies. NF-κB, dynein, Ubc13, VEGF and TF gene expression were upregulated in Mia-PaCa-2 after 24 h of Amblyomin-X treatment. Only NF-κB, Ubc13 and dynein genes were upregulated in SK-Mel-28. Fibroblasts have normalized the expression levels of the targets analyzed in 24 h. Protein expression ofsome targets has been modified in tumor cells while only p50 has been modulated in fibroblasts. Amblyomin-X induced aggresome formation only in tumor cells. The K63 linkage signal was increased in all cell lines and corroborates with Ubc13 upregulation while K48 linkage has decreased only in tumor cells. Amblyomin-X inhibits proteasome and induces aggresome formation only in tumor cells. The molecule seems to trigger NF-κB signaling as a cell response in fibroblasts but do not target proteasome and cell death. Our data indicates that NF-κB, although high expressed, can be inactive to transcript its targets like TFPI, TF and VEGF, since proteasome inhibition can prevent

degradation of IKB, a natural inhibitor of NFkB, which in turns, could remain sequestered and inactive. Moreover, protein expression of p50 subunit has also decreased in tumor cells and its precursor p105 has increased indicating thatproteasome inhibition had affected its proteolysis. Additionally, K63 signaling for aggresome formation and decreased K48 signaling as a cell response, contributes to inactivate NF-κB pathway. Therefore, increased mRNA levels of TF and VEGF in Mia-PaCa-2 indicates that these targets may have its gene expression activated by another pathway independent of NFκB activation, as a tumor response to Amblyomin-X treatment. Aggresome formation and increased TFPI expression may contribute respectively to cell apoptosis and metastasis reduction, effects already observed *in vivo* in previous data, in the mechanism of action of Amblyomin-X.

PB 4.64-5

Correlation between factor VII-activating protease and metabolic control in children and adolescents with Type 1 diabetes

Grangl G, Leschnik B, Pansy J, Schaffer E, Fröhlich-Reiterer E, Borkenstein M, Muntean W and Gallistl S

Medical University Graz, Graz, Austria

Background: Factor VII-activating protease (FSAP) is a circulating serine protease for which a potential role in the regulation of hemostasis and vascular remodeling processes is postulated. Higher levels and activity of FSAP have been reported in patients with deep vein thrombosis, ischemic stroke, or acute coronary syndrome.
Diabetic micro- and macroangiopathy, major complications of diabetes mellitus type I, are associated with endothelial cell alterations and hypercoagulability caused by formation of advanced glycosylation end products due to hyperglycemia. The central role of HbA1c levels for the prediction of micro- and macrovascular complications in patients with type 1 diabetes is generally accepted.
Aims: The aim of this study was to investigate a possible relation between plasma concentrations of FSAP and HbA1c levels in patients with type 1 diabetes mellitus (T1DM).
Methods: Microalbuminuria, levels of FSAP und HbA1c were investigated in 37 patients with type 1 diabetes. FSAP was also determined in healthy age matched controls.
Results: Median age of patients was 13.6 years (3.3–20.7); median duration of diabetes was 6.5 years (0.8–15.7), median microalbuminuria was 4.69 mcg/min (0.1–45.4), median HbA1c was 8.4% (5.6–11.5). FSAP levels were significantly higher in patients with T1DM, 18.3 mcg/mL (11.2–21.4), than in healthy controls, 15.8 mcg/mL (12.6–21.6), $P < 0.01$. In addition, we found a significant correlation between HbA1c and FSAP ($r = 0.42$, $P < 0.05$). This correlation stayed significant after adjustment for age and duration of diabetes. There was no correlation between microalbuminuria und levels of FSAP.
Summary: FSAP levels were significantly elevated even in children and adolescents with type 1 diabetes compared with healthy controls and correlated significantly with HbA1c levels. Our study strengthens the importance of metabolic control in the development of vascular alteration in patients with type 1 diabetes.

PB 4.64-6

Coronary microvascular dysfunction due to essential thrombocythemia and policythemia vera: the missing piece of the puzzle of their increased cardiovascular risk?

Cella G[1], Famoso G[2], Tona F[2], Ballin A[2], Osto E[2], Omenetto E[2] and Vianello F[2]

[1]University of Padua; [2]Cardiovascular Medicine, Padua, Italy

Background and Aim: Essential thrombocythemia (ET) and Polycythemia vera (PV) increase the risk for cardiovascular events. We evaluated coronary flow reserve (CFR) by transthoracic Doppler echocardiography (TDE), as an index of coronary microvascular function, in ET and PV.
Patients and Methods: 49 ET and 17 PV patients (pts) (38 Fand5 F, aged 61 ± 16 and 58 ± 13 years respectively) without clinical evidence of heart disease, and 50 controls matched for age and gender were studied. Coronary flow velocity in the left anterior descending coronary artery was detected by TDE at rest and during adenosine infusion. CFR was the ratio of hyperaemic diastolic flow velocity (DFV) to resting DFV. A CFR ≤2.5 was considered abnormal. The median time from ET and PV diagnosis was 7 years (range 0–24) and 4 years (range 0–10) respectively. Patients with a reduced CFR underwent a computed tomographic coronary angiography.
Results: In ET and PV pts, CFR was lower than in controls (2.9 ± 1.0 and 2.3 ± 0.8 vs. 3.4 ± 0.7, $P < 0.005$ and $P < 0.0001$ respectively). CFR was ≤2.5 in 15 (31%) ET pts and 12 (71%) ET pts compared with controls (4%). At multivariable linear regression analysis adjusted for diagnosis (control, ET and PV respectively), age, gender and cardiovascular risk factors, diagnosis and age were the only determinants of CFR (diagnosis $\beta = -0.424$, $P < 0.0001$; age $\beta = -0.347$, $P = 0.004$ respectively). Patients with reduced CFR, undergone to coronary angiography failed to show any haemodynamic significant stenosis both of the left main coronary artery and of the left anterior descending coronary artery.
Conclusions: In ET and PV patients CFR is lower than in controls, this is due to a coronary microvascular dysfunction rather than to a coronary stenosis. Further studies on a wider population is needed to establish the links between coronary microvascular dysfunction and these myeloproliferative diseases.

PB4.65 – Hormones, pregnancy, women's issues – IV

PB 4.65-1

Impact on the initial pregnancy loss subtype on pregnancy outcomes in the conventionally treated purely obstetric antiphospholipid syndrome

Gris J-C, Bouvier S, Cochery-Nouvellon E, Lissalde-Lavigne G, Mercier E, Balducchi J-P, Mousty E and Marès P

University Hospital, Nîmes, France

Background: In the purely obstetric form of antiphospholipid syndrome (APS) treated according to guidelines, the impact of the initial clinical heterogeneity on the subsequent pregnancy outcomes is uncertain.
Aims: We aimed to design a prospective study in women with a purely obstetric APS.
Methods: We performed a 10-year observational study of 1592 non-thrombotic women who had experienced three consecutive spontaneous abortions before the 10th week of gestation or one foetal death at or beyond the 10th week of gestation (*NOH-APS*, *Blood 2012;119 (11):2624–32*). A total of 517 women finally fulfilled the APS diagnosis criteria, leading to treat the subsequent pregnancy attempt using prophylactic low molecular weight heparin LMWH plus low dose aspirin LDA. We report the relevant risk factors for pregnancy out-

comes, with special emphasis on the initial clinical presentation (spontaneous abortions: $n = 206$ vs. foetal death: $n = 311$). The relevance of other pregnancy loss subtypes (primary vs. secondary), of the presence/absence of an associated systemic illness, of anthropometric characteristics (age >35 years, BMI >30 kg/m^2 or <18.5 kg/m^2, varicose veins), of metabolic characteristics (diabetes mellitus, hypercholesterolemia, hypertriglyceridemia), of life habits (smoking, oral contraceptives) and of haemostatic parameters (positive lupus anticoagulant LA, positive anticardiolipin IgG antibodies aCL-G and IgM antibodies aCL-M, positive anti-beta2-glycoprotein 1 IgG antibodies aB2Gp1-G and IgM antibodies aB2Gp1-M; positive *F5* 6025 or *F2* rs1799963 polymorphisms) was systematically evaluated by multiparametric logistic regressionanalysis.

Results: aB2Gp1-M was finally the single risk factor for spontaneous abortions ($P = 0.013$) whereas initial foetal loss was the single significant risk factor for subsequent foetal loss ($P = 0.014$).

Initial foetal loss ($P = 0.005$) and BMI >30 kg/m^2 ($P = 0.037$) were two independent risk factors for a subsequent pre-eclampsia (PE). None of the studied characteristics was a significant risk factor for PE before 34 weeks of gestation (WG).

Initial foetal loss was the single significant risk factor for a premature birth before 37 WG ($P = 0.0001$) and before 34 WG ($P = 0.0035$).

None of the clinical characteristics/biological markers was a significant risk factor for the birth of a small-for-gestational age neonate (SGA, customised percentile th WG to the 27th day after delivery).

The ischemic placenta diseases (IPD) being defined as a composite endpoint associating PE, placental abruption and SGA neonates, initial foetal loss ($P = 0.049$), aCL-M ($P = 0.025$) and varicose veins ($P = 0.028$) were independent risk factors for IPD.

An initial foetal loss was the single significant risk factor when the IPD definition was extended to stillbirth cases.

Summary/Conclusions: In women with the purely obstetric APS, the initial clinical presentation impacts on the risk of poor outcomes during the first pregnancy attempt conventionally treated.

Initial foetal loss indicates a higher risk of subsequent foetal loss, pre-eclampsia, premature birth, or ischemic placenta diseases than initial recurrent spontaneous abortions, despite treatment.

This fact may indicate insufficient treatment doses and principles in case of initial foetal loss, or the presence of unknown cofactors in APS patients with initial foetal loss. The analysis of the mechanisms of foetal loss is still needed, even in APS women.

PB 4.65-2

Severe preeclampsia: evaluation of D-dimer, PAI-1 and inflammatory cytokine

Pinheiro MB[1], Carvalho M[2], Martins-Filho OA[3], Mota A[2], Godoi LC[2], Alpoim PN[2], Teixeira-Carvalho A[3], Borges KB[2] and Dusse LMS[2]

[1]Universidade Federal de São João Del Rei, Dvinópolis; [2]Universidade Federal de Minas Gerais, Belo Horizonte; [3]Centro de Pesquisas René Rachou-Fundação Osvaldo Cruz, Belo Horizonte, Brazil

Background: Preeclampsia (PE) is a multi-system disorder of pregnancy characterized by hypertension and proteinuria. A predisposition to endothelial dysfunction, which may trigger abnormal activation of the hemostatic and/or inflammatory systems, is thought to play a crucial part in pathogenesis of PE.

Aims: The aim of this study was to investigate the relationship between hemostatic and inflammatory parameters in women with severe PE.

Methods: D-Dimer, PAI-1 (American Diagnostica®), IL-8, IL-6, TNF-α (Human Inflammation kit Cytometric Beads Array (CBA) – BD Biosciences Pharmingen, USA) and IFN-γ (Human Th1/Th2 CBA – BD Biosciences Pharmingen, USA) levels were measured in severe PE ($N = 59$), normotensive pregnant ($N = 49$) and non-pregnant women ($N = 48$).

Results: D-Dimer and PAI-1 were significantly higher in severe PE vs. normotensive pregnant ($P < 0.001$ for both) and non-pregnant women ($P < 0.001$ for both). IFN-γ was higher in severe PE vs. normotensive pregnant ($P = 0.018$) and non-pregnant women ($P < 0.001$) and in normotensive pregnant vs. and non-pregnant women ($P = 0.024$). IL-6 was significantly higher in severe PE vs. non-pregnant women ($P < 0.001$) and in normotensive pregnant vs. non-pregnant women ($P < 0.001$). TNF-α did not differ among groups. D-Dimer and PAI-1 showed an elevated area under ROC curve (0.938 and 0.873). A weak correlation between D-Dimer vs. IL-8 ($r = 0.597$, $P < 0.001$) and PAI-1 vs. IFN-γ ($r = 0.397$, $P = 0.045$) were found in sPE.

Conclusion: D-Dimer and PAI-1 levels showed to be important tools for discriminating severe PE. However, no important correlation between these haemostatic markers and cytokines levels was found. More studies are necessary to improve the knowledge of hemostasis and inflammation in severe PE.

PB 4.65-3

A safe and effective regimen for managing women at intermediate and high risk of pregnancy-related venous thrombosis

Durian M, Roeters van Lennep JE, Duvekot J, Leebeek FWG and Kruip JHA

Erasmus University Medical Center, Rotterdam, The Netherlands

Background: The optimal approach for venous thromboembolism (VTE) prophylaxis during pregnancy and postpartum in women at increased risk of VTE is still not established despite recent efforts to resolve this matter.

Aims: To evaluate the safety (incidence of postpartum hemorrhage [PPH]) and efficacy (incidence of pregnancy-related VTE) of a protocol recommending thromboprophylaxis with 5700 IU anti-Xa nadroparin once daily (or an equivalent dose dalteparin 5000 IU once daily) in pregnancies at intermediate and high risk of VTE.

Methods: This is a single center study performed at the Erasmus University Medical Center in women at intermediate or high risk of pregnancy-related VTE. They received low-molecular-weight heparin (LMWH) according to our protocol only postpartum (intermediate risk of VTE) or during pregnancy and 6 weeks postpartum (high risk of VTE). Pregnancy-related VTE was defined as VTE during pregnancy or within 3 months postpartum. Postpartum haemorrhage (PPH) was defined as blood loss >500 mL and severe PPH as blood loss >1000 mL. The study was not subject to the Medical Research Involving Human Subjects Act and was approved by the Medical Ethics Committee.

Results: One hundred and nineteen pregnancies in 93 women were considered at risk of trombosis of which 57 pregnancies had an intermediate risk and 62 pregnancies had a high risk of VTE. In our cohort, no VTE was observed in women using LMWH prophylaxis. No women were lost to follow-up. The occurrence of PPH was 21.7% (95% CI, 15.2–30.1%) and severe PPH 8.7% (95% CI, 4.8–15.3%). There was no significant difference in PPH between intermediate and high risk pregnancies. Estimated blood loss during delivery was comparable to previous Dutch studies.

Summary/Conclusion: VTE prophylaxis with the current dose of LMWH prophylaxis in pregnant women at an intermediate or high risk of pregnancy-related VTE proved to be safe, since we did not observe an increase in PPH. In our cohort of women the dose of LMWH was effective in preventing pregnancy-related VTE. A randomized trial comparing the current dose LMWH with lower-dose LMWH in pregnant women at intermediate and high risk of VTE is urgently needed.

PB 4.65-4

No increased fibrinolysis in women with menorrhagia

Wiewel-Verschueren S, Knol MH, Lisman T, Bogchelman DH, Kluin-Nelemans HC, Van Der Zee AGJ, Mulder AB and Meijer K
UMCG, Groningen, The Netherlands

Background: Menorrhagia is a common problem. At least 5–10% of women in reproductive age seek medical attention for menorrhagia. Bleeding disorders have been recognized as important etiologic and/or contributing factors in some women with menorrhagia. Increased fibrinolysis might also lead to menorrhagia.
Aim: To investigate fibrinolytic parameters, including clot lysis time (CLT) in women with menorrhagia.
Methods: The study was approved by the Institutional Review Board of the University Medical Center of Groningen. Informed consent was obtained from all patients and controls. We included 102 patients referred for menorrhagia (PBAC-score >100). Patients and controls (28 healthy volunteers without menorrhagia) had haemostatic testing in the 1st week after menstruation. For 79 patients and all controls fibrinolytic parameters (FXI, TAFI-act, PAI, t-PA, PI) and CLT were available. TAFI, PAI and PI act as inhibitors of fibrinolysis, CLT measures overall fibrinolytic potential.
Results: Median age was 46 years (range 23–59) in patients and 40 years (range 27–57) in controls ($P = 0.02$). In 33% ($n = 26$) of the patients a gynecological abnormality was found. Fibrinolytic parameters were comparable in patients and controls, except for TAFI (91% vs. 83.9% $P = 0.02$) and PI (104.8% vs. 96.9% $P < 0.01$), which were significantly higher in patients. CLT tended to be longer in patients than in controls (72.0 min vs. 67.1 min; $P = 0.21$). Patients had lower FXI levels than controls (mean: 100% vs. 124%; $P < 0.01$), although within the reference range. Patients with FXI levels <100% had significantly shorter CLT, lower TAFI, PAI and PI levels than patients with levels >100%. In patients, shorter CLT correlated with lower TAFI and PAI. In controls we observed only a correlation with PAI.
In women with menorrhagia without gynecological abnormalities we found significantly lower TAFI and PAI levels compared to women with gynecological abnormalities (TAFI: 88% vs. 96%, $P = 0.03$; PAI: 16.0 μg/L vs. 25.6 μg/L, $P = 0.03$).
Conclusion: Fibrinolytic capacity is not increased in women with menorrhagia. Overall, the fibrinolytic inhibitors TAFI and PI were even higher in patients than in controls. However, inhibitors of fibrinolysis are lower in subgroups of women with lower FXI and in women with unexplained menorrhagia. The clinical relevance is not clear yet.

PB 4.65-5

Is rotation thrombelastometry a useful method for monitoring of hemostasis in normal pregnancy and puerperium?

Stasko J[1], Duraj L[1], Hasko M[1], Lisa L[1], Sokol J[1], Simonova R[1], Biringer K[2], Danko J[1] and Kubisz P[1]
[1]*Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia*

Aims: Aim of the study was to analyse the changes of hemostasis in normal pregnancy and puerperium by rotation thrombelastometry (ROTEM) and compare these results with those in healthy non-pregnant women.
Methods: Prospective observational study was approved by the etics committee of Jessenius Faculty of Medicine. All study subjects gave their informed consent to participate in the study. Fifty normal pregnant women, mean age 30.6 [19–44] years, were enrolled into study and tested by ROTEM (INTEM and EXTEM) repeatedly during pregnancy and puerperium (T1: 11–12th week, T2: 17–18th week, T3: 25–26th week, T4: 35–36th week and T5: 6–7th week after delivery). Blood count and hemocoagulation tests were studied at the same time as well. In the control group there were 54 healthy women (blood donors), age 30.5 [18–45] years, examined by the same investigations. Statistical analysis was performed by SPSS 16.0 (Chicago, IL, USA).
Results: At almost all time during pregnancy there was the significant reduction of clotting time (CT), more pronouced in EXTEM compared to INTEM. In EXTEM test the significance of CT reduction was as followed: CTT2:CTT1 ($P < 0.005$), CTT3:CTT1 ($P < 0.00001$), CTT4:CTT1 ($P < 0.00001$), CTT5:CTT1 ($P < 0.0001$). In EXTEM test there was also the significant CT reduction of CTT3 ($P < 0.00001$), CTT4 ($P < 0.00001$) and CTT5 ($P < 0.0001$) compared to healthy non-pregnant controls. The maximum clot firmness (MCF) was very significantly increased in both EXTEM and INTEM tests compared to healthy non-pregnant controls (MCFT1-MCFT4 $P < 0.00001$; MCFT5 $P < 0.005$). In EXTEM test the MCF showed the significant increase between MCFT3:MCFT1 ($P < 0.05$) and very significant increase between MCFT4:MCFT1 ($P < 0.00005$). The differences between MCFT2:MCFT1 and MCFT5:MCFT1 were not significant.
Summary/Conclusions: Our ROTEM results testify for a tendency to hypercoagulation in normal pregnancy, especially in the 2nd and 3rd trimester of pregnancy (max. 36–37th week) as well as in puerperium. In our cohort of normal pregnant women the arrangement of hemostasis was not achieved completely even at 6–7th week after delivery (MCF5 not significantly increased). Acknowledgement: Study was supported by projects APVV 222-11, Vega 1/0016/12, UK/319/2012 and CEPV II (ITMS 26220120036) which was cofinanced from EC sources.

PB 4.65-6

Anticoagulation in pregnant women with history of unexplained miscarriage

Mahnel R[1], Alrifai M[2], Fischer R[2], Heidinger K[2], Kelm C[2], Kirsch-Altena A[2], Mondorf W[3], Mondorf C[3] and Kemkes- Matthes B[2]
[1]*Haemostas- Praxis zur Behandlung von Blutgerinnungsstörungen, Frankfurt;* [2]*Haemostasis Center, University Hospitals Giessen and Marburg GmbH, Giessen;* [3]*Haemostas- Praxis, Frankfurt, Germany*

Background: Unexplained miscarriage affects 11–15% of women. Low molecular weight heparin (LMWH) is frequently given to prevent recurrent pregnancy loss. However, only limited data exist concerning LMWH treatment for prevention of miscarriage, especially in non thrombophilic women and in women with one miscarriage.
Aims: The aim of this study is to reveal the rate of live births in patients (with or without thrombophilic disorders) with unexplained miscarriage treated with LMWH during pregnancy.
Methods: 243 women with one ore more unexplained miscarriages were examined. Thirteen patients were lost for follow-up and therefore excluded from analysis, thus 230 women (average age at beginning of gestation: 33 years) with one ($n = 50$) or more ($n = 180$) unexplained miscarriages were examined.
Data were collected during first pregnancy under LMWH treatment. Women with an indication for anticoagulant treatment other than abortion and women with antiphospholipid antibodies were excluded. LMWH was given in prophylactic dosage.
The following thrombophilia parameters were determined: Factor V Leiden mutation, Prothrombin (G20210A) polymorphism, protein C, protein S, antithrombin, antiphospholipid antibodies.
Results: In 41% of pregnant women (94/230) thrombophilia was observed: 51 women with Factor V Leiden mutation, 26 with Prothrombin polymorphism, 3 with protein C deficiency, 13 with protein S deficiency and 1 with antithrombin deficiency.
The proportions of women who gave birth to a live infant were 73% in women with thrombophilia (69/94) and 77% in women without thrombophilia (105/136).

Women who had experienced one miscarriage had – after pregnancy under LMWH – a live birth rate of 88% (44/50), women with more than one miscarriage had a live birth rate of 73% (131/180).
Except vaginal bleeding, no bleeding complications occurred during LMWH treatment. Moreover, no haemorrhagic complications in association with delivery were reported. Furthermore there was no heparin- induced thrombocytopenia or thromboembolism.
Conclusions: Thrombophilia has been identified in about 41% of women with unexplained miscarriage. When LMWH was given during pregnancy, live birth rate in women with only one miscarriage was higher than in women with >2 miscarriages. Thus, thrombophilia seems to be one risk factor for occurrence of miscarriages. Heparin therapy to prevent miscarriage is safe, but it is still unclear whether LMWH improves the chance of live birth in women with unexplained miscarriage.

PB4.66 – Hormones, pregnancy, women's issues – V

PB 4.66-2
May-Hegglin anomaly in pregnancy: a systematic review

Davies JS, Hussein B, Shareif L, Gomez K and Abdul-Kadir R
Royal Free Hospital NHS Foundation Trust, London, UK

Background: May-Hegglin anomaly is an autosomal dominant disorder, characterised by a variable degree of thrombocytopenia, large platelets and inclusion bodies in white blood cells. Bleeding manifestations are generally mild but severe bleeding episodes have been reported.
Aims: To perform a systematic review of the literature to assess the affect of May-Hegglin anomaly on pregnancy outcomes and bleeding manifestation
Method: A systematic review of literature for May-Hegglin anomaly during pregnancy was performed using electronic databases including PUBMED, MEDLINE, and EMBASE. The following keywords were used 'May-Hegglin anomaly', 'pregnancy', 'gestation' and 'inherited thrombocytopenia'. Initial literature review revealed 655 articles. Twenty-six articles were relevant to MHA in pregnancy, and were included in the review.
Results: The review revealed 26 articles (25 case reports and one case series) including 75 pregnancies (five twin pregnancies) in 40 women. In 11 women, first presentation was incidental thrombocytopenia during routine antenatal blood test. Of these, five women were misdiagnosed as ITP, including three who underwent splenectomy for resistant ITP. Postpartum haemorrhage (PPH) and bleeding after miscarriage were presenting symptoms in two women.
Antiplatelet antibody was found in three pregnancies. Only one of them required intervention with IVIG to prevent neonatal alloimmune thrombocytopenia. Postpartum haemorrhage (PPH) was reported in four pregnancies, three were primary PPH, one required blood transfusion, one required platelet and cryoprecipitate transfusion and the 3rd was managed conservatively. There was one secondary PPH that was treated conservatively. Neonatal outcome included 78 live neonates and 2 intrauterine fetal deaths. Thirty four neonates had thrombocytopenia and subsequently were diagnosed with May-Hegglin anomaly, 3 of them required prophylactic platelet transfusion as they developed a very low platelet count and one neonate with platelet count of 29×10^9/L received IVIG as the mother had a positive antiplatelet antibody during pregnancy. No obvious bleeding complications were reported among the neonates.
Conclusion: May-Hegglin anomaly can present challenges during pregnancy and be associated with adverse maternal and neonatal outcome due to bleeding complications. Joint management by obstetrians and haematologists is required to minimise these risks.

PB 4.66-3
Incidence of pregnancy outcomes in women with pregnancy loss subtypes bearing Leiden polymorphisms:comparison with the purely obstetric antiphospholipid syndrome

Gris J-C, Bouvier S, Cochery-Nouvellon E, Lissalde-Lavigne G, Mercier E, Mousty E, Balducchi J-P and Marès P
University Hospital, Nimes, France

Background: By comparison to what is observed in the purely obstetric form of antiphospholipid syndrome (APS) treated according to guidelines, the incidence of pregnancy outcomes in women with current constitutive thrombophilias is uncertain.
Aims: We aimed to design a prospective study in women selected on the same clinical criteria, according to the presence of APS, or of frequent constitutive thrombophilias.
Methods: We performed a 10-year observational study of 1592 non-thrombotic women who had experienced three consecutive spontaneous abortions before the 10th week of gestation or one foetal death at or beyond the 10th week of gestation (*NOH-APS*, *Blood 2012;119 (11):2624–32*).
We compared the frequencies of pregnancy outcomes among women positive for antiphospholipid antibodies (n = 517; treatment: prophylactic LMWH plus low-dose aspirin), women carrying the *F5* 6025 or *F2* rs1799963 polymorphism (n = 279; recurrent abortions: no treatment; foetal death: prophylactic LMWH), and women with negative thrombophilia screening results (n = 796; no treatment).
We report the results comparing APS women and women carrying the *F5* 6025 or *F2* rs1799963 polymorphism ('Leiden polymorphisms').
Results: In women with recurrent abortions, the relative risk of early abortion, foetal death, pre-eclampsia (PE; total PE, severe PE, PE before 34 weeks, HELLP syndrome, PE with a small for gestational age SGA neonate), placental abruption PA, any ischemic placental disease IPD, premature birth before 37 weeks or before 34 weeks and neonatal mortality, computed between non-treated 'Leiden polymorphisms' women (n = 93) and treated APS women (n = 206), were non-significant.
In women with foetal death, by comparison to treated 'Leiden polymorphisms' women (n = 186), treated APS women (n = 311) were at higher risk of premature birth before 37 weeks or before 34 weeks; of PE, severe PE, PE before 34 weeks, HELLP syndrome and PE with SGA neonate; of any IPD. A trend ($P < 0.15$) was observed for increased risks of foetal death, of eclampsia, of SGA neonates and of neonatal mortality. By comparison to non-treated women with negative thrombophilia screening results (n = 313), treated 'Leiden polymorphisms' women were a lower risk of foetal loss, of premature birth, of severe PE and of PE before 34 weeks, a trend being observed for lower risks of SGA neonates and of any IPD.
Summary/Conclusions: In women with recurrent abortions, patients bearing the *F5* 6025 or *F2* rs1799963 polymorphism attempting a new pregnancy without any treatment have similar pregnancy outcome rates than treated purely obstetric APS women. Specific therapeutic developments are unneeded in these Leiden positive women.
In women with foetal loss, treated patients bearing the *F5* 6025 or *F2* rs1799963 polymorphism attempting a new pregnancy are at strikingly lower risk of poor outcomes than treated purely obstetric APS women. They are also at lower risks than non-treated women with negative thrombophilia screening. Prophylactic LMWH given in our selected *F5* 6025 or *F2* rs1799963 positive women with unexplained foetal loss appear to exert some protective effect during pregnancy. This protective effect might depend of the molecular mechanism underlying the previous foetal loss, which identification is thus warranted.

PB 4.66-4

Mild and severe preeclampsia: platelet activation, platelet-leukocyte aggregates and monocytes-tissue factor expression in assessment

Freitas LG[1], Carvalho M[1], Martins-Filho OA[2], Sathler-Avelar R[2] and Dusse LMS[1]

[1]Faculty of Pharmacy – Federal University of Minas Gerais, Belo Horizonte; [2]Centro de Pesquisa Rene Rachou, FIOCRUZ, Belo Horizonte, Brazil

Background: Preeclampsia (PE) is a serious complication of pregnancy associated with high maternal-fetal morbidity and mortality, whose etiology remains unclear. In pure form, it is characterized by hypertension and proteinuria after 20th weeks of pregnancy, in normotensive pregnant women. Studies suggest that platelet activation and aggregation contribute to the hypercoagulable state seen in this disease. Moreover, hemostatic and inflammatory changes associated with normal pregnancy are more exacerbated in PE.

Aims: To assess platelet activation markers and monocytes-TF expression in mild (mPE) and severe (sPE) preeclampsia.

Methods: A cross-sectional study (ETIC 0243.0.203.000-10). Mean fluorescence intensity (MFI) of CD41a, CD61, CD42a, CD62P and $CD62P^+$ (%) were evaluated by flow cytometry in 35 preeclamptic women (20 mPE and 15 sPE), 25 normotensive pregnant (NP) and 31 nonpregnant women (NW). Platelets-monocytes aggregates (APM), platelets-neutrophils aggregates (APN) and monocytes-TF^+ were evaluated in 20 PE (12 mPE and 8 sPE), 20 NP and 20 NW. Data were analyzed by ANOVA/LSD and Kruskal-Wallis/Mann-Whitney. Differences were significant at $P \leq 0.05$ and $P \leq 0.017$ (Bonferroni).

Results: CD62P, $CD62P^+$ (%), CD42a, APM (%), APN (%) and monocytes-TF^+ (%) did not differ among groups ($P = 0.69$; $P = 0.54$; $P = 0.57$; $P = 0.13$; $P = 0.02$; $P = 0.26$). CD61 and CD41a were lower in sPE vs. NW ($P = 0.00$). No difference were found for CD61 and CD41a in sPE vs. mPE ($P = 0.49$; $P = 0.48$), sPE vs. NP ($P = 0.79$; $P = 0.69$), mPE vs. NP ($P = 0.63$; $P = 0.73$) and for CD41a in mPE vs. NW ($P = 0.10$).

Summary/Conclusions: The results showed that PE is associated with reduced CD41a and CD61 expression on platelet surface. It can also be inferred that the circulating platelets are not activated and the activated ones would be trapped in the platelet aggregates, no longer being in circulation.

PB 4.66-5

Is bleeding disorders investigation mandatory in women with verified menorrhagia?

Djukic S[1], Antovic JP[2], Andjelkovic N[1] and Djukic A[1]

[1]Clinical Center and Faculty of Medical Sciences Kragujevac, Kragujevac, Serbia; [2]Karolinska University Hospital & Institute, Stockholm, Sweden

Background: Menorrhagia is caused by bleeding disorders in substantial number of cases and it is very common clinical problem among women of reproductive age.

Objective: To estimate prevalence of coagulation disorders in females with menorrhagia as well as frequency of menorrhagia and its characteristics.

Method: 115 women (36.1 ± 9.6 years) with symptoms of menorrhagia have been studied. Menorrhagia has been verified using semiquantitive method – Pictorial Bleeding Assessment Chart (PBAC) with score >100 (equivalent >80 mL blood). Bleeding time (BT), coagulation screening (PT, aPTT), VWF:Ag and VWF:Ac, FII, FV, FVII, FVIII, FIX, FX and F XI activity, have been analyzed, as well as complete blood count including hemoglobin (Hb) and serum iron.

Results: Menorrhagia (PBAC >100) has been objectively verified in 64 women (55.7%). In comparison with those with normal menstruation, women with menorrhagia had higher SCOR of menstrual cycle (Md = 150.0 vs. Md = 50.0; $P < 0.001$) but not its duration (7.2 ± 2.1 days vs.7.3 ± 1.9 days; $P > 0.05$), lower FVII:Ac (78.0 ± 28.3% vs.100.5 ± 35.0%; $P < 0.001$) and lower FX:Ac (Md = 77.4%, 39.8–141.0% vs. Md = 87.8%, 42.0–143.0%; $P = 0.018$). Coagulation defects have been found in 12 women (10.4%) – decreased FIX:Ac in 4 (3.5%), decreased FVII:Ac in 1 (0.9%), decreased FX:Ac in 1 (0.9%), 1 woman (0.9%) was a hemophilia C carrier, while 5 women (4.3%) matched criteria for mild VWD type 1. Women with coagulation disorders had prolonged PT (Md = 13.1s, 12.2–14.8s vs. Md = 12.5s, 10.6–18, 3s; $P = 0.032$) (after adjustment for the presence of FVII and FX deficiency this finding was persistent for entire group). Anemia was diagnosed at 61 women (53.0%) and these patients had higher SCOR of menstrual cycle (Md = 109.0, 50–778 vs. Md = 100.0, 26–750; $P = 0.036$), they were older (38.6 ± 9.0 years vs. 33.5 ± 9.5 years; $P = 0.005$) and had higher values of FV:Ac (Md = 117.0%, 50.0–241.0% vs. Md = 80.7%, 50.0–199.0%; $P = 0.004$) and FVIII:Ac (Md = 135.0%, 22.0–596.0% vs. Md = 118.5%, 70.0–460.0%; $P = 0.066$) in comparison with those with normal blood tests.

Conclusion: About half of patients with positive history (55.7%) of heavy bleeding really had menorrhagia diagnosed with PBAC score. Ability of women for self-evaluation of blood loss during period was poor. Higher SCOR of menstrual cycle but not also its duration suggests that intensity, but not its duration contributes to abundant menstrual bleeding in women with menorrhagia. Coagulation abnormalities were present at 10.4% of the examined population, predominantly mild VWD. At more than half of the patients anemia was diagnosed and it was primarily associated with inflammation and higher age. We suggest that objectively verification of menstrual loss (PBAC) is mandatory and it seems that bleeding disorders investigation (screening for PT and VWD) predominantly in women with anemia may be useful in the diagnostic algorithm of menorrhagia.

PB 4.66-6

Thrombin generation, APC resistance, protein S and TFPI function in women with a history of a thromboembolism during oral contraceptive use

Tchaikovski SN[1], Thomassen CLGD[2], Costa SD[1], Bremme K[3] and Jan R[2]

[1]Otto-von-Guericke University, Magdeburg, Germany; [2]Cardiovascular Reasearch Institute Maastricht, Maastricht, The Netherlands; [3]Karolinska Institutet, Stockholm, Sweden

Background: Venous thromboembolism (VTE) is a multifactorial disorder that arises as the result of genetic and environmental factors. Oral contraceptive (OC) use is a well-known acquired risk factor for VTE. Up to 40% women, who develop a VTE during OC use have a thrombophilia. Annual risk of a recurrent event among women with a previous hormone-related VTE is about 2%, which suggests persistence of the prothrombotic changes. Global coagulation tests are currently used to assess the over-all coagulation state and function of different coagulation pathways. Thrombin generation assays and activated protein C (APC) resistance tests are associated with a risk for primary and recurrent VTE.

Aims: To identify changes in APC resistance and thrombin generation measured at different assay conditions in a population of women, who had a VTE during OC use.

Methods: We compared thrombin generation, APC resistance as well as the functional activities of protein S and TFPI in plasma of healthy controls and women, who had a thrombotic event during OC use in their personal history. Thrombin generation was measured via calibrated automated thrombography at 1 pM and 10 pM of tissue factor. The function of protein S and TFPI was evaluated in thrombin generation-based assays and expressed as protein S and TFPI ratios. The study was approved by the Medical Ethical committee of the Kar-

olinska Institutet, Stockholm, Sweden. All participants gave written informed consent.

Results: 57 women with VTE during OC use in the anamnesis and 25 non-pregnant healthy control women who were not using hormonal contraceptives were recruited in the present study. 16 participants were excluded from the thrombosis group due to hormonal contraception (progestin-only pill or levonorgestrel-containing intrauterine device) or medication interfering with blood coagulation. Both groups were comparable with regards to age.

The thrombosis group had higher endogenous thrombin potential (ETP) in the presence of APC as well as APC resistance as compared to the control group ($P = 0.014$ and $P = 0.033$ respectively). Furthermore, women with a VTE in the anamnesis had an increased protein S ratio ($P = 0.032$), indicating an impaired function of protein S. Thrombin generation measured at 1 or 10 pM tissue factor and the TFPI ratio did not differ between the groups.

The Pearson Chi-Square test confirmed a significantly higher number of women with a thrombosis in the past among participants with values above the upper quartile (>75%) for the ETP determined in the presence of APC as well as for the protein S ratio ($P = 0.016$ and $P = 0.045$ respectively).

Summary: Women with a previous VTE had higher APC resistance as compared to the control group. This might be explained by a higher number of carriers of the factor V Leiden mutation in the thrombosis group. Furthermore, women in the thrombosis group had an impaired function of protein S that likely contributes to their prothrombotic phenotype.

Overexpression of activated protein C improves host defense during pneumococcal pneumonia

Kager LM[1], De Boer DJ[1], Roelofs JTH[1], Meijers JC[2], Isermann B[3], Van 't Veer C[1] and Van der Poll T[1]

[1]Academic Medical Center, Amsterdam; [2]Academic Medical Center Amsterdam, Amsterdam, The Netherlands; [3]IKCP, Otto-von-Guericke University, Magdeburg, Heidelberg, Germany

Background: During pneumonia, inflammation and coagulation are activated as part of anti-bacterial host defense. Activated protein C (APC) has anticoagulant and anti-inflammatory properties and during pneumonia its levels are decreased. *Streptococcus pneumoniae* is the most common causative pathogen in community-acquired pneumonia.

Aims: We aimed to investigate the effect of endogenous overexpression of APC during experimental pneumococcal pneumonia.

Methods: Wildtype (WT) and APC-overexpressing (APC^{high}) mice were intranasally infected with *S. pneumoniae* (strain 6303). Mice were sacrificed after 6, 24 or 48 h and survival studies were performed. Lungs, liver, spleen and blood were harvested to measure bacterial loads, cytokines, histopathology and coagulation parameters. Additionally, bronchoalveolar lavages (BAL) were done and the BAL-fluid (BALF) and cells were analyzed.

Results: In comparison to WT mice, APC^{high} mice showed decreased bacterial dissemination to liver ($P < 0.05$) and spleen ($P < 0.01$), while no differences in local bacterial loads were measured. Additionally, although no differences in overall lung histopathology were seen, APC^{high} mice showed a significantly decreased total cell influx in BALF due to decreased numbers of neutrophils (both $P < 0.01$), which was accompanied by decreased levels of the pro-inflammatory cytokine TNF-α ($P < 0.05$). Finally, APC^{high} mice showed a strong trend toward a better survival when compared to WT mice ($P = 0.06$).

Conclusions: Overexpression of activated protein C improves host defense during experimental pneumococcal pneumonia. These data contribute to the knowledge of cell-protective effects of APC during severe infections.

PB 4.67-2

SMTP, a novel family of small molecule anti-inflammatory thrombolytic: structure-activity relationships with respect to plasminogen modulation and soluble epoxide hydrolase inhibition

Matsumoto N[1], Suzuki E[1], Koide H[1], Hasegawa K[2], Nishimura N[2] and Hasumi K[1]

[1]Tokyo univ of Agricul and Technol; [2]TMS Co., Ltd., Tokyo, Japan

Background: The SMTP family small-molecules enhance plasminogen activation through conformational change (plasminogen modulation; PM). The SMTP molecule consists of a core unit (a tricyclic γ-lactam moiety with a geranylmethyl group) and an *N*-linked side-chain. SMTP-7, which is a potent thrombolytic with an excellent potential to treat ischemic stroke, is one of the SMTP compounds that comprises >50 congeners differing in the side-chain. The excellent SMTP-7 activity in treating stroke is attributable not only to PM activity (thrombolysis) but also to anti-inflammatory properties, which are implicated in soluble epoxide hydrolase (sEH) inhibition (sEHi). sEH catalyzes the conversion of the anti-inflammatory fatty acid epoxyeicosatrienoic acid (EET) to an inactive corresponding diol, and inhibition of sEH stabilizes endogenous EET, leading to anti-inflammation and neuroprotection.

Aim: The present study aimed at evaluating potencies of a variety of SMTP congeners with different *N*-linked side chains with respect to PM and sEHi activities to elucidate their structure-activity relationships for the design of ideal anti-inflammatory thrombolytic and for the discrimination of the structural requirement for sEHi from that for PM.

Methods: PM activity was determined by incubating plasminogen with urokinase-type plasminogen activator and a chromogenic substrate. sEH activity was determined by incubating mouse sEH with a fluorogenic substrate.

Results: Previous investigations have demonstrated that the *N*-linked side-chain of SMTP is crucial for PM activity. Therefore, we evaluated SMTP congeners with different side-chain for their potentials in PM. The results demonstrated that the presence of both an aromatic group and a negatively ionizable group in the side chain greatly potentiates PM activity. For example, SMTP-7, which has a dimer like structure, with butane-1-carboxylic acid-connected another core unit (which has an aromatic hydroxyl group) as a side-chain, was one of the most potent congeners with respect to PM activity. The *N*-linked side-chain structures of other potent congeners included 4-phenylcarboxylic acid (SMTP-19), 3-hydroxyphenyl-4-carboxylic acid (SMTP-22), 2-hydroxyphenyl-3-carboxylic acid (SMTP-25), and (*S*)-2-phenylacetic acid (SMTP-43). On the other hand, a congener with hydrogen as a side-chain (SMTP-0), consisting of the core unit alone, showed no PM activity but had potent sEHi activity. Thus the presence of the *N*-linked side-chain is not essential for sEHi, clearly discriminating structural requirement for sEHi from that for PM activity. The congeners with hydrophilic or nonpolar side-chains, however, were essentially inactive in sEHi, and the congeners with some isomers of hydroxyphenylcarboxylic acid (including SMTP-25) were more potent than SMTP-0, demonstrating that the side-chain played a role in the tuning of sEHi activity in SMTP congeners.

Conclusions: The *N*-linked side-chain of SMTP is the crucial determinant of its PM activity, while the minimum structural requirement for sEHi is the core unit of SMTP (ie. SMTP-0). Congeners with some isomers of hydroxyphenylcarboxylic acid as a side-chain are potent with respect to both PM and sEHi activities. Certain types of the side-chain affect sEHi both positively and negatively, contributing to the tuning of sEHi activity of SMTP congeners.

PB 4.67-3

Acute fluoxetine treatment increases leukocyte-endothelial interactions in murine peritonitis

Herr N[1], Mezger J[2], Stallmann D[3], Bode C[3] and Dürschmied D[3]
[1]University Hospital Freiburg; [2]University Hospital; [3]University Heart Center, Freiburg, Germany

Background: Activated platelets release serotonin at sites of inflammation where it acts as inflammatory mediator. We found recently that serotonin enhances the recruitment of neutrophils to sites of inflammation. Chronic treatment with selective serotonin reuptake inhibitors (SSRI) depletes the serotonin storage pool in platelets in humans and mice, leading to reduced leukocyte recruitment in murine experiments.
Aims: Here, we examined the direct and acute effects of SSRI on leukocyte recruitment.
Methods: Four week-old C57Bl/6 mice underwent acute (40 mg/kg i.p. 2 h before surgery) treatment with the standard SSRI fluoxetine or vehicle. Serum and plasma serotonin concentrations were measured by ELISA. Leukocyte rolling and adhesion on endothelium was analyzed by intravital microscopy in mesentery venules at resting conditions and after inflammatory stimulation with lipopolysacharide (LPS, 20 mg/kg i.p.). Leukocyte extravasation in sterile peritonitis, triggered by 1 mL 4% thioglycollate i.p. for 4 h, was measured by flow cytometry of abdominal lavage fluid.
Results: Plasma serotonin levels were elevated with large variation among individual mice 2 h after fluoxetine treatment (96 ± 32 after vehicle vs. 336 ± 188 after fluoxetine application, $P = 0.2$, $n = 6$), while serum serotonin did not change. Without further stimulation, acute fluoxetine treatment increased the number of rolling leukocytes (63 ± 8 vs. $165 \pm 17/0.04$ mm^2/min) and decreased their velocity (61 ± 6 vs. 28 ± 1 μm/s, both $P < 0.0001$, $n = 10$). Acute fluoxetine treatment itself also induced leukocyte adhesion (0 vs. $3.5 \pm 0.8/0.04$ mm^2, $P = 0.004$). Stimulation with LPS decreased mean rolling velocity and multiplied leukocyte adhesion in both groups. Adhesion was further amplified by acute fluoxetine application (27 ± 3 vs. $36 \pm 2/0.04$ mm², $P = 0.008$, $n = 10$). Leukocyte migration in sterile peritonitis was not affected by acute fluoxetine treatment.
Conclusions: Surprisingly, acute fluoxetine treatment induced leukocyte adhesion, suggesting an unknown, direct effect on endothelium. This effect could also be mediated by a transient accumulation of serotonin in the plasma, when uptake into platelets is blocked. These observations warrant further investigation since they may have implications for the treatment of depression but also for anti-inflammatory strategies.

PB 4.67-4

Effect of C1-inhibitor glycans on the kinetics of target protease inhibition

Engel R, Roem D, Wagenaar-Bos I, Van Ham M, Zeerleder S and Wouters D
Sanquin Blood Supply Foundation, Amsterdam, The Netherlands

Background: The anti-inflammatory plasma protein C1-inhibitor (C1-inh) is the major inhibitor of the proteases of the contact phase and the classical and lectin pathways of the complement systems. C1-inhibitor is a heavily glycosylated protein with 6 *N*- and 7 *O*-linked glycans known. The sialic acids on the glycans are known to prevent the *in vivo* clearance of the protein but studies to date indicate that C1-inh glycans have no effect on its complex formation with target proteases. However, the effect of C1-inh glycosylation on the kinetics of complex formation with various proteases has not been studied in detail.
Aims: Study the kinetics of inhibition of target proteases by various glycoforms of C1-inh to ascertain a role for C1-inh glycosylation in protease inhibition.
Methods: Various C1-inh glycoforms are prepared either by recombinant protein expression in *Pichia pastoris* or by *in vitro* enzymatic treatment of plasma derived C1-inh (pdC1-inh). Kinetics of C1-inh inhibition of C1s, FXIIa and kallikrein is studied with chromogenic assays.
Results: Three glycoforms of recombinant human C1-inh are successfully produced in *Pichia pastoris*: wild-type (WT), truncated form without the N-terminal 98 amino acids, thus removing all *O*-linked and three *N*-linked glycans (NT98) and a mutant where the additional three *N*-glycans of the C-terminal serpin domain are also removed (NT98Δ). The wild-type and NT98 are similar to the pdC1-inh in their inhibition kinetics to C1s, FXIIa and kallikrein. However, NT98Δ shows significantly reduced association to the proteases. This mutant also exhibits lower heat stability than the WT and NT98. Together this indicates that the three *N*-glycans of the serpin domain play an important role in stability and function of C1-inh.
Studies are now underway to determine the inhibition kinetics of additional glycoforms of the pdC1-inh. Using enzymatic treatment either entire glycans or only the sialic acids are removed. Also a fucosylated form of pdC1-inh, to mimic the glycoform expected in acute phase inflammation, has been prepared.
Conclusions: The *N*-glycans present in the serpin domain of C1-inh are crucial for the stability and function of C1-inh.

PB 4.67-5

The modulation of astrocyte functions by activated protein C

Gorbacheva L[1], Ivanova A[1], Pinelis V[2], Reiser G[3], Ishiwata S[4] and Strukova S[1]
[1]Lomonosov Moscow State University, Moscow; [2]Scientific Centre for Children's Health, Russian Academy of Medical Sciences, Moscow, Russian Federation; [3]Institute for Neurobiochemistry, Otto-von-Guericke University, Medical Faculty, Magdeburg, Germany; [4]Department of Physics, Faculty of Science and Engineering, Waseda University, Tokyo, Japan

Background: Activated protein C (APC) is polyvalent cofactor-dependent serine proteinase. APC has no only exclusive anticoagulation activity, but also protective effects in systemic inflammation and neurodegeneration. Recently neuroprotective effects of APC on stressed neurons, hypoxic brain endothelium has been found and APC may be useful in therapy of stroke (Zlokovic et al., 2005, Gorbacheva et al., 2009, Wang et al., 2012). Astrocytes are the immune cells of human brain. Many pathological processes in brain are accompanied with structural and functional changes of astrocytes. It is known that reactive astrogliosis observed during various inflammatory diseases, encephalopathy, acute brain injuries and neurodegenerative pathologies. However, the participation of APC in regulation of astrocyte function is not yet clear. Thrombin (Th) promotes cell proliferation, which correlated with astrogliosis (Nicole et al., 2005). S100B protein express in high abundance and release by astrocytes (Sen, Belli, 2007), and abnormally elevated levels of S100B contribute to the prominent reactive gliosis.
Goal. In this study the influences of APC on the morphological and functional parameters of astrocytes at thrombin-induced activation were investigated.
Methods: Experiments were performed on cultural astrocytes. Primary cultures of astrocytes from cortex were obtained from brains of 1–3-day-old Wistar rats. Confocal microscopy, Western blot methods and MTT-assay of the cultured astrocytes at Th-induced toxicity and pretreatment with APC were used.
Results: Previously we and other researchers have shown that thrombin and APC can activate the same receptors and induce the different effects (Zlokovic et al., 2005, Gorbacheva et al., 2009, 2010, Wang et al., 2012). Here we demonstrate that the effect of APC on cultural astrocytes is opposite to the high concentration of thrombin. The high concentrations of thrombin were manifested during inflammation, injuries, etc.. Th may be account for the reactive astrogliosis which is

associated with proliferation and morphological changes. Our data point to dose-depended effects of thrombin on astrocytes. The concentration of thrombin higher then 10 nM induced the significantly activation of astrocyte proliferation (on 25% compare to control), the rise of S100 protein (in two times higher then in control), the formation of stress fibres and the amount of free fields in astrocyte cultures. These results indicate that thrombin alters cell migrational status and causes morphological changes in astrocytes. We detected EPCR on cultural rat astrocytes by the special anti-EPCR-antibodies for the first time. The finding of new receptor EPCR on astrocytes make up the possibility of APC mediates itself effects not only via PAR1 receptor, but via EPCR or two receptor PAR1 and EPCR. Pre-treatment and co-incubation of astrocytes with APC led to prevention of the effect of Th on cells. APC decreases to control values the level of S100B, the proliferation of astrocytes, the actin cytoskeletal rearrangement and the amount of free fields in astrocytes culture which were induced by Th.
Conclusion: Thus APC has not only neuroprotective effects but also can prevent the activation of astrocytes and astrogliosis during pathological condition. Our results demonstrate new aspects of APC as a protective agent for brain at trauma and neuropathology.

PB 4.67-6
Gene expression profiling of mouse platelet GPCRs under chronic inflammatory conditions

De Candia E[1], Palmer D[2] and Coughlin SR[2]
[1]Catholic University of Rome, Rome, Italy; [2]Cardiovascular Research Institute-University of California of San Francisco, San Francisco, CA, USA

Background: Some diseases associated to chronic inflammatory stimuli, such as diabetes, obesity and rheumatoid arthritis are associated to high cardiovascular risk. In this study a mouse model of chronic inflammatory stimulus *in vivo* was set up to evaluate modifications of the expression of platelet GPCRs under these conditions
Aims : Aim of this study was to evaluate whether changes of platelet transcritpome may occur *in vivo* as a consequence of inflammatory stimuli
Protocol of the study: Ten C57/Bl6 mice were treated with low dose lipopolysaccharide (LPS), i.e. 0.2 mg/kg s.c., or saline for five consecutive days. Whole blood from treated mice was obtained by vena cava blood draw. A highly purified platelet population was obtained by standard centrifugation and washing procedures followed by negative immunoselection for depletion of WBC, RBC and endothelial microparticles contaminating the platelet suspension. mRNA and cDNA were prepared using commercially available kits. GPCRs expression profiles of platelets from LPS- and from saline-treated mice were obtained by real time PCR Taqman technology. Changes of GPCRs expression on platelets were validated by functional studies on platelets, by measuring P-selectin and aIIb-b3 integrin exposures after agonist stimulation ex vivo, using conjugated MoAbs and flow cytometry.
Results: Treatment of mice with low dose LPS caused changes of the expression of some relevant GPCRs and of the platelet function. LPS treatment caused reduced expression of P2Y1 and of P2Y12 and of CysLT2, a GPCR found to be relevant for mouse platelet function. Accordingly, platelets from LPS-treated mice had reduced exposure of P-selectin and of aIIb-b3 integrin upon ADP and LTC4 stimulation. On the contrary, LPS treatment caused increased expression of PAR3 and PAR4 on mouse platelets. Accordingly, mouse platelets showed increased response to thrombin.
Conclusions: Low dose inflammatory stimuli cause changes of GPCRs expression in mouse platelets and changes of platelet responses to agonists. Similar changes might happen in human diseases with a chronic inflammatory stimulus associated to a high cardiovascular risk

PB4.68 – Inflammation: Clinical – III

PB 4.68-1
Hypercoagulability and hypofibrinolysis in patients with human immunodeficiency virus infection partially resolve after antiretroviral treatment

Sprenger HG, Lisman JA, Mulder AB, Van Der Werf TS, Bierman WF, Meijer K and Tichelaar YI
University Medical Center Groningen, Groningen, The Netherlands

Background: Patients infected with human immunodeficiency virus (HIV) are known to have an increased risk of arterial and venous thrombosis. This may involve changes in the hemostatic status, including hypercoagulability and hypofibrinolysis. Some data suggest that antiretroviral treatment (ART) reduces the increased risk.
Aim: We evaluated levels of coagulation factors, *in vitro* thrombin generation by automated calibrated thrombography and fibrinolytic potential assessed by clot lysis time (CLT) in patients with HIV infection before starting ART and during the first 6 months afterwards.
Methods: Blood was drawn after written informed consent was obtained just before ART was started, as well at 1, 3, and 6 months after starting ART.
Results: We included 40 males (87.5% of Caucasian origin). At baseline, FVIII:C and VWF:RCF were elevated (median levels: 205 and 196 IU/dL, respectively) and free protein S (FPS) was decreased (70 IU/dL). Compared to healthy controls, CLT, endogenous thrombin potential (ETP), peak thrombin, as well as the velocity index derived from thrombin generation curves were significantly increased in patients at $t = 0$ (median levels: 49.9 vs. 67.5 min; 440 vs. 604 nM*min; 121 vs. 176 nM and 61.3 vs. 85.2 nM/min, respectively). After 6 months of treatment, FVIII:C and VWF:RCF were significantly reduced to 159, 129 IU/dL and FPS significantly increased to 84 IU/dL. CLT, ETP, peak thrombin and velocity index all decreased but this did not reach statistical significance.
Summary/Conclusions: Patients with HIV infection were in a procoagulant as well as a hypofibrinolytic state, which partially improved after 6 months of ART.

PB 4.68-2
Thrombomodulin-modified thrombin generation in patients with diffuse peritonitis

Smirnova O[1], Namestnikov Y[1], Gurzhiy D[2], Gamzatov K[2], Zemlyanoy V[2], Lerner A[1] and Papayan L[1]
[1]Russian Research Institute of Hematology and Transfusiology; [2]North-Western State Medical University named after I.I. Mechnikov, St -Petersburg, Russian Federation

Background: The diffuse peritonitis (DP) is a serious and common infection. Its clinical course includes haemostatic abnormalities, ranging from insignificant laboratory changes to excess activation of haemostasis that may result in localized thrombotic complications or disseminated intravascular coagulation. Thrombin generation test (TGT) with the addition of thrombomodulin may be useful as a global method to assess the individual coagulation profile in DP patients.
Aims: The aim of our study was to investigate the process of thrombin generation in patients with DP.
Methods: Venous blood was obtained from 43 patients within 24 h of the diagnosis of DP. The control group comprised 65 healthy volunteers. TGT was performed in platelet poor plasma in a Fluoroscan Ascent® fluorometer at 5 pM tissue factor concentrations in the presence of human recombinant thrombomodulin using dedicated software. The following parameters were analyzed: lag time of thrombin generation (LT, min), endogenous thrombin potential (ETP, nM*min), maximum concentration of thrombin (Peak, nM), time to

reach the peak (TTP, min), and velocity index (VI = Peak/[TTP-LT], nM/min). Statistical analysis of the results was performed by non-parametric. Methods using the median (Me), 95% confidence interval (95% CI) and Mann-Whitney U test (Statistica 6.0).

Results: Except for LT and TTP, there was significant difference between patients and controls regarding ETP (Me (95% CI): 1496 (1133–1919) vs. 779.2 (594.5–919.5), $P = 0.001$), Peak (243 (203.6–312.5) vs. 153.64 (134.9–195.2), $P = 0.04$) and VI (135.5 (87–191) vs. 72 (57–90.5), $P = 0.005$). In addition, ETP, Peak and VI demonstrated a clear tendency to increasing in non-survivors than in survivors (Me: 1574.5 vs. 1493.1, 250.4 vs. 216.5 and 114.4 vs.101.1, accordingly, $P = 0.3$).

Summary: Patients with DP are characterized by considerable hypercoagulability. Thrombomodulin-modified TGT may be a potentially useful tool to identify patients with increased risk of DP mortality.

PB 4.68-3

Elevated platelet count, platelet activation and CRP in gulf war veterans' illnesses; evidence of a chronic inflammatory state?

Johnson GJ, Leis LA, Slater BCS and Bach R

VA Health Care System, Minneapolis, MN, USA

Background: Gulf war veterans' illnesses (GWVI) are chronic, multi-symptom disorders in veterans of war in Kuwait and Iraq in 1990–1991. GWVI are defined according to CDC criteria by symptoms in two or three categories – fatigue, mood-cognition, musculoskeletal pain – not attributable to other diseases. The cause is unknown. A previous study observed impaired platelet activation in a majority of subjects with GWVI who had evidence of blood coagulation activation (Hannan KL, et al. Blood Coagul Fibrinolysis 2000;11:673–8).

Aims: To further characterize platelet function in GWVI we studied 43 subjects (40 male) with GWVI (GWVI+) and 21 male subjects who served concurrently in the war zone but who did not meet diagnostic criteria for GWVI (GWVI-). All participants in the study were free of infections and other known inflammatory disorders.

Methods: The following studies were performed in all subjects: platelet count, immature platelet fraction (IPF), plasma thrombopoietin (TPO), plasma C-reactive protein (CRP), light transmission platelet aggregation and ATP secretion in response to 0.5 mM arachidonic acid, 0.5 μM U46619, 1.0 μM U46619, 0.5 μM ADP, 0.5 μM epinephrine, 1 μg/mL collagen, 10 μM TRAP 6, 50 μM TRAP 6, and spontaneous platelet aggregation.

Results: Significant differences between the group means of GWVI+ and GWVI- subjects were observed for the following: platelet count (236.1 ± 55.4 vs. $205.9 \pm 44.2 \times 10^3/mm^3$; $P = 0.036$); spontaneous platelet aggregation (7.8 ± 2.6 vs. $5.6 \pm 1.2\%$; $P = 0.011$); platelet ATP secretion in response to 50 μM TRAP 6 (17.9 ± 5.5 vs. 12.8 ± 3.3 nmoles ATP/10^9 platelets; $P = 0.013$; CRP (4.0 ± 4.6 vs. 1.5 ± 1.3 mg/L; $P = 0.020$. IPF, TPO, platelet aggregation and platelet secretion in response to other agonists did not differ between GWVI+ and GWVI- subjects. Subset analyses of platelet aggregation and secretion based on medication history revealed no significant differences between GWVI+ and GWVI- subjects. Among subjects who had elevated CRP (>2 mg/L) platelet aggregation in response to 0.5 μM U46619 was significantly elevated (62.0 ± 37.8 vs. $39.8 \pm 39.3\%$; $P = 0.029$).

Summary: Platelet aggregation and secretion were not impaired in GWVI+ subjects. Platelet count, spontaneous platelet aggregation, platelet secretion in response to thrombin receptor agonist, TRAP 6, and CRP were significantly elevated in GWVI+ subjects. In addition subjects with elevated CRP had significantly elevated platelet aggregation in response to thromboxane analog, U46619. The differences between GWVI+ and GWVI- subjects were independent of medication effects.

Conclusion: Platelet activation is not impaired in GWVI, but elevated plasma CRP, platelet count, and platelet U46619-induced aggregation are characteristics not previously described that suggest GWVI is a chronic inflammatory disorder.

PB 4.68-4

Gene expression analysis in patients with spontaneous deep venous thrombosis

Barnabé A[1], Santiago-Bassora D[1], Severino P[2], Carazzolle MF[1], Pereira AG[1], Orsi LA[1], De Paula EV[1], Höehr NF[1] and Annichino-Bizzacchi JM[1]

[1]State University of Campinas, Campinas; [2]Albert Einstein Research and Education Institute, São Paulo, Brazil

Background: Deep venous thrombosis (DVT) is a multifactorial disease and in about 30% of patients no risk factor can be identified. Association of inflammation and haemostasis is thought to play a significant role in the pathogenesis of DVT.

Aim: We hypothesized that distinctive patterns of gene expression in mononuclear cells from patients with DVT could be relevant to the pathogenesis of the disease.

Methods: cDNA microarray technology (CodeLink Bioarrays) was used to study the gene expression profile of five patients with spontaneous DVT, three of their siblings and one healthy individual. DVT patients were selected based on strict clinical characteristics, including no hereditary predisposition or known risk factors. Functional analysis of differentially expressed genes was used to identify biological processes possibly differentially regulated in DVT.

Results: Preliminary analysis showed that 2% of approximately 55,000 transcripts contained in the array had significant differences in expression when spontaneous DVT patients were compared to their asymptomatic siblings and healthy individuals (2-fold change, $P < 0.05$). When all these genes were taken into account we were able to identify the deregulation of genes associated with both haemostasis and coagulation (F2RL2, LPA, FOXA2, FBLN5, PROZ, GNA12 and PAPSS2). Aiming to better describe our data, we divided genes in two groups: up (607 genes) and down-regulated (499 genes) in DVT patients as compared to siblings and healthy individual. Up-regulated genes are involved in 50 biological processes, including, chemotaxis (e.g., CCL1, CCR3, FER, IL8, NUP85, PLA2G1B) cell motility/migration (e.g., APOB, IL8, TGFBR1) and protein transport (eg., STX3, AKAP12, SMURF1). On the other hand, down-regulated genes are involved in 25 biological processes, such as, cell adhesion (e.g., CD93, CD97, ACTN1, ITGA11) and blood circulation (e.g., EPB41, LPA, NFE2). Interestingly, some genes found by Lewis et al. (2011) were similar in our study (FOXP1, ITPR2, MZF1, UBE2D2, LTB).

Conclusions: Evaluation of the significance of these distinctive gene expression profiles between patients with spontaneous DVT compared to their asymptomatic siblings and healthy individuals could reveal novel insights into the pathophysiology of the first DVT episode and of DVT recurrence, as well as new biomarkers or therapeutic targets. Prospective studies are needed to validate these results.

PB 4.68-5

Up-regulation of tissue factor, adhesion molecules, nitric oxide and adiponectin in end stage renal disease. A paradoxical interplay

Fareed J[1], Kaneva K[1], Hoppensteadt D[1], Cunanan J[1], Syed D[1], Singh A[2] and Bansal V[1]

[1]Loyola University Medical Center, Maywood, IL; [2]Brigham and Women's Hospital, Boston, MA, USA

Introduction: End stage renal disease (ESRD) represents the fifth (final) stage of chronic kidney disease characterized by an established kidney failure (GFR <15 mL/min/1.73 m^2). Severe cardiovascular and cere-

brovascular manifestations progressively occur in ESRD, resulting in acute coronary syndrome and stroke. The ESRD patients also exhibit a hypercoagulable state despite the use of heparin during maintenance hemodialysis suggesting the activation of other components of the hemostatic network. To further understand the pathophysiology of ESRD, this study was designed to measure the circulating levels of tissue factor (TF), adhesion molecules, such as p-selectin (P-Sel), soluble ICAM (s-ICAM), nitric oxide and adiponectin (AD).

Methods: This study included 119 ESRD patients undergoing maintenance hemodialysis in conjunction with an ongoing IRB approved protocol on the profiling of inflammatory markers in this syndrome. Citrated blood plasma samples were collected from these patients prior to the routine dialysis session. Blood samples were centrifuged at 3000 g and platelet poor plasma was frozen at −80 °C for further analysis. Blood samples from normal healthy male and female volunteers ($n = 53$) served as controls. Nitric oxide levels (NO) were measured using a commercial kit from R&D systems (Minneapolis, Minnesota) and ELISA based methods for TF, P-Sel, s-ICAM and adiponectin were also purchased from R&D systems. A chromogenic substrate method was used to measure the anti-Xa activity in both the controls and ESRD patients. Tissue factor mediated thrombin generation (TGA) was measured using a fluorogenic substrate method (Technoclone Vienna, Austria).

Results: Tissue factor levels were found to be increased in the ESRD group (20.4 ± 6.1 pg/mL) vs. the control (11.9 ± 2.8 pg/mL). The nitric oxide level was markedly higher in the ESRD group (32 ± 17 μM) vs. the controls (7 ± 3 μM). Wide variations in the range of nitric oxide were noted (3–60 μM), whereas in the normals the range was much narrower (5–12 μM). The p-selectin levels were also elevated in the ESRD group (46 ± 20 ng/mL) vs. the control (31 ± 3 ng/mL). The soluble ICAM levels were higher in the ESRD group (250 ± 112 ng/mL) vs. the control (180 ± 19 ng/mL). The ESRD group also showed a wide variation in the ICAM level, ranging from 20 to 530 ng/mL. Interestingly, the adiponectin levels were also increased in the ESRD group (19.2 ± 9.3 μg/mL) vs. the control (11.2 ± 4.1 μg/mL). The pre-dialysis samples of the ESRD patients exhibited detectable levels of heparin like activity as evident by the inhibition of Xa (13 ± 14% inhibition), which is approximated to >0.1 U/mL heparin.

Summary/Conclusions: These studies suggest that TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased in this group. This may be due to the repeated administration of heparin during dialysis sessions and the use of anti-diabetic and anti-hypertensive medications. Thus, these results suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance. Since adiponectin has anti-atherogenic and anti-inflammatory roles, it may contribute to the regulatory processes to control inflammatory and thrombotic mediators in ESRD.

PB 4.68-6

Increased expression of caspase 4 gene in mononuclear cells from patients with deep venous thrombosis

Santiago-Bassora FD, Barnabé A, Dos Santos A, Deckmann AC, Carazzolle MF, Pereira AG, Orsi LA, De Paula EV and Annichino-Bizzacchi JM

State University of Campinas – UNICAMP, Campinas, Brazil

Background: Deep venous thrombosis (DVT) is a common and potentially fatal condition affecting 1% to 2% of the population worldwide, with an annual incidence of 1 in 500. While hereditary or acquired risk factors are identified in most patients with DVT, about 40% of patients present yet unknown risk factors.

Aims: In the present study, we evaluated the gene expression profile from mononuclear cells of patients with spontaneous DVT (SPONT), risk factor-associated DVT and patients with antiphospholipid syndrome (APS).

Methods and Results: In this study, we performed a comparative analysis of gene expression from mRNA extracted from mononuclear cells of 15 patients with previous DVT of the lower limbs. Patients were divided in subgroups: (i) SPONT without any known hereditary thrombophilia ($n = 5$); (ii) risk factor-associated DVT (either acquired or hereditary thrombophilias) ($n = 5$); and (iii) patients with APS-associated DVT ($n = 5$); all compared to the healthy volunteers. Using bioarray technology, 60 upregulated and 56 downregulated genes were identified in DVT patients when compared to healthy volunteers. Azurocidin 1 (AZU1), Caspase (iv) (CASP4), Cartilage-associated protein precursor (CRATP), Vascular endothelial growth factor (FLTI), Immunoglobulin Heavy Chain Constant region mu (IGHM), Glutathion S-transferase, microsomal 2 (MGST2) and RNA polymerase II subunit (POLR2J) genes were selected for validation with quantitative real-time PCR (qRT-PCR).

Conclusion: The increased expression of CASP4 was confirmed in the same sample of DVT patients without any known risk factors ($P = 0.050$; $n = 4$). CASP 4 has been described induce NF-kB activity and acts in the activation of Caspase 1 which participates in the conversion of proIL1b and proIL-18 to IL1-b and IL-18. In addition, IL-18 may induce the adhesion of T cells, increase the immune response of natural killer cells, enhance production of interferon-g and induce chemotaxis and activation of monocytes. Increased CASP4 expression could thus be involved in the pathogenesis of DVT in these patients. Further studies are warranted in larger cohorts to confirm these findings.

Prevalence of clonal populations of hematopoietic cells with paroxysmal nocturnal hemoglobinuria phenotype in patients with splanchnic vein thrombosis

Ageno W[1], Dentali F[1], De Stefano V[2], Piovella F[3], Bazzan M[4], Piana S[5], Santoro R[6], Poggio R[7], Poli D[8] and Tosetto A[9]

[1]University of Insubria, Varese; [2]Catholic University, Rome; [3]Ospedale San Matteo, Pavia; [4]Humanitas Clinic, Torino; [5]University of Genoa, Genoa; [6]Ospedale di Catanzaro, Catanzaro; [7]Ospedale Galliera, Genova; [8]Ospedale Careggi, Firenze; [9]Ospedale San Bortolo, Vicenza, Italy

Background: Venous thromboembolism is a serious complication in patients with paroxysmal nocturnal hemoglobinuria (PNH) and frequently occurs in unusual sites, such as the splanchnic and cerebral veins. In particular, PNH is a well recognized cause of Budd Chiari syndrome. It has been hypothesized that the presence of mutant PNH clones can be associated with an increased risk of splanchnic vein thrombosis (SVT) even in the absence of overt disease, but the prevalence of PNH clones in non-selected SVT patients remains unknown.

Aims: In a multicentre cross-sectional study, we aimed to determine the prevalence of PNH clones in a group of patients with SVT and without overt PNH.

Methods: Patients with objective diagnosis of SVT within the previous 2 years were eligible for the study. Patients with known or clinically suspected PNH and patients receiving treatments potentially interfering with laboratory assessment of PNH clone were excluded. Information was collected on demographic characteristics, on the site of SVT and the presence of risk factors. All patients underwent blood sampling and the presence of PNH clone was centrally assessed using flow cytometric analysis of granulocytes and monocytes, counting the number of FLAER -ve events Because of the high-sensitivity tech-

nique used, those samples with FLAER -ve events higher than the 95th percentile underwent a second evaluation to avoid false-positive results.
Results: A total of 199 SVT patients were enrolled in the study, 116 (58.3%) were males, mean age was 54 years (range 17–94). Site of thrombosis was portal in 100 patients, mesenteric in 67, splenic in 37, and supra-hepatic in 10. Thrombophilia was diagnosed in 70 (35.2%) patients, whereas JAK2 mutation was present in 28 of 125 (22.4%) screened patients. Other risk factors for SVT included cirrhosis in 28 patients (14.1%), recent surgery in 22 patients (11.1%), and haematological disease in 21 patients (10.6%); in 71 (35.9%) patients SVT was defined idiopathic. Mean time elapsed between SVT diagnosis and study testing was 21 months. Cells with the PHN phenotype (defined as clustering of FLAR -ve events, >5 cell per 50,000 events, confirmed in two independent samples) were detected in 2 (1.01%, 95% CI 0.18–3.99) patients. SVT occurred in the superior mesenteric vein in one patient and in the portal vein in the second patient. SVT was secondary to IBD in one patient and was idiopathic in the second patient. Time between SVT diagnosis was 2 months and 24 months, respectively.
Conclusions: PNH clones can be detected in patients with a history of SVT and no clinical manifestations of disease. Future studies are needed to explore the potential role of this finding in the pathogenesis of SVT and to better define in larger cohorts the cost-effectiveness of screening for PNH clones in this population.

PB 4.69-2
Systemic hypoxia and risk of venous thromboembolism – the Tromsø study

Borvik T[1], Enga KF[1], Brækkan SK[1], Melbye H[1] and Hansen JB[2]
[1]University of Tromsoe, Tromsoe; [2]University of Tromsø, Tromsø, Norway, Tromsø, Norway

Background: Previous autopsy and venography studies indicate that venous thrombosis is initiated in the valvular sinus of veins in an environment characterized by local hypoxia and intact endothelium. Experimental studies have shown thal local hypoxia promotes endothelial expression of adhesion molecules and activation of monocytes with subsequent formation of microparticles with expression of ligands for adhesion receptors at the endothelium and expression of tissue factor (TF) which may initiate targeted thrombus in the valvular sinuses. To the best of our knowledge, however, no previous study has investigated the association between systemic hypoxia and future risk of venous thromboembolism (VTE).
Aims: We wanted to investigate the association between systemic hypoxia, defined by oxygen saturation, and future risk of VTE in a population-based prospective cohort study.
Methods: Pulse oximetry was measured in 8684 men and women who participated in the fifth or sixth Tromsø study, conducted in 2001–2 and in 2007–8. Events of VTE were registered from data of study enrolment until the end of follow-up, December 31, 2010. The best of three pulse oximetry measurements were used in analyses, and values below 70% were considered as invalid. Cox proportional hazard regression models were used to assess age-adjusted and multivariable hazard ratios (HR) with 95% confidence intervals (CI). Age, sex, body mass index and smoking status were included in the multivariable analyses. The study was approved by the regional committee for research ethics, and all participants gave their written consent to participate.
Results: In total, 188 VTE events were registered during a median of 6.62 person-years (Incidence rate: 3.57, 95% CI: 3.10–4.12). The risk of VTE increased by 18% per 3% decrease in oxygen saturation (multivariable HR: 1.18, 95% CI: 0.91–1.55). Subjects with oxygen saturation <97% (21% of the population) had a higher risk of VTE compared to subjects with oxygen saturation of 97% or above (multivariable HR: 1.54, 95% CI: 1.13–2.09). Low oxygen saturation was especially associated with provoked VTE (multivariable HR: 1.65, 95% CI 1.12–2.43) whereas the risk estimates for unprovoked VTE were lower (HR: 1.38, 95% CI: 0.83–2.30).
Conclusions: Our findings may imply an inverse association between systemic oxygen saturation and future risk of VTE. It is not known, however, whether the risk of VTE is a direct consequence of low systemic oxygen saturation or is due to unrecognized confounders.

PB 4.69-3
RDW-CV and MPV as a risk indicators for deep venous thrombosis

Pasker-de Jong PCM[1], Hofstraat S[1], Albers-Akkers M[2], Van Noord P[1] and Van Kraaij M[3]
[1]Sanquin Research, Nijmegen; [2]Interregional Red Cross (INR) Anticoagulation centres, Nijmegen; [3]Sanquin Blood Supply, Nijmegen, The Netherlands

Background: Inflammation has been related to venous thromboembolism, but it is unknown whether MPV and RDW are associated with venous thrombosis risk.
Aims: To study the association of MPV and RDW as indicators of inflammation with venous thromboembolism
Methods: We included 1915 healthy new donors and 150 new VTE patients who visited the blood bank or anticoagulation centre in Nijmegen or Arnhem, the Netherlands, between september 2011 and february 2012. Blood samples were taken at the first visit, and then after 1 month, 3 months and 6 months if still under treatment for patients, whereas donors were sampled at each visit, varying over time. Donors were participants in the ZINC study. All blood samples were analysed with an automated cell counter at the quality control lab of the blood bank in Nijmegen. Patient and donor characteristics were collected from the files at entry.
Results: More patients than donors were male, and patients were 30 years older. At the first visit, MPV was somewhat lower in patients than in controls, and increased over time. Red cell diameter width was statistically significantly higher in patients than in controls, and remained higher. Further results will be presented at the ISTH.
Summary/Conclusion: MPV was not associated with venous thromboembolism in our study, whereas RDW was. One explanation may be that the MPV had changed prior to inclusion in our study due to the thromboembolic even tor its treatment. RDW remained high in patients with thromboembolism. The fact that we included patients on average 6 days after their thromboembolic event and first treatment may have resulted in these findings.

PB 4.69-4
Clinical presentation of isolated distal deep vein thrombosis differs significantly from proximal disease states

Horner D[1], Hogg K[2], Body R[1], Nash MJ[1] and Mackway-Jones K[1]
[1]Central Manchester University Hospitals NHS Foundation Trust, Manchester, UK; [2]The Ottawa Hospital, Ottawa, Canada

Background: There is ongoing lack of consensus on the management of isolated distal deep vein thrombosis (IDDVT). While some clinicians treat as they would for proximal disease, other experts manage the condition as a distinct entity. Limited comparative literature exists on risk profile and presenting clinical features in direct support of this assertion.
Aims: We sought to determine the clinical and aetiological presentation of IDDVT and compare it to that of proximal disease.
Methods: An observational, ambulatory prospective cohort study. Consecutive patients attending an established outpatient thrombosis service during the year 2011 were included. Historical, aetiological and clinical data were collected routinely by attending physicians on a

standardized proforma during the initial clinical encounter. This data was anonymised and stratified by outcome at vascular ultrasound. Descriptive and regression analyses were performed to identify and quantify predictors of distal vs. proximal thrombotic disease.

Results: 1888 patients attended the service with suspected deep vein thrombosis, with a retrospective pre-test probability of 8.3% for acute thrombotic disease. Distribution of acute disease was shared evenly between distal (78 cases [49.7%]) and proximal (79 cases [50.3%]) thrombi.

Distal cases were significantly more likely to be provoked ($P = 0.025$), right sided ($P = 0.039$) and to present with localised pain ($P = 0.003$). Distal cases were less likely to present with entire leg swelling or calf swelling >3 cm (both $P < 0.01$). Laboratory markers of clot burden and inflammation were all significantly reduced in the IDDVT group compared to proximal cases.

Conclusions: Patients with IDDVT are significantly different to those with proximal disease, regarding clinical presentation and risk profile. Our results concur with previous evidence supporting the idea of IDDVT as a distinct disease entity. Diagnostic algorithms which place clinical importance on accurate diagnosis of IDDVT could potentially use these findings to guide investigative strategy and influence therapeutic management.

PB 4.69-5

Pulsed methylprednisolone therapy markedly increases thrombin generation potential in a rabbit experiment

Ashikaga T[1], Yamashita A[2], Muto S[1], Nagae C[1], Akita M[1], Suzuki N[1], Yamazaki S[1], Takayama S[3] and Taki M[2]

[1]St.Marianna University School of Medicine, Kawasaki; [2]St. Marianna University School of Medicine, Yokohama city Seibu Hospital, Yokohama; [3]Daito Bunka University, Tokyo, Japan

Background: We use pulsed methylprednisolone (m-PSL) therapy for various diseases, including intravenous immunoglobulin therapy-resistant Kawasaki disease, encephalopathy and immune thrombocytopenic purpura. Heparin is often administered along with pulsed m-PSL therapy for thrombosis prevention. However, the effects of steroids on blood coagulability and the underlying mechanisms remain to be clarified.

Aims: To clarify the effects of steroids on blood coagulability, we measured thrombogenicity using the thrombin generation test (TGT) before and after pulsed m-PSL injections in rabbits.

Methods: First, we injected m-PSL (30 mg/kg/day, 3 days) into the ear veins of rabbits (Japanese white species, male). The dose of m-PSL was determined according to the treatment protocol for humans. As the control, we injected rabbits with PSS (physiologic saline solution). We examined the parameters of TGT, prothrombin time (PT), activated partial thromboplastin time (APTT), fibrinogen, antithrombin, soluble fibrin (SF), D-dimer, factor VII activity (FVII:C), factor VIII activity (FVIII:C), factor IX activity (FIX:C), and factor XI activity (FXI:C), before and after the injection. Next, we investigated the effects of adding m-PSL or recombinant activated factor VII preparation (rFVIIa) on the thrombin generation potential of rabbit plasma *in vitro*.

Results: Among the TGT parameters, the lag time was shortened (0.8 ± 0.11 times) and the endogenous thrombin potential (ETP) (1.31 ± 0.31 times) and peak (1.91 ± 0.69 times) were increased in the pulsed m-PSL group ($N = 29$) as compared to the control group ($N = 12$), indicating a marked increase in thrombin generation potential. Plasma FVII:C was increased (1.68 ± 0.47 times) in the pulsed m-PSL group. The increased thrombin generation potential could be reproduced *in vitro* by the addition of rFVIIa preparation, but not by adding m-PSL. Neither SF nor D-dimer levels were increased after pulsed m-PSL administration.

Conclusion: In conclusion, our results suggest that administering m-PSL pulsed therapy to rabbits increases FVII:C and markedly increases thrombin generation potential. However, neither SF nor D-dimer levels were increased, indicating that thrombosis was not induced by pulsed steroid therapy alone. Therefore, we propose that administration of an anticoagulant during steroid pulse therapy may be clinically appropriate when thrombotic risk factors are associated with the underlying disease.

PB 4.69-6

Incidence of venous thromboembolism (VTE) after major surgeries and proposal of evidence-based Korean guidelines for the prevention of VTE

Bang S-M[1], Jang MJ[2], Kim KH[3], Yhim HY[4], Kim YK[5], Bae SH[6], Kim SH[7], Mun YC[8], Kim I[9], Jung CW[10], Choi N-K[11] and Oh D[2]

[1]Seoul National University Bundang Hospital, Seongnam-si; [2]CHA University School of Medicine, Seongnam-si; [3]Soonchunhyang University College of Medicine, Seoul; [4]Chonbuk National University Hospital, Jeonju; [5]Chonnam National University Hospital, Hwasun; [6]Catholic University of Daegu School of Medicine, Daegu; [7]Dong-A University College of Medicine, Pusan; [8]Ewha University College of Medicine, Seoul; [9]Seoul National University Hospital, Seoul; [10]Sungkyunkwan University College of Medicine, Seoul; [11]Medical Research Collaborating Center, Seoul National University Hospital, Seoul, South-Korea

Background: VTE is a well-recognized, public health issue in the world. There are well-known international guidelines for thromboprophylaxis. But those are mostly based on the epidemiologic data of Western population and those are not currently applicable for Korean medical environment.

Aims: This study was performed to evaluate the incidence rate of symptomatic VTE after major operations such as orthopedic and non-orthopedic surgeries for the frequent cancers and benign diseases in Korea.

Methods: We used the database of the Korean Health Insurance Review and Assessment Service which is a unified insurance system covers almost Korean. The post-surgical claims data for recent 5 years from 2007 to 2011 were extracted, searched for major surgeries using both the operation and major diagnosis codes. Total 1,009,694 cases were selected. Finally VTE cases within 5 weeks after operation were sorted out using both diagnosis codes of VTE and prescription codes of heparin or low-molecular-weight heparin. VTE means all VTE including deep vein thrombosis (DVT) and/or pulmonary embolism (PE). VTE other than DVT and PE such as upper extremities or splanchnic vein thrombosis were excluded. Overall incidences of VTE, DVT and PE were 0.71%, 0.44% and 0.45%, respectively. Each surgery was grouped as moderate, low and very low risk of VTE according to VTE incidence. Total knee or hip replacement, hip fracture surgery, operations for colorectal, pancreas, ovary or esophageal cancer belonged to high risk and recommended for the use of LMWH, UH or mechanical prophylaxis. Surgeries for stomach, hepatobiliary, cervix, lung or brain tumor were at low risk and needed mechanical prophylaxis. Surgeries for breast, kidney, bladder, prostate cancer, and benign diseases had a very low risk of VTE and need early ambulation only.

Conclusion: Based on these results, we propose the second Korean guidelines for the prevention of VTE after surgery.

PB 4.70-1

The risk of venous thrombosis after a symptomatic arterial event in an older population

Casais P[1], Engbers MJ[2], Cushman M[3], Cannegieter SC[2], Rosendaal FR[2] and Van Hylckama Vlieg A[2]

[1]Institute of Epidemiological Research, Buenos Aires, Argentina; [2]Leiden University Medical Center, Leiden, The Netherlands; [3]University of Vermont, Colchester, USA

Background: Age increases the risk of venous thrombosis (VT) and arterial thrombosis; several studies have shown that a prior arterial thrombosis increases the risk of subsequent VT. Whether this is the case in an older population is not known.

Aims: To determine whether an association is present between a history of a symptomatic cardiovascular event and the risk of VT in an older population.

Methods: These analyses were performed in the AT-AGE study (Age and Thrombosis Acquired and Genetic risk factors in the Elderly). The AT AGE study is a population based two-center case-control study that included 406 patients with a first deep venous thrombosis of the leg or a pulmonary embolism in Leiden, The Netherlands and Vermont, US. The study was approved by the Medical Ethical Committees of the Leiden University Medical Center and of the University of Vermont, USA, respectively. All participants signed the informed written consent. Control subjects aged 70 years and older were recruited from general practitioners (n = 433). Individuals with active malignant disease were excluded. Information on a history of arterial disease was obtained from an interview at home. Arterial events were defined as cardiovascular events, i.e., a history of angina, myocardial infarction, heart bypass surgery, and cerebrovascular events, i.e., a history of stroke or transient ischemic attack. We evaluated the risk of thrombosis associated with a history of an arterial event. For cases, time between the most recent arterial event and the occurrence of venous thrombosis was calculated, and for control subjects the time between the most recent arterial event and the index date. The risk of VT after a symptomatic arterial event was calculated for different time intervals (time since arterial event: <1 year, 1–5 years, and >5 years). Odds ratios (OR) and 95% confidence intervals (95% CI) were assessed using logistic regression analysis, after adjustment for age, sex, body mass index (BMI continuous) and study site (Leiden vs. Vermont).

Results: Among 404 cases (age 78.7 ± 5.6 years, range 70.0–100.9) and 431 control subjects (age 77.5 ± 5.4 years, range 70.3–96.3), a positive history was reported by 138/404 (34.2%) cases and 133/431 (30.9%) control subjects (OR 1.1, 95% CI 0.8–1.5). The year of occurrence of the arterial event was available in 125 cases and in 123 control subjects. Median time since last arterial disease was 6 years (range 0–58 years) for the cases and 8 years (range 0–36 years) for the control subjects. Of the cases 18 (6.3%) and 13 (4.2%) control subjects had an arterial event in the year prior to the index date (OR 1.3, 95% CI 0.6–2.8). No increased risk of thrombosis was found either for the time intervals of 1–5 years (OR 0.9, 95% CI 0.6–1.5) and >5 years (OR 1.2, 95% CI 0.8–1.8) prior to the VT.

Conclusion: Overall, we observed no association between a history of arterial disease and risk of venous thrombosis in this elderly population.

PB 4.70-2

Risk of atherothrombotic events in patients after deep vein thrombosis

Pasha SM, Tan M, Van Rees Vellinga TFD, Klok FA and Huisman MV

LUMC, Leiden, The Netherlands

Background & Aims: Several studies have shown elevated incidences of atherothrombotic events (ATE) in patients with unprovoked venous thromboembolic events (VTE). This association remains understudied in patients with isolated deep vein thrombosis (DVT). We evaluated the incidence of ATE in patients with DVT and compared it to patients with provoked DVT and controls without DVT.

Methods: Patients with compression ultrasonography (CUS) proven unprovoked DVT, provoked DVT, and symptomatic patients, in whom DVT was excluded by CUS, were followed and scored for the occurrence of ATE.

Results: 170 patients with provoked, 74 patients with unprovoked DVT and 991 patients without DVT were included. During follow-up 128 ATE occurred (incidence 6.5/100 patient-years). Adjusted hazard ratio (HR) was not different between patients with DVT and without DVT (1.4; 95% CI 0.76–2.4). In contrast, patients with unprovoked DVT suffered ATE more frequent than provoked DVT patients (3.16; 95% CI 1.1–9.1) and control patients (HR 2.8; 95% CI 1.3–5.7). Notably, when fully adjusted for known ATE risk factors the risk differences between controls, provoked and unprovoked DVT patients diminished: HR 1.1 (95% CI 0.47–2.5) and 1.7 (95% CI 0.80–3.6) respectively.

Conclusion: Our study showed that risk of ATE in patients with unprovoked DVT was higher than in patients with provoked DVT or control patients. Interestingly, after full adjustment for multiple known risk factors, the significant difference between unprovoked DVT patients and provoked DVT patients or control patients diminished. This implicates that the correlation between ATE and DVT is non-causal and the measured cardiovascular risk factors are confounders in this correlation.

PB 4.70-3

An age-related prospective cohort study in patients with retinal vein occlusion: risk factors, antithrombotic treatment and outcome

Sartori MT[1], Barbar S[1], Donà A[1], Piermarocchi S[2], Pilotto E[2], Saggiorato G[1] and Prandoni P[1]

[1]2nd Chair of Internal Medicine; [2]Ophthalmology Unit, Padua, Italy

Background: Cardiovascular (CV) risk factors and thrombophilic states are involved in the onset of retinal vein occlusion (RVO), but their role in relation to patient's age is debated. Treatment with antithrombotic drugs is controversial, although RVO has been surmised as a predictor of a subsequent vascular event.

Aims: To evaluate risk factors, the effects of antithrombotic therapy and the occurrence of vascular events after a first episode of RVO, according to patient's age at RVO onset.

Methods: Patients with central or branch RVO confirmed by fluorescein angiography were enrolled in this prospective cohort study after obtaining informed consent according to Helsinki Declaration. Common CV risk factors (hypertension, diabetes, hyperlipemia, obesity, smoking), congenital and acquired thrombophilia were evaluated. Patients received anticoagulants (LMWH and warfarin) or aspirin for at least 3 months and they were followed every 6–12 months. Vascular events after RVO were recorded.

Results: One-hundred patients with central RVO and 32 with branch RVO were enrolled. Five (8.3%) patients younger than 50 years and 4 (5.5%) over 50 years had a hereditary thrombophilic defect, and the difference was not significant. Antiphospholipid antibodies, hype-

rhomocysteinemia, or PAI-1 increase were present in 29% of patients with no age-related differences. One or more CV risk factors were found in 35 (58%) patients of the younger group, and in 66 (91%) of the older group ($P < 0.001$). Antithrombotic treatment lead to both a satisfactory recanalization of occluded veins and visual acuity improvement especially in younger patients. Vascular events occurred in 19 (14%) cases after 4 ± 3.3 years from RVO; they were more frequent in older than in younger patients (22% vs. 5%, P 0.005).
Conclusion: Distribution of CV, but not of other prothrombotic risk factors, seems to be influenced by age in RVO patients. Patients with a first episode of RVO, especially those older than 50 years, are likely at risk of a subsequent vascular event.

PB 4.70-4
Association of perioperative inflammation and coagulation status with delayed VTE after major surgery

Cheng S[1], Baird C[1], Luzier E[1], Nordenholz KN[1], Matero D[1], McCarter M[1], Pearlman N[1], Gajdos C[1], Tran ZV[2] and Wischmeyer P[1]
[1]University of Colorado School of Medicine, Aurora; [2]Colorado School of Public Health, Aurora, CO, USA

Background: Patients presenting for major abdominal surgery are at increased risk of subsequent venous thromboembolism (VTE). Inflammation and hypercoagulable state are both implicated in the pathogenesis of VTE. It is unclear if perioperative inflammatory biomarkers and viscoelastic coagulation testing are predictive of future VTE.
Aims: We conducted a posthoc analysis of a study on major abdominal surgery patients to assess if the severity of perioperative inflammation and hypercoagulable state on viscoelastic coagulation testing was correlated with VTE at 6 months after surgery.
Methods: This study was conducted with full IRB approval. Patients were randomized to 1 of 2 heparin regimens for postoperative VTE prophylaxis while in the hospital (subcutaneous heparin or low-dose heparin infusion). Blood samples were drawn in the OR prior to incision, and then daily for 5 days. Patients were followed for 6 months for symptomatic VTE (any pulmonary embolism + symptomatic DVT).
Results: 110 patients were randomized. Follow-up was completed in 100% of patients. 18 patients had symptomatic VTE at 6 months. In bivariate analysis of the intention-to-treat population, age, gender, ICU length of stay, smoking status, in-hospital VTE prophylaxis regimen, and BMI had no association with 6 month VTE. Peak IL-6, IL-8, IL-10, and TNF-a levels also showed no correlation with 6 month VTE. The Sonoclot clot rate on day 5 showed a trend towards elevation in patients subsequently diagnosed with subsequent 6 month VTE (40.4 ± 15.1 U/min in patients with VTE vs. 31.9 ± 16.4 U/min in patients without VTE, $P = 0.07$), although this difference did not reach significance. Within the group randomized to low-dose heparin infusion, this difference became significant (48.4 ± 11.8 U/min in patients with VTE vs. 29.9 ± 17.4 U/min in patients without VTE, $P = 0.01$).
Conclusions: In this small study, clinical variables and inflammatory cytokines levels showed no association with delayed postoperative VTE after major abdominal surgery. However, the Sonoclot clot rate, a measure of activated fibrin polymerization, showed a trend towards elevation on the 5th day after surgery in patients who eventually developed symptomatic VTE within 6 months. Further prospective study of the Sonoclot and other viscoelastic coagulation tests for the identification of surgical patients at high risk of VTE after hospital discharge is necessary.

PB 4.70-5
Root cause analysis of hospital-acquired venous thromboembolism: a quality improvement initiative

Diamantouros A, Valenzuela V, Varma G, Brown P and Geerts WH
Sunnybrook HSC, Toronto, Canada

Background: Hospital-acquired venous thromboembolism (HA-VTE) is a serious but largely preventable complication of hospitalization that can result in significant morbidity, mortality and expenditure of resources. A hospital-wide initiative involving guidelines, order sets, education, and audits and feedback has been in place for over 5 years to improve the use of appropriate thromboprophylaxis at a university hospital. Despite these efforts, monthly audits demonstrate that an average of 13% of inpatients do not receive appropriate thromboprophylaxis. In an effort to further improve quality of care, an additional initiative was implemented to identify cases of HA-VTE, conduct a root cause analysis (RCA) for each to identify causative and contributing factors, and provide feedback to the healthcare team involved in the specific patient's care. HA-VTE was defined as symptomatic and occurring in hospital or within 2 months of discharge.
Aims: To improve the quality of patient care with respect to prevention of VTE through the identification of cases of HA-VTE, conduction of RCA and feedback to the healthcare team.
Methods: Cases of symptomatic, objectively-confirmed deep vein thrombosis (DVT) and/or pulmonary embolism (PE) that occurred more than two calendar days after admission and up to 2 months after hospital discharge were identified through the ultrasound imaging department. All cases with HA-VTE were reviewed and classified as potentially prevention HA-VTE (PPHA-VTE) or unpreventable HA-VTE based on hospital thromboprophylaxis policy. For patients with PPHA-VTE, written feedback was provided to the healthcare team and data was entered into an ongoing database to determine both temporal and patient group trends.
Results: In 2012, 73 cases of HA-VTE (average of 1.4 per month) were identified. There were 32 cases (44%) of DVT and 41 cases (56%) of PE. 51 (70%) of the cases were diagnosed during admission and 22 (30%) following discharge. No fatal PEs were identified. RCA of the cases revealed that thromboprophylaxis had been prescribed according to hospital policy in 71%. Approximately half of the cases in which 'appropriate' prophylaxis had been provided were seen in general surgery, gynecologic oncology and trauma patients. 7(22%) of the cases of DVT and 14 (34%) of the cases of PE were determined to be potentially preventable. Approximately half of these cases were seen in general or orthopedic surgery patients. The reasons for which cases were deemed potentially preventable included: no prophylaxis given (19%), inappropriate delay in initiation (43%), incorrect dose of thromboprophylaxis (29%), and inadequate duration (10%). At this stage of data collection and review, there is insufficient evidence of trends to suggest a change in thromboprophylaxis policy.
Summary/Conclusion: This feasible methodology provides insight into the burden of HA-VTE not seen with other strategies. Over the year, among the 73 clinically-important HA-VTE events, 29% were associated with suboptimal thromboprophylaxis. Feedback to the healthcare teams responsible for the care of these patients has led to discussions and strategies for further quality improvement. Ongoing data collection will help guide modifications to our hospital-wide thromboprophylaxis policy and suggest more targeted quality improvement strategies to ensure optimal patient care.

PB 4.70-6

Splanchnic vein thrombosis in Siriraj hospital: etiology and outcome

Chinthammitr Y, Wateperm C and Chanwanichkulchai R
Siriraj Hospital, Bangkok, Thailand

Background: Splanchnic vein is composed of portal, splenic, hepatic, and mesenteric veins. Splanchnic vein thrombosis (SVT), an uncommon condition, has multiple etiologies such as malignancy, some hematologic condition, intraabdominal infection with variable outcome.
Aims: To evaluate etiology of splanchnic vein thrombosis and mortality rate at 1 year.
Methods: Patients with a diagnosis of SVT based on ICD-10 code since January 2008 to December 2009 were included. We performed retrospective chart review for etiologies, clinical manifestation, laboratory results, treatment and outcome of SVT.
Results: The study included 147 patients (91 men) with a median age of 56 years (range 18–90). The sites of SVT included portal vein (89.8%), mesenteric vein (18.4%), splenic vein (12.9%), and hepatic vein (4.1%) whereas 27.9% had multiple vessel thrombosis. Most common etiology was malignancy (68.0%, such as hepatocellular carcinoma [54.4%] and cholangiocarcinoma [8.2%]) followed by cirrhosis (52.4%), local factor (7.5%, such as hepatobiliary infection [5.4%]) and myeloproliferative disorder (2.7%). The most common clinical manifestation was abdominal pain (55.7%) followed by ascites (23.8%), hepatomegaly (23.8%) and weight loss (21.7%). All-cause 1-year mortality rate was 56.5%. Multivariate analysis found that malignancy was significantly associated with 1-year mortality rate (81.2% vs. 10.2%; adjusted HR 13.5, 95% CI 5.2–35.0, $P < 0.001$). Preferred management in malignancy associated SVT was conservative treatment (70.7%). Some patients (19.7%) were treated by anticoagulant mostly in non-malignant cause and they had bleeding complication rate of 13.8%. Among 54 patients who had repeated imaging within 1 year, 37% showed improvement of thrombosis.
Conclusion: Most common etiology of splanchnic vein thrombosis was hepatocellular carcinoma. One-year mortality rate of splanchnic vein thrombosis was 56.5%. Malignancy related SVT had a higher mortality rate than non-malignancy related SVT significantly.

PB4.71 – Paediatric Thrombosis – V

PB 4.71-1

Thromboembolic events emerging during the treatment of childhood acute lymphoblastic leukemia

Aydogan G, Sayilan Sen H, Tugcu D, Akcay A, Aktay Ayaz N, Akici F, Salcioglu Z, Demirkaya M and Gokce M
Kanuni Sultan Suleyman Research and Education Hospital, Istanbul, Turkey

Background: Thromboembolic events are serious complications of childhood acute lymphoblastic leukemia (ALL) therapy, that may result in significant morbidity and occasionally mortality. The rate of thrombosis in 1752 children with ALL from 17 prospective studies was 5.2%. In these studies, the relationship between thromboembolic events and treatment with steroids and L-asparaginase were reported.
Aim: The aim of this study is the evaluation of the prothrombotic risk factors in children with ALL under modified BFM protocol.
Patients and Methods: Three hundred and thirty children with newly diagnosed ALL were recruited in observational cohort study conducted between January 2004 and May 2012. Patients with ALL were searched for any accompanying prothrombotic risk factors. All symptomatic thromboembolic events diagnosed were recorded.
Results: Nine patients of the overall 330 (2.7%) had thrombosis, of them 66.7% had venous thrombosis, and 33.3% had arterial thrombosis. Deep venous thrombosis of the lower extremity was present in one case. Other eight patients had cerebral thrombosis (three arterial and five venous). All the cerebral thrombosis had developed at the induction phase of the therapy. Prothrombotic risk factors were detected in 6 (66.7%) patients (2 had protein S, 1 had protein C, 2 had homozygous, 1 had heterozygous Factor V Leiden deficiency. One patient had prothrombin 20210A mutation). One of the patients with arterial cerebral thrombosis had died. The rate of death due to thrombosis in children with ALL was found as 0.3%.
Conclusions: Thrombosis in children with ALL is an important complication with high morbidity and mortality. As the patients that we follow, when the rate of central venous catheter use has declined, the rate of thrombosis also decrease and then cerebral thromboembolic events become significant relatively. Patients with the prothrombotic risk factors should be followed- up carefully for the possible emergence of cerebral thrombosis and strategies of antithrombotic prophylaxis should be investigated in this setting.

PB 4.71-2

Does management of warfarin by patients with home INR testing improve health related quality of life in children/families

Bruce AK, Massicotte P and Bauman M
University of Alberta, Canada, Canada

Background: Health Related Quality of Life (HRQOL) refers to how an individual's wellbeing may be affected by health and therapeutic management strategies. HRQOL is essential to develop appropriate therapeutic choices, generate research strategies, and adjust policies for improvement of healthcare adherence and outcomes. HRQOL is the 'gold-standard' measurement for patient relevant outcomes. Management of warfarin by patients (MWP) with home INR monitors (i.e. families make their own dose adjustments based on guidelines) has demonstrated that families make suitable dosing adjustments, and have improved control as illustrated by time in therapeutic range. The child and family may also have greater investment in their care with increased responsibility to adhere to therapeutic guidelines. The effect of MWP on HRQOL as a contributing factor to adherence must be determined.
Aims: To determine whether HRQOL improves with the long term implementation of MWP.
Methods: The warfarin KIDCLOT PAC QL© was administered to families on self-management over the period of years; baseline, 1, 3 and 5 years after the initiation of MWP. Each patient and parent was compared to themselves over the years. Focus groups were held during group anticoagulation clinics to ensure patients had opportunity to express their values, perceptions, concerns, and preferences. Three separate focus groups were held: MWP, adolescent MWP, and patient whose warfarin was dose adjusted by healthcare providers. Two staff members/group. Responses were coded to identify themes by two independent researchers.
Results: The mean impact on HRQOL was 29% pre, 33% at 1 year and 28% at 2 years on MWP for parents. The mean impact on HRQOL was 30% pre, 25.7% at 1 year, and 23.5% for children/teens. Focus groups revealed although caregivers felt anxiety about the increased responsibility ('makes me nervous because I feel more responsible') in managing their child's warfarin, a strong preference for MWP existed, as reflected in comments 'makes you more knowledgeable', 'increased flexibility', and a 'greater degree of independence'. Teens indicated that they had 'better awareness' and were 'more independent'. One family decided to leave MWP due to anxiety but then returned to MWP practice after a few months. Five year data is pending as group anticoagulation clinics are held in spring due to access to healthcare in a northern environment.
Conclusions: MWP provides the child/family more investment in managing their health condition as indicated by focus group themes. The KIDCLOT PAC QL © parent proxy inventory measured an increased impact of warfarin on HRQOL in the first year of MWP then a return

to baseline. Focus groups revealed that the patents felt the responsibility of MWP suggesting caregivers have improved awareness and knowledge of the impact of warfarin on their lives. There was a strong preference for MWP secondary to increased understanding, independence, and confidence documented in the focus groups. Finally, MWP nurtures awareness and autonomy in teens. Increased duration of MWP may result in decreased stress, anxiety and increased HRQOL through continued patient/family knowledge acquisition with the support of the health team.

PB 4.71-3

Postthrombotic syndrome in children with limb venous thromboembolic events

Pergantou H[1], Xafaki P[2], Avgeri M[2], Komitopoulou A[2], Adamtziki E[2], Kapsimali Z[2], Mazarakis M[2] and Platokouki H[1]
[1]*Haemophilia Centre/Haemostasis Unit, Aghia Sophia Children's Hospital;* [2]*Haemophilia Centre/Haemostasis Unit, Aghia Sophia Children's Hospital, Athens, Greece*

Background: Postthrombotic syndrome (PTS) is a chronic complication of deep vein thrombosis (DVT), increasingly recognized in children during the last decade. PTS may affect patient's quality of life for many years, due to its devastating sequelae.
Aim: To evaluate the incidence, clinical characteristics, management, and potential predictive factors for PTS in children with a history of DVT.
Patients and Methods: Data of children with DVT in upper and lower extremities, referred to our Unit from January 2000 to January 2012, were retrospectively analyzed. Children suffered malignancies and followed at oncology departments of our hospital were excluded from the analysis, because of incomplete data. For evaluation of severity of PTS the modified Vilalta scoring system was applied.
Results: Thirty children (60% males) were diagnosed with DVT at a median age of 5.5 years. The median follow-up period was 6 years (2–13 years). DVT was present in upper extremities in only three patients, while the rest (90%) suffered a lower extremity DVT with extension to inferior vena cava in 9 (33.3%) and concomitant pulmonary embolism in 3 (11%) patients. Positive family history of DVT or thrombophilia was reported in six cases. PTS was developed in nine patients (30%) −5/9 were boys. Moreover, one additional patient endured amputation of both his limbs due to extensive necrosis. PTS, occurred after a median period of 3 months (1–12 months) following DVT, was initially graded mild in six children and moderate in 3. In comparison to upper extremity DVT, lower extremity thrombotic event was associated with development of PTS ($P < 0.005$). Highly elevated D-dimers were present in all nine PTS cases at DVT diagnosis. Extensive occlusion ($n = 9$), presence of thrombophilic factors -especially a natural inhibitor deficiency ($n = 4$) – and recurrence of DVT ($n = 4$) were associated with development of PTS. All PTS patients had been treated upon DVT diagnosis with anticoagulants for a median period of 24 months (3–60 months), while graduated elastic compression stockings were applied in 8/9 for 1–4 years, soon after PTS development. Appropriate diet was initiated in one obese female adolescent for achieving the optimal body weight. During a median observational period of 5 years (1.5–10 years), the outcome of PTS was: complete recovery in one boy with moderate PTS, improvement from moderate to mild in one boy with initially diagnosed moderate PTS, while PTS grade was defined as unchanged in all six patients with mild and in one with moderate PTS. The better than expected outcomes in all cases may be attributed to early therapeutic interventions.
Conclusion: Given the chronic debilitation following PTS of lower limb in children, it is crucial that future larger prospective multi-centre studies be organized, with the aim to provide better understanding of pathophysiology, risk factors and possible preventive tools for paediatric PTS, in order to improve the long- term quality of life of young patients.

PB 4.71-4

Epidemiology of thrombosis in children with cancer

Piovesan D[1], Attard C[2], Monagle P[1] and Ignjatovic V[2]
[1]*The University of Melbourne;* [2]*Murdoch Childrens Research Institute, Parkville, Australia*

Background: A large amount of research has focused on the epidemiology of thrombosis in adult cancer populations however little has been done in paediatric populations. Many studies examining children with cancer, particularly ALL have identified factors that increase the risk of thromboembolism (TE) including chemotherapy, central venous lines (CVL's), prothrombotic defects, age and surgery. However, there are no clear guidelines for identification of high-risk groups, prophylaxis or management of TE complications in paediatric cancer patients.
Aims: To review the literature regarding the epidemiology, mechanisms, risk factors, prophylaxis and outcomes of thrombosis in children with cancer and to identify areas where more research is needed.
Methods: The PubMed database was searched from 1.01.1990 to 21.12. 2012 using the search terms: cancer, children, epidemiology, paediatric, thrombosis, and thromboembolism.
Results: The incidence of symptomatic VTE in children with cancer is 2.1–7.9%, 30% of which are associated with CVL's. The incidence of asymptomatic VTE is ~40%. The most common location of VTE is CNS representing ~50% of TE events. DVT, particularly upper extremity DVT is common and has been strongly associated with CVL's. Lower extremity DVT, also commonly reported, is associated with prolonged duration of immobilisation in hospitalised patients. The incidence of PE accounts for 20% of VTE events and arterial thrombosis is quite rare at ~3.6%.
Key characteristics that increase the risk of thrombosis in paediatric cancer patients include the cancer type (ALL, AML, lymphoma and sarcoma), age (older patients and neonates), the presence of a CVL, presence of pulmonary/intra thoracic disease, chemotherapy (concomitant treatment of L-asparaginase and corticosteroids particularly during induction therapy, as well as growth factor agents) and prothrombotic defects (FV Leiden mutation, prothrombin G20210A and MTHR variant, particularly children with haematological malignancies).
Outcomes for paediatric cancer patients who have suffered from TE vary but include post-thrombotic syndrome, PE, recurrent TE, destruction of upper venous system and death.
Recent studies suggest that higher D-dimer levels, platelet count and activity allow better prediction of a child's hypercoagulable state and therefore their risk of TE.
Conclusion: The factors involved in aetiology of thrombosis in children with cancer are many and complex. Focused studies aimed at enabling accurate risk stratification are required to allow recommendations for thromboprophylaxis to be developed.

PB 4.71-5

Quality of life of children participating to a formalized INR self-monitoring vitamin K antagonist educational program

Amedro P[1], Bajolle F[2], Cheurfi R[2], Nogue E[1], Lasne D[2], Picot M-Ch[1], Dorka R[1] and Bonnet D[2]
[1]*University hospital, Montpellier;* [2]*Necker hospital, Assistance Publique Hopitaux de Paris (AP-HP), Paris, France*

Background: Children under vitamin K antagonist (VKA) should benefit from a formalized educational program using self-monitoring of their International Normalized Ratio (INR). In France, since the 2008 Public Health Law, children and/or their family who wish to participate to INR self-monitoring must integrate a formalized authorized educational program to anticoagulation therapy led by a paediatric cardiologist.

Aim: Our national reference centre for congenital heart diseases, while building this program, aimed to regularly evaluate the quality of life (QoL) of children.
Methods: All children and parents participating to our INR self-monitoring VKA educational program were invited to complete a QoL questionnaire during each group session. Generic pediatric QoL questionnaires were used (QUALIN for infants <2 years old, PedsQL for children aged 2–18). Both parents independently participated. PedsQL Child self-report QoL questionnaires were used for children above 5 years, under trained nurse supervising. Each family participated to 1–3 educational sessions. This study received the approval of the Ethics Committee. Relations between QoL and patients' characteristics were studied. Patient's clinical instability during the program and duration of life with chronic illness were analyzed as biases which both classically influence QoL assessment.
Results: 111 children (54 girls, 57 boys) participated to our INR self-monitoring program between 2010 and 2012. Indications for VKA were classical within paediatric population: valve replacement (n = 47), total cavo-pulmonary connexion (n = 33), dilated cardiomyopathy (n = 13), Kawasaki disease (n = 8), others (n = 10). No family refused to be enrolled in this study. 476 QoL questionnaires (27 QUALIN, 449 PedsQL) were completed by 265 different persons (80 children, 107 mothers, 78 fathers), depending on the number of group sessions for each family. There were no significant relationships between QoL and patient's sex, type of AVK (warfarin or fluindione), number of group sessions, chronic illness duration or moment of diagnosis (prenatal or postnatal). Qol scores were significantly lower among children with congenital heart disease (n = 80). Fathers and mothers' QoL scoring are rather well correlated but are significantly lower than their child's self- assessment. There are almost no differences of QoL between children under transient VKA treatment (n = 37) and those treated for life (n = 74).
Conclusion: Routine QoL assessment well applies to educational programs with strong joining of families and children. As all patients included in this study are in self-monitoring, we could not evaluate the impact of self-monitoring on patients' QoL. However our results show that classical morbidity factors, which are mostly relevant for doctors, are not always correlated to QoL, which is mostly relevant for patients. We are now finalizing to collect data from a matched population to compare QoL of children under VKA to controls. Our centre leads five official education programs (pulmonary hypertension, anticoagulation, transition to adulthood, pacemaker-Defibrillator and chronic cardiac failure) and aims in further studies to compare QoL of children participating to such programs to those who don't.

PB 4.71-6
Portal vein thrombosis in children and adolescents

Williams S, Fayea N, Al Hinai K, Brandao LR and Labarque V
Hospital for Sick Children, Toronto, Canada

Background: Portal vein thrombosis (PVT) is an important cause of portal hypertension (PH) in children. Complications include upper gastrointestinal bleeding from the rupture of esophageal varices, hypersplenism secondary to splenomegaly, growth retardation, and portal biliopathy. Management may include portosystemic shunting. Unlike neonatal portal vein thrombosis which has low reported rates of portal hypertension of <5%, while gastrointestinal bleeding occurs in up to 80% of children with PVT.
Aims: The aim was to describe the presentation, treatment, and outcomes of an unselected cohort of children presenting with portal vein thrombosis, to determine if the outcome differed with age of presentation.
Methods: The study was approved by the hospital research ethics board and written consent waived. A retrospective chart review of infants and children with PVT presenting to the Hospital for Sick Children from January 2008 to January 2012, identified from the clinical thrombosis database was conducted. Neonates were excluded, and age was limited to 31 days to 18 years at time of presentation. Clinical and radiologic data were collected. Descriptive statistics and Fisher exact testing were completed to compare the two groups; infants (age ≤1 year) and children (age. >1 year).
Results: 36 children with PVT were identified. At the time of presentation, 14/36 patients (38%) had underlying liver disease (biliary atresia (n = 6), sclerosing cholangitis (n = 3), metabolic disease (n = 1), chemotherapy induced liver disease (n = 2), hepatic infiltration (n = 2). The majority of PVTs, 19/36 (52%), were identified incidentally, on abdominal ultrasound completed during work up for other medical illness; (fever and sepsis (n = 7), pre- or post- liver transplant (n = 5), elevated liver enzymes (n = 2), pre Kasai (n = 1), abdominal pain (n = 10). Risk factors (intra-abdominal infection, sepsis or abdominal surgery) were present in 25/36 (70%). Infants (n = 20) had a mean age (±SD) of 5 months (±3), children (n = 16) had a mean age of 10 years (±5). Mean follow-up in infants was 24 months (±24) and in children was 36 months (±37). There was a history of a prior umbilical venous catheter in 10/20 (50%) infants and 1/16 (6%) children (P = 0.0091). Cavernous transformation was found on initial imaging in 2/20 (10%) infants and 7/16 (44%) children (P = 0.049). Gastrointestinal bleeding at time of initial presentation was present in 0/20 infants and in 5/16 (31%) children (P = 0.012). There was no difference between infants and children in hypersplenism (19%) gastrointestinal bleeding in follow-up (11%), PH at time of presentation (20%), PH in follow-up (31%), thrombus resolution (58%), need for portosystemic shunting (8%), growth failure (20%) or thrombophilia [low protein C, protein S, antithrombin] (44%). There was no difference in radiologic resolution with anticoagulation (67%) or without anticoagulation (57%).
Conclusions: In this single institution cohort, limited by the small number of patients, rates of portal hypertension and gastrointestinal bleeding were similar in infants and children, but higher than reported rates in neonates. PVT in infants had a greater association with previous umbilical catheter, and presented less often with cavernous transformation or gastrointestinal bleeding than in children.

PB4.72 – Thrombophilia – V

PB 4.72-1
Clinical characteristics of double heterozygous for factor V Leiden and prothrombin mutation. Findings from the RIETE Registry

Gadelha T[1], Jaras Hernández MJ[2], Hirmerova J[3], Santos M[4] and Monreal M[5]
[1]Hospital Universitario Clementino Fraga Filho, UFRJ, Brasil, Rio de Janeiro, Brazil; [2]Hospital de Cantoblanco, Madrid, Spain; [3]University Hospital Plzen, Pizen, Czech Republic; [4]Centro Hospital de Entre o Douro e Vouga, Santa Maria de Feira, Portugal; [5]Hospital Universitari Germnas Trias i Pujol, Barcelona, Spain

Background: Patients with the double heterozygousy (DH) for factor V Leiden (FVL) and prothombin G20210A (PT 20210A) are rare. Consequently, there is scarce information on their clinical characteristics when presenting with a first episode of acute venous thromboembolism (VTE).
Patients and Methods: RIETE is an ongoing registry of consecutive patients with symptomatic, acute VTE. We compared the clinical presentation of double heterozygous patients for FVL and PT 20210A with single heterozygous and with patients with no thrombophilia.
Results: In all, 6057 patients were tested for FVL and PT 20210A. Of these, 724 were heterozygous for FVL, 552 heterozygous for PTG20210A, 88 double heterozygous, and 4693 tested negative. Their median age was 49 ± 18, 51 ± 18, 45 ± 18, and 56 ± 19 years, respectively. About half of the patients (51%, 45%, 50% and 48%, respectively) had idiopathic VTE, with no difference between subgroups. Among women, 36%, 35%, 39% and 23% respectively were

using estrogens; 6.5%, 6.8%, 10% and 3.3% were pregnant; and 3.0%, 4.8%, 7.7%, and 2.1% postpartum. As for the VTE presentation, 35%, 52%, 34% and 51% respectively presented with acute pulmonary embolism (PE). PE patients with FVL or DH less likely presented with tachycardia (17% and 14% vs. 34% and 33%, respectively) or hypoxemia (17% and 14% vs. 34% and 33%, respectively) than those with PT 20210A or no thrombophilia.
Conclusions: Double heterozygous for FVL and PT 20210A have the first VTE earlier than non thrombophilic and single heterozygous patients. Estrogen use is the most frequent associated risk factor, with the same frequency for double or single heterozygous patients. Double heterozygous patients and heterozygous for FVL have a lower frequency of pulmonary emboli and less hypoxemia.

PB 4.72-2
Challenges in the diagnosis of type II antithrombin deficiency with heparin-binding site defects

Heylen O, Orlando C and Jochmans K
UZ Brussel, Brussels, Belgium

Background: Antithrombin (AT) is a potent inactivator of thrombin and the major inhibitor of blood coagulation. Hereditary AT deficiency is a rare autosomal dominant disorder with a predisposition to recurrent venous thrombosis. Two types are distinguished, quantitative (type I) and qualitative (type II) deficiencies. The latter can be subclassified in mutations that affect binding to heparin (Heparin-Binding Site, HBS), the reactive site (Reactive Site, RS) or both (Pleiotropic Effect, PE). When screening for AT deficiency, measurement of AT activity is the test of choice. Current methods quantify AT activity by chromogenic tests measuring the inhibition of thrombin or FXa by AT in the presence of heparin. Patients with HBS defects can show varying activity levels depending on the assay conditions used and may therefore not be detected. Although HBS deficiencies are associated with a milder thrombotic phenotype, if present in homozygous state or associated with other more prevalent thrombophilic risk factors, such as factor V Leiden or G20210A prothrombin mutation, thrombotic risk is markedly increased.
Aims: To study the suitability of several commercial AT activity assays for the identification of HBS variants and to ameliorate detection of these HBS deficiencies by adjusting assay conditions.
Methods: Our study included 29 patient samples with different HBS variants, all confirmed by molecular analysis. We evaluated three anti-Xa based activity tests (HemosIL® Liquid AT, IL; Coamatic® AT, Chromogenix; Innovance® AT, Siemens) on the ACL Top® 500 instrument and one anti-IIa activity test (Biophen® Antithrombin, Hyphen Biomed) on the ACL Elite® Pro analyzer. We also tried to optimize assay conditions for the Coamatic® test by varying sample dilution, incubation time and analyzer.
Results: The sensitivity of the anti-Xa assays for HBS deficiencies was 59%, 76% and 100% for HemosIL® Liquid AT, Coamatic® AT and Innovance® AT, respectively. Two specific mutations are responsible for this high variability between assays, namely the p.Pro41Leu and p.Arg47His mutations. The anti-IIa assay showed a sensitivity of 47% and was only able to detect some of the p.Leu99Pro and p.Arg47Cys variants. The anti-IIa assay yielded higher activity levels when compared to an anti-Xa assay (Coamatic® on ACL Elite® Pro) with an absolute average increase of 25%. Adapting the sample dilution (1/80 instead of 1/100) in the Coamatic® test did not show any improvement in sensitivity. Lower activity values were obtained with this assay by setting a short fixed incubation time (110 s instead of 100–140 s) with a resulting increase in sensitivity of 76% to 86%. The sensitivity further increased to 96% when another analyzer (ACL Elite® Pro instead of ACL Top® 500) was used. This is probably due to differences in reagent constituents' final concentration in the reaction cuvet.
Conclusion: Several commercial assays fail to detect AT deficiency HBS variants, emphasizing the importance of the assay conditions. Some deficiencies, especially the p.Pro41Leu and p.Arg47His mutations, can be missed. Adaptation of assay conditions, namely the incubation time, showed a significant improvement in sensitivity. However, one should be cautious with these adjustments, as they might evoke a decrease in specificity of the assay.

PB 4.72-3
Molecular markers of blood hipercoagulability and values of overall coagulation potential in double heterozygotes for the FV Leiden and FII G20210A mutation

Miljic P[1], Bodrozic J[2], Djordjevic V[3] and Antovic A[4]
[1]Clinic of Haematology, Belgrade; [2]Clinical Center of Serbia, Clinic of Haematology, Belgrade; [3]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia; [4]Karolinska Institutet, Department of Clinical Sciences, Dandryl Hospital, Stockholm, Sweden

Background: Double heterozygosity for the FV Leiden and FII G20210A mutation is relatively rare thrombophilic condition with prevalence in Caucasian population of about 0.1%. This condition is generally considered as strong thrombophilia, and some authors recommend indefinite anticoagulant treatment after first thrombosis in carriers of this mutations. However, published data regarding risk of thrombosis in double heterozygotes are scarce and reported relative risk for first venous thrombosis ranges from 1.4 (Meinardi JR, 2001) up to 20 (Emmerich J, 2001).
Aim: Aim of this study was to investigate concentration of molecular markers of blood hypercoagulability, and values of overall coagulation potential in individuals who are carriers of both FV Leiden and FII G20210A mutation.
Methods: Among 1850 selected patients with thrombosis or pregnancy loss tested in one center between 2003 and 2010 for both FV Leiden and FII 20210A mutations, we identified 28 double heterozygotes, giving prevalence of 1.6%. Concentration of TAT, prothrombin fragment F1 + 2 and D-dimer were measured in plasma of 16 double heterozygotes by ELISA methods. Overall coagulation potential test, which reflects global haemostatic balance, was measured according methods described by He S et al. (Thromb Res 1999;96:145–56). Results of these tests in 16 double heterozygotes were compared with results of the same tests obtained in 133 heterozygous and 12 homozygous carriers of FV Leiden, 38 heterozygous carriers of FIIG20210A, 53 primary antiphospholipid syndrome (APS) patients and 77 healthy control persons. In all symptomatic individuals blood for analysis was drawn at least 3 months after cessation of anticoagulant therapy or termination of last pregnancy.
Results: Mean concentrations of all three investigated markers of blood hypercoagulability: F1 + 2, TAT complex and D-dimer were higher in double heterozygous group than in other investigated groups. Mean levels of investigated markers were as follows: in double heterozygotes- F1 + 2 1.89 ± 0.89; TAT 7.46 ± 4.68; D-dimer 139 ± 169; in FV Leiden heterozygotes- F1 + 2 1.30 ± 0.56; TAT 5.14 ± 2.15; D-dimer 95 ± 126; in FV Leiden homozygotes- F1 + 2 1.23 ± 0.54; TAT 4.83 ± 1.24; D-dimer 77 ± 40; in FII G20210A heterozygotes- F1 + 2 1.5 ± 0.73; TAT 5.65 ± 2.81; D-dimer 90 ± 114; in primary APS- F1 + 2 1.16 ± 0.51; TAT 6.17 ± 3.23; D-dimer 81 ± 116; and in control individuals- F1 + 2 0.94 ± 0.2; TAT 4.57 ± 1.68; D-dimer38 ± 29). Mean overall coagulation potential in investigated groups was as follows: in double heterozygotes-19.4 ± 6.4; in FV Leiden heterozygotes-17.9 ± 3.8; in FV Leiden homozygotes-16.1 ± 2.6 in FII G20210A heterozygotes-17.1 ± 3.5; in primary APS-17.8 ± 4.7; and in control individuals – 14.5 ± 2.7.
Conclusion: Results of our study indicate an increased level of basal activation of coagulation system in symptomatic double heterozygotes for the FV Leiden and FII G2012A mutation which is higher or comparable to patients with FV Leiden, FII G20210A mutation or patients with primary antiphospholipid syndrome. High values of

overall coagulation potential indicate a shift of haemostatic balance toward blood hypercoagulability in double heterozygotes even in basal state, suggesting presence of strong prothrombotic condition.

PB 4.72-4

Role of promoter polymorphisms of Glutathione Peroxidase (GPX3) gene in the development of Deep Vein Thrombosis in Asian Indian population

Saxena R[1], Akhter MS[1], Rashid H[2], Ranjan R[1] and Sharma A[1]
[1]All India Institute of Medical sciences; [2]Indian Council of medical Research, New Delhi, India

Background: Amongst the various known acquired and inherited factors that alter the haemostatic balance, oxidative stress (OS) plays a pivotal role in the development of thrombosis. OS mediates the pathogenesis of venous thrombosis by allowing the reactive oxygen species (ROS) to enhance platelet hyperactivity and depleting nitric oxide (NO). NO is a well known vasorelaxant that has antithrombotic effects which upon depletion may lead to deep vein thrombosis (DVT). An efficient ROS scavenging mechanism comprising of various enzymatic and non enzymatic antioxidants is determining in the prevention of oxidative assault. Plasma Glutathione peroxidase (GPx3) is a major antioxidant enzyme in plasma, scavenging ROS arising during normal metabolism or after oxidative insult. A deficiency of this enzyme increases extracellular oxidant stress, promotes platelet activation, and may promote oxidative posttranslational modification of fibrinogen that leads to DVT.
Aims: To find out the role of promoter *GPX3* polymorphisms in the development of DVT in Asian Indian population.
Methods: Patients were recruited from outpatient clinics and wards of the Department of Haematology at the All India Institute of Medical Sciences, New Delhi, India. We studied 100 consecutive DVT patients (M:F = 67:33, age range = 18–65 years) confirmed by Doppler ultrasonography, computerized tomography (CT) scan (for cerebral venous thrombosis). Patients with pulmonary embolism, malignancy, pregnancy and diabetes were excluded from the study. Non-related sex and age (+5 years) matched healthy individuals (n = 100) of north Indian origin were also included in the study in order to determine risk posed by the polymorphisms. Most cases (73) were of lower limb thrombosis, and 15 cases were of upper limb thrombosis. Thrombosis at unusual sites was present in 12 cases, these included cerebral (5), abdominal (4), subclavian (1), renal (1) and retinal vein (1). All variants (−942 A/C, −927 T/C, −861 A/T, −568 T/C, −518 T/C) were genotyped in the whole study population (100 patients and 100 controls) by restriction fragment length polymorphism (RFLP) and allele specific PCR. This study was approved by the local ethics committee of the All India Institute of Medical Sciences and was in accordance with the Declaration of Helsinki.
Results: All the polymorphisms were in Hardy-Weinberg equilibrium. Amongst the five SNPs only two −568T/C and −861 A/T SNP show association with the DVT. −861A/T shows both genotypic (P = 0.0151, chi-square = 5.23;O.R. = 2.45) as well as allelic association (P = 0.002, chi-square = 11.32;O.R. = 3.12) while −568T/C shows only allelic (P = 0.03 chi-square = 4.04;O.R. = 4.03) association with DVT.
Conclusion: Susceptibility to DVT in North Indian Asian patients may be associated with some variants (−568T/C and −861A/T) of *GPX3*gene. Relatively small sample size and borderline P-values might bias the results obtained and that the association might be confounded by difference in the two groups or due to varied environmental exposures, which are known to modify the influence of *GPX3* variants on disease risk. However this needs to be replicated and confirmed in a larger multicentric population which will account for the genetic heterogeneity of the Indian population.

PB 4.72-5

Thromboembolic disease in overweight and obese patients

Paredes HJ and Gonzalez MF
M. Francisco Gonzalez M.D.P.A., SUMTER, USA

Background: Overweight and obesity are increasing in the general population; both represent additional risk for thrombotic disease.
Aims: Present information on frequency and associated risk factors for first and recurrent arterial, venous or combined thromboembolic events in overweight and obese patients referred to our center for hypercoagulability assessment.
Methods: Retrospective review of clinical and laboratory data from 249 consecutive patients with hypercoagulability diagnosis. Subjects are classified as overweight, obese or extreme obese based on body mass index by NIH guidelines and stratified by the type of thrombosis and recurrences. Results are presented as frequencies and percentages.
Results: We found 231 subjects with thrombotic disease, 170 (73.6%) were overweight (59), obese(82) or extreme obese (29) with one or more clotting events, 40% females, age of first episode between 17 and 86 years old (mean 47.5+/− 15.1), recurrences in 91.7% of cases, 55 subjects with more than two episodes. Venous thromboembolism was found in 61.2%, while only arterial in 41 patients. Thrombophilic genetic markers were found in 54 subjects; in 64.7% six or more thrombotic risk factors were simultaneously present.
Conclusions: Three of four patients with thromboembolic disease are either overweight or obese with extremely high frequency of recurrence. Genetic markers of hypercoagulability are present in one third and they add to the high presence of other risk factors.

PB 4.72-6

Association of JAK2 V617F mutation and tromboembolic events among patients with essential thrombocytemia and idiopathic myelofibrosis in a Brazilian center: evidence of a retrospective study

Villaca PR, Zeinad-Valim AK, Okazaki E, Linardi CG, Suganuma LM, Seguro F, Chamone DAF and D'Amico EA
Hospital das Clínicas – University of Sao Paulo, Sao Paulo, Brazil

Background: Thromboembolic events are the leading cause of morbidity and mortality in patients with bcr-abl negative myeloproliferative diseases. Recent studies indicate a possible association of JAK2 V617F mutation with the risk of vascular phenomena in this group of patients, especially in individuals with essential thrombocythemia (ET), and less consistent in those with idiopathic myelofibrosis (MF). In this retrospective study we evaluate patients with ET and MF followed up at a large tertiary hospital of the State of Sao Paulo, the prevalence of VTE in this population and its association with JAK V617F mutation.
Results: 105 patients were followed up at our institution with ET, being 71% females. Of this total, 53 (50.4%) had heterozygous JAK2 V617F mutation, and 28 (52.83%) of those patients had thrombosis (18 arterial thrombosis – AT and 10 venous thrombosis-VT). In 52 subjects with TE without the mutation (50.9%), 13 (25%) had previous thrombosis (6 AT and 7 VT). The presence of JAK2 mutation was a risk factor for thrombosis in patients with ET (P = 0.0049). In the group of patients with MF (20 women and 19 men), 19 (48.71%) were positive for the mutation. Only eight patients in this group had thrombosis (7 AT and 1 in VT). In subjects with MF without JAK2 mutation, 4 (20%) developed thrombosis (3 AT and 1 VT). In patients with MF the presence of JAK2 V617F mutation was not an important factor for the development of thrombosis (P = 0.1760).
Conclusion: The myeloproliferative diseases are characterized in most cases by long survival, and its treatment, which includes prolonged use of cytoreductive agents, may be associated with progression to acute leukemia and teratogenicity. These variables lead us to carefully con-

sider the assessment of the thrombotic risk, in order to individualize the treatment in this population so heterogeneous. The presence of the mutation in patients with TE appears to be associated with increased incidence of thromboembolic events, similar to published data. However prospective studies are needed to validate these results and optimize the therapeutic strategy.

Identification of a new thrombophilic disorder that affecting a correct N-glycosylation causes antithrombin deficiency

De La Morena-Barrio ME[1], Martínez-Martínez I[1], De Cos C[2], Sevivas TS[3], Miñano A[1], Padilla J[1], Lefeber D[4], Jaeken J[5], Vicente V[1] and Corral J[1]

[1]Centro Regional de Hemodonación. Hospital Morales Meseguer. UMU. IMIB, Murcia ; [2]Servicio de Hematología, Hospital Puerta del Mar, Cádiz, Spain; [3]Department of Haematology, Centro Hospitalar de Coimbra, Coimbra, Portugal; [4]Institute for Genetic and Metabolic Disease, Radboud University Nijmegen, Nijmegen, The Netherlands; [5]Center for Metabolic Diseases, Universitair Ziekenhuis Gasthuisberg, Leuven, Belgium

Since the description of antithrombin deficiency as the first thrombophilic factor in 1965, an intense search for new defects has been done, with quite frustrating results. This search has identified rare mutations and three common polymorphisms on few haemostatic elements. Genome wide association studies suggest that it is unlikely that new common polymorphisms could play a relevant role in thrombosis. Therefore, rare mutations on genes that might influence key haemostatic proteins are good candidates. To identify new thrombophilic defects we focused our interest on antithrombin since even minor deficiency of this key endogenous anticoagulant significantly increases the risk of thrombosis. Thus, we recruited 29 patients with venous thrombosis and antithrombin deficiency, 4 severe (50%), and 25 moderate (70–85%) that had no mutations in the gene encoding antithrombin (*SERPINC1*). Analysis of plasma by western blot revealed an antithrombin isoform with lower molecular weight in four patients (14%). Glycomic analysis confirmed an impaired glycosylation (reduced sialic acid and galactose content) in all cases. This defect was not specific of antithrombin, as we detected abnormal glycoforms on other proteins (α1-antitrypsin, transferrin and prothrombin). These data encouraged to compare these samples with the commonest congenital disorder of glycosylation (PMM2-CDG), a rare autosomic recessive disorder with a large clinical spectrum including mental and psychomotor retardation, that causes defects in the assembly, transfer, and processing of *N*-linked oligosaccharides. In all four cases, electrophoretic, HPLC and Q-TOF patterns were fully compatible with a PMM2-CDG. Molecular analysis of *PMM2*, the gene affected in this disorder, revealed one case with compound heterozygosis (p.Arg141His and p.Cys241Ser), providing an accurate diagnosis of PMM2-CDG. This patient, with a mild mental retardation, had severe antithrombin deficiency (50%) and developed four thrombotic events, the last two on stable oral anticoagulant therapy. This report, together with previous thrombotic events described in children with PMM2-CDG, sustains that this disorder should be considered as a rare thrombophilic disorder. Interestingly, the remaining three cases only had heterozygous mutations in *PMM2* (p.Arg141His, IVS4 + 21 G>C and IVS2 −13 G>A). These three cases are adult males who developed early thrombosis, but without additional clinical features of PMM2-CDG. Moreover, they all shared moderate hepatic dysfunction due to alcohol abuse. These results strongly suggest a new disorder we called CDG-like, result of the combination of a congenital defect in heterozygosis affecting the *N*-glycosylation pathway (*PMM2*) with an acquired factor also disturbing this pathway (alcohol also interferes with the correct glycosylation) that lead to a CDG phenotype with a high risk of thrombosis but without neurological consequences. Finally, the CDG-like disorder might be underestimated, as the 5 years follow-up of the p.Arg141His CDG-like patient revealed a normal transferrin pattern and no antithrombin deficiency in some samples.

Conclusions: The analysis of antithrombin in thrombophilic patients with antithrombin deficiency has allowed the identification of a new thrombophilic disorder that, affecting the *N*-glycosylation pathway indirectly disturbs this key anticoagulant serpin. Accordingly, our study suggests that a diagnosis of PMM2-CDG or CDG-like might be suspected in patients with antithrombin deficiency and no mutations in the *SERPINC1* gene.

PB 4.73-2

Long-term follow-up in four homozygous protein C deficiencies with late clinical onset

Conard J

Hotel-Dieu-Cochin University Hospital, PARIS, France

Background: Homozygous protein C (PC) deficiency is a very rare and severe hereditary thrombophilia. It is associated with purpura fulminans, massive thrombosis and disseminated intra-vascular coagulation (DIC) in the newborn. However, in a few number of cases, late diagnosis of the deficiency has been made when skin necrosis was observed at the start of oral vitamin K antagonists (VKA) treatment. Long-term anticoagulation is generally recommended in these patients.

Aim: Aim of the study was to assess the antithrombotic prophylaxis and long-term follow-up in severe PC deficiencies with late clinical onset.

Results: Results in one man and three women with genetically confirmed homozygous type I PC deficiencies with late clinical onset are reported. Patients are 35–79 years old. The first episode of venous thromboembolism (VTE) was a proximal deep vein thrombosis (DVT) observed between 17 and 45 years and all patients experienced skin necrosis when VKA (fluindione, acenocoumarol, warfarin) were introduced. One woman had three pregnancies without thromboprophylaxis and without VTE. Deficiency was detected at time of VTE in three cases, and in the 4th one, it was detected because of family history of VTE but homozygous status was detected later when she developed skin necrosis. PC levels without oral anticoagulant treatment are ranging from 10 to 23%. Homozygous amino acid replacements have been found in positions 168 (Pro-Leu), 267 (Ala-Thr), 301 (Gly-Ser) and 178 (Arg-Gln).

Patients have had recurrent episodes and have been followed for 25, 25, 22 and 3 years. Only one patient is on long-term phenprocoumon (long-acting VKA) for 25 years and had no recurrent VTE episode, although ulcers eventually occurred. In another patient, re-introduction of VKA failed on two occasions because of recurrent skin necrosis and she is still on prophylactic dose of LMWH after 23 years. In one patient, VKA were not re-started because of severity of skin necrosis and she is on LMWH for 3 years. The last patient has had over the past 22 years intermittent LMWH treatment at prophylactic doses for episodes of superficial vein thrombosis, after a knee surgery and for long haul flights.

Conclusion: None of these four homozygous patients had purpura fulminans or massive thrombosis as a first episode at birth. All of them had skin necrosis at start of VKA administered for VTE when they were adults. They are genetically confirmed homozygous but PC levels are measurable and patients had a late clinical onset: this latter finding was not known before the first patient we described in 1984. Skin necrosis at the start of VKA treatment is very rare and should be an alert to measure PC plasma level, and PS level as well. These four patients have had different long-term preventive approach. New target-specific oral anticoagulants might be an alternative to VKA treatment.

PB 4.73-3

Inherited thrombophilia as a risk factor for gestational vascular complications

Baptista A[1], Martinho P[1], Fidalgo T[1], Sevivas T[1], Oliveira AC[1], Maçães A[2], Salvado R[1], Barata C[2], Martins N[1] and Ribeiro ML[1]
[1]CHC – Centro Hospitalar e Universitário de Coimbra; [2]MBB – Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: The gestational vascular complications (GVC) are associated to a variety of factors, including the pregnancy physiologic hypercoagulability, acquired prothrombotic risk factors (ARF) and, to an extent that is still under investigation, the presence of thrombophilia. The use of anticoagulant prophylactic therapy (AcPT) is still controversial and the case-by-case approach is yet the preferred attitude.
Aims: In a group of women with GVC of unknown aetiology we aimed to evaluate the role of inherited thrombophilia, to identify ARF and to observe the impact of the AcPT in the success of the following pregnancies.
Methods: We studied the polymorphisms Factor V Leiden, PRT G20210A, PAI-1 4G/5G, ACE I/D, F13A1 Val34Leu and the haplotype M2 within the ANXA5 gene in two groups: the control group of 69 healthy women with none GVC and the patients group of 106 women with a history of at least one GVC. Women with anticoagulant factors congenital deficiency, hyperhomocysteinemia, antiphospholipid syndrome, autoimmune diseases, anatomical defects of the reproductive system, foetal chromossomopathies or foetal losses associated to infections were excluded from the study. Eighteen patients had recurrent miscarriage, 11 foetal death *in utero*, 37 preeclampsia or HELLP syndrome (PE/HELLP), 9 intra-uterine growth restriction (IUGR) and 31 had more than one GVC (>1GVC).
Results: We found a statistically significant association between the genotype PAI-1 4G/4G and the occurrence of GVC ($P = 0.019$; OR = 2.613; IC95% [1.149, 5.492]). When analysing the different subgroups we found the same polymorphism associated to the occurrence of PE/HELLP ($P = 0.011$; OR = 3.478; IC95% [1.294, 9.351]) or >1GVC ($P = 0.023$; OR = 3.175; IC95% [1.135, 8.879]). Regarding the ARF in the patients group, we found that 2 (1.9%) had diabetes, 29 (27.4%) had arterial hypertension and 40 (37.7%) obesity. 58.5% of the patients had at least one ARF, 8 (7.5%) had only ARF and in 8 (7.5%) we did not find neither ARF nor any of the studied polymorphisms. In the group of 30 women presenting at least one of the polymorphisms that had subsequent gestations, 13 were submitted to AcPT. Among the 17 without AcPT, 7 (41.2%) presented GVC (4 PE, 2 PE + IUGR and 1 early miscarriage); only 2 woman (15.4%) with AcPT had IUGR.
Conclusion: In our study only the genotype PAI-1 4G/4G had a statistically significant correlation with GVC, in particular with PE/HELLP. The fact that no prothrombotic risk factors were found in 7.5% of the patients indicates that there are still unidentifiable causes to these pregnancy complications. Although the anticoagulant prophylactic therapy seems to be associated with fewer and less severe GVC, the group is too small to allow any conclusions. Further studies are ongoing.

PB 4.73-4

Effect of genetic variants in the TAFI gene on TAFI levels, the efficiency and safety of anticoagulant therapy in patients with venous thromboembolism in Russian population

Vorobyeva N[1], Doroshchuk N[1], Khasanova Z[1], Dobrovolsky A[1], Titaeva E[1], Postnov A[1], Kirienko A[2] and Panchenko E[1]
[1]Russian Cardiology Research and Production Complex; [2]Russian State Medical University, Moscow, Russian Federation

Background: Several studies have reported that thrombin activatable fibrinolysis inhibitor (TAFI) levels may be partly determined genetically. Results from these studies are conflicting. The influence of TAFI genetic variants on the efficiency and safety of anticoagulant therapy is not yet clear.
Aims: To determine the frequency of the TAFI gene polymorphisms and theirs effect on TAFI levels, the efficiency and safety of anticoagulant therapy in pts with venous thromboembolism in Russian population.
Methods: One hundred and eleven pts (76 men) in the age 18–76 (mean 54 ± 14) years with deep vein thrombosis (DVT) and/or pulmonary embolism (PE) were included in the study. Pts received unfractionated or low molecular weight heparin for at least 5 days followed by long-term warfarin therapy (international normalized ratio 2.0–3.0). TAFI levels were measured at baseline by a chromogenic assay with reagent kits «STA STACHROM TAFI» (Diagnostica Stago). Three TAFI genetic polymorphisms (–438G/A, 505G/A and 1040C/T) were investigated. The follow-up period was 18 months. Endpoints were DVT/PE recurrences and hemorrhagic complications. Results of TAFI levels are presented as a median (interquartile range).
Results: In all pts, median of TAFI levels was 106 (90; 133)%. The frequency of –438GG, –438GA, –438AA genotypes was 67.6%, 29.7% and 2.7%; 505GG, 505GA, 505AA genotypes – 47.8%, 49.5% and 2.7%; 1040CC, 1040CT, 1040TT genotypes – 50.5%, 41.4% and 8.1% respectively. Univariate regression analysis showed that all three polymorphisms were associated with TAFI levels. For the –438G/A and 1040C/T variants, the carriers of rare alleles (–438A and 1040T) were associated with lower TAFI levels than common alleles (–438G and 1040C) – 98 (82; 118) vs. 106 (89; 137)%, $P = 0.004$ and 99 (87; 119) vs. 106 (89; 135)%, $P = 0.002$ respectively. While for the 505G/A, the carriers of the rare allele (505A) was associated with higher TAFI levels – 113 (94; 143) vs. 106 (89; 132)%, $P = 0.067$. During 18 months of anticoagulant therapy, the frequency of DVT recurrences was 17%, and the frequency of hemorrhagic complications was 30% (major bleedings – 2%, minor bleedings – 28%). There were no PE recurrences. We found no associations among all TAFI genetic variants and the risk of DVT recurrences and hemorrhagic complications during 18 months of anticoagulant therapy.
Conclusion: In pts with venous thromboembolism in Russian population, the –438G/A, 505G/A and 1040C/T polymorphisms of the TAFI gene associate with TAFI levels but do not influence on the risk of DVT recurrences and hemorrhagic complications during 18 months of anticoagulant therapy.

PB 4.73-5

The prevalence of thrombophilia in patients with isolated superficial vein thrombosis

Hirmerova J, Seidlerova J, Subrt I and Slechtova J
University Hospital, Charles University in Pilsen, Pilsen, Czech Republic

Background: Superficial vein thrombosis (SVT) shares some common risk factors with deep vein thrombosis (DVT). However, SVT has been considered banal and therefore has drawn little scientific interest until recently. Little is known about the prevalence of thrombophilia in SVT patients.
Aims: The aim of our study was to evaluate the prevalence of thrombophilic disorders in a group of patients with isolated SVT of the legs.
Methods: We examined 74 outpatients (age 58.4 ± 14.8 years, 70.3% women) referred to vascular clinic with SVT on the legs. We obtained family and personal history and performed clinical and ultrasonographical examination, as well as laboratory thrombophilia workup. For statistical evaluation we used Student t-test and χ^2 test.
Results: In most cases (90.5%) SVT occurred on varicose veins, on both legs almost equally (47.3% right side; 50% left side; 2.7% bilaterally). Duration of symptoms was in quite a wide range (9.6 ± 9.1 days). In 71.6% of patients SVT had not been preceded by any trigger, the rest of cases had been provoked by immobilization, injury, erysipelas, tumour, oestrogen therapy or pregnancy. In eight

cases (10.8%) SVT approached saphenofemoral junction at the distance ≤3 centimetres. Positive family history of SVT was reported by 33.8%; that of DVT by 35.1% patients while positive personal history of SVT had 47.3% and that of DVT 28.4%. Factor V Leiden (FVL) was found in 13 persons (17.6%); in three cases even in a homozygous trait. Other thrombophilias were less frequent – mutation in prothrombin gene G20210A was revealed in 6.8%; antithrombin deficiency in 7.1%; protein S deficiency in 4.1%, protein C deficiency in 1.4% and antiphospholipid antibodies in 2.7%. The prevalence of thrombophilic disorders was higher in men and younger individuals with SVT but the only factor significantly associated with thrombophilia was positive family history of DVT.

Summary/Conclusions: In the group of 74 outpatients with SVT we found relatively high prevalence of thrombophilic disorders (39.2%), the most prevalent one was FVL. The presence of thrombophilia in these patients was significantly associated with positive family history of DVT. Our results suggest that patients with SVT and positive family history of DVT be potentially considered for thrombophilia screening. These findings deserve further evaluation in a larger study and may become a small contribution to our changing approach to SVT management.

PB 4.73-6

Evaluation of the INNOVANCE Free PS Ag assay: an easy and reliable assay for the automated determination of free protein S

Pilgrim S, Esch V, Kolbe-Scheu K, Schleifer M and Lichte A
Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany

A new latex particle-enhanced immunoassay for the quantitative determination of free protein S, INNOVANCE® Free PS Ag, has been developed. Validated assay applications are available on Siemens BCS® and BCS XP systems as well as on Sysmex® CA-1500, CA-7000 and CS-2000i/2100i systems. INNOVANCE Free PS Ag reagent components are liquid and ready to use. They can be stored on board the systems up to 48 h (BCS/BCS XP, Sysmex CA-1500/CA-7000 systems) or 72 h (Sysmex CS-2000i/2100i systems), and may be used up to 8 weeks after first opening of the reagent vials.

INNOVANCE Free PS Ag assay applications are linear over the measuring range of 10–150% of the norm free protein S with a limit of quantification of 5% of the norm. No high-dose hook is seen up to a theoretical concentration of 550% of the norm free protein S.

The INNOVANCE Free PS Ag assay measures free protein S molecules without showing cross reactivity to protein S/C4BP complexes. No interference by rheumatoid factors up to 3640 IU/mL or by heterophilic antibodies up to 3641 ng/mL was detected.

No interference by endogenous and exogenous interference substances was observed up to concentrations of: 1000 mg/dL hemoglobin, 60 mg/dL bilirubin, 2570–3066 mg/dL (depending on the system used) triglycerides, 625 mg/dL cholesterol, 7.5 IU/mL unfractionated heparins, 10 IU/mL low molecular weight heparins, 11 g/L fibrinogen, and 24.8 × 10E-7 per mL platelets.

Different INNOVANCE Free PS Ag lots show highly comparable results over the whole measuring range.

Thus, the INNOVANCE Free PS Ag assay offers an easy and reliable automated method for the determination of free protein S in human plasma.

Disclosure of Interest: Authors are coworkers of Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany.

INNOVANCE Free PS Ag assay is not availbale for sale in the U.S.

PB4.74 – Fibrinolysis and FXIII

PB 4.74-1

Fibrinolysis wave as a possible cause of rethrombosis

Zhalyalov AS[1], Panteleev MA[2], Ataullakhanov F[3] and Shibeko AM[3]
[1]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow; [2]National Research Center for Hematology, Moscow; [3]HemaCore LLC, Moscow, Russian Federation

Background: Plasminogen activators are used for the treatment of thrombotic events in patients with thromboembolism and stroke. However, there are possible complications of this therapy like secondary thromboembolism or rethrombosis, the cause of which is not clear.

Aims: In this work we evaluated the underlying mechanisms of fibrinolysis and coagulation system interaction, which might be responsible for the secondary thromboembolism, using a newly developed model of spatial fibrin clot growth and lysis.

Methods: A thin layer of unstirred human blood plasma contacting with the surface with immobilized tissue factor was monitored to register the fibrin clot growth and its lysis. Plasma was supplemented with streptokinase, urokinase or tissue plasminogen activator at different concentrations close to the concentrations used in thrombolytic therapy to test their ability to cause clot lysis. Time when the clot started to grow and when it started to dissolve, and rates of these processes where used to evaluate the influence of plasminogen activators on the systems of plasma coagulation and fibrin clot lysis.

Results: Fibrinolysis started in area of activation of coagulation and propagated towards the direction of clot growth. The spatial rate of clot lysis (66 ± 9 μm/min) did not depend on the concentration or the type of thrombolytic agent (measurements were performed in the concentration range of TPA 0.75–20[μg/mL], urokinase 180[UI/mL], streptokinase 200[UI/mL]). In contrast to the lysis rate, the time when fibrinolysis started increased with the decrease of TPA concentration (1.7 ± 0.3 min for 20 μg/mL TPA; 29 ± 14 min for 0.75 μg/mL TPA).

Conclusion: The subject of this study corresponds to situation if any clotting occurs during the plasminogen activator therapy. A possible mechanism of secondary thrombosis may be related with the wave of lysis, which started from the place of clot growth, detaching the clot from the vessel wall and thus forming an embolus for rethrombosis. Plasminogen activator concentration defines only the time when the lysis will start, but not the overall efficacy of the drug, i.e. when the lysis started, the time of clot dissolution will be the same for all activator concentrations.

PB 4.74-2

Polymorphism thr325ile in thrombin-activable fibrinolysis inhibitor gene in dyslipidemic subjects from Brazil

Santos IR, Carvalho MG, Sousa MO, Ferreira CN and Gomes KB
Federal University of Minas Gerais, Belo Horizonte, Brazil

Background: Thrombin-activable fibrinolysis inhibitor (TAFI) is a plasma zymogen synthesized in the liver, which plays an important role in hemostasis, acting as a potent inhibitor of fibrinolysis in its activated form. Studies have shown that increased plasma concentrations of TAFI could be a risk factor for thromboembolic and coronary artery disease (CAD). These diseases are a major cause of morbidity and mortality worldwide, constituting a public health problem. The role of hyperlipidemia is well known in the evolution of CAD, since its presence increases the formation of atherosclerotic plaque and subsequent thrombus formation. Many individuals with alterations in lipid profile are undiagnosed or undertreated, persisting

with an altered lipid profile and thereby increasing the risk of coronary events.
Aims: In this study the frequency of the Thr325Ile polymorphism (+1040C/T) in the TAFI gene in dyslipidemic and normolipemic individuals was evaluated and correlated with TAFI plasma levels.
Methods: 107 dyslipidemic patients from 30 to 60 years were evaluated and compared with a control group of 101 normolipemic subjects of similar age. All subjects gave informed consent and the study was approved by ethics committee from the Federal University of Minas Gerais, Brazil. The molecular analyses were performed by PCR-RFLP. Citrated plasma TAFI levels were determined using an ELISA test. Statistical analyses were performed using SPSS 13.0 software, by the chi-square test, Mann-Whitney and Spearman rank correlation.
Results: The T allele frequency in the case group was 0.327 compared with 0.248 in the control group, but the difference was not significant ($P = 0.213$). Also for the genotype frequencies there was no significant difference between the two groups ($P = 0.210$). However, a significant difference was found between medians of TAFI plasma levels between the dyslipidemic group (8.5 mg/mL) and the normolipemic group (7.21 mg/mL), with P value <0.01. There was a negative correlation between TAFI antigen levels and the presence of the TT genotype ($r = -0.209$, $P = 0.002$). A negative correlation was also observed between the levels of TAFI and the presence of the allele T ($r = -0.159$, $P = 0.021$).
Conclusions: These results suggest that dyslipidemia may be associated with higher levels of TAFI while the +1040T allele seems to be associated with lower levels of TAFI.

PB 4.74-3
Residual perfusion defects in patients with pulmonary embolism and fibrinolytic system

Cellai AP[1], Lami D[2], Cenci C[2], Marcucci R[2], Fiorillo C[2], Becatti M[2], Mannini L[1], Poli D[1], Abbate R[2] and Prisco D[2]
[1]AOU-Careggi; [2]University of Florence, Florence, Italy

Background: The relative balance between clot formation and lysis is considered to reflect the thrombotic potential but few methods are available to study this issue. Little is known about the pathophysiology of persistent vascular obstruction abnormalities after pulmonary embolism (PE). In previous studies we have observed a slight increase in CLT of pateints with previous PE vs. controls.
Aims: To assess the behaviour of fibrinolytic system components in patients with complete or incomplete restoration of pulmonary perfusion after an episode of acute PE.
Patients and Methods: We studied 80 patients after stopping oral anticoagulant therapy for an acute episode of PE. Ventilation/perfusion lung scan and echocardiography were performed to detected a percentage of residual vascular obstruction (RVO). Persistent perfusion defects were defined as a los of pulmonary vascular obstruction ≥10%, according a previously validated method of analysis of scintigrafic data. The Analyses of Clot Formation, Morphology, and Lyses were performed using the Clotting and Lysis assay according to Carter (2007) and clot lysis time CLT according to Lisman (2005) TAFI (ag), PAI (ag) and t-PA (ag) plasma levels were measured with commercially available ELISA whereas α2-Antiplasmin (α2-AP), plasminogen and factor XIII were measured using Berichrom reagents with the BCS system. Fibrinogen was evaluated with Clauss assay and plasmin mediated lysis of fibrin β-chain according to Morris (2006). ECLT was measured according to Buckell (1958).
Results: Ventilation/perfusion lung scan was available for 71 patients. Patients with RVO ≥10% were 18/71(25.4%) and without RVO were 53/71(74.6%). Median plasma levels of t-PAag, TAFIag, α2-AP, fibrinogen, lysis of fibrin β-chain and fXIII were similar between patients with and wthout RVO. CLT was not different between the two groups. Finally, by analysisng plasma turbidimetric parameters through EuroCLOT assay, statistically significant differences ($P < 0.05$) were observed between patients with RVO and without. A similar behaviour was observed in PAIag plasma levels (0.005) and ECLT($P = 0.049$).
Conclusion: An alteration of endogenous fibrinolysis, regarding to behaviour of Lysis assay and PAI-1 plasma levels, seems to be a special feature of PE patients with incomplete restoration of pulmonary perfusion.

PB 4.74-4
Molecular basis of 21 severe FXIIIA deficiency cases: 11 novel mutations detected

Shanbhag SD, Ghosh K and Shetty S
National Institute of Immunohaematology NIIH [ICMR], Mumbai, India

Background: Congenital FXIII deficiency can be due to defects in either *F13A* gene (known as type 2 defect) or *F13B* gene (type 1 defect). Bleeding disorders as a result of mutations in the *F13B* gene occurs rarely (<5% of reported factor XIII deficiency cases). The incidence of severe FXIII deficiency is one in 3–5 million people and is inherited in an autosomal recessive pattern. This rare bleeding disorder affects people of all races and there is often a history of consanguinity within most of the families of FXIII deficient patients. FXIII deficiency is a serious lifelong bleeding diathesis, common symptoms ranging from neonatal umbilical stump bleed to impaired wound healing, prolonged bleeding from injury site, intracranial haemorrhage, menorrhagia and recurrent miscarriages in women.
Aims: To study the molecular basis of FXIII deficiency cases and to provide genetic diagnosis in affected families.
Methods: We have analysed 21 severe FXIII deficient patients, diagnosed on the basis of their clinical history, normal screening coagulation and clot solubility assay. Genomic DNA was extracted by the phenol chloroform method, and mutations were detected by direct DNA sequencing of the *F13A* gene. 15 of 21 patients had history of primary consanguinity.
Results: 17 mutations were detected in 21 FXIII deficient patients, of which 8 were missense (6 novel, 2 recurrent), 6 nonsense (3 novel, 3 recurrent), and 2 patients showed a novel single base pair deletion; two patients showed a known splice site mutation in exon 14. A large deletion in exon 3 is suspected in 2 unrelated patients because of repetitive failure of PCR amplification of this exon. Six polymorphisms were detected in these patients, of which one is novel.
Conclusion: We have identified *F13A* gene mutations in 21 FXIII deficient patients, and observed a high heterogeneity in the mutation profile. The data obtained would assist in establishing a National Mutation Database, and enable an accurate carrier and antenatal diagnosis in affected families.

PB 4.74-5
Mutation analysis in patients with decreased fibrinogen level

Baran B[1], Odnoczko E[1], Stefanska-Windyga E[1], Mital A[2], Ivaskevicius V[3], Oldenburg J[3] and Windyga J[1]
[1]Institute of Hematology and Transfusion Medicine, Warsaw; [2]Medical University of Gdansk, Gdansk, Poland; [3]Institute of Experimental Haematology and Transfusion Medicine, University Clinic, Bonn, Germany

Background: Fibrinogen is a 340-kDa glycoprotein synthesized in hepatocytes that circulates in plasma at a concentration of 1.5–4.5 g/L. The three genes encoding fibrinogen Bβ (*FGB*), Aα (*FGA*), and γ (*FGG*) are clustered in region of approximately 50 kb on human chromosome 4.

Aims: The objective of this study is the molecular characterization as well as genotype-phenotype analysis of patients with decreased fibrinogen level.
Methods: We examined 17 patients (9 [53%] females, 8 [43%], males). Each patient was asked about the type of clinical manifestations (bleeding, thrombosis). The *FGA, FGB, FGG* genes were analysed by automated direct sequencing of all coding regions and exon/intron splicing sites on ABI 3130 sequencer. In all patients, the functional concentration of fibrinogen (Clauss method; Multifibren*U, Siemens) and thrombin clotting time (BC-Thrombin Reagent, Siemens), were determined. Additionally, in group of eight patients rotational thromboelastometry (ROTEM®-delta; FIBTEM, Pentapharm), was performed. Von Willebrand factor (VWF) and factors VIIII, IX, XI activities, were analyzed in study subjects with bleeding symptoms. In patients with thrombosis we looked for common thrombophilic defects: *F5* p.R506Q and *F2* c.G20210A genotypes, antithrombin and protein C activities, free protein S antigen level.
Results: In our patient population 5/17 (29%) were asymptomatic, 4 (24%) – stated a tendency for bleeding, 6 (35%) – had thrombotic complications and 2 (12%) females – reported miscarriages. Direct sequencing approach revealed six novel mutations (not registered in GEHT www.geht.org as well as HGMD www.hgmd.cf.ac data base) in six patients (*FGG*: c.78 + 5G>A, p.D178H, p.R223I, p.G240R, p.D314Y, p.W395S), and three previously reported mutations (*FGA*: p.R35H, *FGB*: p.G444S, *FGG*: p.A108G) in eight patients. All patients with identified mutation were heterozygous. In three cases, no changes in analysed sequence had been found. Fibrinogen concentration was 0.4–1.4 g/L (normal range: 2–5 g/L). Thrombin time was prolonged in all patients (22–45.5 s; normal: <21s). Activities of VWF and factors VIII, IX, XI in four patients with bleeding tendency, were in normal ranges. In six study subjects with thrombosis, no thrombophilic defect has been revealed. Thromboelastometry (ROTEM®) showed reduced maximum clot firmness in five patients (MCF-FIBTEM 4–8 mm; norm 9–25 mm). In this group 2/5 patients were asymptomatic (causative mutation c.78 + 5G>A; no mutation in second one), 2/5 had miscarriages (p.A108G, p.R223I), 1/5 has thrombotic event (p.W395S). In three patients with the same mutation p.R35H, MCF-FIBTEM was normal: 11–16 mm; one was asymptomatic and two experienced thrombosis.
Summary: Studies on fibrinogen gene mutations might enable better understanding of pathophysiology and clinical course of inherited hypo-/dysfibrinogenemia as well as assist in optimal tailoring of haemostatic/antithrombotic treatment.

PB 4.74-6
Role of genotyping in FXIII deficiency

Weerens R, Van Heerde WL, Schoormans S, Diekstra A and Brons P

Nijmegen Univeristy Medical Centre, Eindhoven, The Netherlands

Background: FXIII deficiency is a rare autosomal recessive disease, caused by genetic defects in the A subunit located on chromosome 6 (p24–25) or the B subunit located on chromosome 1(q32-32.1). More than 95% of the patients with FXIII deficiency are affected by a mutation in the A subunit. Currently more than 70 A subunit mutations have been identified. Mutations in the B subunit are very rare, only seven are known. Two different tests are available to detect FXIII deficiency. The clot solubility test is a qualitative test only able to detect severe deficiency (<1%). The quantitative test analyses FXIII activity levels by indirectly measuring the amount of measuring ammonia released by FXIII(a) in the first step of transglutaminase reaction. Patients with severe FXIII deficiency have plasma levels between 1 and 5%. Recently we were confronted with a young immigrant patient suspected with a tumor in his upper leg but showed to have a large hematoma. Screening assays showed slightly elevated PT and APTT levels, increased D-dimer (2400 ng/mL) levels and a low Hemoglobin concentration. Further analysis showed that the patient was suffering from FXIII deficiency. The qualitative assay was negative corresponding to <1% FXIII. The quantitative assay however showed levels of 4–7% FXIII, suggesting a less severe phenotype.
Aim: To clarify the discrepancy between the quantitative and qualitative assay results.
Methods and Results: We sequenced the genes of both subunits of factor XIII. Our patient had no mutations in the B-domain but carried a homozygous missense mutation in exon 3: c233G>A (p.Arg78His) of the A-domain. This mutation is located in the beta-sandwich, which is highly conserved. International registries have reported that other mutations in the same region have shown to be pathogenic. The patient is currently treated with FXIII-A_2B_2 concentrate (Fibrogammin P) every 6 weeks.
Conclusion: Our case illustrates that in patients with a discrepancy between qualitative test result (i.e. <1%) and quantitative analysis of FXIII activity, genotyping is recommended. As the clot solubility test can only detect severe deficiency, test results can be normal in patients with mild to moderate FXIII deficiency. Additionally, the quantitative assay has a cut off point around 5% making it less sensitive to detect severe FXIII deficiency. In patients with unknown FXIII deficiency genotype, diagnosis can be missed if only a one analysis is performed. We recommend to sequence FXIII gene subunits when a discrepancy between qualitative and quantitative tests is found or if one only FXIII activity assay is performed.

PO 001

Correlation of hemostatic parametres with age in patients with myocardial infarction

Antonijevic MN[1], Zivkovic I[1], Jovanovic L[1], Vukosavljevic D[1], Radovanovic N[1], Perunicic J[1], Radanovic A[2], Matic D[1], Djordjevic V[3] and Obradovic S[4]

[1]Clinical Centre of Serbia, Belgrade, Serbia; [2]Medical Centre, Trebinje, Bosnia-Herzegovina; [3]Institute of Molecular Genetics and Genetic Engineering; [4]Military Medical Academy, Belgrade, Serbia

Background: Age is a well-known risk factor for thrombosis though the mechanisam of more frequent thrombosis occurence in older patients has received little attention in clinical research so far.
Aim: Identifying specific hemostatic parametre changes related to the age of myocardial infarction patients.
Methods: The study involved a group of 173 patient with myocardial infarction older than 45. We investigated blood count parametres and hemostatic markers (antithrombin, protein C, FVII, FVIII, vWF, FX, FXII). The statistical analysis was done using primarily Spearman's correlation test.
Results: The average patient age was 61.28 ± 10.38 years. There was detected a negative age correlation with haemoglobin levels ($P = 0.002$), white blood counts ($P < 0.001$) and antithrombin ($P < 0.001$). A positive age correlation with vWF ($P = 0.023$) was determined. The levels of FVIII showed only a tendency towards higher levels ($P = 0.056$). Protein C, FVII, FX, FXII levels did not demonstrate any correlation with age.
Conclusion: Detecting phatogenic parametres responsible for acute myocardial infarction occurence may contribute to the establishment of adequate preventive measures and therapy optimalisation. It is necessary to conduct more comprehensive research to gain more reliable results in this field.

PO 002

Diagnosis of acquired hemophilia due to pregnancy

Apostolovska R, Dejanova -Ilijevska V, Nikolova I, Neceva V and Bojadzieva-Makarovska T

Institute of transfusion medicine, Skopje, Macedonia

Background: The acquired hemophilia (AH) is potentially life-threatening bleeding disorder caused by the spontaneous development of autoantibodies against plasma coagulation factors, most frequently to FVIII (as in our case). Diagnosis can be difficult because is a very rare condition (approximately one person per million each year), the patient does not have the usual personal or family history but have distinctly different clinical symptoms who are differ from those of hereditary hemophilia.
Aims: Importance of performance of laboratory tests for a rapid and adequate diagnosis of AH.
Methods: Presented is a case of AH in a 24-year-old woman (PF) diagnosed after delivery. Analyzed were: screening haemostasis, correction of aPTT with normal plasma, biological activity of FVIII and LAC and evaluation of inhibitors of FVIII by Bethesda coagulation method.
Results: A few days after the delivery, 24-year-old woman was admitted at the Outpatient Department in the Institute of Transfusion Medicine -Skopje. She had prolonged postpartum bleeding and bruises. Screening haemostasis showed: aPTT = 110″ (normal rang: 27″–37″) and PT = 12″ (normal rang: 10″–15″); the aPTT does not correct with normal plasma (88″). We suspected AH or LAC. LAC was negative. The diagnosis was confirmed by the finding of a decreased level of FVIII = 0, 19% (normal 50–120%), and presence of inhibitors to FVIII = 166 BU (normal < 0, 60 BU). Woman was hospitalized at the Clinic of Hematology. After 8 days treatment aPTT was 74″ (71″), and FVIII = 0, 21%; 25th day of treatment aPTT = 55″ (41″), FVIII = 2, 09% and inhibitors to FVIII = 9 BU. After 1 month treatment the laboratory findings were normal: aPTT = 33″, FVIII = 55% and inhibitors to FVIII = 0, 45 BU without relapse.
Summary/Conclusions: Rapidly and accurately – a timely diagnosis will enable clinicians to apply treatment strategies – control of bleeding and eradication of the inhibitor. Collaboration with an experienced Hemophilia centre is recommended.

PO 003

Haemostatic changes in cirrhotic patients

Baccouche H, Labidi A, Mahjoub S, Raissi A, Ben Mohamed W, Filali A and Ben Romdhane N

Rabta Hospital, Tunis, Tunisia

Introduction: Liver cirrhosis leads to the impairment of coagulation protein synthesis. The aim of this study was to assess the alterations of haemostatic parameters in the evolution of liver cirrhosis scored according to Child's classification.
Methods: A case control study including 51 cirrhotic patients and 51 healthy subjects matched by age and sex was conducted. Disease severity was estimated according to Child Pugh classification. Prothrombin time (PT), activated partial thromboplastin time (APTT). Procoagulant factor activity (factor I, VII, II, V, VIII, XII) and inhibitor factor activity (Protein C, protein S) were detected with clotting assay. Antithrombin activity was detected with chromogenic assay. Search for Anticardiolipin and antiB2cardiolipin antibodies wasinvestigated. Statistical analysis was performed using SPSS software version 19.0.
Results: There were 25 males and 26 females. Mean age at inclusion was 56.8 years old [range16–86]. Patients were categorized as class A in 13 patients (25.5%), class B in 23 patients (45.1%), and class C in 15 patients (29.4%). Mean level of PT and APTT were significantly prolonged in cirrhotic patients than in controls. Procoagulant factors and anti-coagulant factors were significantly lower in cirrhotic patients: factor VII (54.87 vs. 96.7; $P < 0.0001$), factor II (42.7 vs. 99.6%; $P = 0.002$), factor V (50.3 vs. 97.8%; $P = 0.008$), factor XII (59.4 vs. 93.6%; $P < 0.0001$), antithrombin (50.2 vs. 100.6%; $P < 0.0001$), protein S (49.6 vs. 81.6%; $P < 0.0001$) and proteinC (45.7 vs120.6%; $P < 0.0001$). However, mean level of factor VIII was significantly higher in cirrhotic patients (115.87 vs. 95.8%; $P = 0.03$). On the other hand, anticardiolipin antibodies were more frequent in cirrhotic patients than in controls (47.9 vs. 12.5%; $P = 0.005$) but not B2 glycoprotein antibodies (2.1 vs. 0%). When comparing patients according to disease severity, factor (VII, II, V, XII), protein S and protein C decreased significantly from class A to C (respectively, $P < 0.0001$, $P = 0.012$, $P = 0.009$, $P = 0.002$, $P = 0.001$, $P = 0.001$). However, factor VIII and protein S increased without reaching a significant level.
Conclusion: Patients with liver cirrhosis are characterized by decreased levels of most of procoagulant factors. In fact, prolonged PT has been considered until recently as an index of bleeding. However, decreased levels of anti-coagulant factor in association with the elevated level of factor VIII suggest that patients may have a tendency to thrombosis. Accordingly, these hemostatic modifications lead to a fragile balance which could bend to either bleeding or thrombosis.

PO 004

Factor VIII inhibitor and pulmonary embolism developing in a patient after meningioma resection: clinical and laboratory aspects

Bryant A[1], Kershaw G[2], Zebeljan D[1], Motum P[1] and Das R[1]
[1]*Liverpool Hospital, Liverpool;* [2]*Royal Prince Alfred Hospital, Sydney, NSW, Australia*

Background: Acquired haemophilia A is caused by the presence of a factor VIII inhibitor in a non-haemophiliac individual. It is a rare but potentially life-threatening event, with an estimated incidence of 1 per 1.48 million persons per year. These inhibitors can occur in association with auto-immune disorders, malignancy, post-partum or arise in individuals without known pre-disposing factors.
Aims: This paper describes the clinical and laboratory features of a case of FVIII inhibitor and pulmonary embolism developing in a patient following meningioma resection.
Methods: Basic laboratory investigations were coagulation screens, mixing tests and Bethesda assay for factor VIII inhibitors. Lupus anticoagulant testing was by diluted Russell's Viper Venom time (DRVVT) mixing tests according to published guidelines. Coagulation factors were assessed by one-stage assays.
Results: A previously well 65-year old female presented to the emergency department with a 2-month history of headaches. MRI revealed a right frontal lobe extra-axial mass measuring approximately 5.5 × 6.0 × 6.0 cm with a 2.2 cm midline shift and subfalcine herniation. On resection, a meningioma was diagnosed. On postoperative day 5, the patient was anti-coagulated with low dose molecular weight heparin (LMWH) for DVT prophylaxis. By day 70, at the same time she was developing excessive haematomas of 3–4 cm around the LMWH injection sites, she also developed a pulmonary embolism. This was treated with therapeutic dose LMWH, followed by warfarinisation. After 2 weeks of therapeutic LMWH/warfarin, a progressive increase in the APTT was noted, peaking at 141 (normal range 25–37). The APTT had been normal prior to exposure to LMWH. A haematology consultation was requested. Mixing tests revealed a slow acting inhibitor with APTT on immediate mix of 44 s rising to 66 s after incubation. One-stage factor assays showed a FVIII:C level of 1 U/dL and FIX:C of 48 U/dL. A FVIII inhibitor of 9.1 BU/mL was detected by day 100, peaking at 22 BU/mL by day 110. The presence of a lupus anticoagulant was excluded by a normal dRVVT ratio of 0.95 (< 1.20). In view of these changes anticoagulation was immediately reversed and an IVC filter was inserted. The patient subsequently suffered repeated major bleeding episodes requiring emergency treatment with recombinant FVIIa and packed cells. Immunosuppressive therapy with cyclophosphamide, prednisone and rituximab was commenced. By post operative day 140, the FVIII inhibitor had reduced to less than 0.5 BU/mL indicating successful clearance of the inhibitor. The patient remains inhibitor-free with normal FVIII:C and is off all immunosuppression. The IVC filter has been removed.
Summary/Conclusions: The development of a FVIII inhibitor causing acquired haemophilia A is an uncommon but serious cause of bleeding. This patient had two known predisposing factors for the development of an inhibitor: malignancy and surgery. Early recognition of the inhibitor was essential to allow cessation of the patient's anticoagulation therapy. Eradication of the inhibitor was achieved with a combined approach of steroids, cyclophosphamide and rituximab.

PO 005

Unusual thrombotic complications in patients with acute promyelocytic leukemia

Colovic NR[1], Suvajdzic N[1], Kosanovic-Jakovic N[2], Vidovic A[1], Miljic P[1], Djunic I[3], Mitrovic M[3], Virijevic M[3] and Tomin D[1]
[1]*Medical Faculty University of Belgrade;* [2]*Clinic for Eye Disease/ Medical Retinal Department Clinical Center of Serbia;* [3]*Clinic of Hematology, Clinical Center Serbia, Belgrade, Serbia*

Background: The risk of thrombotic events persists in patients with acute leukemias during remission induction chemotherapy and even after achieving complete remission. The treatment of acute promyelocytic leukemia (APL) with all-trans retinoic acid (ATRA) results in rapid resolution of the coagulopathy and bleeding, but paradoxically induces thrombosis in a small number of patients.
Material and Methods: Case 1. We present a 45-year old man, with low risk APL in whom thrombosis of v. centralis retinae occurred in complete cytologic and molecular remission while on maintenance therapy with ATRA. While in complete remission inJanuary 2012 he noticed vision disturbances which gradually progressed to complete loss of vision on left eye. Ophtalomologic examination detected occlusion of left v.centralis retinae with oedema of maculae. Screening tests for thrombophilia have been done: Fibrinogen 5.28 g/L, PV 89%/75–120%), partial thromboplastin time 26 s (25–35 s), KCT 94.1 s (70–90 s), LA_1, 41.3 s (< 45s), Antithrombin III 130% (80–120%), PCG 0.46 (> 0.8), PC 142% (70–140%), APCR 1.7 (2.1–3.5), PS 104% (63–135%). With PCR-RFLP method it was found that the patient was heterozygous carrier for factor 5 Leiden mutation (G1691A) and heterozygote for MTHFR C677T with hyperhomocysteinaemia. The risk for thrombotic events is especially evident in APL where various thrombogenic factors have been identified, but also co-morbid conditions such as arterial hypertension, diabetes and hyperlypidemia may be contributing factors for thromboses as well as inherited thrombophilia.
Case 2. A-49-year-old female presented with a history of headache, weakness and fatigue and CT cerebral scan revealed a subdural haematoma above right cerebral hemisphere. Physical finding was normal. Laboratory examinations revealed: Haemoglobin (Hb) 82 g/lm white blood cells (WBC) 5.7 × 10^9/L, platelets 47 × 10^9/L. D-dimer 15 μg/L, PT 66&. Bone marrow aspirate contained 73% blast cells with Auer rods in some cells, POX+. Immunophenotype of mononuclear bone marrow aspirate showed C34, CD38, cMPO, cCD68, CD117, CD13, CD33, CD11a, CD11b, CD4, CD64, CD56, CD2+. Cytogenetic analysis revealed *t*(15;17) in three mitoses and molecular examination presence of PML/RAR alpha+ transcript. The patient was treated according to PETHEMA protocol with idarubicin and ATRA. During the period of aplasia she developed thrombosis of v.hepatic sin (Budd Chiari syndrome) typ II which was with LMWH treated. The patient achieved complete remission of APL. She was further treated with LMWH until complete resolution and recanalisation of hepatic vein.
Conclusion: APL, a subtype of AML is characterized by life-threating bleeding and occasionally with thromboembolic events occuring typically during induction remission therapy with ATRA and idarubicin. In younger patients with APL accompanied with an unusual thrombotic event haemostatic and molecular tests for inherited and acquired thrombophilia should be performed.

PO 006

Transiently prolonged prothrombin times with reduced factor VII levels in acutely ill children

Creagh MD[1], Benyon L[2], Takada A[2], Johns S[1], Carson P[1] and Harris S[1]

[1]Royal Cornwall Hospitals NHS Trust, Truro; [2]Peninsula College of Medicine & Dentistry, Plymouth, UK

Background: Over the course of 3 years, eight children with prolonged prothrombin times (PT) were identified, with further testing demonstrating a consistent reduction in factor VII and a variable reduction in a range of vitamin K dependent clotting factors (V, IX & X). Correction of the PT was demonstrated when the patients returned to normal health. A literature search revealed limited case reports of vitamin K depletion in adults, suggesting linkage to poor dietary intake of Vitamin K rich foods, but of unclear clinical consequence, specifically for haemorrhage.

Aims: To determine the clinical circumstances and possible causation of prolonged PT's in children, the relationship to dietary intake of Vitamin K rich foods and the potential consequences for haemorrhage.

Methods: Patients were identified by abnormal laboratory PT (with activated partial thromboplastin time) screening tests on admission to hospital. The children ranged in age from four to seventeen years. Six were boys and two were girls. Dietary intake was formally assessed in three patients and by retrospective examination of clinical correspondence for the remaining five.

Results: Eight acutely unwell children had prolonged PT's (range 15.6s–22.2s [reference range 10.0–15.0s]). Four cases were associated with bleeding, of which two were post tonsillectomy, one with tonsillitis and one following abdominal trauma with bleeding identified on laparoscopic investigation. Of the remaining four children, none of whom had bled, two had meningitis, one with pneumonia and one with a perforated appendix who underwent surgery. All eight children had lowered factor VIIc levels (range 21–54 IU/dL [referance range 65–150 IU/dL]). Three children considered at risk for haemorrhage received vitamin K1, one post laparotomy, one with meningitis and with one pneumonia, with no subsequent bleeding episodes. In two of these children the PT rapidly responded to intravenous Vitamin K1, while one child with more persistently lowered factor VII levels received 4 weeks of oral Vitamin K1 with correction of the PT and factor VII. Of the other five children the PT and factor VII levels improved when they returned to normal health. In three of the children, formally assessed for dietary intake, their parents reported chronically poor dietary intake of Vitamin K rich foods prior to the acute illness. Of the remaining five children, it was concluded that there was probable dietary disturbance in the days prior to hospital admission.

Conclusions: Transient prolonged PT's and low FVII's may be identified in acutely unwell children, in association with both chronic and probably acute poor dietary intake for Vitamin K. This may be of significance if a child faces a haemostatic challenge, as the depletion of Vitamin K dependant factors may increase the likelihood of bleeding. Assessment of a child's dietary and haemorrhagic history is advisable for acutely ill children. Further study needs to be undertaken in children on the dietary consequences of acute illness, the effects on vitamin K intake and coagulation parameters, to determine whether this may contribute to haemorrhagic risk.

PO 007

Assessing the range of dietary vitamin K intake in children undergoing tonsillectomy

Creagh MD[1], Benyon L[2], Takada A[2], Johns S[1], Carson P[1], Burley G[1], Harris S[1] and Flanagan P[1]

[1]Royal Cornwall Hospitals NHS Trust, Truro; [2]Peninsula College of Medicine & Dentistry, Plymouth, UK

Background: Vitamin K is essential for production of the coagulation factors II, VII, IX and X, such that deficiency or antagonism can compromise haemostasis. Known causes of vitamin K deficiency include liver or malabsorptive disease, and iatrogenic causes. Dietary deficiency is not currently considered a risk factor. This Department has recently observed eight acutely ill surgical and medical paediatric patients with transient prolonged prothrombin times (PT) and factor-VIIdeficiency, unexplained by illness or drug treatment, in whom it was concluded that dietary deficiency of vitamin K was the likely causation.

Aim: To assess vitamin K intake in paediatric patients undergoing tonsillectomy and the possible consequences for haemostasis.

Methods: A pro-forma survey was undertaken by the parents of children undergoing tonsillectomy, at the time of a pre-admission clinical assessment. As there is no well-established measure in common clinical use for assessing vitamin K intake, a score was developed based on the subjective assessment by the parents for the frequency for intake of a range of foods, common to the local diet, in the preceding week. The vitamin K intake for each food was used, divided according to defined content of vitamin K per common measure (USDA National Nutrient Database) and ascribed as high, moderate or low, each category gaining 3, 2, or 1 points whilst a standard portion was assumed. Results were expressed as a score whereby the vitamin K content points were multiplied by the frequency of food consumption over the preceding week. The scores were histographically profiled and analysed for probability distribution and skewness. In addition parents were asked to comment on their child's diet when they were acutely unwell with tonsillitis. Subsequently the clinical and laboratory record at the time of surgery was assessed for complications and interventions including coagulation screening.

There were eighteen subjects, of whom 15 had progressed to tonsillectomy. The profile for the range of scored results for vitamin K intake was negatively skewed (skewness: −0.131) showing the majority of subjects had a high score, suggesting an adequate vitamin intake. Three children had four minor complications of surgery including: epistaxis (n = 1), vomiting (n = 2) and a vasovagal event (n = 1). No subject required coagulation screening at the time of surgery so PT prolongation and coagulation factor deficiency were not analysable. Fifteen children had had recurrent tonsillitis, in 61% of whom their parents reported probable reduction of vitamin K intake when they were ill.

Conclusion: The variability of vitamin K content in the diet of children prior to tonsillectomy diet has been highlighted. It is possible that during an acute episode of tonsillitis or prior to surgery, paediatric patients may undergo a dietary change which does not favour an adequate vitamin K intake and may result in transient changes in coagulation parameters and be a risk for haemorrhage. Further dietary studies of vitamin K would necessitate a larger sample size with an improved validated clinical measure for assessing intake.

PO 008

Acquired hemophilia A with severe anemia

Dahmani B, Lascar S, Fissore-Magdelein C, Sorlin P, Magdelein X and Robino C

CH Monaco Princesse Grace, MONACO, France

Background: Acquired hemophilia A (AHA) is a rare bleeding disorder caused by an autoantibody to coagulation factor (F) VIII. It is charac-

terized by soft tissue bleeding in patients without a personal or family history of bleeding.

Aim: To increase awareness of this disorder among clinicians, because bleeds in AHA are often spontaneous, and the severity does not correlate with the factor VIII level or strength of the inhibitor.

Methods: Diagnosis and treatment methods are based on clinical experience and involve coagulation studies and the use of coagulation factor concentrates.

Results: Diagnosis and treatment: A 88-years-old woman presented to our hospital, after a fall, with hematoma and functional impotence of the left lower limb. Here hemostasis was previously normal. She did not have any family history of bleeding disorders. Laboratory tests revealed a white blood cell count of 8350 cells/μL with an initial hemoglobin level of 5.6 g/dL and platelet count of 313 × 103 cells/μL. Coagulation studies revealed a normal prothrombin time, and prolonged aPTT of 70 s. The presence of an inhibitor of coagulation was diagnosed via prolonged aPTT and a mixing study that did not correct with the addition of normal plasma PTT when an immediate mixing test was performed; with a ratio of patient's plasma to normal plasma of 1:1. Quantitative assays factor VIII activity 4% and the presence of factor activity inhibitor measured at 1.5 Bethesda units in the serum. Acquired hemophilia A (AHA) was diagnosed.

Four units of red blood cells were transfused, and 75 UI/kg/day of human factor VIII during 3 days, oral prednisone therapy 1 mg/kg/day, plus human erythropoietin 'Darbepoetin alfa' 40 μ once a week, every Friday during 5 weeks. Here aPTT, and factor VIII gradually improved.

Summary/Conclusion: Clinicians should suspect a diagnosis of acquired hemophilia in patients with unexplained persistent and profound bleeding from soft tissue and mucosa and in any patient who presents with bleeding and a prolonged aPTT without other cause, and without any history of bleeding. Our patient was discharged with prednisone as immunosuppressive therapy with treatment plan for a slow tapering of steroids as well as careful monitoring of here coagulation parameters disorders.

Further diagnostic investigations in terms of finding an underlying cause for the acquired hemophilia were done, we did not find any etiological factors associated with AHA [autoimmune disease, drugs, solid tumor, vaccination, hematologic malignancies, skin disorders, respiratory disorders, infections, others (diabetes, surgery), idiopathic]. Treatment should be focused on controlling the immediate bleeding episode and suppressing the immune reaction against the coagulant factor. Immunosuppressive therapy with steroids or cyclophosphamide for inhibitor eradication should begin immediately after diagnosis is made.

PO 009

Multiple myeloma presenting with acquired factor VIII inhibitor – a case report

Fidelis F[1], Oliveira R[2], Guimaraes JP[2], Graciott E[2], Pires G[2], Rezende P[2], Ribeiro D[2] and Ribeiro D[2]

[1]Hospital das Clinicas da UFMG; [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Introduction: Acquired factor VIII inhibitor (AFI) is a very rare entity with an estimated incidence of 0.2–1 per million and a mortality rate ranging from 8% to 22%. This condition occurs in association with drugs, viral and parasitic infections, in autoimmune conditions such as graft vs. host disease, solid tumors and myeloproliferative and lymphoproliferative disorders. Only five cases of AFI have been associated with multiple myeloma (MM). Acquired factor VIII inhibitor usually presents with bleeding (cutaneous and mucosal) while hemarthrosis, which is commonly seen in patients with congenital hemophilia, is very infrequent in AFI.The diagnosis of the acquired inhibitor is usually made with the laboratory finding of an elevated activated partial thromboplastin time (aPTT) that cannot be corrected by plasma mixing study (incubating for 2 h at 37 °C equal volumes of patient plasma and normal plasma), and further confirmed by low factor VIII activity/antigen levels along with elevated factor VIII inhibitor levels using the Bethesda assay. Treatment is usually based on steroids and cyclophosphamide.

Case report: A 39-year-old man was referred to our hematology unit to evaluate a diagnosis of myeloma. Two months prior to this presentation he started with hematomas in his body and pain in your right thigh. He visited many medical services looking for a diagnosis.

The patient had no history of bleeding disorders. The physical exam was normal.

Amagnetic resonance was performed and showed lytic lesion in acetabulum and some images suggesting blood collections in psoas and gluteo muscles.

His initial labs showed a normal hemogram and the coagulation profile demonstrated a normal protrombin time and an elevated activated partial thromboplastin time of 58s (control, 31s).

Serum protein electrophoresis showed a biclonal band between beta gamma region. An IgA paraprotein was identified by Imunofixation. Bone marrow aspiration showed normal celularity with 28% of plasma cell infiltration.

In our Unit he was submited to further evaluation. X-ray films of the bones revealed no lytic areas. The serum Beta2 microglobulin level was normal. The liver function was normal, also serum calcium and serum dehydrogenase. Activated partial thromboplastin time was repeated and could not be corrected by mixing with normal plasma. Additionally, other coagulation tests including fibrinogen and factor assays (IX, XIII, X) were in normal rangeslFactor VIII activity level was found to be 4% while the Bethesda assay confirmed the presence of an AFI.

A diagnosis of IgA multiple myeloma (Durie Salmon stage IA and International Scoring System stage I), associated with acquired FVIII inhibitor was made and treatment with cyclophosfamide, dexametasone and thalidomine was started.

He is receiving the second cycle and activated partial thromboplastin time measured in the last visit was 49s (control, 34s) and he hasn't been no bleeding or new hematomas.

Conclusion: This case demonstrates that AFI can be seen in plasma cell disorders such as MM, and can be the first manifestation of these diseases. Therefore this association should be remembered in patients with hematological malignancies and excessive bleeding not related with low platelet counts and with abnormal coagulation tests.

PO 010

Factor X inhibitor: an unexpected bleeding disorder with a therapeutic challenge

Fouassier M[1], Cherel G[2], Graveleau J[1], Bezaa A[2], Trossaërt M[1], Loubiere C[2], Ardillon L[1], Lenting PJ[2], Ternisien C[1], Denis CV[2], Sigaud M[1] and Christophe OD[2]

[1]CHU de Nantes, Nantes; [2]Inserm U 770, Le Kremlin-Bicêtre, France

Background: Isolated factor X (FX) deficiency is a rare coagulopathy. It may be hereditary or even more rare an acquired condition. Acquired FX deficiency states are usually secondary to systemic amyloïdosis in which FX binds irreversibly to amyloid fibrils or in association with some malignancies. Sporadically, transient selective FX deficiency has also been reported in the absence of amyloidor cancers.

Patient and Results: A 86-year-old patient was referred to our department for persistantepistaxis and gum bleeding. His medical history consisted of high blood pressure, appendectomy, total hip replacement and ileus requiring surgery. None of these surgical procedures had been complicated with abnormal bleeding. Clinical examination showed several hematomas: left forearm, right testis and right buttock. Initial laboratory testing revealed a platelets count of 196 × 10^9/L, normal fibrinogen concentration (4.6 g/L) but a low haemoglobin level

of 7.3 g/dLrequiring blood transfusion. There was no sign of vitamin K deficiency. Furthermore, serum protein electrophoresis and immunoelectrophoresis were normal and there was no immunoglobulin free-light chain in serum, indicating neither amyloïdosis nor monoclonal gammopathy.
Laboratory abnormalities includedsignificantly prolonged prothrombin time (PT), activated partial thromboplastin time (aPTT) and an aPTT mixture assay was slightly above the reference interval. Specific factor assays revealed a profoundly decreased FX activity (0.01 IU/mL), whereas FX antigen was 0.3 IU/mL. Although a Bethesda inhibitor assay for a FX inhibitor was negative, patient plasma fully inhibited FX activity in Russell's viper venom and tissue factor/factor VIIa-based FX chromogenic assays. Moreover, an immunosorbent assay showed the presence of anti-FX IgG antibodies, which did not react with murine FX or other human vitamin K-dependent coagulation factors. Typing studies revealed that patients' immune response towards FX involves preferentially IgG1 and IgG4. Pre-incubation of FX with patients' IgG did not alter FX clearance following injection in mice.
Therapy with an infusion of Prothrombin Complex Concentrates was initiated but immediately stoppedbecause of an anaphylactic shock, and treated successfully by epinephrine and corticosteroids. The treatment further resulted in normalization of FX levels.
Conclusions: Prothrombin complex concentrates are given as replacements in cases of acquired or inherited deficiency. However, our study showed that allergy or anaphylaxis should be considered especially when the patient has an idiopathic, isolated acquired FX deficiency with no history of bleeding, and no primary pathology that could cause FX deficiency. Corticosteroids alone (1 mg/Kg/d) permitted to obtain an increase of FX activity and a clinical improvement with no further hemorrhagic event.
These data also demonstrate that acquired FX inhibitors appearing in transient selective FX deficiency in the absence of amyloid or malignancies can display specificity against restricted functional domains of FX.

PO 011

Recombinant activated factor VII in treatment of bleeding complications in thrombocytopenic patients

Galstyan G, Makarova P, Polokhov DM and Orel E
Scientific Center for Hematology, Moscow, Russia

Background: Hemorrhage in patients (pts) with thrombocytopenia usually is treated with platelet transfusions. In cases of an inefficiency or impossibility of platelet transfusion recombinant activated factor VII (rFVIIa) may be useful.
Aim: Aim of the study was to evaluate efficacy of rFVIIa to control of bleeding in thrombocytopenic pts and relationship between clinical response and coagulation tests.
Methods: We observed 6 pts with thrombocytopenia and hemorrhagic syndrome who didn't answer platelet transfusions due to alloimmunization or who couldn't receive platelets because of religious beliefs (Jehovah's Witness). All pts were treated with single bolus dose (40–90 mcg/kg) of rFVIIa (Koagil VII, Masterclone, Russia). APTT, INR, FVII:C level,
endogenous thrombin potential (ETP) and Thromboelastography (TEG) were evaluated before rFVIIa administration, in 15 min, in 60 min and in 120 min after rFVIIa administration.
Results: In all pts clinical response was achieved. In 3 pts gastrointestinal bleeding was stopped. In patient with subarachnoid hemorrhage after injection of rFVIIa good clinical response was achieved despite low platelet level (6 10^9/L). Administration of rFVIIa allowed to execute invasive procedures (lumbar puncture, catheterization of central vein). In patient with aplastic anemia (Jehovah's Witness) and very low blood platelet count (1 × 109/L) two repeated injection of rFVIIa reduced hemorrhagic syndrome (epistaxis, petechia) and, allowed to perform catheterization of central vein. The plasma concentration-time profile of FVII:C and ETP demonstrated a dose dependent increase. The peak of increase of FVII:C (from 59% to 545%) and ETP (from 1000 to 1200 nM min) was noted in 15 min after rFVIIa administration. However maximal clinical response and normalization of TEG parameters (R, MA) were observed only in 60 min, when the level of FVII:C started decreasing (to 430%). In 120 min level of FVII:C remained higher than norm (370:), but parameters of TEG came back to initial levels.
Conclusion: rFVIIa treatment showed an improvement in the control of bleeding in pts with thrombocytopenia who for various reasons couldn't receive therapy by platelet concentrates. Clinical response and improvement of parameters of TEG didn't coincide with increase of a level of FVII:C in plasma.

PO 012

Long-term follow up in Acquired Hemophilia A: clinical courses and outcomes observed in a single Hemophilia Centre

Gamba G[1], Ghidelli N[1], Lodo F[1], Montani N[1] and Ambaglio C[2]
[1]University of Pavia; [2]Fondazione IRCCS Policlinico S.Matteo, Pavia, Italy

Background: The prospective study from the European Acquired Hemophilia Registry (EACH2) reported the clinical outcomes of a large number of patients after < 1 year follow up.
Aim of the study: To report the clinical courses and outcomes in patients with Acquired Hemophilia A (AHA) enrolled during 5 years in Hemophilia Centre of Pavia.
Methods: Since June 2007 to July 2012 AHA has been diagnosed in 18 pts (8 women and 10 men) aged between 27 and 93 years. Twelve pts were over 70 years. AHA was idiopathic in 9 pts (50%), attributed to Autoimmune diseases in 4 pts (22%), to malignancies in 3 pts (17%), to pregnancy (PPAHA) in 2 pts (11%). The pts have been treated on demand with by passing agents (aPCC or rFVII) during acute bleeding and with immunosuppressive drugs [PDN ± CTX and in 3 cases of failure with rituximab), to eradicate the inhibitor.
Results: One man (62 year) with malignancy and one woman (89 years) with idiopathic AHA died after 2 months from AHA diagnosis for causes not related to hemorrhagic complications. Stable Complete Remission (CR) of AHA was obtained in 12 pts (66%) after a period of time variable from 1 month to 2 years. Three pts achieved remission only during PDN treatment (clinical follow up 26 months, 10 months and 6 months) Among the 8 pts (44%) in CR followed for more than 3 years, 2 pts relapsed: in the first pt with previous PPAHA after 35 months of CR, not in relation to another pregnancy, in the second pt with idiopathic AHA after 25 months of CR. Two pts died respectively after 4 years and 1 year from achieving CR for causes not related to AHA.
Conclusion: The causes of death in patients with history of AHA is frequently not related to this disease. CR is obtained in a large percentage of cases, nevertheless relapses can occur even after a long period from CR, so that a clinical follow up is lifelong recommended.

PO 013

Haemostatic parameters including Factor VIII levels in different types of tuberculosis in Northern India

Gupta N, Kutiyal A and Garg S
Maulana Azad Medical College, New Delhi, India

Background: Vascular occlusions- cerebral and peripheral- are encountered in our patients with tuberculosis with upto 10% being peripheral venous thrombosis and cerebral arterial in 6- 41%. Haemostatic abnormalities in these clinical subjects is inadequately studied especially from developing countries which report 95% of the 5.8 million new cases annually (WHO 2009).

Aim: To study the coagulation parameters including coagulation Factor VIII level in different types of tuberculosis at baseline and after intensive phase antitubercular treatment.
Methodology: One hundred and twenty eight adult patients over 12 years of either sex with newly diagnosed tuberculosis of different sites- categorized as pulmonary, CNS, disseminated and others- were included after written informed consent. Along with detailed clinical assessment, the haemostatic parameters assessed included CBC, Prothrombin Time (PT), Activated Partial Prothrombin Time (APTT), Factor VIII level, Fibrinogen and D-dimers. These parameters were repeated after 2 months of intensive standard antitubercular therapy (ATT).
Results: Mean age of the 128 subjects was 31.55 ± 15.03 years, range 12–75 years. Pulmonary, CNS, disseminated and other types of tuberculosis comprised 30.5%, 28.9%, 17.2%, and 23.4% respectively.
Abnormal PT and APPT at baseline was seen in 64 (50%) and 23 (18%) cases respectively whereas the mean coagulation Factor VIII level was 125.08 ± 72.83%. The Factor VIII was deranged in 45 (35.15%) cases, being high in 28.12% and low in 7.03%. Baseline fibrinogen levels were altered in 73 (57%), with 62 being elevated beyond 400 mg%. D-Dimers were high in 57.8% patients. Platelets were disturbed in 66 (51.5%), with thrombocytopaenia in 47 and thrombocytosis (exceeding 400×10^9/L) in 19 cases.
After intensive phase ATT for 2 months, the PT reverted to normal in 32 (50%) of 64 abnormal at baseline across all tuberculosis ($P < 0.01$). APTT did not show a similar trend. Coagulation Factor VIII levels did not change significantly after ATT (125.08 ± 72.83 vs. 126.21 ± 37.65 IU/mL) whereas the fibrinogen levels decreased significantly from 391.43 ± 167.34 to 272.33 ± 92.66 mg% ($P < 0.01$). Cases with elevated D-dimers came down to 12.5%. All the abnormalities in platelet counts- thrombocytopaenia as well as thrombocytosis-reverted to normal within the 2 months of ATT.
Subgroup analysis on the four different types of tuberculosis mirrored these results except for the PT in disseminated tuberculosis where the *P* value was 0.08.
Conclusions: Platelet disturbances were seen in half of the patients with tuberculosis, thrombocytopaenia being thrice as common as thrombocytosis. Elevated PT/INR was present in half of all cases whereas APTT was deranged in 18%.
Coagulation Factor VIII levels were high in 28% cases, high fibrinogen levels in 48% cases and high D-dimers in 58%. These elevated fibrinogen, D-dimers, and coagulation Factor VIII levels observed in patients with different types of tuberculosis may favour a risk to hypercoagulable state and which improved with anti-tubercular therapy.

PO 014
Snake venom induced coagulopathy

Hiremath V
Vijayashree Diagnostics, Bangalore, India

Background: Snake venom induced mortality and morbidity is a neglected health hazard in tropical and sub-tropical regions particularly in rural areas of the world. Snake venom secreted from highly specialized venom glands, has evolved to capture prey. Primarily, the venom is evolved to immobilize, kill and digest the prey and is a potent defensive weapon. It is a complex mixture of enzymatic and non-enzymatic components affecting various organs and haemostatic system.
Aim: The present study aims at evaluating snake venom induced coagulopathy, with differential effect of 'big four' venomous snakes of India (*Naja naja*, *Daboia russelli*, *Echis carinatus* and *Bungarus caeruleus*).
Method: The effect of 'big four' snake venoms on haemostasis was evaluated using pooled human citrated plasma and citrated plasma obtained from venom injected rats. Routine clotting assays (PT, APTT), Fibrinogen content, specific factor assays were used to determine the effects on haemostasis and visco-elasticity tests for clot formation were used to evaluate pro-coagulant/anticoagulant nature of snake venoms.
Results: The findings revealed differential action of venom from big four snakes towards coagulation cascade. The results showed that of *D. russelli* and *E. carinatus* venoms exhibited pro-coagulant activity, whereas *N. naja* and *B. caeruleus* venoms are anticoagulant in nature. *E. carinatus* venom showed strong pro-coagulant and *D. russelii* venom showed defibrinating effect. *N. naja* venom showed stronger anticoagulant than *B. caeruleus* venom. Further, the mechanism by which *N. naja* venom exhibits anticoagulant effect was evaluated. Clotting times in PT and APTT assays were prolonged with the increasing concentration of the venom, with minimal effects on fibrinogen level, FX and FVII activities. Interestingly, FVIII is significantly decreased with the increasing concentration venom and this decrease was time-dependent. FVIII was completely inactivated after 12 min at 1 mg/mL of venom. Similar results were obtained in plasma from venom injected rats (60 min after injecting respective lethal dose of *N. naja*, *E. carinatus*, *D. russelli* and *B. caeruleus* through intraperitoneal route), with slight variations. In contrast, no effect was seen 30 and 45 min after venom injection. Thus, *N. naja* venom exhibited anticoagulant effect under both *in vitro* and *in vivo* conditions. Similarly, *D. russelii* venom exhibited defibrinogenating activity in both conditions. In contrast, *E. carinatus* venom exhibited pronounced pro-coagulant effect *in vitro* and anti-coagulant effect *in vivo*. *B. caeruleus*venom exhibited negligible effect towards rat plasma.
Conclusion: The marked differential effect on coagulation cascade will be useful in treatment of snakebite victims, based on the characteristic haemostatic effect. The administration of specific anti snake venom based on the observed effects will be an important strategy in treatment and management of snakebite victims.

PO 015
Bleeding into tongue – case history of acquired haemophilia A

Hrdlickova R[1], Cermakova Z[2], Blahutova S[1] and Ryzi M[1]
[1]The University Hospital in Ostrava; [2]Medical Faculty, University of Ostrava, Ostrava, Czech Republic

Background: Acquired haemophilia A is a rare form of acquired coagulopathy caused by autoantibodies against coagulation factor VIII. It is characterized by major bleeding complications often life-threatening.
Aims: The authors report case history of acquired haemophilia in 85 years old woman with medical history of hypertension, ischemic heart disease, ischemic stroke without neurological consequences and no past bleeding history during operation (appendectomy and hysterectomy for myomas) and no family history of coagulopathy. The first sudden onset of bleeding was observed in the oral cavity – mostly into the tongue and under tongue oral mucosa when she was admitted to the department of internal medicine for generalized worsening.
Methods: Laboratory investigations showed a prolonged APTT-R (activated partial tromboplastin time ratio) 4.1 and normal PT (prothrombin time) and TT (thrombin time). Fibrinogen and antithrombin were normal. Failure of correction on mixing study prompted further evaluation of individual clotting factors activity: FVIII (0.8%), FIX (47.7%), FXI (52.7%), FXII (38.8%). The low FVIII:C (FVIII activity) was confirmed by testing with Actin FS, Siemens (insensitive to lupus antikoagulant) – 1.8%. The FVIII inhibitor titer was quantified 13.6 BU (Bethesda units). However, lupus anticoagulant was also confirmed by platelet neutralization procedure (PNP).
Result: Bleeding complications were well controlled by bypassing agents rVIIa at a dose 100 μg/kg every 3 h during the first day and by aPCC (activated prothrombin complex) at a dose 90 IU/kg twice daily when hematuria or soft tissue bleeding and diffuse bruising manifested. Immunosuppressive therapy was initiated with methylprednisolone 500 mg infusion first 3 days and continues with combination prednisolon 1 mg/kg and cyclophosphamide 1 mg/kg. After 6 weeks

from therapy initiation antibody titer did not drop significantly. Inhibitor eradication was successful after the use of second line agent rituximab 375 mg/m² weekly for 4 weeks. The inhibitor completely disappeared after 128 days from diagnosis and patient is still in remission (9 months of dispenzarization). Underlying associated disease was not found except only laboratory manifested lupus antikoagulant.
Summary/Conclusion: Rituximab used as a second line therapy in elderly patient was well tolerated, only infection complications were observed after this treatment – bronchopneumonia and urine infection. Patient is still in remission in this time.

PO 016

Acquired hemophilia A: literature review and report of two cases

Lluch-Garcia R, Valero-Nuñez M, García-Navarro I, López-Martínez A, Luis-Hidalgo MM, Bautista-Claver T, Sancho-Tello R, Mena F and Mayans-Ferrer JR
Arnau De Vilanova Hospital, Valencia, Spain

Background: Acquired hemophilia A (AHA) is a hemorrhagic disorder caused by autoantibodies, generally IgGk4, directed against circulating factor VIII (FVIII) of coagulation which neutralize its procoagulant function.
Is a rare bleeding disorder with an estimated anual incidence between 1 and 1.5 per million per year, with a biphasic behavior, with a first peak occurring among young adults due to cases in women in the postpartum period, and a second major peak in elderly patients.
In approximately 50% of cases, FVIII autoantibodies occur in patients lacking any relevant concomitant disease and remain idiophatic, while the rest cases may be associated with hematologic malignancies, solid cancers, autoimmune disorders, infections, drugs or other illnesses.
The diagnosis is based on the initial detection of an isolated prolongation of activated partial thromboplatin time (APTT) which does not normalize by mixing study and a reduced FVIII levels, with evidence of FVIII inhibitor activity.
The treatment of AHA is based on two aspects: treatment of acute bleeding and eradication of the acquired FVIII-inhibitor.
Patients: Two clinical cases are presented, one acquires and one secondary. An 87 years old man with no past medical history and a 60 years old man with rheumatoid artritis, AHAI an refractory anemia. Both consulted for mucocutaneous bleeding, objectifying lengthening of TTPA isolated, not corrected with mixing test, decreased en FVIII level and detection inhibitor against FVIII. The 87 years old patient also presented TVP in the right leg with positive lupus anticoagulant. Both were treated with hemostatic treatment with rFVIIa. Treatment was prescribed corticosteroids vs. inhibitor (1 mg/kg/weight) y rituximab (375 mg/m^2/per week X 4 doses). In a case was added previously cyclophosphamide. Both patients responded with increased in FVIII level above 40% and cessation of bleeding manifestations.
Discussion: AHA is a rare autoinmune bleeding disorder. Bleeding into the skin, muscles and soft tissues are the principal clinical manifestations.
The diagnosis should be considered in patients with unexplained bleeding and prolonged activated partial thromboplastin with no previous personal or family history of bleeding. In laboratory the mixing test (mixture of patient plasma and normal plasma) is important, in AHA APTT does not normalize after this test with reduced FVIII levels and an inhibitor against FVIII.
AHA treatment is based on three aspects: 1) treatment of bleeding with bypassing agents as a first-line treatment (aPCC and rFVIIa), 2) eradication of the inhibitor with immunosuppressive agents (prednisone alone or with cyclophosphamide as a first-line treatment) and 3) treatment of the underlying disorder. Rituximab may be useful as first-line therapy in patients for whom immunosuppressive agents fails or are contraindicated.
After treatment AHA must be monitored with regular APTT, FVIII activity and FVIII inhibitor titer measurement with accurate clinical evaluation.
AHA is a rare coagulation disorder that usually presents to clinicians without previous experience. Prompt recognition is very important to initiate an early management.
Noted for its rarity deep vein thrombosis with hemorrhagic disease in one of our cases.

PO 017

Our experience in the use of prothrombin complex concentrate in patients with acute haemorrhage

Lokar L[1], Lokar M[2], Bizjak B[1] and Šega M[1]
[1]University Clinical Center Maribor; [2]University of Maribor, Maribor, Slovenia

Background: Prothrombin complex concentrate (PCC) is recommended for rapid reversal of vitamin K anticoagulants which is essential when acute bleeding or emergency surgery occurs. Prothrombin complex concentrate produce more rapid effect with a better clinical outcome, and do not cause volume overload compared with fresh-frozen plasma (FFP).
Aim: Our goal is to report our institutional experience with Prothrombin complex concentrates for the treatment of acute bleeding in the surgical settings.
Methods: This is a retrospective analysis in a University Clinical Center Maribor with 1288 beds. We report a case series of 64 patients with acute haemorrhage who were treated with PCC in the last 2 years.
Results: During 2011–2012 sixty-four patients received PCC, 75% (fourty-eight of sixty-four) men and 25% (sixteen of sixty-four) female. The most common causes of bleeding among patients were cardiac or vascular surgery (17), abdominal surgery (12), multi-trauma (12), obstetrical complications (1), neurosurgery (14), urology (4), orthopedic surgery (1) and patients in internal intenive care unit (3). Forty-five percent (twenty-nine of sixty-four) patients were on anticoagulant therapy with warfarin or acenocoumarol. Ten of them were neurosurgery patiens, three cardiovascular, six multi-trauma, six abdominal surgery, three urology and one hematologic patient. Six of twenty-nine patients who were receiving anticoagulants were overdosed while twenty-three patients were in therapeutic range. The median dose of PCC administred was 1800 units per patients (25–50 IU/kg body weight). Most patients with INR in therapeutic range achieved an INR of 1.5 or less after one prothrombin complex concentrate infusion while patients with INR above therapeutuc range did not.
Conclusions: Rapid reversal of excessive anticoagulation with PCC should be undertaken in patients with serious bleeding at any degree of anticoagulation. These patients have much better outcome than patients treated only with FFP and vitamin K.

PO 018

Acquired haemophilia: why the delay in diagnosis?

Louw S
NHLS, Johannesburg, South Africa

Background: Acquired haemophilia is a rare but potentially life-threatening bleeding disorder resulting from the autoimmune depletion of a coagulation factor, most commonly factor VIII. Patients without any previous bleeding history presents with sudden onset of haemorrhage. Urgent laboratory diagnosis and quantification of the inhibitor is necessary in order for appropriate treatment to be instituted.
Case study: A 32 year old patient presented to a tertiary care facility at 37 weeks gestation with spontaneous labour and a breech presentation. The patient underwent an uneventful Caesarean section. Post surgery the patient's abdomen was distended with ongoing haemorrhage from the surgical scar. The haemoglobin remained low (< 6 g/

dL) despite multiple blood transfusions resulting in a re-look laparotomy and bilateral uterine artery embolisation. The first PI/PTT was performed 4 days after admission with a twice normal aPTT but no correction study was done. The prolonged aPTT was confirmed on repeat testing with the first correction study performed 12 days post admission. The aPTT failed to correct and factor VIII and IX levels were performed 14 days post admission followed by quantification of the factor VIII inhibitor. At the time of diagnosis the patient had received more than 50 units of packed cells, multiple platelet and FFP units and developed a femoral artery aneurysm at a vascular access site. After the correct diagnosis the patient received appropriate haemostatic agents and therapy to eradicate the inhibitor.

Discussion: Delayed diagnosis of acquired haemophilia can have serious consequences. This delay has also been documented in other centres with a range of 3 days to 9 months from the onset of bleeding to correct diagnosis. Omission of baseline haemostatic parameter testing and lack of thorough analysis of abnormal laboratory results contribute to the delayed diagnosis.

Keywords: Acquired haemophilia; life-threatening; laboratory diagnosis.

PO 019

Bleeding tendency associated with a coagulation inhibitor in two patients with monoclonal gammopathy of undetermined significance

Low J, Jarvis S, Desai S and Joseph J

St Vincent's Hospital, Sydney, NSW, Australia

Background and Aims: Acquired haemostatic defects affecting coagulation, fibrinolysis or platelet function may occur in patients who have abnormal levels of monoclonal protein (M-protein) in the blood. We present the cases of two patients with a monoclonal gammopathy of undetermined significance (MGUS) – [WHO ICD-O Code (9765/1)], who presented with a history of moderate bleeding and an abnormal APTT.

Methods and Results: Patient 1 was a 70 year old female who presented for elective insertion of a permanent pacemaker. She had developed a bleeding tendency later on in life, mainly related to invasive procedures and surgery. She was known to have a MGUS with an IgA Lambda M-protein of 7 g/L and considered to have a lupus anticoagulant (LA) on testing performed elsewhere. The APTT (Actin FS, a lupus insensitive reagent) was prolonged at 57s (Reference Interval 25–35s) and there was no correction in mixing studies, demonstrating the presence of an inhibitor. The prothrombin time and fibrinogen level were normal but the thrombin time (TT) was slightly prolonged at 13 s (RI 10–12s. The intrinsic factors were markedly decreased (1–4%), rising only slightly higher when tested with higher dilutions of the patient plasma, suggesting the presence of a LA like inhibitor. The inhibitor also interfered with factor specific inhibitor assays (Bethesda). However, LA testing (RVV and APTT with Actin FSL and Actin FS) performed in our laboratory, was negative. Chromogenic Factor VIII was 114%. The patient was managed with infusion of fresh frozen plasma (FFP) prior to the procedure, which went ahead without any bleeding complications whilst in hospital or following discharge.

Patient 2 was a 53 year old male with a several year history of mild to moderate bleeding after surgical procedures which were managed with infusions of FFP. The APTT was always prolonged with an inhibitor type profile similar to Patient 1 in that intrinsic factors were moderately reduced in the presence of a LA-like inhibitor but LA testing was negative on different occasions except for one. Some years later, he was found to have an IgG Lambda M-protein of 9 g/L with a diagnosis of MGUS.

Conclusions: It was concluded in these 2 cases of patients with MGUS and a history of bleeding, that the abnormal APTT was due to the presence of the M-protein (one an IgG and the other an IgA), the mechanism of action remaining unclear. These laboratory studies illustrate the difficulties in distinguishing a lupus like inhibitor from other inhibitors. With both patients, intrinsic factor assays were affected by the presence of the inhibitor to various degrees with increasing factor levels measured in higher dilutions of the patient plasma. This interference with factor assays was also evident in Bethesda inhibitor assays but no specific factor inhibitor could be demonstrated. Nor was there any consistent laboratory evidence of the presence of a lupus anticoagulant. Both cases were managed successfully with FFP infusions, although the rationale for the efficacy of FFP also remains unclear.

PO 020

Acquired Von Willebrand syndrome: about one observation

Messaoudi R, Hadj T, Benlaledj D, Rahal Y, Chérif-Hosni A, Bensahli M, Bekadja MA and Arabi A

University hospital Oran, Oran, Algeria

Introduction: Von Willebrand syndrome is an acquired rare bleeding disorder developing in an elderly patient with no history hemorrhagic staff or family. Mechanisms are multiple, the most common autoimmunity, adsorption on the surface of tumor cells or accelerated proteolysis.

Objective: Difficulty therapy in a patient with Von Willebrand-acquired. Observation: patient aged 69 with a history of mono arthritis in 1972 operated for cholelithiasis in 1976 tonsillectomy in 1995 extraction of a molar in 1995, 2007 giant hematoma of the right buttock after intramuscular injection. In 2010, the etiological severe haemorrhagic syndrome following the bite of a language concluded acquired von Willebrand disease. Laboratory tests showed normal bleeding time 7 min (ivy-incision), an aPTT of 51 s (M/T = 1.64) while the TP is normal rate factor VIIIC collapsed to 12.60% and Von Willbrand factor VWF Ag: 7%, vWF-RCo 3%, the ratio RCo/Ag < 0.43, the systematic search for autoantibodies discovered an anti-VWF 8 IU (neutralization test) associated with anti VIII-7UB by Bethesda Nijmegun method. In France, in April 2012 angina secondary to thrombosis of the circumflex artery. In the pre-opéraoire is diagnosed with von Willebrand disease. The patient was operated under emergency Willebrand factor without incident.

Discussion: (1) The acquired Willebrand disease: age, lack of personal history and/or family history of hemorrhagic disease. Our patient has a mono arthritis, decreased VWF-RCo and FvW-RCO/Ag ratio < 0.7. VWF antibody that is found in 16% (Ref 1) cases is found in our patient is most associated with anti-VIII. (2) In our patient, the mechanism character is selected according to the criteria defined by the International Register of von is probably related to mixed proteolysis accelerated by the existence of a thrombus in the circumflex artery (21% of cases in the literature) and an autoimmune mechanism in the presence anti-VIII and anti-VWF (2–6% of cases in the literature). The existence of a mono arthritis is a chronic course of disease in favor of a system that would settle low noise. (3) The susceptibility of our patient bleeding risk and thrombotic risk may be increased by age, and history of hypertension and dyslipidemia. (4) feature in our patient, it presents a antiFVW and anti VII acquired therapeutic problem.

Conclusion: Von Willebrand syndrome is a disease acquired exceptional. But we must think in the elderly and therefore to search systematically.

Inhibitor characterization in acquired haemophilia and its influence on bleeding profiles and treatment response: CIHA-01 project

Mingot ME[1], Marco P[2], Aznar JA[3], Altisent C[4] and GTHI group[5]
[1]Regional Universitary Hospital Carlos Haya, Málaga; [2]Alicante General Universitary Hospital, Alicante; [3]Universitary Hospital La Fe, Valencia; [4]Vall d'hebron Hospital, Barcelona, Spain; [5]SETH, Thrombosis and Haemostasis Spanish Society, Spain, Spain

Background: Acquired haemophilia (AH) is a rare autoimmune bleeding disorder induced by autoantibodies against clotting factors. The most frequent target is factor VIII (FVIII). Clinical picture is an acute or recent onset of bleedings in subjects without personal or family history of bleeding disorders, associated with a long activated partial thromboplastin time (aPTT). Bleeding pattern is different from congenital haemophilia, typically with more mucocutaneous and soft tissue events. There is no correlation between residual FVIII, inhibitor titer and severity of bleeding, we propose that FVIII target epitopes could influence inhibitor characteristics, bleeding profile and treatment results.
Aims: To recognize FVIII epitopes target in AH.
To analyse any correlation between these epitopes, inhibitor kinetic and titre, bleeding severity, haemostatic and eradication treatment response.
To identify changes in inhibitor characteristics throughout AH treatment.
Methods: This is a prospective, descriptive, non-interventional observational study. Ethics Committee evaluation and informed consent are requested from all patients. Expected number of patients: 30 (expected diagnosis rate of 40 cases-year, and an inclusion rate of 35%). Sampling schedule: At diagnosis, 14 days post-diagnosis, 56 days after remission and free from eradication treatment. If eradication fails and an alternative therapy is initiated, sampling schedule will be repeated. Demographic data to include: age, sex, underlying disorders, bleeding profile, haemostatic and immunosuppressive treatment, transfusions and treatment adverse events. Haemostatic parameters: FVIII activity (one stage coagulation method), mixing test (one stage based on Kasper method), FVIII inhibitor titer (Bethesda method) and epitope mapping by immunoblot analysis.
Results: Patients recruitment started in June 2011 and it is still open. By December 2012, 26 centers have applied for inclusion. Nineteen patients have been included. Four of them died before second sample extraction. Six subjects have completed the study. Nine patients are on sampling period. In the six evaluable patients, median age is 63 years-old (range 19–82). AH was idiopathic in all cases but one (drug associated). The median pick inhibitor titre is 21 BU (Bethesda Units) (range, 17–400). Kinetic was type 2 only in one case. Three patients show reactivity against light chain and A1 and A2 domains, two patients against light chain and other one against A2 domain. First line treatment was prednisone or prednisone and cyclophosphamide in all cases. Two patients required second-line treatment. One patient did not respond to eradication therapy even after 3° lines treatment. He was a 65 years-old, idiopathic HA, kinetic type 1 and 30BU inhibitor of antibody against the light chain. Only one patient changed antibody specificity during immunosuppressive therapy. He is a drug-associated AH, 400BU titer, type 1 kinetic, specificity against light chain and A1 and A2 domain. He failed 1° line treatment and in sample just before 2° line treatment, specificity moved to light chain.
Conclusions: By the moment is not possible to get any conclusion. We hope to collaborate with knowledge to predict clinical profile and treatment response in AH.

PO 022

Accuracy of thromboelastometry analysis in detecting patients treated with vitamin k antagonists

Nagler M[1], Bachmann LM[2] and Wuillemin A[3]
[1]Inselspital University Hospital, Berne; [2]Medignition Inc., Zug; [3]Luzerner Kantonsspital, Lucerne, Switzerland

Background: The accuracy of thromboelastometry analysis to rule-out patients treated with oral anticoagulants (OAC) such as vitamin k antagonists (VKA) is unknown. Existing studies suggest limited sensitivity, but no accuracy analysis has been done. A low sensitivity may limit the clinical value of thromboelastometry in trauma patients because VKA are common, are associated with an increased risk for bleeding, and represent an important risk factor for mortality in this setting.
Aims: We investigated the extent of accuracy as determined by sensitivity, specificity and the negative likelihood ratio of thromboelastometry analysis in detecting patients treated with VKA and we calculated the probability that a patient is treated with VKA given a negative test result.
Methods: To preclude confounding variables such as dilutional coagulopathy, thrombocytopenia or acute traumatic coagulopathy, the investigation was conducted in stable patients without other risk factors for bleeding. The study was approved by the local ethical review board and all participants provided written informed consent. We enrolled patients consecutively that were evaluated for risk of recurrent venous thromboembolism between February 2011 and October 2012 at our institution. Participants were stratified according to (a) oral anticoagulation with VKA and (b) no anticoagulation. Thromboelastometry analysis was conducted using two ROTEM® delta analysers. Detection of VKA was defined as EXTEM measurements above reference ranges established by others (clotting time > 79 s; maximum clot firmness < 50 mm). Patients were considered as OAC patients if international normalised ratio (INR) was 1.7 or above at the time of thromboelastometry analysis.
Results: For this preliminary analysis, data from 63 patients treated with VKA (17.6%) and 294 patients without anticoagulation were available. Two hundred and seventeen of the 357 patients were female (60.8%), median age was 43.5 years (IQR 30.4–59.2 years). OAC was done almost exclusively with phenprocoumon. Thromboelastrometry analysis was abnormal in 42 patients with OAC and in three patients without, and it was normal in 21 patients with OAC. Sensitivity was 66.7% (95% CI: 53.7–78.1%), specificity was 99.0 (95% CI: 97.1–99.8%), and the negative likelihood ratio was 0.51 (95% CI: 0.37–0.68). When using a pre-test probability of 17.6%, the probability that a patient is treated with VKA given a negative thromboelastometry result is 9.8% (95% CI: 7.8–12.7%).
Summary/Conclusions: The results of our investigation indicate that thromboelastometry analysis is of limited value in ruling-out that a patient is treated with VKA. Therefore we suggest, that thromboelastometry analysis does not substitute INR determination in trauma patients.

PO 023

Haemodilution with Nacl solutions below 600 mOsm/L Induce hypercoagulability while concentrations above 1200 mOsm/L progressively impair coagulation as evaluated with thrombelastography *in vitro*

Ogweno GO and Gwer S
Kenyatta University, Nairobi, Kenya

Background: Solutions of Nacl at various concentrations are the mainstay of trauma resuscitation. Though acute trauma associated coagulopathy has been attributed to haemodilution, the role of fluid osmolality remains large unexplored.
Methods: Citrated whole blood was collected from 10 healthy volunteers and haemodiluted (20%v/v) with (mOsm/L) 300,600, 1200, 1500,

and 1800 of Nacl solutions *in vitro*, undiluted sample acting as control. Thrombelastography[TRADEMARK] (Haemoscope, Niles) after recalcification was used to assess coagulation. Kruskal-Wallis was used for statistical analysis.

Results and Discussion: Nacl solutions concentrations of 300 and 600 mOsm/L shortened r and k values while alpha angle and maximum amplitude were increased, but not significant. Solutions at 1200, 1500 and 1800 mOsm/L lengthened r and k values with reduction of alpha and maximum amplitude. It is evident that concentrations below 600 mOsm/L are either hypercoagulable or do not impair coagulation. In contrast, solutions above 1200 mOsm/L progressively induce hypocoagulability. Significance level was < 0.01.

Conclusion: At 20% v/v haemodilution, Nacl solutions below 600 mOsm/L maintain, while concentrations above 1200 mOsm/L impair whole blood coagulation. Impairment is more on clot strength than clot formation time suggesting effect of on either fibrin polymerization or platelet function. Further tests are warranted to clarify the observation herein.

PO 024

Monitoring anticoagulation during Extra-Corporeal Membrane Oxygenation (ECMO) in patients with acute respiratory failure

Passamonti SM, Panigada MP, Artoni A, Mietto C, Bucciarelli P and Martinelli I

Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinico, Milan, Italy

Background: Extra-corporeal membrane oxygenation (ECMO) is a viable alternative to mechanical invasive ventilation in selected patients with acute respiratory failure. To avoid blood clotting in the circuit, patients need to be anticoagulated with intravenous heparin in continuous infusion to maintain an activated partial thromboplastin time (aPTT) ratio between 1.5 and 2.5. A standard dose of antithrombin concentrate (1000 U/24 h) is often supplemented when plasma levels drops below 50%. In such patients aPTT monitoring can be hampered by several confounding factors, mainly due to the acute inflammatory condition. Hence, alternative laboratory tests should be looked for.

Aim: To asses the reliability of aPTT in monitoring anticoagulation with heparin during ECMO, compared to an anti-factor Xa assay.

Methods: Observational study of 12 consecutive patients during veno-venous ECMO with daily blood sampling.

Results: Mean ECMO duration was 9 ± 4 days. Overall, a moderate correlation between aPTT and anti-Xa assay was observed ($r = 0.52$). Anti-Xa levels were positively correlated with antithrombin levels ($r = 0.61$).

Conclusions: To monitor heparin anticoagulation in patients on ECMO, aPTT and anti-factor Xa measurements can be considered equivalent.

PO 025

Multiple inhibitory effects associated with IgG kappa multiple myeloma

Remotti L, Ingratti MF, Sánchez Luceros A, Grosso SH, Meschengieser S, Blanco AN and Lazzari MA

Academia Nacional de Medicina, Buenos aires, Argentina, CABA, Argentina

Background: Haemostatic alterations are often detected in patients with monoclonal gammopathies such as multiple myeloma (MM). They frequently show abnormal coagulation tests (thrombin times, fibrin degradation products (FDP), platelet aggregation, and bleeding time), due to the interference of the paraprotein present in their plasma.

Aims: The aim of this report is to present the case of a patient with multiple myeloma whose prothrombin time (PT), activated partial thromboplastin time (APTT) and thrombin time (TT) were significantly prolonged and did not correct by mixing with normal plasma.

Case Report: A 47-year-old man with IgG kappa multiple myeloma was referred to our institute, because he had had episodes of haematuria and epistaxis without previous history of bleeding in major surgeries.

Results: Coagulation screening of patient's plasma showed prolonged APTT (ratio 4.6; RV: 0.87–1.13), PT (ratio 1.5; RV: 0.82–1.13) and TT (ratio 1.6; RV: 0.75–1.25), and slightly high fibrinogen clotting activity (430 mg/dL). Mixing tests did not correct neither the APTT (ICA 72; control < 10), the PT (1.31; control 1.19) or TT (1.38; control 1.1) suggesting an inhibitory effect on different coagulation pathways. FDP were negative.

Screening (APTT and dRVVT) and confirmatory tests were performed showing results compatible with positive lupus anticoagulant like effect (LA-like). No time dependent inhibitory effect (characteristic of the anti FVIII inhibitors) was detected.

Moreover, FVIII and IX coagulant activities were very low (2 UI/dL and 1.2 UI/dL respectively) probably due to the interference of LA-like effect and/or the paraprotein effect; an apparent activity increase was observed on progressive dilutions of patient's sample for both factors.

Coagulation activity of the extrinsic pathway factors was normal except for FV (52 UI/dL). Mixing tests did not correct FV activity and no apparent activity increase was observed on progressive dilutions of patient's sample. These behaviour was compatible with a specific inhibitory effect on FV activity.

In addition, the inhibitory effect on TT was normalized by progressive dilutions of patient's plasma, suggesting an interference of the paraprotein on the polymerisation of fibrin.

Conclusion: Interferences on coagulation tests due to the paraprotein effect have been previously described mainly on thrombin time; LA-like activity was also reported in multiple myeloma patients. Anti-FV autoantibodies have been identified rarely in patients with monoclonal gammopathies The results of the case presented here suggest multiple inhibitory effects. In addition to the interference on fibrin polymerisation and LA-like activity, an inhibitory effect against FV was also detected; further studies are necessary in order to characterize this effect. None of them can be clearly associated with the clinical symptoms of the patient.

PO 026

A sensitive mixing test to screen for clotting factor inhibitors

Rojnuckarin P and Akkawat B

Chulalongkorn University, Bangkok, Thailand

Background: Mixing studies are helpful for clotting factor inhibitor screening in cases with APTT prolongation. However, the standard consensus procedure is lacking.

Aim: The objective is to develop a sensitive inhibitor screening assay in bleeding patients. The test is preferably insensitive to lupus anticoagulants (LA) in this setting.

Methods: Plasma samples investigated for APTT prolongation ($N = 90$) were tested for factor VIII or IX inhibitors and LA. Positive mixing was defined as an ability of one part of patient plasma to prolong APTT of one part of pooled normal plasma (PNP) after 2-h incubation. Two controls, which were also incubated for 2 h, were PNP mixed with test plasma immediately before the APTT test and PNP mixed with buffer. The cutoff APTT ratio difference of 0.05 was the

laboratory percent coefficient of variation (%CV). Three lots of APTT reagents were investigated.
Results: There were 18 (20%) clotting factor inhibitor cases. The mean titer was 1.7 ranging from 0.67 to 4.0 Bethesda units. Fifteen samples of LA were regarded as negative. The mixing study using any lots of APTT reagents showed 100% sensitivity for clotting factor inhibitors. The sensitivity for LA was lower. The majority of factor inhibitors were time-dependent, while the LA inhibition was mostly immediate. One lot of the reagent displayed 93.1% specificity, but the other 2 lots showed higher false positive rates.
Conclusion: We described a sensitive screening test for clotting factor inhibitors. However, optimal lots of APTT reagents need to be determined to obtain excellent specificity.

PO 027

Two cases of acquired haemophilia A associated with chronic myelomonocytic leukaemia

Uaprasert N, Wongrakpanich S and Rojnuckarin P
Chulalongkorn University, Bangkok, Thailand

Background: Acquired haemophilia A (AHA) is an uncommon, but potentially fatal bleeding diathesis caused by autoantibody against circulating coagulation factor VIII (FVIII). The underlying causes of AHA can be identified in approximately half of patients, of which malignancies account for 10–20%. Heretofore, there has been only one case report of AHA concomitant with chronic myelomonocytic leukaemia (CMMoL).
Aims: We reported two more cases of AHA with CMMoL in our hospital and reviewed possible causal relations between these two rare blood disorders.
Methods: We retrospectively reviewed patients diagnosed as AHA in King Chulalongkorn Memorial Hospital from 2003 to 2012. Of 14 documented AHA, eight patients had no apparent underlying conditions, while three had systemic lupus erythematosus, two CMMoL and one indolent B-cell non-Hodgkin lymphoma. Surprisingly, two cases of CMMoL were found as an underlying aetiology connected to AHA.
Results: Case 1: A 41-year-old male presented with left gluteal abscess and excessive bleeding after drainage. Screening coagulogram revealed isolated prolonged aPTT uncorrected by mixing study. Autoantibody against FVIII was detected at a level of 107.5 Bethesda units (BU). Complete blood count demonstrated leukocytosis with marked monocytosis. Bone marrow study was compatible with CMMoL. He received cyclophosphamide combined with prednisolone. Unfortunately, he did not show any response and subsequently died due to suspected intracranial hemorrhage. Case 2: A 54-year-old male presented with multiple large spontaneous ecchymoses, hematoma at the entire left arm after venipuncture, and gross hematuria. Initial laboratory investigation revealed leukocytosis with marked monocytosis as well as isolated prolonged aPTT. The quantitative assay for FVIII inhibitor revealed a level of 21 BU. The bone marrow examination was consistent with CMMoL. He received prednisolone monotherapy for inhibitor elimination and rapidly achieved complete response 3 weeks after the initiation of immunosuppressive therapy. The pathogenesis of CMMoL-associated AHA remains unknown. The tumour cells may express neoantigens, which their structures mimic FVIII, and subsequently trigger the development of FVIII autoantibodies. In addition, abnormal T-cell responses to antigen presentation as well as dysregulation of B- and T-cell interactions, especially when neoepitopes from malignant clones are over-exposed, may result in the development of FVIII inhibitors. An alternative explanation is immune dysregulation resulting in autoimmune complications. Autoimmune phenomena have been sporadically reported in patients with CMMoL such as vasculitis, polyarthritis, Coombs negative haemolytic anaemia and immune thrombocytopaenia. These autoimmune disorders were able to be successfully treated with immunosuppressive therapy. In addition, autoantibodies against circulating coagulation factors such as FVIII and factor XI in patients with CMMoL were previously reported.
Conclusion: We reported two case of CMMoL-associated AHA. The pathological basis involved in the development of FVIII autoantibodies in CMMoL remains poorly understood. The optimal managements for this rare association require further studies.

PO 028

Haemostatic function in hypothyroid state

Vavilova TV[1], Ivanov AM[2] and Egorova EN[2]
[1]*North-West State Medical University named after I.I.Mechnikov;* [2]*S.M.Kirov Military Medical Academy, Saint-Petersburg, Russia*

The link between haemostatic disorders and thyroid function is uncertain. In some cases hypothyroidism is associated with acquired von Willebrand syndrome and may have several haemostatic abnormalities such as modification of the coagulation proteins and bleeding tendency.
The aim to investigate haemostatic function in patients with overt hypothyroid state.
Methods and Objectives: Fifty-one patients were included – 31 with hypothyroid state 18–71 years old (53.5 ± 10.6), eight male, 23 female and 20 control persons with light thyroid gland structure changes, but without thyroid dysfunction 29–76 years old (53.9 ± 9.7), eight male 14 female. Quik test, APTT, thrombin time, fibrinogen (Clauss), antithrombin, plasminogen, protein C, protein S, factor VIII activity, von Willebrand factor antigen, D-dimers were measured (STA Compact, Stago reagents). The results are presented as median, 25 and 75 percentiles (Me [25%; 75%]); statistic Mann-Witney U-criteria was used.
Results: There were no any significant changes of Quick test, thrombin time, antithrombin, plasminogen, protein C, protein S and D-dimers in hypothyroid patients. But APTT as screening test and some additional tests showed hypocoagulation tendency. APTT was prolonged in hypothyroid group up to 30.1 [29.0;33.0] s compared with controls – 28.0 [26.0;30.0] s, $U = 183.5$, $Z = -2455$, $P = 0.014$. Factor VIII activity was significantly reduced up to 69 [58;80]% (97[75;119]% in controls, $P = 0.016$); von Willebrand factor antigen chanced in the same manner – from 102 [64;120]% up to 65 [56;79]%, $P = 0.006$. From the other hand fibrinogen was higher in thyroid hypofunction but inside the reference range: 3.9 [3.3;4.5] g/L vs. 3.3 [3.1;3.6] g/L, $P = 0.028$.
Conclusion: There are clear tendency to hypocoagulation in patients with decreased level of thyroid function, which may be suspected according to APTT results and confirm by factor VIII activity and von Willebrand factor antigen. It seems to be important in any cases of surgery or haemorrhagic syndrome in this patients.

PO 029

Acquired factor VIII inhibitor associated to prostate cancer in elderly

Villaca PR, Okazaki E, Zeinad-Valim AK, Rocha RF, Chamone DAF and D'Amico EA
Hospital das Clínicas, University of Sao Paulo, Sao Paulo, Brazil

Background: Acquired factor VIII inhibitor is a rare bleeding disorder and accounts for 1.3–1.5 cases per million per year, with the mortality rate around 22%. It occurs most frequently in elderly people, and the incidence increases with age. Clinical features are characterized by a large spectrum of bleeding, from subcutaneous bruising to life threatening bleeding, such as muscle, intracranial or gastrointestinal hemorrhages. Search for an underlying cause is negative in up to 50% of the cases. Some relevant conditions associated are: rheumatoid arthritis, systemic lupus erythematosis, malignancy, pregnancy and pemphigoid. Treatment is based on the control of bleeding and eradication of the

inhibitor. We describe a case of acquired FVIII inhibitor and lupus anticoagulant in a patient with prostate cancer, succesfully treated with corticosteroids plus azathioprine.

Case report: A 77-year-old man with controlled reumatoid arthritis and prostate cancer was referred with a history of bleeding after exeresis of a node in the left forearm and spontaneous multiple hematomas (upper and lower limb, and chest). Coagulation tests revealed a prolongation of activated partial thromboplastin time (APTT), and failure to correct after 1:1 mixing with normal plasma FVIII activity was severely decreased (< 1%), with increased FVIII inhibitor level (512 BU). Other coagulation factors were normal. Lupus anticoagulant was negative at the time of the diagnosis. Treatment with activated prothrombin-complex concentrate (FEIBA), steroids and azathioprine led to improvement of his clinical symptoms. After 5 months of immunossupressive therapy it was observed normalization of coagulation parameters (FVIII > 50%, inhibitor negative). Surgery for the cancer was not indicated for urologic issues related to the age. Before 3 months of the complete withdrawal of immunosuppressive therapy, he presented another decrease of FVIII activity with no correction of APTT after mixing study, and a positive test for inhibitor. In order to investigate the cause of the lower level of FVIII, it was performed lupus anticoagulant test and substrate chromogenic FVIII assay (SCA) to quantify the inhibitor was performed. The presence of LA was confirmed, FVIII (SCA) was normal and FVIII inhibitor was negative using this methodology. After 2 months without immunossupressors, the inhibitor was still negative (< 0.6BU).

Summary: Treatment of acquired FVIII is usually performed with corticosteroids plus cyclophosphamide. The decision to use azathioprine was based on the mortality rate of 22% due to infectious complications, possibly related to myelotoxicity of cyclophosphamide, and the frequent occurrence of factor VIII acquired inhibitors in elderly people. Lupus anticoagulant is common in cancer, and it can interfere with the determination of coagulation factors. It is important to use sensitive assays to avoid inadequate treatment. As the cancer was not eradicated, it is possible that the inhibitor relapses. This is an interesting case of acquired FVIII inhibitor associated to cancer in an elderly patient, which treatment with prednisone and azathioprine resulted in eradication of the inhibitor.

PO 030

Parameters of hemostasis in patients with deep frostbites and malnutrition

Vitkovsky Y, Konnov V and Shapovalov K

Chita State Medical Academy, Chita, Russia

Aim: The aim of the study is to provide indicators of hemostasis in patients with deep frostbites and malnutrition.

Research Methods: Conducted a prospective nonrandomized controlled study in 59 patients of both sexes with the local cold injury, that were hospitalized to City Clinical Hospital -1 of Chita during the winter period of 2009–2011. The composition of therapy consisted of anticoagulants of direct action under the protocol. The object of the study was the blood of patients. Blood sampling was not carried out up to reactive period of local cold injury. Inclusion criteria: deep frostbites, hospitalization up to reactive period of the local cold injury, hospitalization in the early and late reactive periods of the local cold injury. Exclusion criteria: age younger than 16 years; age older than 60 years; sepsis; acute renal failure. The control group included 23 healthy volunteers of similar age and sex.

Patients were divided into two groups of nutritional status. Nutrition assessment was conducted on amount of balls of the table Luft V.M. and Kostyuchenko A.L. 'Indicators of the severity of malnutrition' at the beginning of hospitalization. The first group included 22 patients with eutrophia, that have secured a total of 28–30 balls. The second group consisted of 37 patients with malnutrition, the result of which does not exceed 27 balls. Twenty patients of the first group and 32 patients of the second group were hospitalized in the first 2 days after the injury. Assessment of platelets was performed twice in these patients: in the early reactive period of the local cold injury (ERP) and in the late reaction period (LRP) of the local cold injury again.

Research methods were assessment and quantitative comparison of platelets, expression of tissue factor (TF) and tissue factor pathway inhibitor (TFPI), antithrombin-III (AT-III). These data are presented as median and interquartile range. Comparison of the groups was used the Mann-Whitney test.

Results of the study: Comparison of platelets were revealed higher ($P < 0.001$) in both groups, then control group 301 (255;356) in 1 mkl in the ERP and LRP. Comparison of platelets was revealed lower ($P = 0.042$) in patients with malnutrition, than in patients with eutrophia: 187 (117;291) vs. 214 (196;325) in 1 mkl. Were no differences of comparison of platelets ($P = 0.832$) between groups 1 and 2: 471 (287;648) and 445 (278;600) in 1 mkl. TF expression were revealed higher ($P < 0.001$) in both groups, then control group 33.1 (28.9,37.8)%. Were no differences of this parameter between groups 1 and 2: 54.8 (45.4;61.8) and 61.6 (51.4;70.5)%. TFPI was revealed higher ($P = 0.021$) in patients with eutrophia, then control group 3.2 (2.7;3.6) and ($P = 0.022$) then the group with malnutrition: 2.9 (1.7;3.8) vs. 3.8 (3.6;4.1) ng/ml. AT-III was revealed lower in patients with malnutrition: 72.0 (55.0;97.1)% vs. 101.7 (87.9;111.7)% of control group ($P = 0.005$) and vs. 101.7 (87.9;111.7)% of the group with eutrophia ($P = 0.047$).

In conclusion, patients with deep frostbites and malnutrition have changes parameters of hemostasis.

PO 031

Some hemostatic parameters in patients with severe influenza A/H1N1, requiring artificial ventilation

Vitkovsky Y, Malyarchikov A and Shapovalov K

Chita State Medical Academy, Chita, Russia

Background: Change in blood coagulation system is an essential consequence of the cytokine cascade, resulting from activation of immunoreactive system in response to the introduction infected. Strains of some viruses, including influenza virus, have not only epithelial, but endothelial activity. Endothelial cells are involved in the implementation of a wide range of biological effects, including an active effect on all parts of hemostasis.

Objective: To investigate the change in blood coagulation system in patients with severe pneumonia against influenza A/H1N1, on mechanical ventilation.

Materials and Methods: A study in 16 patients aged 25–50 years with influenza A/H1N1 pneumonia complicated by severe. The control group consisted of 20 healthy volunteers. All patients were treated in the intensive care unit of City Clinical Hospital 1 in Chita in November 2009 study was conducted on 1–2, and 7–8 per day of hospitalization. Evaluated fibrinogen, APTT, INR, SFMC. Statistical analysis was performed using the software package Microsoft Excel.

Results: Found that patients with severe pneumonia against the background of influenza A/H1N1 on the 1–2 day of onset fibrinogen levels decreased by 17% relative to the control, APTT decreased by 26%, INR increased by 1.2 fold, the number SFMC increased by 87%. While the 7–8 day fibrinogen increased by 63%, APTT decreased by 15%., INR increased by 1.1 fold, the number of SFMC has increased by 7.2 fold compared to the control group. The development of pneumonia in patients during influenza A H1N1, certainly accompanied by the presence of systemic inflammatory response syndrome (SIRS), implying an increase in plasma immunoreactive system mediators (leukotrienes, prostaglandins, etc.). This can lead to multiple organ failure. Lungs contain the most, compared to other organs, the number of endothelial cells. As a result, the direct damage to the lung tissue by virus, and the presence of multiple organ failure, affecting the endothelium, which leads to a deviation of the functioning of blood coagulation and the development of hypercoagulability.

PO 032

A retrospective study of treatment and outcome of consecutive patients with Acquired Haemophilia A

Yap ES[1], Lee SY[2], Saw S[2] and Chee YL[1]

[1]National University Hospital; [2]National University Hospital, Yong Loo Lin School of Medicine, Singapore, Singapore

Background: Acquired Haemophilia A (AHA) is a rare autoimmune bleeding disorder with an incidence of 1.34–1.48 per million per year. Bleeding results from the development of inhibitory autoantibodies to FVIII and is fatal in 8–22%. Prompt diagnosis is crucial so that treatment can begin immediately. This comprises control of acute bleeding, inhibitor eradication and treatment of the underlying disorder. There is limited data in Asian patients with the largest report comprising only 46 patients.

Aims: This is a retrospective review of our cohort of 15 patients with AHA in our institution.

Methods: All consecutive AHA patients treated at NUH between Jan 2006-Dec 2012 were included. Clinical and laboratory data were extracted from case records. AHA was diagnosed using UKHCDO 2006 criteria. Major bleeding was defined using ISTH 2005 criteria. Complete remission (CR) was defined as normalization of FVIII level, undetectable inhibitor and no immunosuppression.

Results: Fifteen patients were included, six females and nine males. Their median age was 68 (range, 38–92 years). All presented with spontaneous bleeding, 10 with major bleeding. The 3 commonest sites were skin ($n = 12$), muscle ($n = 8$) and genitourinary ($n = 3$). An underlying cause was found in three patients – post-partum, acute myeloid leukaemia and connective tissue disease. Median FVIII level was 4% (range, < 1–9%), median inhibitor titre was 80 BU/ml (range, 9–576 BU/mL). Twelve patients received bypassing agent FEIBA and 1 received FVIII concentrate. two patients did not receive any bypassing agents as they had minimal bleeding. All major bleeding episodes responded to treatment. Median number of days of FEIBA treatment was 6.5 (range, 0–20 days), and median dose of FEIBA per kg weight was 69 U/kg/day (range, 39–167) for the first 3 days. Thirteen patients received immunosuppression with prednisolone and cyclophosphamide and 2 with prednisolone alone. All patients normalized their FVIII level with 9 achieving CR (60%) at a median of 190 days (range, 17–231 days). One patient relapsed after CR. Four patients had immunosuppression-related toxicity including 3 Grade 3 sepsis and 1 fatal sepsis. One patient who achieved CR died on AML treatment.

Conclusion: Despite the older age and presentation with major bleeding in 66.7%, the outcome of our case series is excellent. All bleeding episodes responded to treatment and all patients normalized their FVIII levels with immunosuppression. Although a pan-European registry (EACH2) recently reported on 501 patients, there are only Three published case series in Asia with 70 cases in total. Similar to other Asian patients, our patients were less likely to have a secondary cause (20% of cases) and more likely to have durable CR (60%). In contrast, the EACH2 study a secondary cause was found in 48% and relapse rate was 33%. However, the median time to FVIII > 70 IU/dl and CR were longer for our cohort at 82.5 and 190 days respectively compared with 40 and 74 days respectively for EACH2 patients. This may reflect the lack of an underlying cause and/or different immunosuppression tailing regimens.

PO 033

Activated prothrombin complex concentrate in acquired haemophilia A: an Italian registry-the F.A.I.R. study

Zanon E[1], Milan M[2] and Schino M[3]

[1]2Chair of Internal Medicine, Haemophilia Center, [2]Haemophilia Center Padua, Padua; [3]2Senior Medical Affair Manager- Baxter, Roma, Italy

Background: Acquired Haemophilia A is a disease characterised by bleeding manifestations and alterations in coagulation tests (lengthening of the activated Partial Thromboplastin Time-aPTT) in patients having no previous personal or family history of coagulation disorder. It is an autoimmune disorder, due to the presence of auto-antibodies specifically directed against factor-VIII (FVIII-inhibitor). It is a rare condition, with a reported incidence of around 1–4 cases per million/year. The risk of AHA increases significantly with age (range 55–78 years), with an approximately equivalent sex ratio. This disease is associated with high rate of mortality, usually due to delay in diagnosis and inadequate management of hemorrhagic episodes. Recent data have shown that excellent or good haemostasis was obtained with Activated Prothrombin Complex Concentrate (aPCC, FEIBA®, Baxter) administered at doses of 50–100 U/kg every 8–12 h in 76–100% of treated bleeding though no standardised treatment protocols are available.

Aim: The purpose of this study is to evaluate the dosage, efficacy and safety of aPCC, used for bleeding episodes, in an Italian population of 50 AHA patients.

Patients and Methods: The FAIR study (Feiba in Acquired haemophilia A, an Italian Registry) is an observational, non interventional, retrospective/prospective study on safety, efficacy and dosage of Feiba in AHA. Fifty patients with confirmed diagnosis of Acquired Haemophilia A according to standard laboratory methods and treated with aPCC are expected to be enrolled in this study. It is planned to analyse 25 patients retrospectively and 25 prospectively. Ten sites are expected to be involved in the study, after the approval of local ethics committees. General information (i.e. patients' medical history, FVIII levels and Inhibitor titre and information about bleeding episode management, adverse events) is collected into an electronic case report form (eCRF). Subjects have to be older than 18 years and they shall have given a written informed consent.

Conclusion: Data from the Italian Haemophilia Registry database will be used to better assess the dosage, efficacy and safety of aPCC in patients with acquired haemophilia A in order to make standardised protocols available for treatment of bleeding episodes.

PO 034

Evaluation of an automated method for the measurement of dabigatran in plasma

Byrne MB, Doyle M, White B, Ryan K, O'Donnell J and O'Connell N

St James's Hospital, Dublin, Ireland

Background: Dabigatran (Pradaxa®) is a novel oral anticoagulant currently licensed for use inEurope for the primary prevention of venous thromboembolic events in adults who have had an elective total hip or knee replacement surgery. It is also used for the prevention of stroke or systemic embolism in adults with non-valvular atrial fibrillation with one or more risk factors. Its anticoagulant effect is achieved via direct inhibition of thrombin. Dabigatran is cleared primarily by renal excretion with a half life of 13 h with normal renal function. It may be necessary to monitor levels of Dabigatran in instances where clearance is compromised, in life threatening bleeding or in situations where thrombosis persists despite anticoagulation.

Aims: A reliable reproducible assay is required to measure levels of Direct Thrombin Inhibitors (DTI) in plasma. A commercial CE

marked kit (Hemoclot Thrombin Inhibitors CK002L, Hyphen BioMed) for the quantitative measurement of direct thrombin inhibitors in citrated human plasma was verified for use with the ACL TOP automated coagulation system (Instrumentation Laboratory).
Method: The method is based on the ability of Dabigatran to inhibit a constant and defined concentration of thrombin. Citrated plasma is diluted with saline and mixed with Normal Pooled Plasma (NPP) at a ratio of two parts NPP to one part diluted plasma and a thrombin time is performed on this mixture. The level of Dabigatranis calculated by reading from a standard curve using calibrators with known levels of the drug. The assay was controlled at the lower and upper range of measurement for the calibration curve. Evaluation included calibration precision and stability, sensitivity and assay precision.
Results: Linear calibration curves ($R^2 > 0.985$) were achieved for the assay with an inter-assay calibration precision (CV%) at < 5%. Peak plasma concentrations are in the range of 0.10–0.40 μg/ml and trough concentrations are in the range of 0.02–0.15 μg/ml. Two calibration curves were constructed with an achieved sensitivity ranging from 0.05 to 0.50 μg/ml. Assay precision was acceptable with a CV% of < 10%. Overall performance characteristics were satisfactory for this assay.
Conclusion: In specific instances where measurement of Dabigatran is necessary, the Hemoclot Thrombin Inhibitor assay is deemed suitable for use in our laboratory.

PO 035

Level ranges for a new latex agglutination immunoassay for free protein S antigen in a pregnant women cohort

Delgado BRC, Gomes HC, Carvalho M, Goncalves LR, Araujo F, Montenegro N and Namora G
Centro Hospitalar São João, Porto, Portugal

Background: In normal pregnancy the haemostasis balance modifies towards hypercoagulability, to decrease bleeding complications on delivery. There is an increase in concentration of most clotting factors, a decrease in some of the natural anticoagulants, namely protein S (PS), and reduced fibrinolytic activity. PS deficiency is a well known risk for thrombosis. Free PS (fPS) assay measures unbound PS fraction and can be used as a surrogate marker for PS activity.
Aims: We evaluated a pregnant women cohort to establish range values of fPS during normal pregnancy for a new immunoassay, INNOVANCE® Free PS Ag kit (Siemens, Marburg, Germany).
Patients and Methods: A study cohort of 56 pregnant women without personal or familial thrombophilia, mean age 31 years (15–41), was divided in four groups according to number of weeks of pregnancy: three patients in first group (until 22 weeks), 9 in second group (23–28 weeks), 24 in third group (29–35 weeks), and20 in fourth group (36–41 weeks) were evaluated. Blood samples were collected by venipuncture into 3.8% sodium citrate tubes. Plasma was separated into aliquots within 4 h of collection and stored at −70 °C until analysis. Free Protein S was measured in duplicate on a BCS® XP System by latex agglutination test, using INNOVANCE® Free PS Ag kit (Siemens, Marburg, Germany).
Results: A histogram showed a normal distribution of fPS levels in the study cohort. Subgroup analysis was performed: in first group fPS was 56.0% (44.8–67.3), in second group 53.4% (44.0–62.7), in third group 50.4% (47–53.7) and 49.6% (44.0–55.2) in fourth group. Despite a decreasing tendency of fPS until term, no statistically difference was found between the four groups. Due to the weak contribution of the results of the first group, we used the results of the other groups (23–41 weeks) to determine the normal range of fPS in pregnancy. Comparing this cohort to a previously studied control group of blood donor women without hormonal contraceptive methods and fitting age range, a statistically difference ($P < 0.001$) was found, with a mean fPS of 50.9% (28.4–70.6%, CI 90%) in the cohort analyzed vs. a mean fPS of 86.5% (57.8–126.7%, CI 90%) in control group.
Conclusion: Our results of fPS in pregnant women are similar to previously reported. The use of distinct normal ranges for specific populations allows risk stratification of thrombosis, namely in pregnant women.

PO 036

At what time derived fibrinogen must replace the clauss assay

Freire I, Azevedo AP and Gago T
Hospital São Francisco Xavier, Lisboa, Portugal

Background: Dabigatran is an oral, reversible thrombin inhibitor that has shown promising results so far, with the advantage that laboratory monitoring is not needed/deemed. However, clinicians and pathologists must be aware how coagulation assays are affected when handling emergency interventions, bleeding complications or overdoses.
Aims: To show how a derived fibrinogen assay that usually has a bad behavior in measuring high and low levels of fibrinogen can be useful, when some of thrombin reagents used for clauss fail to detect fibrinogen levels in patient's samples with dabigatran.
Methods: Three common coagulations assays (TP; APTT and Fibrinogen) were done in two elderly (male: 88 and female: 83 years old) when admitted in our hospital. Both presented a personal history of atrial fibrillation, hypertension, metabolic disease and abnormal renal function and both were medicated with dabigatran (150 mg bid). For both patients, TP and APTT were prolonged but only in one patient clotting time for APTT was not achieved; the levels of fibrinogen by clauss method were less than 0.30 g/L for both patients. In face of these results pathologists wanted to know the levels of dabigatran regarding that only one of the patients had bleeding complications. The levels of dabigatran found were above 700 ng/mL, higher for the hemorrhagic patient which was consistent with APTT but as Ddimer was normal and there wasn't any explanation for the low level of fibrinogen a derived fibrinogen was performed, and normal results for fibrinogen were found, between 3.0 and 5.0 g/L. It was performed derived fibrinogen vs. clauss in other patients medicated with dabigatran for concentrations between 70 and 540 ng/mL, and verified that only above 400 ng/mL of dabigatran the results of fibrinogen were very different between the two methods. It was also performed for those samples the clauss with another reagent and the results were similar to the derived fibrinogen, although lower for the clauss method.
Conclusions: Current knowledge is that none of the global tests are elective to assess the anticoagulant effect of dabigatran: APTT shows poor dose-response linearity and intermediate responsiveness to increase dose beside be depend of the reagent used; TP presents good linearity but poor responsiveness; TT has excellent linearity but excessive responsiveness and when fibrinogen is performed the results with clauss method for overdoses are not reliable, they are extremely affected by the reagent used and can be extremely dangerous when offered to the clinician, in view of our results we think the derived fibrinogen could be a good alternative to assess the anticoagulant stage in overdoses.

PO 037

Effect of primary tube underfilling and hemolysis on PT, APTT, antithrombin and D-Dimer assays; implementing the pre-analytical sample integrity checks of the Sysmex CS-2100i System*

Hoogendoorn H[1], De Haan J[2], McGrath J[1] and Ali E[1]
[1]*Hemostasis Reference Laboratory Inc., Hamilton, ON, Canada;* [2]*Siemens Healthcare Diagnostics Products GmbH, Marburg, Germany*

Background: Pre-analytical visual inspection of primary blood collection tubes is a subjective and inconsistent procedure at best. A new

generation of hemostasis analyzers offers pre-analytical sample-integrity checks (PSI) to detect incorrect primary-tube fill volumes as well as interfering levels of hemolysis, icterus, and lipemia. We looked at the effect of incorrect tube fill and hemolysis on several hemostasis assays with the optical based system above as well as a mechanical detection based analyzer, and questioned whether PSI checks can replace visual inspection in routine lab workflow.

Methods: Normal and heparin-spiked blood samples were modified by various levels of hemolysis or by controlled underfilling of collection tubes. Samples were then tested for PT (Thromborel® S reagent), APTT (Dade® Actin® FSL reagent) and antithrombin (INNOVANCE® Antithrombin assay) on both the Sysmex® CS-2100*i* (CS-2) and STA Compact® (STA) analyzers.

In a separate part of the study, normal samples were spiked with 0.5 μg/mL D-Dimer and then submitted to the same levels of underfilling and hemolysis (INNOVANCE® D-Dimer assay on CS-2, Liatest® D-Dimer assay on STA).

Finally, the pre-analytical integrity of 1548 blood samples from several outpatient clinics were inspected visually by lab technologists and by the CS-2 PSI checks prior to testing.

Results: Underfilling and hemolysis resulted in longer PT on both analyzers. APTT was prolonged with tube underfilling and shortened with increasing hemolysis on both analyzers. Moreover, APTT of heparinized samples normalized when free hemoglobin levels exceeded 400 mg/dL. Tube underfilling caused lower AT results with both systems. Hemolysis did not affect AT results on the CS-2, but caused decreasing AT results on the STA before becoming unreadable. D-Dimer measurements on both systems were hardly affected by underfilling. In contrast, hemolysis caused dramatically increasing D-dimer results on STA, but no noticeable effect on D-Dimer results on the CS-2.

All sample tubes with improper fill volumes (> 110% or < 90%) or hemolysis (≥ 0.5%) were detected by the PSI checks of the CS-2.

During inspection of the 1548 samples, 267 were found to have low fill volume by visual checks and 226 by PSI checks on the CS-2. Comparison of negative samples (no underfilling) with positive samples (underfilling detected by both visual inspection and PSI) demonstrated significant differences ($P < 0.05$) for the above assays. Samples detected visually but not with PSI-checks did not differ in result from the negative samples.

Conclusions: PT, APTT, AT and D-Dimer assays are sensitive to improper tube filling and/or hemolysis, irrespective of the type of analyzer. Pre-analytical factors can interfere significantly with the assay result, even to the extent that a different diagnosis is suggested.

These results suggest that assessment of underfilling and hemolysis by the PSI checks on the CS-2 analyzer may provide an objective, reliable and efficient alternative to visual inspections.

*Sysmex CS-2100*i* System is not available for sale in the U.S.

PO 038

A modified coagulation time (activated partial thromboplastin time) assay for the measurement of very low levels of factor VIII activity

Kaneko M, Saito Y, Kanno NY and Yatomi Y

The University of Tokyo Hospital, Tokyo, Japan

Background: It is essential to accurately determine the level of blood coagulation factor VIII (FVIII) activity to evaluate the severity of haemophilia A. In general, FVIII activity is assessed by activated partial thromboplastin time (APTT) coagulation time with the use of FVIII deficient plasma. However, the precision of the assays are usually not standardized and hence guaranteed at the levels less than 1% of FVIII. The reasons for this are thought to be due to the differences in FVIII sensitivity of the APTT reagents and varying characteristics of FVIII-deficient plasma, e.g., their residual FVIII activities.

Aims: The accurate measurement of FVIII activity, even at low ranges less than 1%, is presumed to be possible by the modified APTT assay when we select suitable combination of APTT reagent and FVIII-deficient plasma. For this purpose, we sought to identify the APTT reagent and FVIII-deficient plasma, enabling high sensitivity in the detection of FVIII activity and the resultant measurement of the FVIII activity in its very low range.

Methods: The assay was performed with APTT reagents as follows: HemosIL SynthASil reagent APTT (Instrumentation Laboratory), Coagpia APTT-N (Sekisui Medical), Thrombocheck APTT-SLA, and Thrombocheck APTT (Sysmex). Besides normal human pooled plasma obtained from healthy volunteers, HemosIL Calibration Plasma and Coagtrol N (Sysmex) was used as normal plasma. The assessment of FVIII activity was performed with FVIII-deficient plasma products as follows: HemosIL Factor VIII Deficient Plasma and two kinds of factor VIII-deficient plasma (Sysmex and George King Biomedical). FVIII activity of normal human pooled plasma was defined as 100% arbitrarily, and the FVIII activity of each normal plasma was determined. Plasma of 50% FVIII activity was prepared by separate combinations of each normal plasma and each FVIII-deficient plasma. Thereafter, serial dilutions of mixed plasma were assayed by various APTT reagents on Coapresta-2000 (Sekisui Medical). Factor VIII activity was evaluated by APTT coagulation method using three FVIII deficient plasmas, and by chromogenic method using COATEST SP (Chromogenix).

Results: Prolongation of coagulation time based on APTT was widely varied among the samples of serial dilution of the mixed plasmas, and significant difference was observed at the levels less than 5%. We assumed that larger extension rate of APTT prolongation results in higher sensitivity and more accurate measurement of FVIII activity. It was found that the combination of the George King's deficient plasma and HemosIL SynthASil was favorable. As for the detection of factor VIII activity, the combination of reagents and plasmas were similar to the result from APTT study. There was remarkable difference among FVIII deficient plasmas, and measurement level of FVIII activity was lower using the George King's deficient plasma and COATEST SP. However, there are no reference materials for measurement of FVIII activity. Thus, further studies are necessary to assess this preference in order to quantitate the true value of FVIII activity.

Summary/Conclusion: Appropriate combination of reagents and plasmas based on their characteristics may improve the sensitivity of FVIII activity measurement.

PO 039

Interference in von Willebrand factor latex immunoturbidometric assays, lupus anticoagulant assays and one-stage factor assays in a patient with splenic marginal zone lymphoma

Kershaw G[1], Mui B[2] and Cunningham I[2]

[1]Royal Prince Alfred Hospital; [2]Concord Hospital, Sydney, NSW, Australia

Background: Latex immunoturbidometric assays (liatests) are commonly used assays for the measurement of von Willebrand factor (VWF) antigen and some types of VWF activity assays. Because these assays are based on agglutination of antibody-coated latex particles by target antigen at typically use low sample dilution, there is potential for interference by non-specific agglutinating agents in the test plasma. The most common of these is rheumatoid factor, but others include human anti-mouse antibodies.

Aims: To describe a case of grossly discordant results observed between a VWF antigen liatest and a VWF activity liatest in a patient with splenic marginal zone lymphoma.

Methods: VWF antigen (VWF:Ag) assays were performed on the STA-R analyser by liatest. VWF activity (VWF:Ac) assays were performed on the CA-1500 analyser by a method employing two steps: firstly, binding of plasma VWF to a recombinant glycoprotein 1b (rGp1b) containing two gain-of-function mutations; secondly aggluti-

nation of the VWF-rGP1b complex by latex particles coated with anti-Gp1b (Siemens Innovance). Collagen binding activity was measured by enzyme-linked immuno-sorbent assay. Ristocetin cofactor activity (VWF:RC) was assessed by aggregometry with formalin fixed platelets and ristocetin. Lupus anticoagulant (LA) tests were by APTT and DRVVT-based assays.

Results: The INR was 1.8 and APTT 63 s (RI: 25–37 s).The VWF:Ag could not be measured at standard sample dilution (1/2) due to analyser flags. At 1/15 dilution the VWF:Ag was 1134% (RI: 55–200%) reducing to 386% at 1/50 dilution. Free protein S antigen was also not measurable due to a marked 'dose-hook' effect seen at several dilutions. At standard dilution (1/3) the VWF:Ac level was 11% (RI: 50–185%). The VWF:Ac rose progressively with dilution and peaked at 17,152% at 1/384 sample dilution, falling to 5171% at 1/1536 sample dilution. VWF:RC was 345% (RI: 50–200%) and VWF:CB was 218% (RI: 45–180%). Both LA sensitive and LA insensitive APTTs were 15–20 s prolonged with non-correction in 1:1 mixing tests and final LA ratio of 1.00 (negative for LA). The DRVVT screen clotting time was normal on neat plasma. Assays for coagulation factors VIII, IX and IX showed non-parallelism. Coagulation factors II, V, VII and X showed normal levels. The patient had a greatly raised IgM anticardiolipin antidody (ACA) titre of 4640 MPL (RI: < 20 MPL). Total IgM was mildly elevated at 3.49 g/L (RI: 0.5–3.0 g/L).

Summary/Conclusions: This is an unusual case of interference in several types of coagulation assays, the exact cause of which is not clear. Of particular interest was the marked effect of the inhibitor on the rGp1b-based VWF:Ac assay. The patient most likely has elevated VWF levels of approximately 300% based on VWF:RC levels. The interference may possibly be due to the markedly elevated IgM anticardiolipin antibody. Scientists should be aware of potential interference in immunoturbidometric assays caused by unusual inhibitors, possibly IgM ACA, which may only be suspected from discordant results seen in assays based on differing principles.

PO 040

Hypercoagulability markers in renal transplanted patients: association to inflammatory response

Mota APL[1], Gomes KB[1], Martins-Filho OA[2], Pinheiro MB[1], Carvalho MG[1] and Dusse LMS[1]

[1]UFMG – Universidade Federal de Minas Gerais, [2]Centro de Pesquisas René Rachou – FIOCRUZ, Belo Horizonte, Brazil

Background: Renal transplant is able to trigger an intense inflammatory response and alterations in the hemostatic system. However the pathophysiological mechanisms leading to these changes are not completely understood.

Aims: The aim of this study was to investigate hypercoagulability and inflammatory biomarkers in patients undergoing renal transplant without clinical signs of rejection according to renal function.

Methods: We evaluated the plasma levels of regulatory (IL-4, IL-5 e IL-10) and proinflammatory cytokines (IL-8, IL-6, IL-1b, TNF-α, IL-12p70, IFN-γ) by flow cytometry BD® Biosciences Pharmingen, USA and hemostatic parameters (thrombomodulin/TM, von Willebrand factor/FvW, ADAMTS13 and D dimer/D-Di) by ELISA American Diagnostica® Inc. This study was approved by the Ethics Committee at Federal University of Minas Gerais, Brazil and informed consent was obtained from all participants. The research protocol did not interfere with any medical recommendations or prescriptions.

Results: Results showed an increase of D-Di and tendency to increase of IL-6 levels in the subgroup with creatinine plasma level > 2.0 mg/dL compared to subgroup with creatinine < 1.4 mg/dL. The regulation of inflammation in the short term post-transplant was mediated by IL-5 and the pro-inflammatory state in the long was mediated by IL-12. Multinomial regression analysis revealed that ADAMTS13 was associated with creatinine plasma levels. A multivariate logistic regression analysis showed that the Di-D plasma levels were associated with glomerular filtration rate.

Conclusion: These results suggest that the D-Di was a promising marker to estimate renal function. Besides, ADAMTS13 has shown promise for estimating renal function.

PO 041

Correlation between hemostatic molecular markers under warfarin anticoagulation

Nagao T, Shiga T and Uchiyama S

Tokyo Women's Medical University, Tokyo, Japan

It is well known that novel oral anticoagulants (NOAC) can be monitored with exact precision by neither conventional prothrombin time nor activated partial thromboplastin time. To investigate the possibility of new surrogate markers for NOAC efficacy, we evaluated the utility of two hemostatic molecular markers indicating thrombin or fibrin generation among patients with nonvalvular atrial fibrillation (NVAF) undergoing chronic warfarin anticoagulation.

We recruited patients with NVAF who were treated with warfarin for at least 6 months continuously. Two hemostatic molecular markers, prothrombin fragment 1 + 2 (F1 + 2) and soluble fibrin monomer complex (SFMC), and PT-INR were measured simultaneously.

Blood specimens from 69 patients with NVAF (mean age = 73.4 ± 9.3, 22 females) were taken into investigation. Among INR ranges between 1.11 and 3.76 (mean INR = 1.94), there existed a significant negative correlation between INR and F1 + 2 ($r = 0.4668$, $P < 0.0001$), whereas most samples (67/69) showed an SFMC measurement under the sensitivity limit (< 0.3 μg/mL) and a lack of correlation with INR and F1 + 2 of SFMC.

This study revealed the utility of F1 + 2 as a new surrogate marker for chronic anticoagulation including that with NOAC, whereas SFMC is not tenable as such due to poor sensitivity.

PO 042

Use of the thrombin generation test in patients with ischemic cerebral pathologies

Novelli C, Morelli B and Giorgetti A

Legnano Hospital, Legnano (MI), Italy

Background: The patients referred to the neurology department of the hospital of Legnano with suspected ischemic undergo imaging studies and laboratory investigations; of these is also included screening for thrombophilia, which aims to highlight anomalies in hemostatic system. This screening includes assays (with functional methods) of the major physiological inhibitors of coagulation (antithrombin, protein C and protein S) and the main mutations associated with increased risk of thrombosis (FV Leiden and FII20120A). In addition to these parameters we have included, in the thrombophilic screening, the dosage of prothrombin fragment 1 + 2 (F1 + 2) and thrombin-antithrombin complexes (TAT) for the evaluation of the activation of coagulation and fibrinolysis.

Aims: Recently we have included in the protocol of thrombophilic screening also the test of thrombin generation in order to assess the ability to detect the presence of a hypercoagulable state.

Methods: Fifty-eight consecutive patients were investigated pertaining to the neurology department with suspected ischemic pathology. The surveys were conducted during the period January to December 2012. On the day of sampling the following tests were performed: PT, aPTT, fibrinogen, protein C, protein S, and D-dimer; the other tests were performed subsequently on aliquots of plasma stored frozen at −80 °C until the moment of the analysis. The thrombin generation test was performed on CAT (Calibrated Automated Thrombogram) System of Thrombinoscope, Stago group. As activator of coagulation was used tissue factor 5 pM.

Results: We evaluated the following parameters: Lag time, ETP, Peak, tt Peak, Velocity Index e Start Tail, The group of patients had mean

values, SD and ranges for the above parameters respectively equal to 2.93, 0.88, 2.0–7.3, 1600, 338, 905–2582, 280, 86, 79–583, 5.93, 1.37, 4.3–11.7, 102.8, 47.9, 18.2–291, 23.4, 3.6, 16.7–39.7.
The control group represented by 61 blood donors instead showed mean values, SD and ranges for the parameters above, respectively equal to 2.85, 0.32, 2.33–3.33, 1448, 193, 1176 -1676, 253, 43, 186–320, 5.9, 0.78, 5.0–7.3, 88.1, 3.1, 45–187, 22,5, 4.9, 19–25.
Using a statistical sofware (MedCalc) were compared the values thus obtained with the Mann-Whitney test and the values were equal to 0.451, 0.201, 1.143, 0.548, 0.265 AND 0.868 respectively for Lagtime, ETP, Peak, Velocity Index and Start Tail.
Conclusion: Was not reached statistical significance for any of the parameters considered, but the values achieved for Peak and ETP in some patients with ischemic stroke were significantly higher than the maximum limit found in the control group. Further studies should be conducted on a larger number of patients, but the results obtained in our study are already suggestive of useful employment of the test in patients with acute cerebral ischemic disease.

PO 043

Is it necessary to monitor dabigatran efficacy?

Sigutova P, Hajsmanova Z and Korelusova I
University Hospital Pilsen, Plzen, Czech Republic

Background: Dabigatran etexilate acts as a reversible direct thrombin inhibitor without activity of antithrombin as a cofactor. At present the recommendation for prevention assume dabigatran use as an alternative to vitamin K antagonist therapy. For patients with a lower risk of bleeding is appropriate and effective dose of 150 mg twice daily, at a higher risk of bleeding is secure a lower dose of 110 mg twice daily. In patients with only one serious risk of thromboembolism we can use dabigatran in a single daily dose of 110 mg. Dabigatran is rapidly absorbed from the gastrointestinal tract with concentration peak 2 h after administration. In the Czech Republic the recent approval of dabigatran for the prevention of ischemic stroke in patients with chronic atrial fibrillation is accompanied by rather widely expanded application of this drug. Simple dosage without monitoring is one of the advantages of dabigatran. On the other hand in the case of life-threatening bleeding or urgent surgery haematologists should have rapid coagulation test at hand to solve the question how to evaluate haemostasis in these patients.
Aims: To have own experience with dTT in patients with bleeding complication.
Methods: Calibrated quantitative diluted thrombin time (dTT; Hemoclot Thrombin Inhibitors; Hyphen BioMed, France) was used for the quantitative determination of dabigatran etexilate. Measurements were performed on coagulation analyzer STA-R Evolution. We examined 51 patients in the age range 45–90 years treated with dabigatran 150 mg twice daily in the period from March to September 2012. Blood samplings were analysed after a minimal 3-day dosing and 12 h after last administration.
Results: Prolonged tests APTT and TT compared with the level of dabigatran measured by dTT were found quite different in all our patients. dTT remains the only specific test determining the actual haemocoagulative status.
Conclusion: Our small analysis verified, that the simple coagulation method based on inhibition of constant defined thrombin concentration should be always available in the coagulation laboratory because it helps to clinicians to determine the impact of dabigatran on the immediate patient's bleeding complications. Expansion of elderly complicated patients receiving dabigatran is expected and so this simple dTT test can bring another experience in the short future.
Therefore, this method is successfully used in our routine laboratory praxis.

PO 044

Evaluation of assay performance of the rivaroxaban screening assay TECHNOCLOT® RIVAROXABAN SCREEN

Wagner L[1], Binder NB[1] and Siegemund A[2]
[1]Technoclone GmbH, Vienna, Austria; [2]Labor Reising-Ackermann, Leipzig, Germany

Background: Rivaroxaban is a new oral direct Factor Xa (FXa) inhibitor. The increasing use of the new oral anticoagulants administered for prevention of VTE in patients after orthopedic surgery creates the need of their measurement in the clinical routine. Anti-Xa assays calibrated with special Rivaroxaban calibrators are used for precise determination of rivaroxaban concentrations in patient samples.
It has been shown that rivaroxaban interferes with routine clotting assays, like PT, APTT or factor assays. For correct interpretation of the results it is necessary to have information on rivaroxaban in the sample.
A simple sreening assay was developed to screen for the presence of rivaroxaban in patient samples.
Aim: The aim of this study was to evaluate the performance of the new clotting assay for screening rivaroxaban in patient plasma samples.
Method: Technoclot® Rivaroxaban Screen is a clotting assay based on the activation of FXa in the patient sample. Rivaroxaban beeing a direct Xa inhibitor will prolong the clotting time in patient sample in comparison with normal plasma sample. The normalized ratio will give the information on rivaroxaban presence in the sample.
Patient samples and normal plasma spiked with different concentrations of rivaroxaban were used for assay evaluation.
Results: In normal samples the normalized Ratio was found to be between 0.8 and 1.2.
Samples with rivaroxaban gave ratios of > 1.3, the ratios being correlated to the rivaroxaban concentration. Patient sample with 52.2 µg/L had a ratio of 1.39.
Conclusions: Our data demonstrate that Technoclot® Rivaroxaban Screen is a simple method suitable for screening samples with rivaroxaban even in laboratories were only routine clotting tests are performed.

PO 045

New immunodepleted plasmas for determination of Factor VIII and IX activity

Watson C[1], Gehrisch S[2] and Siegert G[2]
[1]Leicester Royal Infirmary, Leicester, UK; [2]Medical Faculty TU Dresden, Dresden, Germany

Background: STA®-ImmunoDef VIII and IX (Diagnositca Stago) are new immunodepleted human plasmas to be used with STA®-C.K. Prest® for the determination of factor VIII and factor IX activity in plasma.
Aims: Performances of these reagents were evaluated on patient samples (including Haemophiliac patients) across a wide range of factor VIII and factor IX activities. Two laboratories were involved: Leicester, UK for factor VIII and Dresden, Germany for factor IX.
Methods: For each factor, calibrations were performed using STA®-Unicalibrator (one unique calibration curve) and Internal Quality Controls (IQC) were tested using STA®-System Control N + P on STA-R®. For factor VIII study, 144 patient's plasmas were tested in 15 runs: 63 Deficient VIII samples (including 16 Severe Haemophilia A patients), 53 normal samples and 28 other samples (including 10 interferences).
For factor IX study, 144 patient's plasmas were tested in 13 runs: 57 Deficient IX samples (including 16 Severe Haemophilia B patients), 66 normal samples and 21 other samples (including 11 interferences).
Samples were tested with the new products along the working range, STA®-ImmunoDef VIII (0.7–400%) and STA®-ImmunoDef IX

(0.7–300%), and results were compared to the ones obtained with a reference method STA®-Deficient VIII or IX with STA®-C.K. Prest® on STA-R® analyser.
Correlations were analyzed through linear regressions and differences were plotted in Bland & Altman graphs. During the analysis, the stability of calibration was evaluated by comparing results obtained with a systematic calibration and results obtained with the calibration of the first day.
Results: Analysis of IQC results shows good day to day reproducibility: CV < 5% based on factor levels. IQC results also suggest that systematic calibration is not required.
The correlations between new and current reagents show equivalence of results.

- Factor VIII: $y = 0.973x + 1716$ ($r = 0.994$)
- Factor IX: $y = 0.984x + 2.635$ ($r = 0.989$)

Results for clinical haemophilia segregation were also in good agreement, especially for Severe Haemophilia.
Conclusion: Results show good consistency between STA®-Immuno-Def and STA®-Deficient used with STA®-CK Prest® for all the assay working range. Besides, these studies strongly suggest there is no need for a systematic calibration. Finally, results confirmed that Haemophiliac patients are well segregated with these new products.

PO 046

Coagulation profile in polycythemia vera and essential thrombocythemia patients in Medan Indonesia

Widjaja SS[1], Tambunan KL[2], Siregar Y[1] and Koh S[3]
[1]Faculty of Medicine USU, Medan; [2]Faculty of Medicine UI, Jakarta, Indonesia; [3]NUHS Singapore, Singapore, Singapore

Thrombosis, the main complication of Polycythemia Vera (PV) and Essential Thrombocythemia (ET) patients, can significantly affect the prognosis and quality of life. In this cohort study we study the coagulation profile of 35 PV and ET patients. We measured the TAT-Complex, Beta thromboglobulin (βTG), von willebrand factor (vWF), fibrinogen and D-dimer. Results TAT-Complex was increased in 22 cases (63%, $P = 0.011$), βTG was increased in 35 cases (100%, $P = 0.443$), vWF 7 cases (20%, $P = 0.030$), fibrinogen 10 cases (29%, $P = 0.000$). Thrombosis were excluded with D-dimer negative, and found out there's 10 cases of thrombosis. Most of the cases has the history of thrombosis (32 cases, 91%) with arterial thrombosis 13 cases (39%), venous thrombosis 10 cases (28.6%) and microvascular disturbances 21 cases (60%). History of thrombosis show statistically significant ($P = 0.011$) to develop thrombosis.
Conclusion: Most of the PV and ET patients showed significant hypercoagulable state towards thrombosis.

PO 047

Adverse efects of PEG-Asparaginase treatment in paediatric population and relation with APOE polymorphisms and hereditary thrombophilia

Azevedo J[1], Coucelo M[2], Constanço C[3], Sevivas T[4], Santos S[3], Brito M[1], Benedito M[2], Martins N[2] and Ribeiro LML[2]
[1]Serviço de Oncologia HP- CHUC; [2]Serviço Hematologia CHC-CHUC; [3]Serviço de Hematologia do CHC- CHUC; [4]Hematologia CHC- CHUC, Coimbra, Portugal

Background: Asparaginase, including its peguilated formulation (PEGAsp) is effective in induction/consolidation schemes for Acute Lymphoblastic Leukaemia (ALL). It is associated with adverse effects such as allergy, thrombosis, pancreatitis and deranged lipid metabolism, which can be severe and delay treatment.
The identification of subgroups at risk would allow us to define preventive and early intervention strategies to address PEGAsp treatment associated complications.
Aims: Analise the incidence of adverse effects related to PEGAsp administration for ALL in paediatrics and its relation with hereditary thrombophilia risk factors and *APOE* polymorphims; to identify subgroups at risk.
Methods: Analysis of children (< 18 years) with ALL (B and T) treated in our Centre since May/2007 with regimen DFCI05–01, which includes PEGAsp; ALL risk stratification: standard (SR), high (HR) and very high risk (VHR).
Severe adverse effects (sAE)- those causing PEGAsp administration delay or suspension: allergy, extreme hypertriglyceridaemia (HTG, TG > 11 mM, fasting), pancreatitis and thrombotic events.
Genetic thrombophilia risk factors assessed: PRT A20210G, FV Leiden and MTHFR C677T, by PCR-Mutiplex. *APOE* genotype (polymorphisms e2, e3, e4) was determined by direct sequencing.
Results: Forty-eight children were studied (SR-23, HR-19, VHR-6). A 54.2% ($n = 26$) suffered sAE, of which 2 were allergic reactions, with a higher rate of sAE in highest ALL risk groups: HR-84.2%, VHR-66.7%, as compared with SR-26%. In the 24 children with non-allergic sAE, 14 HTG (SR-2, HR-10, VHR-2) and 7 pancreatitis (SR-3, HR-4) were documented. Twenty-three percent of patients suffered a thrombotic event, 91% of which were documented in the highest risk ALL groups (HR-8, VHR-2, SR-1).
Heterozygous (htz) PRT A20210G was found in one child (SR) and htz FV Leiden in another (HR); eight children were homozygous (hmz) MTHFR C677T (SR-3, HR-5).
Genotype *APOE* was determined in 46 children: 74% e3/e3 ($n = 34/46$), 15.2% e3/e4 ($n = 7/46$), 8.7% e2/e3 ($n = 4/46$) and only one e4/e4 (2.1%).
We did not find any correlation between *APOE* genotype and HTG or pancreatitis.
Of those 10 high ALL risk patients with thrombosis, 1 was htz FV Leiden, four patients carried allele e4 (e3/e4) (one with htz FV Leiden); 6 were e3/e3 (3 hmz MTHFR C677T and 1 with strong anticoagulant lupic). Among the HR/VHR groups, only 2 children, who carried both the allele e4 and hmz MTHFR C677T, did not suffer any thrombotic event during the observation period, one of which was under prophylactic enoxaparin due to known risk factors (MTHFR C677T homozygosy and oral anticonceptives therapy).
Conclusion: In this series of 48 children with ALL treated with PEGAsp, we documented a 54.2% frequency of sAE, with a higher incidence in high ALL risk. As previously described, the overall incidence of sAE was associated with high ALL risk score and an older age at diagnosis. Thrombotic events occurred at a high frequency in our patients (23%), 91% in children with a high ALL risk score (HR/VHR).
A larger series is warranted to confirm a possible emerging hypothetical association between *APOE* and/or *MTHFR* polymorphisms and thrombotic events among our high risk ALL risk paediatric population.

PO 048

Long-term use of Low-Molecular-Weight Heparins (LMWH) for cancer-associated venous Thromboembolism: Clinical Practice and Patients' Perception in the TROPIQUE study

Cajfinger F[1] and Farge Bancel D[2]
[1]SOMPS Hôpital de la Salpêtrière; [2]Saint Louis Hospital, Paris, France

Background: Long-term treatment with LMWH is the recommended standard for treatment of venous thromboembolism (VTE) in cancer patients. In a previous study, the prescription of LMWH in France was shown to comply poorly with established recommendations [1]. Few data are available on the long-term prescription in clinical practice and treatment follow-up in cancer patients. Study objectives are to document the prescription and use of curative doses of LMWH, to

assess whether treatment follow-up is consistent with established recommendations and to assess patients' perception of the therapy. Clinical outcomes such as VTE recurrence and bleeding are also documented.

Methods: This is an ongoing prospective, observational, multicenter study in cancer patients with symptomatic VTE and an indication for treatment with LMWH for at least 6 months. Adult patients, aged 18 years or more, willing to participate, with diagnosed malignancy and recent symptomatic VTE in whom a treatment with LMWH has been initiated within less than 7 days, are consecutively included in the study. Patients already treated with LMWH for more than 7 days or with a contra-indication to LMWH are not eligible to participate. Main study outcome measures include the proportion of patients treated with LMWH according to the French established recommendations as well as patients' expectation and satisfaction based on the validated Perception AntiCoagulant Treatment Questionnaire (PACT-Q) [2].

Assuming a normal patient distribution and the unfavorable hypothesis that only 50% of patients are treated according to the national recommendations, 384 patients are needed to obtain conclusive results with a precision of 5% and a risk error of 5%. Incidences of 7% of VTE recurrence and 6% of major bleeding are expected. A total of 400 patients are therefore planned to be included in the study. PACT-Q scores will be calculated per item at baseline (PACT-Q1) and globally at study end or at treatment discontinuation (PACT-Q2). Scores will be expressed in means and medians.

As of end of January 2013, 50 sites were activated and 70 patients were enrolled. Completion of enrollment is expected by June 2013.

Conclusion: The results obtained from this study will add significantly to the knowledge regarding the long-term treatment with LMWH to prevent recurrent cancer-associated VTE in real clinical practice and patients' treatment perception as PACT-Q are applied for the first time to this patient population. Important prospective data on the long-term management of cancer patients with symptomatic VTE will be generated, and analyses of clinical parameters will add important information that may help to further tailor therapy and improve compliance with established recommendations.

PO 049

Evidence of the 'off-label' usefulness of FEIBA® to manage the critical gastro-intestinal bleeding in patients with haematological malignancies

Cultrera D, Cipolla A, Caraci MR and Di Raimondo F

Haemophilia Regional Reference Centre, Catania, Italy

During the clinical course of haematological malignancies in patients with acute leukemias at onset of disease as well as in or after the intensive chemotherapies, the massive gastro-intestinal (GI) haemorrhages constitute life-threatening complications. In this scenario, several coagulation abnormalities and severe thrombocytopenia are considered causative factors of GI bleeding. The complex treatments include administration of platelet concentrates (PC), red blood cell (RBC) units, antifibrinolytic drugs, plasma infusions, somatostatin acetate and H_2-antagonist intravenously, even recombinant activated FVII (rFVII) boluses with unsatisfactory results. In the past decade we experienced that FEIBA®, at 90 IU/KG infusions were capable to stop dramatic GI bleeding in patients with haematological malignancies not respondent to various therapeutic attempts.12 consecutive patients (seven females and five males), age ranging 19–79 years, with acute myeloid leukaemia (n = 4), non-Hodgkin lymphoma (n = 3), at onset of disease (n = 4) and during intensive combined chemotherapy (n = 8) were considered during 14 episodes of massive GI bleedings. In all patients the haemostatic profile showed as expected several coagulation changes as PT and aPTT slight prolongation, D-dimer elevation and fibrinogen in normal range, sometimes Protein C and Protein S together with Antithrombin III variable reduction. No sepsis findings were documented. Severe thrombocytopenia (< 20.000/μL) and marked anaemia (Hb < 7 g/dL, Hct < 21%) were also present. By FEIBA® administration (90 IU/Kg) at first infusion (n = 3), at second infusion (n = 5) after 6 h, at third infusion (n = 2) after 12–18 h, at fourth infusion (n = 4) after 24 h, we achieved GI haemorrhages complete control with safe and efficacious outcomes, even without PC in six patients. Interestingly, in five patients we carried out during their critical haemorrhagic occurrences an endoscopy with videocapsula to explore the site of GI tract lesion. We noted small bowel origin of bleeding (n = 3) and in caecum/ascendent colon (n = 4).Obviously, the surgeon excluded the operation as well as the digital subtraction angiography (DSA) to perform trnscatheter embolization even in emergency owing to massive bleeds and/or critical conditions of the patients. It is noteworthy that after FEIBA® in 4 of these same patients we demonstrated by endoscopic videocapsula non GI haemorrhages, thus providing strong evidence that bleeds has been resolved. Despite the mechanisms by which FEIBA® determines bleedings' stopping in life-threatening haemorrhages of patients with haematological malignancies are to be defined, from our observation and for critical practice we propose FEIBA® employment safely in GI dramatic and massive bleeds, even if this indication is off-label, but efficacious based on clinical endpoints and suggest use of this drug in patient who needs a rapid control of GI bleeds.

PO 050

Association of Factor V Leiden mutation with thrombosis in newly diagnosed cases of acute leukemia in Pakistan

Naz A, Ahmed S, Nadeem M and Shamsi T

National Institute of Blood Disease and Bone Marrow Transplantation Center, Karachi, Pakistan

Background: Acute Leukemia is commonly occurring of blood cancer with very high morbidity and mortality rate through out the globe. Newly diagnosed acute leukemia patients may have significantly high risk of thrombosis.

Aims: The purpose of study was to estimate the risk of thrombosis with frequency and association of Factor V Leiden in newly diagnosed cases of acute leukemia and as well as in healthy individual served as control.

Patients and Method: Case control study was conducted in haematology and research departments of National institute of blood disease and bone marrow transplantation from March 2011 to December 2012 after approval of Institutional review board. Total 90 cases including newly diagnosed cases of 27 with AML, 38 with ALL and 25 healthy blood donors served as control were selected with signed consent that were already screened from other thrombophilia markers including Protein C, Free Protein S, AT III and activated protein C system. Activated protein C system was tested using ProC-Global assay (Dade Behring, Marburg, Germany). A decreased response, normalized ratio (NR) below 0.80 is suggestive of presence of homozygous Factor V Leiden mutation. Genomic DNA was isolated by standard Qiagen column. Factor V Leiden mutation confirmed by restriction fragment length polymorphism (RFLP) for a 220 base pair (exon 10-intron10) fragment of factor V. The Fragment was amplified by polymerase chain reaction using the specific primers. Amplified product was digested by restriction enzyme Mnl1 and separated by electrophoresis on 6% acrylamide gel and stained with silver nitrate. Simple descriptive and chi square test was applied for the statistical analysis of data by using SPSS version 17.0.

Results: Only 2 cases of acute myeloblastic leukemia were identified as homozygous Factor V Leiden mutation with thrombo-embolic events out of 65 patients of acute leukemia with mean age of 25.38 ± 13.85 years. The frequency of FVL G1691A polymorphism was 7.4% in acute myeloblastic leukemia patient compared to none in control and acute lymphoblastic leukemia patients ($P < 0.05$).
Conclusion: Our study suggests that chances of finding FVL mutation leading to thrombosis are higher in acute myeloblastic leukemia than acute lymphoblastic leukemia in newly diagnosed patients. Prospective studies with larger sample size are required to validate our findings.

PO 051

Thrombotic complications associated with chemotherapy: an analysis of 356 patients

Tamamyan G, Danielyan S, Zohrabyan D, Safaryan L, Voskanyan A, Sargsyan L, Hakobyan L, Avagyan A and Harutyunyan L

'Muratsan' Hospital Complex of Yerevan State Medical University, Yerevan, Armenia

Background: Thrombosis is a well recognized complication of cancer and is associated with severe organ damage and a high mortality. It is well known, that chemotherapy potentiates the risk of thrombosis. The type and the stage of cancer, as well as patients' age are also among the risk factors.
However, many studies were conducted in this field; still the mechanisms for chemotherapy and cancer-associated thrombosis are not well known and there are a lot of gaps to be filled.
Aims: The main aims of this study were to investigate the association between chemotherapy and thrombosis, to determine the frequency of those thrombotic complications and to identify patients with cancer at a high risk for developing these thrombotic episodes.
Methods: During 4 years of this study (from 2008 to 2012) 356 cancer patients were treated and observed at the Clinic of Chemotherapy of 'Muratsan' Hospital Complex of Yerevan State Medical University, from which 48 patients were children until 18-year-old. Retrospective data was collected concerning thrombotic complications associated with chemotherapy and the analysis was done. All the patients with prior thrombotic events before chemotherapy treatment were excluded from our study group.
Results: In children group there was no incidence of thrombosis during and after chemotherapy. Among 308 adult patients 9 cases (2.9%) of thrombosis were evaluated. Three patients (25%) from 12 patients with testicular cancer, 3 (9.1%) from 33 lung cancer patients, 2 (11%) from 17 patients with B-cell lymphoma and 1 (1.5%) in 66 breast cancer patients had thrombotic complications. One of those three patients with lung cancer resembled pulmonary thromboembolism.
Summary/Conclusions: However, the incidence of thrombosis in whole group of study is not so high, but it is significant in some subgroups, especially in testicular cancer, B-cell lymphoma and lung cancer. Therefore, early prophylaxis of thrombosis in mentioned groups of patients is quite important and can reduce thrombotic complications and thrombosis-associated morbidity and mortality.

PO 052

Diagnosis of functional and structural platelet disorders – implication for oncology

Vasilenko I[1], Matveeva A[1], Polyakov P[2], Bichenkov O[2] and Balkanov A[2]

[1]N.I.Pirogov Russian National Research Medical University; [2]M.F.Vladimirsky Moscow Regional Clinical and Research Institute (MONIKI), Moscow, Russia

In the past years, the prevalence of malignant neoplasms of the oral cavity and nasopharynx has grown up to 28.8% per 100 thousand of population and lethality during a year since the moment of cancer diagnosis in this location reached 40.3%. In the majority of patients with advanced oral and nasopharyngeal tumors, radiation therapy (RT) remains a single method of treatment. One of the main causes of the contemporary RT failure is a presence of chronically hypoxic radioresistant cell fraction within a tumor. The low-level laser radiation is used for radiomodification of these cells. However, till now, there are none of approaches worked out allowing objective assessment of therapeutic results and prediction of the disease outcome. Studying the mechanisms of thrombosis and metastasis in oncologic practice convincingly showed an important role of thrombocytes in these processes. Chemo- and radiotherapy also influence hemostasis condition. The objective of the study is elaboration of the method to estimate the efficiency of treatment of oncologic patients with different stages of the disease receiving radiotherapy combined with low-level laser radiation as a radiosensitizer.
A total of 45 patients with malignant oral tumors (MOT) were examined in dynamics: 20 patients were treated with only RT, 25 – with RT in combination with intravenous blood laser radiation (radiation power 25 mw, wave length 632.8 nm). The control group included 30 practically healthy people. All patients underwent distant gamma-therapy (DGT) using uncommon regimen of dose fractioning in summarized focal doses isoefficient 72–73 Gy. Analysis of the morphofunctional condition of live unfixed and unstained thrombocytes was carried out in the real time using express-method of vital computed phasemetry on the bass of device-program complex for cellular diagnostics using cytomorphometry and microelectrophoresis. Morphological structure size parameters and adhesive activity of circulating population was assessed. ADP-induced aggregation was used as a reference method.
In patients examined, the number of immovable cells, slightly or highly activated, and degenerative cells was, on the average, 27.6, 44.4, 25.5 and 2.5 vs. 63.1, 20.9, 12.3 and 3.7% of the norm. Increase in the mean diameter values of circulating thrombocytes by 23.4, 26.8 and 30.3% was noted as well as of perimeter by 17.6, 21.3 and 24.6%, and square by 30.2, 32.5 and 38.1% in patients with II, III and IV MOP stages, accordingly. The cellular height and volume reflecting granules condition decreased by 10–15%. With growth of DGT dose, the number of active thrombocytes increased and the size parameters also changed. Inclusion of intravenous blood laser radiation into the course of radiotherapy enabled normalization of thrombocyte structural-and-voluminous characteristics (growth of the height and volume, diminishing of diameter, perimeter and square) and reliable reduction of their activating potential.
Thus, application of the express-method of vital computed phasemetry of thrombocytes in oncologic practice allows objective determining the level of intravascular activation of thrombocytes. Morphometric and functional thrombocyte parameters can serve criteria of the efficiency of the radio- and laser therapy carried out.

PO 053

LMWH generics as first line drugs in prophylaxis of thrombotic complications in cancer patients

Vorobev A

The First Moscow State Medical Sechenov University, Moscow, Russia

Background: The most perspective methods of prophylaxis of thrombophilia and thrombosis in cancer patients is administration of low-molecular weight heparin (LMWH). That is connected with a number of its features: 30% of LMWH activity are performed through AT III and 70% through TFPI; LMWH activates fibrinolysis by exemption t-PA from endothelium; LMWH is inhibit leukocytes procoagulant activity; LMWH less often cause the heparin-induced thrombocytopenia. LMWH is effective in case of warfarin resistance. LMWH administration does not required constant laboratory control. The purpose: To specify an optimum schedule of administration LMWH for

prophylaxis of thrombotic complications in cancer patients in perioperative period.

Materials and Methods: Two hundred and twenty-six cancer patients at random was divided in three groups in accordance to scheme of heparin administration: I – LMWH (Hemapaxan) 24 h prior to surgery treatment, further once a day on 0.4 mL (4000 IU) within 10 days in the postoperative period – 75 patients II – LMWH (Hemapaxan) once day on 0.4 mL (4000 IU) within 10 days in the postoperative period – 77 patients III – Unfractionated heparin on 5000 IU 3 times a day within 10 days in the postoperative period – 74 patients Lab Methods a quantitative estimation of platelets aggregation in the presence of Adrenaline, Collagen and ADP in various concentration (10–3, 10–5, 10–7) to determine degree of their activation. Determination of a platelets marker of activation – platelets antiheparin factor 4 (PF4). DIC-syndrome markers: D-dimer, TAT, prothrombin fragments F1 + 2.

Results: Before surgery treatment the rate of subcompensated DIC-syndrome was 18.5–50% depending of localization and degree of tumor expansion. After surgery treatment the rate of subcompensated DIC-syndrome considerably increased, and was found signs of decompensated DIC-syndrom. In total the rate of patients with DIC-syndrome was 52–75%. In the first group normalization of levels of thrombophilia markers (TAT, PF4, F1 + 2) was observed in 3–5 days after surgery treatment. In the II group thrombophilia markers tended to normalization in 5–7 days after operative intervention. In III group normalization of thrombophilia markers was found out only after 7 days. Some patients remained increased level of D-dimer up to 10 days. Besides that, in 28 patients (13.7%) was found extensive painful hematomas in a place of heparin injection.

Conclusions: Perioperative period is the extremely dangerous for thrombotic complications risk and demands careful control of a hemostasis system functions. At present till now still there is no uniform tactics of thrombotic complications prophylaxis in perioperative period. The scheme offered by us: LMWH (we have studied the effectiveness of biosimilar grug – Hemapaxan) 24 h prior to operative intervention, further once a day on 4000 IU within 10 days in the postoperative period can be recommended for all cancer patients as the program-minimum, however for 10th day of application of such scheme it is necessary to control of a condition of hemostasis system in order to determine necessity of continuation of prophylaxis application of LMWH. Besides that, we consider necessary to provide the analysis of genetic forms of thrombophilia and APS for all cancer patients with clinically expressed thrombotic complications.

PO 054

Diffuse intracranial haemorrhage in Factor V deficiency: two case reports

Karimi M, Moghaddam M, Gerdabi J, Afrasiabi A, Dehbozorgian J, Ardeshiri R and Zahedi Z

Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran

Background: Factor V (FV) deficiency is a rare autosomal recessive bleeding disorder and its prevalence has been estimated to be 1 out of 1,000,000 populations. Factor V deficiency can present from mild to severe bleeding symptom such as bruising, nose and mouth bleeds. In severe forms of factor V deficiency, joint bleeding and risks of central nervous system bleeding can be seen in newborns.

Aim: We report two cases of severe FV deficiency, presenting with intracranial hemorrhage (ICH).

Methods: Case 1 is a 6- month male infant who was admitted to emergency Hospital because of lethargy and pallor. He had normal condition after a Normal Spontaneous Vaginal Delivery. The patient's parents were not relatives. Coagulation screening showed a prolonged Prothrombin time (PT) of 25s and upper limit of normal Partial Thromboplastin time (PTT) of 40s and His hemoglobin was 5 g/dL. Computed tomography (CT)-Scan was undertaken and revealed a large intraparenchymal in the left frontoparietal lob, with significant edema and mid line shifted to the right side (Figure 1). Coagulation factor assays revealed a FV plasma activity < 0.5%. FFP treatment was stopped for 24 h because of poor venous access after 1 month of ICH. Unfortunately patient passed away 1 day later.

Case 2 is a 4- month old boy who was admitted in Hospital with skin bleeding, convulsion and poor feeding. There was no history of a hemorrhage diathesis in their family, and parents were second degree relative. He had ICH and spontaneous bleeding from gums. A non-stop bleeding had occurred after circumcision at 20 days after birth and he had been treated with FFP without diagnosis. Coagulation tests showed prolonged PT and PTT and plasma FV activity was below one percent. FFP (15 cc/Kg) was transfused to patient once a day and he became clinically stable. After 1 month, FFP infusion was reduced to once a week after 1 month of therapy.

Conclusion: An intraventricular hemorrhage associated with FV deficiency was first reported by Whitelaw et al. in 1984. Deficiency of FV leads to in severe bleeding symptoms such as ICH. So, FV activity should be considered in newborn or infants with ICH as well as FX, FVII and FXIII assays that clearly are common causes of ICH in newborns. FFP is the only method of treatment in patents with FV deficiency, and prophylaxis with FFP is recommended in patients with severe bleeding symptoms or in cases of ICH.

PO 055

Congenital combined deficiency VII and V associated with thrombocytopenia

Messaoudi R, Hadj T, Benlaledj D, Moulasserdoune K, Rahal Y, Chérif-Hosni A, Seghier F and Touhami F

University hospital Oran, Oran, Algeria

Although they are very rare, the combined deficits V and factor VII congenital deficiencies and combined deficiency VII and other factors the factor IX, X, XI, lack of protein C are known (1). We report the case of an association of congenital combined deficiency VII and V associated with mild thrombocytopenia. Patient and methodsIt is a patient aged 42 years, nonconsanguineous parents, ménarchie at the age of 12 years, menorrhagia scarce, married, G4P1, scalable current pregnancy 33 weeks, with a history of death in two- utero at 7 months and the other 2 months during the first two pregnancies, a girl aged 5 years in good health born by cesarean section requiring two blood units and 2 units of fresh frozen plasma. Has a herniated disc without any treatment. Not taking medication. The only problem serious bleeding was observed at the age of 7 years after injury of the hand. If not the patient had multiple dental extractions without special precautions, no bleeding postpartum at different deliveries, no epistaxis, no gingivorragie. C is in search of the etiology of deaths in- utero we found a moderate thrombocytopenia 98,000/mm^3, TP 58%, APTT:32 s. (Witness 34 s), Fibrinogen 4.60 g/L. The assay showed a differential deficit at 36% V, VII deficiency in 36%, 104% II, the X-92%, VIIIc 286%, 116% plasminogen. The dosage of 78% ATIII, Protein C at 105%, Protein S A71% 261% RPCA. The search for lupus anticoagulant negative. Given the large size of platelets, a research Dystrophy Jean Bernard Soulier negative by flow cytometry. The study of the family could not be made for the grandparents and parents of the patient. Consists of siblings three sisters and five brothers: one older sister 44 years this D deficiency in 52% V, Y brother aged 33 has a V deficiency in 54%, A brother aged 40 has a combined deficit in V (34%) and VII (56%), explorations have not been made in other siblings.

Discussion: VII deficiency has been described associated with unexplained mental retardation, a epicanthal folds, the ductus arteriosus and other anomalies that remain unexplained. The rarity of a disease can teach us many things in physiology and pathophysiology study that deficits and/or frequent illness. In addition, these deficits must be combined very few in mind before a certain replacement therapy apparently isolated deficit remaining inadequate or ineffective.

PO 056

Registry of inhibitors in mild and moderate haemophilia A patients in Spain

Cid AR[1], Jiménez Yuste V[2], Nuñez RJ[3], Mingot E[4], Sedano C[5], Palomo A[4], López-Fernández MF[6], Paloma MJ[7], Altisent C[8] and Prieto M[9]

[1]Hospital La Fe, Valencia; [2]Hospital Universitario La Paz, Madrid; [3]Hospital Virgen del Rocio, Sevilla; [4]Hospital Universitario Carlos Haya, Malaga; [5]Hospital Marqués de Valdecilla, Santander; [6]Complejo Hospitalario A Coruña, Coruña; [7]Hospital Virgen del Camino, Pamplona; [8]Hospital Vall d'Ebrón, Barcelona; [9]Hospital General Yague, Burgos, Spain

Background: Inhibitor development occurs less frequently in mild and moderate haemophilia A patients than in severe ones. The development of alloantibodies against factor VIII (FVIII) in these patients is often associated with important clinical problems such bleeding phenotype changing into a more severe form. We have tried to determine the characteristics of the patients who develop inhibitors in this pathology in our country.

Patients and Methods: All patients with mild and moderate haemophilia A and inhibitors registered at several centers of hemophilia in Spain in the last 20 years were included. Demographic and hemophiliac data (date of birth, ethnicity, FVIII level, family history of haemophilia and inhibitor development, F8 gene mutation) were obtained. We also obtained data related to inhibitors: initial and maximum historical titres, kinetic reaction type, inhibitor against exogenous o both endogenous and exogenous FVIII, exposure days (ED) and intensive replacement therapy before inhibitors. We collected data of treatment to bleeding episodes and immune tolerance induction if performed.

Results: Fifteen patients (four with moderate and eleven with mild haemophilia A) developed inhibitors in this period. All our patients were Caucasian. In twelve of them information about F8 gene mutation is available. Six cases have a mutation considered as high risk for inhibitor development (four R2150H and two R593C mutations). Average age at which inhibitors developed was in the age range of 28 (3–64) and 38 (6–47) for moderate and mild haemophilia patients. Eleven patients (73%) had an inhibitor considered as high titre. In the majority of the patients (8/13) inhibitor development occurs after more than 50 ED. Only 6 out of the 15 patients underwent eradicator treatment, 5 of which (83%) responded positively.

Conclusions: Several patients present mutations associated to high risk for inhibitor development. As well as in severe haemophilia, the majority of inhibitors show high titres. Apart from this disease, inhibitors may develop at an advanced age showing many ED. Many patients do not undergo proper treatment and the inhibitor may disappear. The mild and moderate haemophilia patients with inhibitors showed quite a significant difference as compared to severe haemophilia A patients.

PO 057

Fluctuation in factor VIII levels in a patient with hemophilia B

Guler N[1] and Büyükkaya P[2]

[1]Ondokuz Mayis University, School of Medicine; [2]Ondokuz Mayis University, Samsun, Turkey

Background: In here, we want to share an interesting patient with Hemophila B in whom Factor VIII levels are fluctuating. 31 years old male patient was following with hemophilia B and Hemophila A since 2 years old. He had been diagnosed as combined factor deficiency because of low Factor VIII (7%) and low Factor IX (5%) levels. He was followed by adult hematology department after 22 years old. When we checked his Factor VIII levels were such as: 7%, 138%, 208%, 117%, 52%, 63%, 15%, 64%, 29%, 80%, 80%, 19%, 19%, 101% during last 29 years. We checked whether Fresh Frozen Plasma (FFP) replacements were done just before these measurements, the situation was safe. There was not any replacement. Factor inhibitors for VIII and IX were always negative. His Factor IX levels were consistent such as 5%,%7 during last 29 years.

The level of vWF Ag was 97%, in the same way there was not FFP replacement just before this measurement. His blood group is O Rh +. Patient's mother, father and sister's blood groups are also O Rh +.

According to patient's history his mother and sister have got same situation as low Factor VIII and low Factor IX. However, we could not reach their old charts.

Summary: Finally, if our patient would carry hemophilia A gene, his factor VIII levels never can be as high as 138% or 208%. Because of his blood group there is a big suspicion for the reason of these fluctuations; it can be a von Willebrand disease in O blood group patient. After this evaluation we accepted patient as only as Hemophilia B not together with Hemophilia A despite low Factor VIII levels such as 7%, 15%, 19% and 29%. We planned to study of ristocetin cofactor activity. We are still thinking that whether there is a big waving in his vWF Ag level or vWF activity results in very low (7%) and high Factor VIII levels (208%).

PO 058

Structural comparison of a new recombinant rFVIII molecule, turoctocog alfa, and commercially available FVIII products

Kristensen AK, Kjalke M, Klausen NK, Ezban M and Vad K

Novo Nordisk, Maaloev, Denmark

Background: Turoctocog alfa is a new recombinant FVIII molecule (rFVIII) with a truncated B-domain consisting of 21 amino acids from the naturally occurring B-domain.[1] Commercially available rFVIII products are either produced from the full-length gene resulting in a heterogeneous mixture of heavy chains with different lengths of the B-domain attached (Advate® or Kogenate FS®) or from a construct with a 14 amino acid B-domain attached (ReFacto AF®). The essential role of the B-domain is to facilitate the secretion from the FVIII synthesizing cells. As the B-domain is not required for procoagulant activity, the biological activity of turoctocog alfa and Advate® *in vitro*[2] and *in vivo*[3] is comparable.

Aim: To compare the structure and homogeneity of turoctocog alfa to commercially available rFVIII products.

Methods: The FVIII-related components present in Advate®, Kogenate FS®, ReFacto AF® and turoctocog alfa have been analysed using SDS-PAGE with and without thrombin digestion followed by *N*-terminal amino acid sequencing of excised bands, size exclusion (SE)-HPLC and reverse phase (RP)-HPLC.

Results: SDS-PAGE of turoctocog alfa showed the expected major bands corresponding to the heavy chain (HC) and light chain (LC) in addition to a minor band corresponding to the single chain (scFVIII). The same band pattern for HC, LC and scFVIII was observed for ReFacto AF®, while several high molecular weights bands corresponding to HC with different length of the B-domain attached were observed for Advate® and Kogenate FS®. Following thrombin digestion, all rFVIII products showed the expected bands corresponding to the A1 and A2 domains and the activated LC. In addition to intact A2, ReFacto AF® contained two components with lower mass likely due to *C*-terminal cleavage within A2.[4] For turoctocog alfa the major components in the RP-HPLC profile consisted of HC and LC and a small amount (approximately 3%) of scFVIII. Heterogeneity of HC was observed for all rFVIII compounds. Turoctocog alfa had two components, one with *C*-terminal at amino acid 740, i.e. at the end of the A2 domain, and one containing the 21 amino acid B-domain. Advate® and Kogenate FS® both contained several HC degradation products corresponding to HC's with different lengths of the B-domain attached. For Advate®, a specific LC component containing part of the B-domain was observed. The SE-HPLC of turoctocog alfa and

ReFacto AF® have similar profiles, while variation due to the heterogeneously processed B-domains was observed for Advate® and Kogenate FS®.

Conclusion: The major difference of the commercially available rFVIII products is the variation in length of the B-domain: Advate® and Kogenate FS®, encoded by the full-length gene, showed highly heterogeneous profiles in SE- and RP-HPLC, while ReFacto AF® and turoctocog alfa both exhibit more homogeneous profiles. For Advate®, a specific LC variant containing part of the B-domain was observed. After thrombin cleavage all rFVIII compounds contain the expected pattern of A1, A2 and activated LC, however, ReFacto AF® also contains smaller size A2 domains. In summary, turoctocog alfa is a highly homogeneous rFVIII product.

PO 059

The activity of glycoPEGylated recombinant FVIII (N8-GP) can be measured in both two-stage chromogenic and one-stage clotting assays

Krogh-Meibom T, Olsen EHN, Kjalke M and Ezban M
Novo Nordisk A/S, Maaloev, Denmark

Background: N8-GP is a 40KDa glycoPEGylated recombinant human FVIII. The PEG group is selectively attached to a unique O-linked glycan in the B-domain of turoctocog alfa, which upon activation is released and generates activated FVIII (FVIIIa) similar to native FVIIIa.[1] N8-GP and FVIII have similar potency in animal bleeding models, however N8-GP has longer duration of effect. In humans N8-GP has a 1.6-fold prolonged half-life compared to rFVIII. N8-GP is in late stage clinical development for bleeding prophylaxis in haemophilia A.

Aim: To evaluate N8-GP relative to non-PEGylated rFVIII in two-stage chromogenic and one-stage clot assays.

Methods: Different FVIII compounds (turoctocog alfa, N8-GP, Advate®, and Haemate®) were analysed in two-stage chromogenic assays and in one-stage clotting assay with different APTT reagents. Reference materials (plasma, rFVIII, N8-GP) were calibrated against WHO FVIII standard.

Results: The activity of N8-GP and turoctocog alfa was comparable when measured in two-stage chromogenic assays. Thus, chromogenic assays do not appear to be affected by the PEG group of N8-GP. In the one-stage clot assay the activity measured for turoctocog alfa, Advate® and Haemate® was within 100 ± 25% of labelled value irrespectively of APTT reagent used. APTT reagents containing ellagic acid in general gave activities for N8-GP within 100 ± 25% of labelled value, e.g. the use of Actin FS® and STA Cephascreen® resulted in recoveries of N8-GP close to 100%. Other reagents, in particular the silica-based reagents, resulted in activities below 75%. The latter suggested some interaction of silica-based APTT reagents with the PEG group of N8-GP. Full recovery was achieved for all APTT reagents when using the N8-GP standard. Addition of free PEG to the assay buffer did not influence the performance of rFVIII in the one-stage clot assay, i.e. the interference is only observed when the PEG moiety is attached to rFVIII.

Summary/Conclusion: As for rFVIII (e.g. turoctocog alfa), the activity of glycoPEGylated recombinant FVIII (N8-GP) can be reliably measured against the WHO FVIII standard in two-stage chromogenic as well as in one-stage clotting assays with ellagic acid-based APTT reagents. Other APTT reagents provided reduced recoveries, probably due to interference of the PEG group of N8-GP with APTT reagent. The reagent specific variations can be normalised by introduction of an assay specific conversion factor or by using a N8-GP standard. The data illustrate the need for evaluating performance of new FVIII products in various activity assays using different reagents.

PO 060

Selective measurement of PEGylated human recombinant factor VIII (BAX 855) in laboratory animal plasma

Turecek PL, Weber A, Engelmaier A, Minibeck E, Hainzelmayer S, Schwarz H-P and Scheiflinger F
Baxter Innovations GmbH, Vienna, Austria

Background: Quality-determining attributes of protein therapeutics such as half-life, immunogenicity or resistance against proteolytic degradation, can be improved by the covalent attachment of polyethylene glycol (PEG), i.e. PEGylation. Monitoring the resulting PEGylated protein in preclinical settings requires a composite assay type that not only measures the parent, unmodified protein, but also its PEG moiety introduced by PEGylation.

Aim: We therefore developed a ligand-binding assay (LBA) to selectively measure PEGylated human recombinant factor VIII (rFVIII; BAX 855), and validated it for use in pharmacokinetic studies in macaques, rats and FVIII-deficient mice.

Method: The LBA uses a combination of an anti-PEG antibody and a polyclonal anti-human FVIII antibody-peroxidase conjugate as a reporter antibody. PEGylated rFVIII BAX 855 is selectively captured via its PEG moiety by the plate-bound anti-PEG antibody and then detected by binding of the reporter antibody. Concentration-dependent responses were obtained with a calibration curve ranging from 0.18 to 2 ng FVIII-bound PEG/mL. We validated the LBA in the matrix of macaque, rat and FVIII-deficient mouse plasma, according to the EMA guideline on bio-analytical assay validation.

Results: Using the combination of anti-PEG capturing antibody and anti-FVIII reporter antibody allowed us to specifically measure human PEGylated rFVIII in all three plasma matrices. This was posible even in macaque plasma where usually a high degree of cross-reactivity interferes with the specific immunological measurement of human FVIII. The assay's selectivity allowed measurement of BAX 855 without interference by endogenous FVIII in wild-type animal models. Results of the assay validations proved the LBA suitable for its intended use in all three species: Mean accuracy, expressed as the recovery of BAX 855 spiked at five relevant concentrations to the plasma of macaques, rats and FVIII-deficient mice, was 91.9%, 96.4% and 91.7%, respectively, with all individual values in a ± 20% range, even at the lower limit of quantification. Intra- and inter-run precision also complied with accepted recommendations for assays of this type. The three animal plasma matrices showed no influence on the linearity of the dilution series obtained for BAX 855-containing plasma samples. The LBA's mean total errors, giving the sum of absolute accuracy and precision, were 11.0%, 16.4% and 15.2% for rat, E17 mouse and macaque plasma spiked with BAX 855 at FVIII-bound PEG concentrations ranging from 10 to 400 ng/mL, and were < 35% at the assay's lower limit of quantification.

Summary/Conclusions: A ligand-binding assay was developed and successfully validated for measuring the PEGylated rFVIII preparation BAX 855 in the plasma of laboratory animals. The concept of using paired antibodies, and in particular, the application of an anti-PEG antibody to capture the PEGylated protein, can be extended to measurement of other PEGylated biologicals using an appropriate reporter antibody.

PO 061

Modification-dependent activity assay: A new assay type for selective activity measurement of PEGylated human factor VIII (BAX 855)

Turecek PL, Weber A, Engelmaier A, Haindl S, Mohr G, Schwarz H-P and Scheiflinger F

Baxter Innovations GmbH, Vienna, Austria

Background: Quality-determining attributes of protein therapeutics such as half-life, immunogenicity or resistance against proteolytic degradation can be improved by the covalent attachment of polyethylene glycol (PEG), i.e. PEGylation. Optimally, PEGylation does not or only minimally reduces the biological activity of the modified molecule. Measurement of the activity of the resulting PEGylated protein can be achieved with a new type of activity assay, which only measures the protein's activity as long as the PEG moiety is present. This assay type is therefore termed modification-dependent activity assay (MDAA).

Aim: We developed and validated a modification-dependent activity assay to selectively measure the FVIII activity of the PEGylated human recombinant factor VIII (rFVIII) preparation BAX 855 in normal and in FVIII-deficient human plasma without interference by non-PEGylated FVIII.

Method: The MDAA combines the use of an anti-PEG antibody with an FXa-based chromogenic FVIII activity assay. PEGylated rFVIII BAX 855 is selectively captured by the plate-bound anti-PEG antibody, and non-PEGylated compounds including endogenous FVIII when present are removed by washing. The activity of the bound PEGylated FVIII is then determined by chromogenic FVIII activity assay. The assay, which, due to its underlying principle, shows absolute specificity for PEGylated FVIII, was validated for measurement of BAX 855 in human plasma samples according to the EMA guideline on bio-analytical assay validation.

Results: The six-point calibration curve of the MDAA ranged from 2.2 to 69 mU FVIII/mL; thus, it was as sensitive as conventional chromogenic assays. Using this MDAA for measurement of samples from a preclinical pharmacokinetic study in a FVIII-deficient mouse model (E17 mice) provided almost overlapping time vs. activity curves compared with those obtained with the conventional chromogenic FVIII assay. Results of the validation proved the MDAA suitable for its intended use: Mean accuracy, expressed as the recovery of PEGylated rFVIII BAX 855 spiked at five concentrations ranging from 0.07 to 2 U/mL to normal human plasma and FVIII-deficient plasma was 97.1% and 96.1%, respectively, with all individual means in a $\pm$ 12% range even at the lower limit of quantification (LLOQ). Intra- and inter-run precision clearly complied with accepted recommendations with relative standard deviations of less than 12%, even at the LLOQ. The selectivity of the capturing step was confirmed by competition with PEG and an anti-PEG antibody: In both cases, a dose-dependent signal reduction was obtained.

Summary/Conclusions: A highly selective MDAA was developed and successfully validated for measurement of the PEGylated rFVIII preparation BAX 855 in normal human plasma and FVIII-deficient plasma. This particular concept of specifically capturing PEGylated rFVIII before measuring its activity can be extended to other PEGylated proteins. The results obtained with this newly developed assay type will allow to determine whether or not the PEGylated protein is still intact.

PO 062

Differentiation of the natural, full length recombinant FVIII molecule from B-domain deleted recombinant FVIII with respect to its hemostatic potency

Turecek PL, Schrenk G, Gritsch H, Romeder-Finger S, Knappe S, Dockal M and Scheiflinger F

Baxter Innovations GmbH, Vienna, Austria

Background: A variety of recombinant FVIII (rFVIII) preparations that provide efficacious replacement therapy in hemophilia A patients are available. These preparations include full-length rFVIII (FL rFVIII), which is equivalent to the naturally occurring FVIII molecule, and genetically engineered B-domain deleted rFVIII (BDD rFVIII). Determination of an accurate FVIII activity is crucial for manufacturing, and especially for product dosing in clinical settings and testing of patient plasma. Several studies have demonstrated that assessing reliable FVIII activity for BDD rFVIII is a significant challenge due to the major discrepancy in results obtained with FVIII chromogenic and 1-stage clotting assay. Moreover, FVIII 1-stage clotting activity depends on the type of aPTT reagent used.

Aims: The objective of the study was to evaluate differences in potency determination between FL rFVIII and BDD rFVIII with respect to their dependency on the type of aPTT reagent used in the 1-stage clotting assay.

Methods: Potency of FVIII was measured by a FVIII chromogenic activity assay and 1-stage clotting assay, using different commercial available aPTT reagents. Both the 8th international standard for blood coagulation factor VIII concentrate (NIBSC #07/350) and human normal plasma served as assay reference standards. The performance of the two different types of rFVIII products was compared by calculating the ratios between FVIII 1-stage clotting and chromogenic activities.

Results: Depending on aPTT reagent type, FVIII potencies varied within a relatively broad range, independent of which type of assay reference standard was used. The resulting ratios between FVIII 1-stage clotting and chromogenic activity showed a broader variance for the BDD rFVIII products than for FL rFVIII products.

Summary/Conclusions: Although further investigation is required to substantiate our observation, dependence on aPTT reagent type appeared more pronounced for BDD rFVIII than for FL rFVIII. As clinical laboratories use a number of commercial aPTT reagents with different compositions, determination of the correct potency and concentration in plasma post infusion of BDD rFVIII might be more challenging than for the natural, full-length rFVIII molecule.

PO 063

Factor XI deficiency: a family report

Benlaldj D[1], Bougherza M[2] and Seghier F[1]

[1]University hospital of Oran; [2]Regional Military University Hospital of Oran, Oran, Algeria

Background: Factor XI (FXI) deficiency is an autosomal recessive inherited coagulation disorder associated with a mild bleeding tendency, absence of spontaneous bleeding and this manifestations are weakly correlated with plasmatic FXI level.

Methods: We describe an asymptomatic family withe FXI deficiency. The patient 65 year old man; diagnosed after a systematic blood test, his wife, her two girls and son were tested. Factor XI level were determined by one-stage plasma clotting assay. Von Willebrand Factor (VWF) activity were determined by visual method.

Results: The patient and her two girls have a severe deficiency (FIX level 2%). The wife patient and her son have a minor deficiency (respectively FXI levels 56% and 46%). Previous studies suggested that VWF activity may influence bleeding tendency. The absence of bleeding history in this familly and the result of VWF activity level (mean 116%, range 81% $-$135%) that suggest a role of VWF.

Conclusion: This result suggests the necessity to perform assay of VWF activity in investigation of factor XI deficiency, to evaluate a bleeding tendency.

PO 064

Factor XI deficit: cases report

Ruades Ninfea MA, Duboscq C, Ceresetto J, Prieto S, Shanley C, Stemmelin G, Rabinovich O, Palmer S and Bullorsky EO

Hospital Britanico de Buenos Aires, BUENOS AIRES, Argentina

Background: Factor XI deficit is a uncommon condition with a estimated incidence of one case per million. Bleeding as clinical manifestation are polymorphic, and also the relationship between the level of factor XI and bleeding events.
Aims: To describe clinical presentations, diagnosis, level of factor XI and treatment the nine patients in our center.
Methods: The factor levels were done by one stage clotting method (at least two dilutions). Fibrinogen levels were made with a Clauss method, and the Factor VW levels with antigenic and immuneturbimetric methods. All test were made with an optic automated coagulometer.
Results: The mean age was 48 years old (range 9–73), 7 was female. The diagnosis as screening preoperative test when prolonged APTT was found in six patients, post surgical bleeding 2, as metrorrhagia in 1 of cases. None presented as spontaneous or severe bleeding before the diagnosis was made. The factor XI measured were between 9% and 50%, two patients presented severe Factor XI deficit with a level less than 15% (one with metrorrhagia and the other without bleeding manifestations) and seven patients the deficit was mild with a factor XI level between 30 and 50%. No molecular test and platelet Factor XI were available in our country. In six patients we used fresh frozen plasma, in two anti fibrinolytics and in one DDAVP, previously to the surgical procedure since there is no factor XI concentrate in *Argentina*. None of them had post surgical bleeding.
Conclusion: (1) Factor XI is an uncommon condition, but must be ruled out in a patient with a prolongued APTT with correction in mix assays; (2) In pre surgical intervention are effective fresh frozen plasma, antifibrinolytics and DDAVP as an alternative to Factor XI concentrate.

PO 065

Prevalence of Venous Thrombo-Embolism & Related Morbidity and Mortality among hospitalized patients in Saudi Arabia (SAVTE Registry)

Abo-El-nazar Y[1], Al-Hameed F[2] and Group SR[3]

[1]Um AlQora University; [2]KSAU-HS Univeersity; [3]Savte Group, Jeddah, Saudi Arabia

Background: Venous Thrombo Embolism (VTE) is a serious and potentially fatal condition. Its prevalence and incidence has not been clearly defined on a large scale bases in Saudi Arabia. Appropriate prophylaxis can lead to favorable and cost-effective results.
Aims: The primary objective is to determine the percentage of VTE patients who received appropriate anti-thrombotic prophylaxis according to ACCP guidelines. The secondary objective is to determine the mortality due to VTE events, type of VTE events, and percentage of patients prescribed the anti-coagulant therapy and adherence to it after discharge.
Methods: Seven major tertiary hospitals in the Kingdom of Saudi Arabia have participated in this study. During the period from 1 July 2009 till 30 June 2010, all cases of VTE recorded in the hospitals, were collected using patients' medical records and computerized databases of the hospitals. Only patients with confirmed diagnosis of VTE were included in the analysis.
Results: One thousand two hundred and forty-one of confirmed VTE were included in the study analysis. A 58.3% of them were DVT only, 21.7% were PE and 20% had both DVT and PE. A 21.4% and 78.6% of confirmed VTE occur in surgical and medical patients respectively. A 40.9% of total VTE cases received prophylaxis.
Only 63.2% of surgical patients and 34.8% of medical patients had received appropriate prophylaxis ($P < 0.001$). Mortality rate was 14.3% of all patients. A 89.4% of survived patients were on anti-coagulation therapy at discharge, and 71.7% were adherent to it on follow-up.
Conclusions: VTE is a significant cause of morbidity and mortality in hospitalized patients. All efforts should be made to reduce the gap between guidelines and practices in implementing appropriate VTE prophylaxis.

PO 066

Acute Deep Venous Thrombosis secondary to May-Thurner syndrome: a case report

Acosta KRA, Ganzon MS, Carino RG and Esposo EA

St. Luke's Medical Center, Quezon City, Philippines

Background: We report a case of a 31 year-old female with pain and swelling of the left lower extremity as the initial presentation of acute deep venous thrombosis (DVT) secondary to May-Thurner Syndrome, a rare case with unknown overall prevalence or incidence, that results in iliofemoral DVT due to an anatomical anomaly where the left common iliac vein is compressed between the right common iliac artery and the lumbar vertebrae. She had a two-day history of pain and swelling of the left lower extremity, difficulty ambulating, warmth, and purplish discoloration of the skin. On physical examination, the left lower extremity had purplish discoloration, varicosities, increased capillary refill time, grade three pitting edema, warmth, tenderness from the medial part of the thigh to the calf and limitation of movement. Its circumference was greater than the right lower extremity by 10 cm. Pulses were full and equal, with intact reflexes, sensory, and no masses or inguinal lymphadenopathy.
Aims: May-Thurner Syndrome is often unrecognized due to the prevalence of other more easily recognized risk factors for DVT. A more invasive study, such as venography, is necessary to correctly identify and manage this anatomical anomaly to prevent debilitating sequelae.
Methods: Duplex scan of lower extremities showed acute DVT partially occluding the left common iliac and distal external iliac veins, proximal to distal femoral vein, and popliteal vein. CBC, PT, and PTT were unremarkable. She had elevated Factor VIII levels at 201%, and low protein S level at 19%, prompting investigation for thrombophilia which yielded negative findings. On further work-up, venography revealed stenotic, anomalous vein originating from the left iliac vein, obstruction from the left common iliac vein to mid-proximal femoral vein and collaterals in the common femoral vein to the left common iliac vein. Workup for anti-phospholipid antibody syndrome, systemic lupus erythematosus, malignancy, lymphedema, and infection were negative.
Results: Management was aimed at clearing the thrombus present and correcting the underlying compression of the left iliac vein. Methods of clearing the thrombus include anticoagulation and thromboreductive strategies. Initial anticoagulation with Enoxaparin was overlapped with Warfarin for long-term anticoagulation. She also underwent catheter-directed thrombolysis with Alteplase, and ilio-femoral, popliteal, and posterior tibial thrombectomy after IVC filter insertion; however, treatment failed as evidenced by persistence of pain and swelling on the left lower extremity, and occurrence of pulmonary embolism. Subsequently, femoro-femoral vein bypass using cross-over great saphenous vein and AV fistula creation to the femoral venous bypass graft were successfully performed, followed by chronic anticoagulation with Rivaroxaban. Clinical improvement was noted with completely resolved pain and swelling on the left lower extremity after 6 months.

Follow-up duplex scan of lower extremities also showed marked improvement.

Summary/Conclusions: A comprehensive diagnostic approach is essential to accurately identify this anatomical anomaly as a cause of iliofemoral DVT, especially in a young female with unilateral pain and swelling of lower extremity. Long-term anticoagulation and thromboreductive strategies, while indicated, are not adequate to prevent long-term sequelae in May-Thurner Syndrome, and a more invasive therapeutic approach, surgery, is indicated.

PO 067

The role of clinical scores in the diagnosis of pulmonary thromboemboli

Comert S, Caglayan B, Mutlu S, Fidan A and Kiral N

Dr.Lutfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey

Background: Pulmonary thromboembolism (PTE) is a common disease, that requires prompt diagnosis and treatment due to the high morbidity and mortality. Clinical scoring methods are used for the diagnosis of PTE in addition to the algorithms that includes clinical, radiological and laboratory parameters. Wells and the modified Geneva clinical scores are two of these methods.

Aim: The aim of this study was to compare the roles of these two methods in the diagnosis of PTE.

Methods: The demographic and clinical characteristics, risk factors, Wells and modified Geneva scores, arterial blood gas values, radiographic and computed tomography angiography findings of patients hospitalized in our clinic with the pre-diagnosis of PTE between January 2010 – December 2012 were retrospectively analyzed. The role of Wells and modified Geneva clinical scores in the diagnosis of PTE was evaluated and compared with each other by Mann–Whitney-U test using the SPSS 17.0 program, $P < 0.05$ was considered statistically significant.

Results: Two hundred and twelve patients, 104 (49.1%) female and 108 (50.9%) male, hospitalized with the diagnosis of PTE were included in the study. The mean age of patients was 60.6 ± 17.7 yeras, 124 of these patients (58.5%) were treated with the diagnosis of PTE and 88 (41.5%) of them consisted of patients who were diagnosed besides PTE. Twenty-three (18.5%) of cases were in low, 99 (79.8%) were in moderate and 2 (1.6%) of them were in high clinical probability with the Wells scoring method. On the other hand, 98 (79%) of patients were in moderate and 26 (21%) of them were in high clinical probability with the modified Geneva scoring. The mean Wells and modified Geneva scores were 2.74 ± 1.08 and 2.83 ± 6.51. It is determined that Wells score and the modified Geneva score were statistically significant in the diagnosis of PTE ($P = 0.03$, $P < 0.0001$).

Conclusion: As a result, a variety of clinical scoring methods are important in achieving the diagnosis of PTE. In our study, Wells scoring method is found more valuable than the modified Geneva scoring.

PO 068

Retrospective evaluation of pulmonary thromboembolism cases

Comert S, Caglayan B, Mutlu S, Fidan A and Kiral N

Dr.Lutfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey

Background: Pulmonary thromboembolism (PTE) is a common disease, that requires prompt diagnosis and treatment due to the high morbidity and mortality.

Aim: The aim of this study is to evaluate retrospectively the clinical, laboratory and radiological findings of patients that diagnosed and treated as PTE.

Methods: The demographic and clinical characteristics, risk factors, arterial blood gas values, radiographic and computed tomography angiography findings of patients hospitalized in our clinic with the diagnosis of PTE between January 2010 – December 2012 were retrospectively analyzed.

Results: The most common risk factors were older age (> 65) (48.4%), deep venous thrombosis (44.4%), immobilisation (27.4%) and surgical operation in last 4 weeks (14.5%). The most common symptoms observed in our patients were dyspnea (75.0%), cough (29.8%), chest pain (27.4%), hemoptysis (21.0%) and unilateral lower extremity pain (14.5%), respectively. Chest X-ray reveals parenchymal lesions in 82 (66.1%), pleural effusion in 57 (46.0%) and linear atelectasis in 28 (22.6%) of the cases. Serum d-dimer level was high in 121 (97.6%) cases. Fifty-one (41.1%) of patients had hypoxemia and 69(55.6%) had hypocapnia arterial blood gasses. Thrombosis was detected in 44.4% of cases at lower extremity Doppler ultrasonography. A 62.9% of the patients were diagnosed with V/Q scintigraphy while 37.1% of them were diagnosed with computed tomography angiography of the thorax.

Conclusion: We consider that clinical evaluation is also important besides the radiological and laboratory examinations in PTE suspected cases. The morbidity and mortality can be reduced if PTE is kept in mind especially in patients with risk factors.

PO 069

D-dimer, P-selectin and Microparticles are superior to duplex ultrasound in the diagnosis of DVT

Eissa DG, Ghozlan MF, Osman A and Mahmoud HM

Ain Shams University, Cairo, Egypt

D-dimer, P-selectin and Microparticles are superior to duplex ultrasound in the diagnosis of DVT.

Background: Diagnosis of DVT is based upon clinical suspicion in patients at risk and confirmatory duplex ultrasound imaging of the deep venous system of the affected extremity. Currently, no single blood test exists alone to diagnose DVT and the most widely used test, D-dimer, is useful to exclude the diagnosis of DVT due to its high sensitivity, but cannot establish the diagnosis due to its poor specificity.

Aim: This study was performed to determine the significance of D-dimer, P-selectin and microparticles biomarkers in the diagnosis of DVT.

Methods: Three groups of individuals were examined: 50 normal individuals (Group I); 50 symptomatic patients for DVT whose duplex ultrasound was positive (Group II) and 50 symptomatic patients with normal duplex ultrasound (Group III). Measurment of D-dimer by immunoturbidimetric assay, P-selectin by flowcytometry and microparticles by ELISA was performed for all individuals.

Results: D-dimer, P-selectin and microparticles were significantly higher in groups II and III compared to group I individuals. Group II vs. Group III individuals had D-dimer values of 4.41 ± 2.07 vs. 2.1 ± 1.37 mg/L ($P = 0.000$); P-selectin values of 31.91 ± 14.9 vs. 22.96 ± 10.7%($P = 0.021$) and microparticles levels of 42.12 ± 14.1 vs. 21.08 ± 14.61 nM ($P = 0.000$). Using ROC curves, we determined D-dimer cut-off level of 0.92 mg/L, P-selectin value of 17.8% and microparticles level of 16.5 nM that can accurately differentiate normals from duplex positive patients for DVT. In Group III, 14 patients developed thrombosis in a period of time ranging from 3 to 7 days which necessitates the establishment of new cut-off levels for each of the three studied markers to differentiate duplex negative patients for DVT without thrombosis from those of the same group who developed thrombosis being 2.81 mg/L for D-dimer (57% sensitivity and 94% specificity), 30.2% for P-selectin (57% sensitivity and 94% specificity) and 26 nM for microparticles (43% sensitivity and 100% specificity).

Conclusion: D-dimer, P-selectin and microparticles can be used to diagnose DVT. In addition, newly estimated cut-off values for the three studied biomarkers can confirm the presence of DVT in patients

and thus they can start anticoagulation therapy even before duplex ultrasound turn positive or when it is unavailable.
Keywords: D-dimer, P-selectin, microparticles, DVT.

PO 070

Normalized activated protein C sensitivity ratio and protein S-specific activity are useful predictive markers for venous thromboembolism

Kobayashi T[1], Hirai K[1], Kasamatsu N[1], Kobayashi M[1], Iwase T[1], Kanai T[1], Matsuoka T[1], Sugiyama K[2] and Tsuda T[3]
[1]Hamamatsu Medical Center; [2]Hamamatsu Univercity School of Medicine, Hamamatsu; [3]Shino-Test Corporation, Sagamihara, Japan

Background/Aims: Predicting venous thromboembolism (VTE) is very difficult and effective markers have yet to be established. This study aimed to determine whether the normalized activated protein C sensitivity ratio (APC-sr) and protein S (PS) activity/antigen ratio (PS-specific activity) are useful predictive markers for VTE.
Patients and Methods: APC-sr and PS-specific activity were examined in scheduled surgical patients and in patients with VTE onset before anticoagulation in Hamamatsu Medical Center between January 2010 and March 2012. Citrated plasma was obtained perioperatively from surgical patients. APC-sr was determined by an endogenous thrombin potential (ETP)-based assay with computer-assisted calibrated automated thrombography. The total PS activity assay is comprised of three solutions, Reagent 1 (APC), Reagent 2 (Factor Va) and Reagent 3 (Factor Xa, prothrombin and S-2238), and is readily applicable to automated analyzers. To measure total PS activity, the PS-C4bBP complex in plasma was first dissociated by diluting samples and adding liposomes with high affinity for PS. PS antigen was assayed by latex agglutination by an anti-PS monoclonal antibody. Then, PS-specific activity was calculated. Pulmonary embolism (PE) and deep venous thrombosis (DVT) were diagnosed and then confirmed by CT scanning or Doppler blood flow scanning. Approval for this study was granted by the Hamamatsu Medical Center Review Board in 2009. Informed consent was obtained from all participants prior to blood collection.
Results: Twenty orthopedic patients, 30 patients with abdominal malignancies, six pregnant women who had cesarean deliveries, and 22 symptomatic VTE patients (16 PE, 6 DVT alone) were enrolled in this study. Among 56 surgical patients, one with a gynecological malignancy developed DVT postoperatively. The mean (± SD) preoperative APC-sr was 1.27 (± 0.69) in orthopedic patients, 1.27 (± 0.68) in abdominal malignancy patients, and 1.82 (± 0.45) in pregnant women. These values were somewhat high, and increased through the 3rd to 4th days postoperatively. APC-sr in patients with VTE at the onset before anticoagulation was 2.92 (± 1.47) ($P < 0.01$, Games-Howell test). These data indicate a reduction of sensitivity to APC in these patients. PS-specific activity was less than 0.7 (−3 SD) in 7 of 19 VTE patients (36.8%) and in 6 of 16 PE patients (37.5%). Total PS activity was less than 60% in 5 of 19 VTE patients (26.3%) and in 4 of 16 PE patients (25%). Moreover, APC-sr and PS-specific activity were 2.76 and 0.61, respectively, in a patient with postoperative DVT. There was an inverse correlation between APC-sr and total PS activity. Cut-off values calculated employing a receiver operating characteristic curve were 2.0 (sensitivity 71%, specificity 88%) for APC-sr, and 0.72 (sensitivity 37%, specificity 94%) for PS-specific activity.
Conclusion: These data suggest APC-sr (> 2.0) and PS-specific activity (< 0.72) to potentially be useful predictive markers in patients at high risk for VTE.

PO 071

DVT to VTE: a nursing evolution or revolution?

Lavery RC and Speers H
Belfast Health & Social Care Trust, Belfast, Northern Ireland

As part of the Emergency Department at the Belfast City Hospital, an outpatient deep vein thrombosis (DVT) service, a nurse led clinic was setup to triage all patients presenting with suspected DVT. Eighty-five percent of all patients reviewed did not have a DVT whilst all suspected pulmonary embolus were admitted directly.
The Belfast City Hospital ED has faced a period of temporary closure. This posed a challenge to the nurse led service. An options appraisal review took place and it concluded to only manage those patients with confirmed DVT, pulmonary embolus with a PESI score of 0 and superfical thrombphlebitis.
We have collated our data and present the findings of the new challenging patient cohort.
At a total of 120 patients have been managed with an average of 8.5 per week. The age range was 18–99 years with 45% male. Of 90 patients diagnosed with a DVT two-thirds were in proximal lower limb. Risk factors for VTE included 31 with a previous personal history of VTE, 17 with a positive family history, 8 of the females were on OCP/HRT. One in every four patients was diagnosed with a hospital acquired thrombosis (HAT), 3 post partun, 13 general medical/surgical, and 17 related to trauma/orthopaedics. Of these patients just 14 had received chemical thromboprophylixis, 3 were risk assessed but not prescribed.
Whilst the change in service has been challenging it has also been rewarding, as we have been motivated into developing new care pathways for patients and information leaflets relevant to the many questions which we are most frequently asked.

PO 072

Thromboses of unusual localization and pregnancy

Makatsaria A, Makatsaria A, Bitsadze V, Kitsenko E, Khizroeva D and Panfilova O
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

Background: Thromboses of atypical localizations are life-threatening complications in pregnant woman.
Materials and Methods: From 2001 to 2012 we observed 27 cases of thromboses of unusual localization at pregnant women: splanchnic system thromboses (Badd-Kiari syndrome, mesenterial, splanchnic veins and portal vein), thromboses of renal veins and retinal veins, thromboses of the upper extremities, a catheter – associated thromboses which haven't been associated with oncology, thromboses of brain venous sinus. Among them 18 cases were associated with pregnancy, 6 – with oral contraceptives, 3 – with IVF.
Analyses for the genetic and acquired defects of a hemostasis were conducted in all patients. At 24 of 27 pts thrombophilia was detected: the phrothrombin mutation (geterozygous)- at 6 pts, a homozygous mutation of factor V Leiden – at 1 pts, heterozygous – at 6, hyperhomocysteinemia – at 50%, AFA circulation- at 67%, at one patient we detected a combination of prothrombin mutation and F V Leiden. In almost all cases the combination of the genetic and acquired forms of thrombophilia was detected.
Twelve from these patients in the subsequent were observed for pregnancy-course. Anticoagulant treatment was carried out since the pregnancy beginning, during all pregnancy and within 6 weeks of the postoperative or postnatal period with enoksaparin sodium (from 0.6 to 2 ml daily). There were no repetitions of thromboses of common and unusual localization, as far as there were no hemorrhagic complications.

PO 073

A comparative study of two automated assays for D-Dimer used in patients admitted in the Emergency Department in a university hospital

Marques-Verdier A

CHU of Clermont-Ferrand, Clermont-Ferrand, France

Background: D-dimers are the products of degradation of fibrin by plasmin. Their detection is evidence of the activation of fibrinolysis. When a patient is admitted for suspected venous thromboembolism (VTE), a clinical score determine the probability, low, medium, high for this diagnosis. In case of low or moderate probability, D-dimer test is useful with a sensitive test: if the D-dimer result is below the positive threshold, this result can rule out the diagnosis of VTE.

Aims: The aim of our study was to compare the results between two automated quantitative assays used in our laboratory.

Methods:

- 548 plasma samples from 541 adult patients admitted to the emergency department were tested from July to December 2012. Seven patients had two samples at 6 months, or during the same hospital stay or during two successive hospital stays.
- Exclusion criteria included pregnancy and age over 60 years.
- 249 samples (45%) were collected from men and 299 (55%) from women.
- The median age was 38 years in both sexes (range 16–60 years).
- The 548 samples were tested by simple determination within 2 h after the admission of patient to the emergency department. Two methods were used: a quantitative automated turbidimetric immunoassay (STA-Liatest D-DI on STA-R analyzer, Diagnostica Stago) and a quantitative automated enzyme immunoassay automated (VIDAS D-Dimer Exclusion, BioMérieux SA).
- The detection limit was different between the two assays: 0.220 microg/ml (FEU) for STA-Liatest D-DI and 0.045 microg/ml (FEU) for the Vidas method.
- The clinical cut-off used for subjects aged less than 60 years was 0.500 microg/ml (FEU).

Results:

- 493 patients (90.0%) had normal results and 12 (2.2%) had abnormal results with the two tests.
- 40 patients (7.3%) had a normal result with the STA-D-DI Liatest assay and an abnormal result with Vidas assay. The median value of the differences was 0.190 microg/ml (range 0.060–0.390). Nineteen samples were slightly above the upper cut off level used in the Vidas D-dimer assay. The collection of clinical data (Wells score, diagnosis, radiology) is in progress.
- three patients (0.5%) had an abnormal result with the STA-D-DI Liatest assay and a normal result with the Vidas D-Dimer assay. There were small variations in either side of the clinical cut-off. Neither the rheumatoid factor, nor monoclonal gammapathy were looked for.

Summary/Conclusions: These two methods of determination of D-Dimer well give concordant results for 92.2% of plasmas tested.

But the rate of discordant results (7.3%) seems high (although two tests have different sensitivity) and a study of the clinical features of patients is underway to understand.

PO 074

Inferior vena cava agenesis as cause of deep venous thrombosis in a young patient: case report and literature review

Mello TBT[1], Giovelli J[2], Lopes AD[2] and Borges AP[2]

[1]Mario Gatti Hospital; [2]Centro Médico Hospital, Campinas, Brazil

Background: Inferior vena cava agenesis (IVCA) is a rare anomaly with an estimated prevalence at 0.5% in the general population. Deep venous thrombosis (DVT) is the main clinical feature associated with this condition.

Aims: We report clinical date of DVT associated IVCA in a young patient, together with a literature review surrounding this association.

Methods: We performed a systematic literature review of published reports based on Pub Med and Medline up to December 2012.

Results: The 13 years old male teenager was admitted to our teaching hospital complaining of 2 day of severe lower abdominal pain. The abdominal ultrasound showed chronic inferior vena cava thrombosis with extensive collaterals and a partial thrombosis in mesenteric vein and an image suggesting ileoileal intussusception. He underwent laparotomy with successfully correction of the problem. Due the chronic nature of thrombosis, none anticoagulant was initiated. The patient recovered and was discharged. Four days after, he returned to hospital with severe back and groin pain. The CT scan revealed an infrahepatic AVCI with venous drainage through dilated lumbar venous collaterals into the azygous system in addition an extensive bilateral iliofemoral-popliteal venous thrombosis. The thrombophilia screening was negative. The patient was put on lifelong oral anticoagulation and remains well at 2 years follow-up. The literature has reported 86 cases of IVCA associated DVT, with a median age of 30 years (8.5–67), a male sex predominance (64 patients/74%) and in 40% of the cases the site of DVT was the bilateral proximal veins of the legs. An interesting finding is that, due the aberrant collateral venous drainage in rare cases the thrombosis mimicked ureteric colic or lumbar disc herniation. The majority of the cases (88%) the treatment consisted solely of long term anticoagulation.

Conclusion: This is the first case of IVCA associated with bowel obstruction. IVCA should be regarded in young patients (predominantly males) with spontaneous bilateral DVT.

PO 075

Role of D-dimer monitoring for the diagnosis of deep vein thrombosis in patients undergoing neurosurgery for brain tumor

Sartori MT[1], De Bon E[1], Della Puppa A[2], Dalla Valle F[1], Piovella C[1], Padoan A[3], Ciccarino P[2], Bernardi D[3], Scienza R[2] and Prandoni P[1]

[1]2nd Chair of Internal Medicine; [2]Neurosurgery; [3]Laboratory Medicine Unit, Padua, Italy

Background: Patients undergoing neurosurgery for brain tumor remain at risk for deep vein thrombosis (DVT) despite the use of multimodality prophylaxis. Clinical suspicion may be challenging in this setting due to consciousness alteration, sensitivity and/or motor deficits in the post-operative period. Lower limb venous ultrasound (US) monitoring would be useful, but it is often not feasible in clinical practice. D-dimer measurement may help early detection of DVT, but its transient increase after surgery may lead to misinterpretation.

Aims: To evaluate the behaviour of D-dimer levels before and after surgery in patients operated for brain tumor, with or without DVT confirmed by US.

Methods: Consecutive patients undergoing craniotomy for high grade glioma (GBM) or meningioma were tested for D-dimer (normal value < 225 μg/L) before (T0), 1 day (T1) and 7 days (T2) after neurosurgery. Each patient received complete compression US of lower limbs at T0 and T2 to verify the presence or absence of DVT. During the hospital stay, all patients received multimodality antithrombotic prophylaxis with elastic stockings, intermittent pneumatic compression and low-dose LMWH. Informed consent according to Helsinki Declaration was obtained by each patient.

Methods: Forty-two patients, 27 males and 15 females with a mean age of 61.0 ± 11.5 years, were enrolled; 25 patients had GBM and 17 had meningioma. Two patients had DVT before surgery and were excluded; six patients developed DVT within 7 days after surgery. Median (IQR) D-dimer levels in patients with and in those without

DVT were 144.5 (133–839) μg/L and 110 (61–167) μg/L at T0, 909 (537–1486) μg/L and 560.5 (308–1023) μg/L at T1, 1994.5 (1733–2063) μg/L and 110.5 (61–167) at T2, respectively. The differences were significant by ANOVA between patients (F 9.9, p 0.0032) and within patients at T2 (F 9.18, $P < 0.001$). Age and gender adjusted analysis did not change the results. In each patient the T2-T1 difference (delta T2-T1) in D-dimer values was calculated. If a delta T2-T1 cut-off level of 116 μg/L was used, D-dimer demonstrated a sensitivity of 100% (95% CI 0.46–1.00), a specificity of 87% (95% CI 0.69–0.95), and a negative predictive value of 75% (CI 0.57–0.87) for DVT.

Conclusions: In patients undergoing craniotomy for brain tumor, a close monitoring of D-dimer during the hospital stay might be useful to exclude a suspicion of DVT, avoiding to perform US, when a decrease in D-dimer levels is observed after the transient rise related to the surgical intervention.

PO 076

Prevalence of perioperative asymptomatic proximal deep vein thrombosis following gynecological cancer surgery in Thai patients

Sermsathanasawadi N, Thangrod R, Hongku K, Wongwanit C, Ruangsetakit C, Chinsakchai K and Mutirangura P

Siriraj Hospital, Bangkok, Thailand

Background: The long belief that acute deep vein thrombosis is rare in Asian patients is challenged by many recent studies. Incidence of thromboembolism among Asian patients had increased. However, thromboprophylaxis for perioperative cancer surgery in Asian countries is not routinely performed. Gynecologic malignancies were the most common cancer which associated with acute deep vein thrombosis among Thai patients.

Aims: In this study, we reported the prevalence of perioperative asymptomatic proximal deep vein thrombosis of 100 patients with gynecologic cancer.

Methods: Duplex ultrasonography of proximal vein of legs was performed in each patient before and 7–14 days after gynecologic cancer surgery. Demographic data were collected including: age, sex, height, weight, body mass index (BMI), previous diagnosis of treatment of DVT and PE, history of irradiation and chemotherapy, family history of VTE, recent immobilization of lower extremities (more than 3 days), recent surgery within 3 month, recent trauma within 3 month, recent admission of severe medical illness, other associated cancers, varicose vein, thrombophilia, use of contraceptive pills, hormonal therapy, number of pregnancy, cardiac diseases and cerebrovascular disease. Hospital charts were reviewed for the following information: site of cancer, type of cancer, staging of cancer, type of operation, patient position, type of anesthesia, duration of anesthesia, duration of surgery, duration of postoperative immobilization, blood loss and blood replacement, complication, duration of ICU stay and duration of hospital stay.

Results: The results showed that preoperative prevalence of asymptomatic proximal DVT of legs was 5% and postoperative incidence of asymptomatic proximal DVT of legs was 2.11%. We found only 1 case of symptomatic pulmonary embolism associated with asymptomatic proximal DVT of lower extremities.

All DVT cases had adenocarcinoma of ovary or uterus, but not cervical cancer. Risk factors of venous thromboembolism were comparable between DVT and non DVT group except number of children which was higher in DVT group.

Conclusion: So the patients with adenocarcinoma of ovary and uterus especially in patients who have high number of pregnancy seem to be the greatest risk of perioperative VTE. Our result might make the physicians concern the high prevalence of VTE in perioperative period of gynecologic cancer of Asian patients.

PO 077

Evaluating the effectiveness of warfarin therapy in patients with deep vein thrombosis of the lower limbs

Verkholomova F[1], Manukyan I[2], Serebriyskiy I[3], Krylov A[2], Ataullakhanov F[4] and Shulutko A[2]

[1]CThPPhChPh; [2]I.M. Sechenov First Moscow State Medical University; [3]Hemacore LLC; [4]Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russia

Aim: Patients with DVT to anticoagulation vitamin K antogonist (VKA) observed the inefficiency applied therapy. The aim of our study was to investigate the risk of ineffective therapy.

Methods: We tested 60 patients with DVT (aged 56 ± 15 year-old, M/F 34/26). Patients were treated with unfractioned heparin (UFH) in dosage of 450 U/kg 3 times per day starting from day 1 for 5 days and with UFH combined with Warfarin starting from day 6 till day 10. From day 11 patients were treated with Warfarin only. Tests for D-dimer, international normalized ratio (INR) and Trombodynamics were performed at day 0, 10 and 15. Data are presented as median (25%, 75%).

Trombodynamics (HemaCore LLC, Russia) – a new global coagulation test based on video-microscopy of a fibrin clot growing from an imitated damaged vessel wall (surfaces with immobilized tissue factor) in space, the growth rate of the fibrin clot V was measured (norm 20–30 μm/min).

Results: INR from day 10 till day 15 increased from 1.4 (1.1; 2.1) to 2.6 (1.7; 3.6). As a result of anticoagulant therapy on 10 day, V decreased significantly from 23.0 (21.7; 27.5) to 9.1 (6.1; 14.1) μm/min ($P < 0.05$). By day 15, patients were divided into two groups. In the Group 1 ($n = 48$), the growth rate of the fibrin clot V where remained low 12.2 (8.2; 15.6), in Group 2 ($n = 12$) the level of V increased to 22, 3 (20.6;23.5) μm/min.

D-dimer level on day 10 of anticoagulant therapy decreased from 792 (422; 1161) to 276 (167; 370). On 15 day in the Group 1 D-dimer level was 192 (116; 244) μg/L. In the Group 2, there is a significant increase in D-dimer level to 530 (164; 826) μg/L, compared with the Group 1 ($P < 0.05$). Four of the six patients in the Group 2, which had D-dimer level higher than 400 μg/L having INR within the therapeutic range 2–3.

Conclusion: The increase of the growth rate of the fibrin clot V to normal levels in the patients with DVT on VKA therapy may indicate a risk group with elevated D-dimer.

PO 078

How we understand DIC today in Russia

Bokarev IN

I.M. Sechenov First Moscow State Medical University (MSMU), Moscow, Russia, Moscow, Russia

Background: Today there are many discussions on the definition of acute and chronic DIC. For the practical physicians it makes many problems in their work.

Aims: How to recognize it and what to do. In Russia we discussed this problem many years and came to this decision.

Methods: Guideline of the Russion Association on Thrombosis, Haemostasis and Vascular Patholy. Constant Intravascular Microcoagulation(im) and DIC-Syndrom.

Constant presence of the markers of IM in plasma of healthy and sick people give us the basis to think, that intravascular blood clotting is going constantly, and there is need to underline its existence by the term 'Constant intravascular microcoagulation'- CIMC.

The intensity of CIMC may be different. The level of the markers of IC of blood, which is measured in plasma of the healthy people must be adopted as 'normal'. The increase in intensity of IC may be discovered in some transient disorders and following physical stress. After those situations have passed, the intensity of intravascular clotting can

return back to the 'normal' level. Certain chronic diseases exhibit a constant increase of the intensity of IC, which does not exhibit any special traits except of the clinical picture of the main disease. Previously these states were named 'Chronic intravascular microcoagulation'. It is possible, that special regulation of this stage of the CIMC can improve the prognosis of the disease.
Levels of the CIMC intensity. 1-st grade NORMAL. 2-nd grade-Transient increase CIMC 3-d grade: Sustaned increased CIMC. 4th grade DIC-SYNDROM.
DIC-syndrome is only the stage of CIMC, where the increase of its intensity is an independent cause of the damage of body-organs and body-tissues, such as bleeding, multiple organ damage, hypotony, micro- and macrothrombosis and its different combinations.
Diagnostic criteria for CIMC, grade 4:-bleeding, or-low blood pressure, or- acute heart, lung, kidney, liver insufficiency without acute local ischemia Together with: fibrinogen level lower than normal +platelet level is lower than normal. Fibrinogen level and platelets numbers may be formally at the normal level, if they were increased earlier. Progressive reduction of fibrinogen level and platelet numbers must be the basis for DIC diagnosis and for the beginning of the treatment.
Results: Successful treatment of the main disease and good constant control of the coagulation tests-(fibrinogen and platelets- obligatory, D-dimer, and fibrin-monomer(TPP)-desirable) are the best way of DIC-prevention.
Conclusion: Inspite of the existing reports on the successful treatment of DIC-syndrome there is very high mortality of those patients with DIC. This fact is the basis for the future special research, which may answer the question on the importance of prevention DIC-syndrome by anticoagulant therapy. Further information is needed to determine the influence of difficult ways of increasing coagulation- fibrin formation, platelets and fibrinolitic activity is the mechanismus of the peculiar 'DIC-syndrom'.

PO 079

Normal prothrombinase activity, systemic thrombin activation, and lower antithrombin levels in patients with DIC at an early phase of trauma: comparison with Acute Coagulopathy of Trauma-Shock (ACOTS)

Gando S, Yanagida Y, Sawamura A, Hayakawa M, Kubota N, Wada T, Ono Y and Yamamoto H

Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background: We tested the hypotheses that increase in systemic thrombin activation occurs both in disseminated intravascular coagulation (DIC) with the fibrinolytic phenotype and acute coagulopathy of trauma shock (ACOTS), and that the patients diagnosed as having ACOTS overlap or are identical to those with DIC.
Methods: With the approval of the Institutional Review Board and after written informed consent was obtained from either the patients or their next of kin, 57 trauma patients, including 30 patients with DIC and 27 patients without DIC were prospectively studied. Patients with ACOTS, defined as a prothrombin time ratio > 1.2, were also investigated. Twelve healthy volunteers served as control subjects. The levels of soluble fibrin, antithrombin, prothrombinase activity, soluble thrombomodulin, and markers of fibrin(ogen)olysis were measured on days 1 and 3 following trauma. Systemic inflammatory response syndrome (SIRS) and the Sequential Organ Failure Assessment (SOFA) were scored to evaluate the extent of inflammation and organ dysfunction.
Results: DIC patients showed more systemic inflammation and higher SOFA scores, and were transfused with more blood products than the non-DIC patients. On day 1, normal prothrombinase activity, increased soluble fibrin, lower levels of antithrombin, and increased soluble thrombomodulin were observed in DIC patients in comparison with control subjects and non-DIC patients. These changes were more prominent in DIC patients who met the International Society on Thrombosis and Haemostasis overt DIC criteria. The multiple regression analysis showed that antithrombin is an independent predictor of high soluble fibrin in DIC patients. Higher levels of fibrin and fibrinogen degradation products, D-dimer and the fibrin and fibrinogen degradation products/D-dimer ratio indicated increased fibrin(ogen)olysis in DIC patients. Almost all ACOTS patients overlapped with the DIC patients. Therefore, the changes in the measured variables in ACOTS patients coincided with those in DIC patients.
Conclusions: Normal prothrombinase activity and insufficient coagulation control give rise to systemic increase in thrombin generation and its activity in patients with DIC with the fibrinolytic phenotype at an early phase of trauma. The same is true in patients with ACOTS, and shutoff of thrombin generation was not observed.

PO 080

New diagnostic strategy of sepsis induced disseminated intravascular coagulation (SEDIC); a validation study

Ichiki R, Ishikura H, Nishida T, Nakamura Y, Kawano Y, Murai A and Umemura T

Fukuoka University, Fukuoka, Japan

Background: The majority ill patients a systemic inflammatory response have coagulation abnormalities. In the pathogenesis of sepsis, inflammation and coagulation play a pivotal role. Evidence of an extensive cross-talk between these two systems is increased recently. However, there are different diagnostic criteria in sepsis and disseminated intravascular coagulation (DIC). So we defined the new diagnostic criteria of sepsis induced DIC (SEDIC) as follow; Presepsin (PSEP) level > 900 pg/mL and Protein C (PC) activity < 45%.
Aims: In this study, we attempted to validate this scoring system.
Methods: A single center, prospective, observational study was carried out. Patients who had one or more systemic inflammatory response syndrome (SIRS) criteria were included in this study. The blood samples were collected at the time of admission. The patients were classified into the three groups. SIRS and sepsis were diagnosed according to the American College of Chest Physicians/Society of Critical Care Medicine guidelines. The scoring system for Japanese Association for Acute Medicine (JAAM) DIC was used for diagnosis of DIC. We examined the severity of illness of the patients was evaluated according the APACHE II score and organ failure was assessed by the SOFA score. All patients were followed up for 28 days after enrollment in the study, and 28-day all-cause mortality was assessed.
Results: A hundred fifteen patients were enrolled for this prospective study from July 2011 to December 2012. Twenty nine patients (19.2%;29/151) were SEDIC, sixty-one were pre-SEDIC (40.4%; 61/151) and sixty-one were non-SEDIC (40.4%; 61/151). SEDIC scoring system significantly reflected the positive rate of sepsis ($P < 0.0001$) and JAAM DIC ($P < 0.0001$), SOFA score ($P = 0.0015$), APACHE II score ($P = 0.0316$) and JAAM DIC score ($P < 0.0001$). The 28-day mortality rate was significantly worsened, depending on the cutoff points in the respective criteria (SEDIC 31.0%; pre-CEDIC 19.7%; non-SEDIC 1.64%, $P < 0.0001$).
Conclusions: From these results, we strongly believed that the SEDIC scoring system has an acceptable property for the diagnosis of sepsis induced DIC. Moreover, PSEP and PC were able to be measured with very simply and quickly. So we strongly suggest that this scoring system can be useful for early treatment in a critical care setting.

PO 081

Serum des-R prothrombin activation peptide fragment 2: a novel prognostic marker for disseminated intravascular coagulation

Kim JE, Chung S, Kim HK, Yeon EH, Shin YS and Kim CW
Seoul National University College of Medicine, Seoul, South-Korea

Background: Disseminated intravascular coagulation (DIC) is diagnosed based on the combination of predisposing underlying conditions and laboratory tests for plasma coagulation markers. Because the collection of blood plasma samples is a fastidious procedure, the serum sample method may be preferred for measurement of coagulation markers when feasible.
Materials and Methods: The novel serum marker des-R prothrombin activation peptide fragment 2 (des-R F2) was measured using a sandwich enzyme-linked immunosorbent assay in 181 patients suspected of having DIC. Thrombin generation potential was estimated with a calibrated automated thrombogram.
Results: Serum des-R F2 was generated with an *in vitro* clotting process within a serum separation tube after blood collection. Low levels of prothrombin and thrombin generation potential resulted in low serum des-R F2 levels. Serum des-R F2 was significantly decreased in overt DIC. Levels of des-R F2 correlated with DIC severity and other coagulation markers. Of note, the decrease in serum des-R F2 levels was a significant marker for predicting mortality.
Conclusions: The serum marker, des-R F2, can be used for the investigation of DIC severity and prognosis. It should be considered a useful marker, especially when only serum samples are available.

PO 082

Kasabach Merritt Syndrome (KMS) in infant with hepatoblastoma

Komvilaisak P, Jirapradittha J, Kiatchoosakun P, Jetsrisuparb A and Wiangnon S
Srinagarind Hospital, Khon Kaen, Thailand

Hepatoblastoma, the most common liver tumor in children, rarely present in association with consumptive coagulopathy, thrombocytopenia and microangiopathic hemolytic anemia. A 39 week gestation G2P1 infant was uneventful pregnancy born by vaginal delivery weighing 2750 g. His APGAR score at 1, 5 min were 9, 10 respectively. His physical examination showed huge liver mass extending to iliac crest without bruit and dyspnea. At day 2 of his age, he developed respiratory distress with cardiopulmonary failure requiring endotracheal intubation, mechanical ventilation and inotropic drugs. Echocardiogram showed patent ductus arteriosus 3–5 mm. with left to right shunt and good left ventricular contractility. He also developed early neonatal jaundice from hemolytic anemia requiring double phototherapy. Exchange transfusion was performed three times according to microbilirubin level nevertheless extensive phototherapy. Blood morphology was compatible with disseminated intravascular coagulopathy. Computerized tomography of abdomen showed marked hepatomegaly with huge heterogenous mass occupying in right liver size $10.1 \times 8.1 \times 9.5$ cm, neither calcification nor capsular refraction. Alpha fetoprotein was > 400,000 IU/mL. His abdominal circumference was increased from 34 to 38 cm within 9 days. Differential diagnosis between infantile hemangioendothelioma and hepatoblastoma was made. Due to KMS, treatment including dexamethasone, propranolol and alpha interferon for infantile hemangioendothelioma was commenced without success. Hepatic embolization was not done due to limitation of small catheter. Pediatric surgery team for tissue diagnosis and hepatic artery ligation was consulted but not done due to poor prognosis. He was expired from respiratory failure. An autopsy of liver was compatible with hepatoblastoma. KMS could rarely occur in association with hepatoblastoma.

PO 083

Coagulation abnormalities in adult hemophagocytic lymphohistiocytosis

Manchanda N
Indiana University School of Medicine, Indianapolis, IN, USA

Background: Hemophagocytic lymphohistiocytosis (HLH) in adults is a rare and serious multi-system illness with a grave prognosis. While associated with several malignant, inflammatory and infectious processes, it often has a genetic basis involving genes controlling the immune response. (1) Delays in diagnosis and the non-specific nature of clinical findings as well as laboratory tests often contribute to the high mortality associated with this disease process. Detailed diagnostic criteria have been proposed to make the diagnosis of HLH more uniform and predictable. (2) These include several abnormalities associated with the coagulation cascade including thrombocytopenia and hypofibrinogenemia. However, there are few descriptions of the potential origin or clinical course of patients who present with significant abnormalities in these variables. Several publications suggest consumptive disseminated intravascular coagulation (DIC) or severe liver dysfunction as being etiologically involved in causing severe hypofibrinogenemia. (3).
Aim: To further elucidate the factors associated with thrombocytopenia and hypofibrinogenemia in adult onset HLH
Methods: We performed a retrospective chart review on 7 consecutive adult patients with a diagnosis of HLH seen over an 18-month period at the Indiana university hospital system. The diagnosis of HLH was confirmed in all patients using the latest diagnostic criteria. (2) We evaluated the data with regression and correlation analysis utilizing non-parametric methods. SPSS software (US) was used for data-analysis.
Results: The age range of patients was 32–76 years, with three men and four women. A malignancy was diagnosed on presentation in 3 of 7 patients, a documented infection was present in 3 of 7 and 3 of 7 cases were idiopathic. Laboratory tests included platelet count, fibrinogen, ferritin, prothrombin-time, d-dimer, ALT and serum bilirubin. DIC was graded according to ISTH 2007 criteria. Fibrinogen was found to be profoundly diminished (< 50 mg/dL) in 2/7 patients, one with malignancy associated HLH and the other with an idiopathic illness. An elevated prothrombin time or depressed platelet count were not associated with low fibrinogen levels. Liver malfunction reflected by increasing bilirubin and ALT values were also not associated with low fibrinogen. Presence or absence of overt DIC was not associated with low fibrinogen (Spearman rho associated $P = 0.47$). Appropriate non-parametric analysis was done in all cases.
Conclusion: Hypofibrinogenemia and thrombocytopenia have been used as diagnostic markers for hemophagocytic lymphohistiocytosis. In our preliminary study of seven patients, two of whom had severe hypofibrinogenemia, we found no correlation between hyprofibrinogenemia and thrombocytopenia, elevated prothrombin time, liver function abnormalities, age or diagnosis of DIC. While several patients had markedly diminished platelet counts, these did not correlate with low fibrinogen levels. Our data suggest that low fibrinogen values in this disease process may need an alternate explanation other than DIC or liver malfunction. We plan to extend our study to more patients with HLH to further elucidate the origins of low fibrinogen levels found in this disease.

PO 084

Catastrophic evolution of disseminated intravascular coagulation as initial manifestation of recurrent prostate cancer

Mello TBT[1], Gama P[1], Mantalvão SL[2] and Annichino-Bizzacchi JM[2]

[1]Mario Gatti Hospital; [2]Campinas State University, Campinas, Brazil

Background: Disseminated intravascular coagulation (DIC) has been extensively documented in prostatic cancer, with an incidence of 10%.in advanced stages. In the majority of the cases the coagulopathy is subclinical and overt bleeding is rare. Moreover, DIC as an initial manifestation of disease is unusual.

Aims and Methods: We describe clinical and laboratorial characteristics of a patient in whom DIC was the presenting sign of recurrence in prostate cancer.

Results: A 76-years- old man was admitted to emergency department of our teaching hospital with a 7 days history of diffuse spontaneous ecchymoses and an extensive hematoma in left upper limb. His past medical history included successfully treatment for prostate cancer 2 years ago. He referred that in the last follow-up visit 3 months ago the disease was in remission. Laboratory evaluation revealed: platelets count $89 \times 10^3/\mu L$ (normal: $150–400 \times 10^3/\mu L$); the prothrombin time (PT): 30 s, INR: 1.8 (normal: < 1.25), the activated partial thromboplastin time (APTT): 22.8 s, R: 1.2 (normal: < 1.25), fibrinogen level: 66.9 mg% (normal:200–400 mg%), D- dimer: 4.4 mg/L (normal: < 0.55 mg/L). A test for serum prostate-specific antigens was 9932 ng/ml (normal: < 4 ng/ml). Other parameters of blood count, as well as renal and liver functions tests were within normal values. Bone marrow biopsy showed prostatic adenocarcinoma, and the patient was referred to oncology. After 10 days of onset of symptoms he returned to the hospital with loss of consciousness. The brain CT scan demonstrated an extensive intraparenchymal hemorrhage and the patient died. The treatment for cancer had not yet started.

Conclusions: DIC without evident cause should always prompt a search for a neoplastic disease, especially in eldery. The delay in diagnosis and treatment can be fatal.

PO 085

Evaluation of two automated soluble fibrin assays for use in the routine hospital laboratory

Westerlund E[1], Woodhams B[2], Eintrei J[3], Söderblom L[3] and Antovic JP[3]

[1]Emergency Unit, Stockholm, Sweden; [2]Haemacon, Kent, UK; [3]Karolinska Institutet, Stockholm, Sweden

Background: Fibrin monomer (FM) (which alone or in complex with fibrinogen circulates as soluble fibrin [SF]) is an early product formed after the initial action of thrombin on fibrinogen before the formation of cross-linked fibrin. It is a much earlier produced fragment than D-dimer which only forms after plasmin cleavage of cross linked fibrin. FM could be considered as an earlier thrombotic marker potentially expressing better specificity and sensitivity than D-dimer, especially in disseminated intravascular coagulation (DIC). The manual semi quantitative method SF method (FS Test) is both time consuming and the evaluation of the result is often complicated and operator dependent.

Aim: To evaluate two automated soluble FM assays and compare them with FS Test.

Methods: Fifty-one consecutive samples referred for SF testing with positive D-dimer (Roche) and 30 samples from emergency unit (patients expected to have coagulation activation) were tested with both the STA-Liatest FM (Stago) and the LPIA-Iatro SF (Mitsubishi) and compared with the FS Test method.

Results: All samples testing positive with the semi quantitative SF method were also positive with both of the automated methods. Slightly more than half of the samples positive for D-dimer and negative with the old semi quantitative method were also positive with both automated methods. Eight samples positive for D-dimer were negative with all three SF/FM methods. Of the 30 samples obtained from the emergency unit only one was positive with all four methods. Fifty-five samples negative in the manual SF test were positive by D-dimer. Of these, 30 were also positive by the STA-Liatest FM test and 33 were positive with the LPIA-Iatro SF test. Kappa coefficient between F.S. Test and STA-Liatest FM was 0.41 (moderate agreement) and between STA-Liatest FM and LPIA-Iatro SF was 0.66 (good agreement) (Fisher's exact test $P < 0.0001$). Intra- and inter-assay CV's for both low and high controls were < 3% for the STA-Liatest FM and around 10% for the LPIA-Iatro SF.

Conclusion: Both STA-Liatest FM and LPIA-Iatro SF showed a good correlation with the old SF method. All samples positive with the old method were also positive with new methods, thus excluding the risk of obtaining increased false negative results. Probably, as a consequence of the increased assay sensitivity, both of the automated quantitative tests gave more positive results than the semi quantitative SF test. The STA-Liatest FM gave better precision and the assay was easier to perform than the LPIA-Iatro SF.

PO 086

The expression and secretion of ADAMTS13 in human microvascular endothelial cells

Wang A[1], Wu J[1], Ding K[1], Liu X[1], Cai X[1], Zhu W[1], Sun Z[1], Yu Z[2] and Ruan C[2]

[1]Anhui Provincial Hospital Affiliated to Anhui Medical University, Hefei; [2]Jiangsu Institute of Hematology, Suzhou, China

Background: Like other vascular endothelial cells,our study has confirmed that ADAMTS13 also express in human microvascular endothelial cells. However, could human microvascular endothelial cells secret ADAMTS13 protein? Does the secretion of ADAMTS13 from human microvascular endothelial cells be regulated? These questions are still unknown.

Aims: our study is aim to investigate that whether ADAMTS13 is expressed and secreted by human microvascular endothelial cells, and whether the secretion is to be regulated.

Methods: We used different concentrations of TNF-alpha (from 0 to 10 ng/ml) to stimulate human microvascular endothelial cells, Collected and concentrated cell supernatants, and directly detected and observed the expression and secretion of ADAMTS13 in human microvascular endothelial cells, by using real-time quantitative PCR, Western blot technology and immunofluorescence microscopy methods. We also detected the proteolytic activity of ADAMTS13 by using GST-VWF73-His peptide as a specific substrate.

Results: We found that ADAMTS13 expression did exist in microvascular endothelial cells and its supernatant, and by a dose-dependent manner, 10 ng/ml TNF-alpha inhibited ADAMTS13mRNA expression which could reduce 59% comparison with the control group, The results were confirmed from the levels of ADAMTS13 protein. And 10 ng/ml TNF-alpha inhibited ADAMTS13 activity which could drop to 38% comparison with the control group in human microvascular endothelial cells' supernatant.

Conclusions: The study suggests that human microvascular endothelial cells could also express and secret ADAMTS13, which may be a very relevant compartment for plasma ADAMTS13 level. And the expression and secretion of ADAMTS13 in human microvascular endothelial cells also be regulated by TNF-alpha.

PO 087

Twin pregnancy with a very low ADAMTS13 activity and existence of schistocytes together with thrombocytopenia

Guler N[1], Büyükkaya P[2], Kelkitli E[2] and Ozatli D[2]
[1]School of Medicine, Ondokuz Mayis University; [2]Ondokuz Mayis University, Samsun, Turkey

Background: Twenty-nine years old woman with 18 weeks twin pregnancy was admitted to hospital with complaint about ecchymosis. Hemoglobin and platelet values were 11.4 g/dL, 4.000/μL, respectively. There were 3–4 schistocytes in per microscopic field at 100× magnification in her peripheral blood smear. After this observation we checked hemolysis laboratory. Direct and indirect coombs were negative. Other tests were such as: LDH 176 U/L, total/direct bilirubin 0.5/0.13 mg/dL, haptoglobulin 52 mg/dL (30–200). In urine analysis, urobilinogen and erythrocyte hemoglobin were 0.2 mg/dL and 200 erythrocyte/μL, respectively. There were 6–8 erythrocytes in urine sample. DIC parameters were such as: PT: 9.59 s, PTT 23.9 s, Antithrombin III 104%, D-Dimer 1.3 mg/L (0.1–4.4), fibrinogen 2.7 g/L, Thrombin time 19.35 s. Creatinine, AST and ALT were normal.
Her blood pressure was always within normal limits.
We sent sample for ADAMTS13 antigen and activity because of schistocytes were observed in serial peripheral smears.
Corrected reticulocyte was normal (1.24%). The reason for normal values of reticulocyte, LDH, bilirubine, we diagnosed patient as ITP not TTP despite schistocytes. Steroid of 1 mg/kg and 2 g/kg of IVIG were started. Platelet was increased to 54,000 at the end of 1 week however decreased to 20,000 in 13th days of treatment. We repeated to IVIG and continued to steroid. Platelet increased to 164,000 and dropped to 117,000 in 3th days and 10th days of second IVIG treatment, respectively. At that day; fifteen days later after sample sending; results for ADAMTS13 came. ADAMTS13 antigen was 1.08 (0.5–1.6 μ/mL); ADAMTS13 activity was < 0.2 (40–130%), ADAMTS13 inhibitor was 13.6 (< 15 U/mL). Patient's LDH and bilirubin were still normal, so that very low ADAMTS13 activity (< 0.2) level was inconsistent with patient's other laboratories except schistocytes. She treated 1 month steroid and then dose decreased. After 3 months, patient's hemoglobin and platelet are still normal. Now, she is at 31 weeks of her twin pregnancy. Her platelet 262,000 and health of babies are good.
Conclusion: We wanted to share this twin pregnancy patient because of that: despite the existence of schistocytes and very low ADAMTS13 activity there was not obvious laboratory for hemolysis.

PO 088

Alterations of plasma VWF and ADAMTS13 activity in the patients receiving bone marrow transplantation

Han Y, Hu L, Su J, Wang Q, Bai X, Wang Z, Wu D and Ruan C
The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Thrombotic complications are common and potentially fatal in patients undergoing bone marrow transplantation (BMT). Plasma ADAMTS13, a von willebrand factor (VWF)-cleaving protease, may play a role in the pathogenesis of transplantation related thrombosis by cleaving the prothrombotic ultralarge VWF into less active VWF multimers.
Aims: To investigate the alterations of plasma ADAMTS13 and VWF in BMT recipients during the course of transplantation, and to evaluate their clinical significance in the transplantation-related thrombotic complications.
Methods: A total of 113 hematologic patients receiving allogeneic-BMT were enrolled in this study, the sodium citrate anticoagulated plasma was collected in −2, 0, 2 and 4 weeks following transplantation. Fluorescence resonance energy transfer substrate VWF73 (FRETS-VWF73) assay was established to detect the plasma ADAMTS13 activity while VWF antigen was measured by ELISA. Of all the patients recruited for his study, eight patients were diagnosed to have the thrombotic disorders and 49 patients were classified to have acute graft-vs.-host disease (aGVHD). The alterations of ADAMTS13 activity and VWF level in the plasma of patients were analyzed during transplantation, and the correlation between ADAMTS13/VWF and transplantation-related thrombosis was evaluated using the SAS program (version 9.3).
Results: The average plasma ADAMTS13 activity in 113 cases following transplantation at each period were less than the healthy controls ($P < 0.01$), while the VWF antigen level in each period were higher than the controls ($P < 0.05$). Among all the patients after pretreatment, 69 showed decreased plasma ADAMTS13 activities (69/113, 593%), including nine patients with more than 60% (9/113, 8.0%) decrease, while the average plasma VWF antigen level of this 69 patients was significantly increased in patients after pretreatment ($P < 0.05$). Considering thrombotic complications, the data showed that eight patients with thrombotic complications had decreased plasma ADAMTS13 activity ($P < 0.01$) and increased VWF antigen level after pretreatment ($P < 0.01$) as compared with the non-thrombotic patients; three out of 8 (37.5%) showed more than 60% decrease in plasma ADAMTS13 activity. The level of ADAMTS13 activity dropped in the 49 patients with aGVHD as compared with healthy controls ($P < 0.01$), but there was no significant difference between patients with and without aGVHD. Twenty-five patients showed decreased plasma ADAMTS13 activities only at the onset of aGVHD occurrence ($P < 0.01$), in which two of them decreased more than 60% (6%). Logistic regression analysis showed that the ADAMTS13 activity declined by more than 60% was the risk of thrombosis ($P < 0.01$), while decreased ADAMTS13 activity after pretreatment was not the risk factor for aGVHD.
Conclusions: We observed decreased plasma ADAMTS13 activity and increased plasma level of VWF antigen in patients following transplantation after pretreatment, especially in the patients with thrombotic complications. Regression analysis showed a decrease more than 60% in plasma ADAMTS13 activity is the risk factor of thrombotic complications, which was not correlated to the development of aGVHD although ADAMTS13 activity reduced in the patients when aGVHD occurred. Therefore, the plasma ADAMTS13 activity could be an important parameter for the development of vascular disorder, which has a potential role for the early diagnosis and therapy of thrombotic complications.

PO 089

Von Willebrand Factor, ADAMTS13 activity, inflammatory marker and their relationships with risk factors of coronary artery disease

Lasom S, Komanasin N, Settasatian N, Settasatian C, Kukongviriyapan U, Mongkolwongroj P, Intharapetch P, Tantipanichteerakul K, Senthong V and Tatsanavivat P
Khon kaen university, Khon kaen, Thailand

Background: Coronary artery disease (CAD) is associated with endothelial dysfunction and inflam−mation which in turn accelerated thrombosis in individuals with CAD risk.
Aims: This study aimed to assess the relationships among von Willebrand factor (vWF) antigen, a disintegrin-like and metallo−protease with thrombospondin type 1 repeats 13 (ADAMTS13) activity and levels of high sensitive-C reactive protein (hs-CRP) as an inflammatory marker with the risk factors of CAD.
Methods: The plasma levels of vWF antigen (vWF:Ag), ADAMTS13 activity and plasma hs-CRP were determined in 16 patients with CAD and 11 individuals without CAD. vWF:Ag levels and ADAMTS13 activity were measured by an in-house enzyme-linked immuosorbent assay (ELISA) and collagen binding based on ELISA method respectively, whilst hs-CRP was assessed by using nephelometry method. The ratio of the vWF:Ag level to ADAMTS13 activity was calculated.

Results: The vWF:Ag levels, ADAMTS13 activity and hs-CRP levels were decreased in CAD group compared to those of non-CAD group. However, the differences were not significant ($P = 0.629$, 0.445 and 0.445, respectively). The ADAMTS13 activity was significantly lower and the hs-CRP levels were significantly higher in males than those in females (65.88 ± 20.13 vs. $86.40 \pm 15.28\%$, $P = 0.016$ and 1.92 ± 5.84 vs. 0.89 ± 0.52 mg/L, $P = 0.047$). The vWF:Ag levels were significantly increased in smokers compared to the non-smoker group (0.85 ± 0.32 vs. 0.57 ± 0.28 IU/mL, $P = 0.031$). Individuals who have risk factors for CAD including age ≥ 60 years old, hypertension, smoking and obesity showed tendency of an increase in hs-CRP, vWF:Ag levels and vWF:Ag/ADAMTS13 activity ratio, whereas the ADAMTS13 activity was decreased when compared to those without risk factors. However, no significant differences of these parameters between both groups were found ($P > 0.05$). The inflammatory marker, hs-CRP levels were negatively correlated with ADAMTS13 activity ($r = -0.383$, $P = 0.049$).
Conclusions: Alterations of ADAMTS13 activity as well as hs-CRP levels in male and increased vWF in smokers were demonstrated in this study. This might suggest the association of these parameters with the risk factors for CAD and might be applied for the prognostic markers of poor clinical outcome of the patients. However, to confirm this association, a larger number of subjects should be recruited in further study.

PO 090
Fibrinogen concentration and tensile strength of clots

Savushkin AV
Chita State Medical Academy, Chita, Russia

The thromboembolism can be the cause of death and invalidity. Destruction of an initial blood clot or thrombus leading to embolus formation depends on many factors. Fibrinogen seems to be one of them and, probably, the most important one. As fibrin net is the strength base of a clot its concentration must determinate the firmness of a whole thrombus. There is no information about it in publications.
The aim of our work was to study if the tensile strength of blood and plasma clots depended on fibrinogen concentration.
Thirty samples of blood were obtained from volunteers. Centrifugation was used to get plasma. Clotting took place inside the cell of the special measure stretching equipment. After coagulation had completed cylindrical blood or plasma clot (diameter 6 mm) was stretched before rupture. The critical rupture force and the fibrinogen concentration were measured. The last equaled 9.26 + 2.23 mcM/L.
The equation of linear regression of dependence between the rupture force and the fibrinogen concentration was calculated.
For blood clots it was: F = 0.13 C + 32.6
(correlation coefficient 0.5, correlation relation 0.66).
For plasma clots it was: F = 0.51 C + 43.1
(correlation coefficient 0.61, correlation relation 0.69).
Where: F – critical rupture force, mN; C – fibrinogen concentration, mcM/L.
Thus the linear statistical dependence was shown to be between fibrinogen concentration and tensile strength of blood and plasma clots.

PO 091
Elimination of coagulation factor XIII from fibrinogen preparations

Smith EL[1], Cardinali B[2], Ping L[2], Ariëns R[1] and Philippou H[1]
[1]University of Leeds, Leeds, UK; [2]University of North Carolina, Chapel Hill, NC, USA

Background: Activated factor XIII (FXIIIa) catalyses cross-linking between alpha- and gamma-chains of fibrin during clot formation and also cross-links the major plasmin inhibitor, alpha 2-antiplasmin to fibrin. Contamination of FXIII can be found in commercially available sources of fibrinogen purified from human blood.
Aims: To elucidate FXIII contamination in different commercially available fibrinogens purified from human blood, and to characterise two main techniques to remove FXIII from these fibrinogen preparations.
Methods and Results: Commercial fibrinogen was prepared according to the manufacturers' instructions, and further purified to remove any FXIII contamination by one of two methods (i) ammonium sulphate precipitation wherein ammonium sulphate was added to 20% (w/v) with 10 mM $CaCl_2$ and the sample was centrifuged to remove precipitated material, including FXIII; (ii) affinity chromatography employing an IF-1 antibody (Kamiya Biomedical, Seattle, WA, USA, a calcium dependent antibody that binds to the D-region of fibrinogen), which includes a high salt wash that aids the dissociation of other proteins from column bound fibrinogen. The ammonium sulphate precipitation method allows large scale purification, whereas the affinity chromatography is more suitable for small volumes due to the maximum fibrinogen binding capacity of the column (typically < 5 mg dependent on amount of antibody immobilised). All commercial fibrinogen preparations that had not been specifically depleted of FXIII showed FXIII-A subunit was present in a western blot. Additionally, they showed varying degrees of FXIII activity as shown by an in-house FXIII activity assay by incorporation of biotin-pentylamine into either casein or fibrin substrates. Both the in-house (ammonium sulphate precipition or IF-1 antibody affinity) and commercially FXIII depleted samples showed no activity of FXIII in the fibrinogen preparations. However, batch to batch variation of the degree of FXIII-A subunit antigen was observed in the ammonium sulphate method although this was inactivate.
Summary and Conclusion: Fibrinogen from commercial sources is highly contaminated with FXIII antigen and shows significant cross-linking activity. In instances where it is key that fibrinogen is free of FXIII contamination we recommend that either ammonium sulphate precipitation is employed where large amounts of fibrinogen are required. However, where small amounts of fibrinogen are required we recommend that the fibrinogen is applied to affinity purification with an IF-1 antibody column.

PO 092
Fibrinogen deficiency and surgical hemostasis-our first experience

Stambolieva D[1], Timova T[1], Malinova T[2] and Sorova M[1]
[1]Institute for transfusion medicine Skopje; [2]Institute for transfusion medicine, Strumica, Macedonia

Aim: Fibrinogen is a blood plasma protein produced by liver who plays essential role in coagulation. It is converted into fibrin, catalyzed by thrombin and also induces platelet activation and aggregation by binding to the platelet reception GP2a/3b.
Case report: We report a case of a 9 years old boy who has to be prepared for surgical intervention with Dg: Hernia inguinal lat.dex. Prior to get ready him, we determined its blood group and Rhesus factor, also and screening coagulation tests. PT and aPTT were normal, but TT was abnormally prolonged (referenced value for that day reagent was 22,7″, received value was 55,7″). We used equal parts of normal plasma and patient plasma and elaborated a correction test-the result was corrected to 26,5″. Our first suspicion was that there is deficit of coagulation factor or eventually some undiagnosed liver disease. In our biochemistry laboratory immediately was worked out the level of fibrinogen and liver tests. Liver tests were normal, but Fibrinogen level was decreased to 0.9 g/L, without any symptoms of bleeding before, as the mother said to us. We suspected that this is probably isolated factor deficiency (for which no factor concentrate is available in our country). We also do not produce cryoprecipitate in our transfusion service, because of technical reasons. So we decided to consult transfusiologist and hematologist in the reference centre in our capital town.

The results were confirmed in their laboratory that the case is hypofibrinogenemia with instructions the boy to be prepared for surgery with fresh frozen plasma – 20 mL/kg tt. That was done, although we know the limitation of plasma-low fibrinogen level, large volume and risk of viral transmition. After the plasma treatment, fibrinogen level was increased to 3, 6 g/L, TT was normalized and the surgery was successfully finished.

Conclusion: This is the first case of fibrinogen deficiency in our transfusion centre. There were different opinions between us, specialists of transfusion medicine and surgeons about relationships between plasma fibrinogen level and preoperative hemostasis. We agreed together in one-if fibrinogen level is depleted, the supplementation is the key for the maintenance of hemostasis function-to 2 g/L for surgeon hemostasis. The following is this case is to determinate exactly is this is an inherited or some aquired hypofibrinogenemija.

PO 093

Detection of alpha-2-antiplasmin heterogeneity in plasma by immunoprecipitation and SDS-PAGE/ western blotting

Abdul S[1], Malfliet JMC[1], Ariëns R[2], Leebeek FWG[1], Rijken DC[1] and Uitte de Willige S[1]

[1]Erasmus University Medical Center Rotterdam, Rotterdam, The Netherlands; [2]University of Leeds, Leeds, UK

Background: Alpha-2-antiplasmin (a2AP), the main natural inhibitor of the fibrinolytic system, occurs in blood in different molecular forms: a plasminogen-binding (PB-a2AP) form and a nonplasminogen-binding (NPB-a2AP) form. These molecular forms can be distinguished from each other by the presence or absence of an intact *C*-terminus. This *C*-terminus is crucial for the initial interaction with plasmin and is a key component of a2AP's rapid and efficient inhibitory mechanism. NPB-a2AP has functionally been characterized via a modified crossed immunoelectrophoresis technique. However, efficient methods to isolate and biochemically characterize the NPB-a2AP have not yet been described.

Aims: We aimed to develop an efficient method to detect and biochemically characterize the different forms of a2AP, especially NPB-a2AP in plasma by immunoprecipitation (IP) and SDS-PAGE followed by Western blotting.

Methods: An IP method was set up to precipitate the different forms of a2AP present in human plasma using a2AP-specific antibodies. Magnetic protein G Dynabeads were labeled with a polyclonal total-a2AP antibody to capture all the molecular forms of a2AP. Covalent binding of the antibody to the protein G at the surface of the Dynabeads was ensured by chemical crosslinking. Human normal pooled plasma, depleted from IgGs present in plasma, was added to the bead-antibody complex for a2AP antigen capture. A2AP was eluted from the bead-antibody-complex by heating for 10 min at 95 °C in the presence of SDS. Lastly, the eluted a2AP was reduced at 95 °C and run on a 10% SDS polyacryl amide gel followed by Western blotting. The molecular forms of a2AP were detected using a polyclonal total a2AP antibody, and a monoclonal antibody specifically directed to the *C*-terminus of a2AP to distinguish PB-a2AP and NPB-a2AP. Fluorescently-labeled secondary antibodies were used to visualize the different protein bands with an Odyssey scanner.

Results: With our developed method we were able to detect different a2AP forms present in plasma on a Western blot. Using a polyclonal total a2AP antibody as well as a specific antibody directed to the *C*-terminus of a2AP, we confirmed the presence of NPB-a2AP in plasma. PB-a2AP had an estimated molecular mass of 70 kDa, confirming the known molecular mass of a2AP. NPB-a2AP had an estimated molecular mass of 60 kDa, which indicated an approximately 10 kDa molecular mass difference between PB-a2AP and NPB-a2AP.

Summary/Conclusions: In summary, we have developed a fast and efficient method to isolate and biochemically characterize the PB-a2AP and NPB-a2AP from plasma using immunoprecipitation and SDS-PAGE followed by Western blotting. This method will be used to identify the *C*-terminal cleavage site of a2AP by mass spectrometry.

PO 094

T-PA and PAI-1 levels in Tunisian Behçet patients

Baccouche H[1], BelFeki N[2], Khanfir M[2], Mahjoub S[1], Houman MH[2] and Ben Romdhane N[1]

[1]Rabta Hospital; [2]Rabta University Hospital, Tunis, Tunisia

Background: Behçet's disease (BD) is a systemic vasculitis. Endothelial damage is one of the ethiopathogenic mechanisms which can be associated with defects in coagulation and/or fibrinolysis.

Objectives: Assess the fibrinolytic activity in Tunisian patient with BD through the determination of tissue type plasminogen activator (t-PA), and plasminogen activator inhibitor 1 (PAI-1) levels.

Investigate the link of these findings to patients'clinical features, activity and severity.

Methods: A-44-BD patients were enrolled according to the criteria of the international study group on Behçet's disease. According to the Yosipovitch severity scale, patients were divided into three subgroups: mild, moderate and severe disease. The activity index was elaborated according to the Yazici scale. Concentration of t-PA was determined by enzyme linked immunoabsorbent assay (ELISA) in patients and compared to 46 healthy controls. Because of financial considerations, PAI-1 levels were determined in only 12 patients.

Results: Mean age was 40 years (sex ratio M/F: 42/15).Mean level of t-PA was 4.85 $\pm$ 7.36 ng/mL in patients. No difference was found compared to controls (5.62 $\pm$ 8.49 ng/mL). Among patients, there was no correlation between t-PA levels and clinical manifestations. No association was found with severity index (6.5 vs. 4.5 ng/mL). T-PA levels were higher in severe and moderate subgroups than in mild one. Mean PAI-1 level was 10.7 ng/mL. It was significantly decreased in patients with ocular involvement (1.66 vs. 19.75 ng/mL; $P = 0.03$). PAI-1 levels were higher in active form than in inactive one and in severe and moderate subgroups. There was no correlation between t-PA and PAI-1 variations.

Conclusions: PAI-1 and t-PA vary in Behçet's disease. These findings reflect endothelial dysfunction which is the cornerstone of the etiopathogenesis in BD. Further studies with larger groups are needed to elucidate the impact of fibrinolytic parameters in BD.

PO 095

Functional characterization of metalloproteinases (colombienases) with fibrinolytic activity from Bothrops colombiensis venom

Guerrero B[1], Girón M[2], Salazar AM[1] and Rodríguez-Acosta A[2]

[1]IVIC; [2]Universidad Central de Venezuela, Caracas, Venezuela

The hemostatic system is designed to maintain the blood fluidity by inhibiting blood coagulation and platelet aggregation and promoting fibrinolysis. Thrombosis is probably the most frequently symptom among cardiovascular diseases. At the present time, trying to improve the safety and efficacy of fibrinolytic therapy, several investigators have been tracking to find out fibrinolytic enzymes from different snake venoms.

Aims and Methods: Functional characterization [hemorragic, ADP-Platelet aggregation, fibrino(geno)lytic, proteolytic (extracellular matrix and basal membranes proteins- type IV collagen, laminin, gelatin and fibronectin), hemolytic, edematogenic and cytotoxic (cardiac myoblasts cultures) activities] of fibrinolytic enzymes isolated from *Bothrops colombiensis* venom.

Results and Discussion: Colombienases directly act on the fibrin, without activating the fibrinolytic system (plasminogen/plasmin), they degrade the fibrinogen Aα and Bβ chains, as well as α-polymers,

dimers γ-γ and α and β chains of fibrin and the fibronectin molecule; additionally Colombienase-2 degrade fibrinogen γ chains. Laminin and type IV collagen were resistant to the Colombienases action. Gelatin-zymogram showed in *B. colombiensis* crude venom several active bands (< 148 > 64 kDa) that may correspond to P-III class metalloproteinases. Additionally, Colombienase-2 presented an active band at approximately 22 kDa. In contrast Colombienase-1 did not show gelatinolytic activity. All these activities were abolished by metalloproteinases inhibitors. Colombienases have an insignificant edematogenic activity, and both enzymes lacked hemorrhagic, hemolytic, cytotoxic, plasminogen activator or coagulant activities, and no effect on platelet aggregation induced by collagen or ADP. All these characteristics let us to classify these enzymes as P-I class metalloproteinases that lack the disintegrin domains and/or rich-in-cysteine, which appear to be important for the induction of apoptosis and hemorrhagic activity. Additionally, Colombienase-1 was recognized by a polyvalent anti snake venom but Colombienase-2 was not recognized by this antivenom, suggesting that this protein presents low antigenic determinants or that their presence in crude venom is low, unable to induce an antibody response. Knowing the fibrinogenolytic activity of Colombienases, this toxin should be administered in a high dose to induce an adequate neutralizing immune response in animals.
Conclusions: The direct fibrino(geno)lytic activity of the Colombienases, besides its poorly toxic effect, could be considered potential thrombolytic agents, given they property of dissolving fibrin clots or preventing their formation.

PO 096

Plasminogen activity in patients with ligneous conjunctivitis and hydrocephalus in Indonesia

Pudjianto S[1], Setiabudy RD[2], Mangunatmadja I[1] and Susiyanti M[1]
[1]Faculty of Medicine, Univ. of Indonesia; [2]Faculty of Medicine, University of Indonesia, Jakarta, Indonesia

Background: Plasminogen is plasmin precursor, an important enzyme needed in fibrinolytic system which is also important in wound healing. It was reported that type 1 plasminogen deficiency results in pseudomembranous diseases which manifested as ligneous conjunctivitis. Besides ligneous conjunctivitis, it is also associated with occlusive hydrocephalus.
Aim of study: The aim of our study was to investigate plasminogen activity in patients with ligneous conjunctivitis and hydrocephalus.
Methods: Seventy seven subjects were enrolled in this study, consisted of one patient with ligneous conjunctivitis and his parents, 21 patients with hydrocephalus, 20 normal children, and 33 normal adults. The plasminogen activity of normal subjects was used as reference value. Citrated plasma was obtained from each subject, and plasminogen activity was measured by chromogenic substrate using reagents from Sysmex company, Japan. This study had been approved by the ethical committee of the Faculty of Medicine University of Indonesia and informed consent for each subject had been obtained. Our study was conducted at Cipto Mangunkusumo Hospital, Jakarta, Indonesia in September 2012 until January 2013.
Results: Within run coefficient of variation (CV) plasminogen activity in normal range was 3.1%, between day was 5.4%. In pathological range between day CV was 9.6%. Plasminogen activity in patient with ligneous conjunctivitis was 11.9%, very low compared with normal children whose median was 116.8%(70.9–133.5%). His parents plasminogen activity was 68.45% and 80.65% which were quite low compared with the activity in normal women 118.65%(112.48–124.43%) and the activity in normal men 115.91% (110.60–121.24%).. Among hydrocephalus patients, 5 out of 21 showed plasminogen activity < 80%, 2 of them were 79.4%, one patient was 79.8%, two of them neonates whose plasminogen activity were 57.1% and 55.4%.
Conclusion: This study suggests the possibility of heterozygote defect in a patient with plasminogen activity lower than 80% and the reference range for plasminogen activity should not be as low as 75% as believed today. This needs further study about chromosome defect in subjects with plasminogen level < 80%, including hydrocephalus patients.

PO 097

Computational study of Textilinin as an anti bleeding agent to improve the stability and activity

Rahimi H, Abdoli S and Mahdian R
Pasteur Institute of Iran, Tehran, Iran

Background: textilinin-1, a serine protease inhibitor from Pseudonaja textilis venom binds to and blocks the activity of a range of serine proteases, including plasmin and trypsin. This compound is a more specific plasmin inhibitor than aprotinin while the side effects are much fewer. So, it could be the possible drug in surgery. Although a number of plasmin inhibitors are introduced, they are suffered from poor potency and/or specificity of inhibition that either results in reduced efficacy and decreased clinical application. Consequently, there is a need for further development of high-affinity plasmin inhibitors that maintain selectivity over other serine proteases.
Aims: The generation of new mutants by using the computational study to improve the activity and stability of textilinin-1 and decrease the side effects.
Methods: Based on the structural, evolutional and functional information, new mutants were designed. Then, to predict the three dimensional structure of each mutant, 10,000 model were generated by MODELLER package. The Ramachandran plot, verify 3D and Z-score were used to confirm the quality of the best model. The Gromacs 4.5.5 was employed to energy minimization of the selected models by which the models were put in a water box for 5 nano second molecular dynamic simulation. Finally, the binding affinity was investigated using ClusPro software.
Results: Most mutants (ten ones) were stable after modeling and 5 nano second simulation. A better binding to substrates were observed for four mutants including A18V, R15L, V16A and E34I. The Canonical loop (17–21), which is important for binding to serine proteases, was conserved in all mutants but the structural shift toward beta-sheet structure were found in two mutants: PCRVRF (13–18) and RV (15–16). Replacement of Ala 18 substitution with Val lead to more conformational space for interaction with substrates. Moreover, the mutants interaction with water is probably accelerated by the surface charge reduction.
Conclusion: To find the improved mutant with higher stability and activity, the computational study would be a hopeful method.

PO 098

Circumcision in patients with haemophilia: a single centre experience

Akcay A, Salcioglu Z, Tugcu D, Sayilan Sen H, Aydogan G, Akici F, Gokce M, Aktay Ayaz N, Guvenc U and Sander S
Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Circumcision is the oldest and most frequent surgical procedure in the world and especially in Turkey as is seen in the other Islamic countries because of religious and traditional pressures.
Aims: In this study, we aim to report the experience of circumcision at our clinic in a total of 58 patients with hemophilia (Haemophilia A = 49, Haemophilia B = 9) between 1990 and 2013.
Methods: We retrospectively reviewed medical records of 56 haemophilia patients without inhibitors and two haemophilia A patients with inhibitors who had been circumcised. Factor concentrates were given before and after circumcision for 5–7 days. By-passing agents were used for circumcision in haemophilia patients with inhibitors. In all patients antifibrinolytic agents were used also. Fibrin glue was not

used during circumcision procedures. Circumcisions performed with an open method, with dorsal slit technique.
Results: In 27 (47%) patients factor activities were < 1%, 14 (24%) were between 1 and 5% and 17 (29%) were > 5%. Their ages of circumcision were ranged from 3 months to 14 years (median 8 years). Ten of 58 patients without inhibitors were referred to our centre with bleeding after the circumcision before diagnosis of haemophilia. One of these ten patients had moderate bleeding and nine of them had mild bleeding. Forthy-eight patients with haemophilia were circumcised in our centre under general anaesthesia. In three (6.25%) patients without inhibitors had moderate bleeding, despite adequate factor replacement. Transfusion was not needed. Thrombotic events were not observed during factor replacement therapy and antibody occurrence was not detected in these patients.
Conclusion: Examination of hemostasis tests carefully before circumcision leads to the recognition of patients with bleeding diathesis. Our experience showed that circumcision for patients with haemophilia should be carefully performed by surgeons together with paediatric haematologist, under appropriate conditions in haemophilia centres which has comprehensive coagulation laboratory.

PO 099

Iliopsoas hemorrhage in congenital factor deficiencies: the experience of Çukurova University, Adana, Turkey

Antmen B, Sasmaz I, Karagun BS, Leblebisatan G and Kilinc Y
Cukurova University, Adana, Turkey

Background: Iliopsoas hemorrhage is a serious complication of bleeding disorders that occurs most commonly in patients with severe hemophilia and less commonly von Willebrand disease and Factor V deficiency and is considered as potentially life threatening condition and significantly associated with morbidity. Despite its clinical importance, there are few reports on the mode of presentation, treatment and sequela. In this study, we presented our experience about iliopsoas hemorrhage in patients with severe bleeding disorders.
Aim: In this study, we evaluated our patients with iliopsoas hemorrhage and compared with literature.
Patients and Methods: From 1995 to 2012, 19 patients with iliopsoas hemorrhage were evaluated inÇukurovaUniversity, Hemophilia center. The findings of physical examination, pain locations, complications were assessed. Iliopsoas hematomas were confirmed by ultrasonography, CT or MR scan. The treatment strategies were noted.
Results: We evaluated 29 episodes of iliopsoas bleeding from 19 patients with congenital factor deficiencies (CFD). There were 13 with hemophilia A, 4 with hemophilia B, 1 with factor V deficiency, and 1 with von Willebrand disease. Age range was from 45 days to 19 years. Fourteen patients had one episode, three had two episodes, one had three episodes, one patient with severe hemophilia A with inhibitor had six episodes. Three patients had a high titer inhibitor against factor VIII. Iliopsoas hematomas were confirmed by ultrasonography in all patients. Five patients needed erythrocytes transfusion. The mean duration of therapy was 11.55 ± 3.54 days, and the duration of hospitalization was 10.50 ± 3.54 days. Patients with inhibitors were treated with by-passing agents. In six bleeding episodes of one severe hemophilia A patient with inhibitor treated with recombinant factor VIIa (rFVIIa). Activated prothombin complex concentrates (aPCC) was given in two episode in two severe hemophilia A patients with inhibitor. Long term complications included paresthesia in five patients in the distribution of femoral nerve and quadriceps atrophy in four patients.
Conclusion: Iliopsoas hematoma is a serious bleeding event in patients with hereditary clotting disorders. In this report, we present our experience and treatment modality in 28 episodes of serious iliopsoas hematoma in hereditary congenital factor deficiencies.

PO 100

The effect of water exercise on atrophic muscles associated with limited range of motion in severe haemophilia A patients

Antmen B
Cukurova University, Adana, Turkey

Aim: Haemophilia causes musculoskeletal problems over many years secondary to recurrent hemarthrosis. In this study, the effects of water exercises on the musculoskeletal system of severe haemophilia A patients with muscle and joint problems are described.
Materials and Methods: Eleven severe haemophilia A patients on prophylaxis treatment participated in the study.
Result: After completing a protocol of regular exercise, subjects displayed statistically significant increases in mid-thigh, upper thigh and calf circumference ($P < 0.05$). Compared to pre-exercise values, significantly increased strength leg extensor and flexor as well as range of motion were also observed ($P < 0.05$). In addition, serum levels of growth hormone were found to be significantly higher at the completion of all exercise protocols vs. pre-exercise levels ($P < 0.05$).
Conclusion: These results show that some easily performed exercise protocols such as water exercises can promote muscle development and increase range of motion of the joints. Water exercise is especially preferred, because it is not a contact sport and the likelihood of collision is very low. Thus, potential future deformities may be prevented if appropriate exercises are started without delay following an acute episode of bleeding.

PO 101

How well is haemophilia known among non-hematologists?

Ar MC[1], Erdem S[1], Sarici A[1], Salihoglu A[2], Yokus O[1], Sametoglu F[1] and Yurttas B[2]
[1]Istanbul Training and Research Hospital; [2]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Haemophilia is a rare inherited bleeding disorder caused by the deficiency of the clotting factors VIII or IX.
Haemophilia A (FVIII deficiency) is the most common form of the disorder, present in about 1/5000–10,000 male births. Haemophilia B (FIX deficiency) occurs in around 1/20,000–34,000 male births. Haemophilia, once a disease of the childhood, now became a clinical problem extending into the adult ages with the advent of modern treatment tools. It is frequently observed that physicians facing with adult people with haemophilia (PwH) either exaggerate the bleeding risk and avoid offering treatment for non-haematological conditions or underestimate the bleeding tendency leading to increased morbidity and mortality. This lack of knowledge about haemophilia greatly hampers the management of both the bleeding episodes and other clinical conditions.
Aim: The aim of the present survey was to determine the level of awareness about haemophilia among non-haematologist physicians treating adult patients in Turkey.
Methods: Fellows and consultants who are not primarily taking part in the clinical management of the PwH were included in the study. They were asked to complete a questionnaire with 10 multiple choice and 14 true/false questions about the diagnosis and treatment of haemophilia. Physicians were also expected to report about their personal experience on haemophilia.
Results: A total of 133 physicians from aStateHospitaland aUniversityHospitalentered the study. All of the participants correctly identified haemophilia as an inherited bleeding disorder. However, 83.5% only knew that the manifest disease was primarily associated with male gender. Only 1/5 of the subjects were aware of acquired haemophilia. One hundred and six physicians (79.7%) could correctly recall the most frequent sites of bleeding. Seventy percent of the subjects chose aPTT as

the screening test for haemophilia. One in 10 physicians thinks that platelet transfusion is an integral part of haemophilia management. Almost 60% of the physicians had seen 1 or more PwH for a consultation. However, more than 70% of the included physician stated that they would preferably not encounter with PwH and refer them to a haematologist even for the treatment of non-haematological problems. Almost all physicians agree that emergency treatment of bleeding episodes should be known by all but regular follow-ups and the adulthood medical problems should be managed by the haematologist or the internist.

Summary/Conclusion: The results of this survey showed that the study group was partially informed about haemophilia. The most striking two outcomes were: (1) Eighty percent of the physicians had not heard of acquired haemophilia; (2) In the era of home replacement therapy more than 2/3 of the physicians still thought that joint bleeds should be treated in the hospitals. These findings suggest an obvious need for increasing the level of awareness about haemophilia among non-haematologists. This survey would help in redesigning the basic as well as continuing medical education programmes to defeat the fear against haemophilia.

PO 102

Hematuria in congenital coagulation factor deficiencies

Balkan C, Karadas N, Karapinar D and Kavakli K
Ege University Children's Hospital, Izmir, Turkey

Background: Spontaneous gross hematuria or subclinic microscopic hematuria is not an uncommon manifestation in severe hemophiliacs and has been thought to reflect tubular damage.

Aims: In this retrospective study, we evaluated the prevalence of hematuria in hemophiliacs and other congenital factor deficiencies in a comprehensive care center.

Methods: All medical records of hemophiliacs who attended this comprehensive hemophilia care centre between 1990 and 2012 were evaluated. Six hundred and twenty-nine patients with congenital hemorrhagic diathesis (383 hemophilia A (HA), 77 hemophilia B (HB), 99 type-1, 16 type-2 and 14 type-3 vonWillebrand's Disease (VWD), 16 FVII deficiency, 8 FV deficiency, 5 FX deficiency and 11 rare factor deficiencies) were evaluated retrospectively in this study.

Results: Hematuria was determined in 39 of 383 HA patients, 12 of 77 HB patients, 5 of 129 VWD patients and 3 of 40 patients with the other factor deficiencies. The first attack of hematuria occurred at the age of 3–34 years (mean 15.5 $\pm$ 6.9 years). Hematuria was seen in 59 of all hemophilia patients. Thirty four of these hemophiliacs had only one hematuria episode, 8 had two, 4 had three, 3 had four episodes and 10 had five and more episodes. Hematuria was seen in 29 severe, 20 moderate and 2 mild FVIII and FIX deficiencies. Inhibitors were positive in 7 of these patients.

While there were no significant findings in ultrasonography in 41 of 59 patients (70%) who had hematuria, nephrolithiasis was observed in seven patients (12%), pyelocaliectasis in one patient (1.7%) and renal cyst in one patient (1.7%). Ultrasonography was not performed in nine patients.

While eight patients (13.6%) received only hydration therapy, 43 patients (72.9%) received both hydration and factor replacement therapy. Five patients (8.5%) received hydration and factor replacement therapy. Two patients (3.4%) received fresh frozen plasma and 1 patient (1.7%) received fresh frozen plasma with combined prednisone therapy.

No cause for hematuria was identified in 46 of these patients (78%). Nine patients (15.3%) had nephrolithiasis, 1 (1.7%) had poststreptococcal glomerulonephritis, 2 (3.4%) had urinary tract infection, 1 (1.7%) had renal cyst.

Conclusion: Our results are consistent with the other investigations which rarely demonstrate urinary system abnormalities in these patients. The long-term outcome of hematuria is largely unknown.

PO 103

SNC bleeding: experience on a single haemophilia center (1990–2013)

Baques A, Peres Bianco RP, Guerrero G and Candela M
Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Central nervous system (CNS) bleeding is one of the most severe manifestations that occur in patients with Hemophilia, with a high morbimortality.

Aims: The objective of this study was to evaluate retrospectively 110 patients affected with Hemophilia A (HA) and Hemophilia B (HB) who had CNS bleeding, on a single center from 1990 to 2013, inorder to establish incidence of recurrence, death rate, neurological impairment, most frequent location, and efficacy of treatments.

Design and Methods: Of one thousand and nine hundred ambulatory visits, we enrolled 110 patients: 93 patients with HA (78 patients with HAs, eight patients with HAm and seven patients with HAl), 17 with HB (14 patients has HBs, 2 has HBm and 1 with HBl).

They were presented 156 (12 events per year) central nervous bleeding episodes, 27 patients (17, 2%) (21 HA, 6 HB) experienced a recurrence and 10 (6%) (HAs 8, HAm 1, HAl 1) had more than one recurrence. Twenty two (19, 8%) patients had an early onset of CNS bleeding before the first 2 years of life, (15 HAs, 1HAm, 4HBs) others 88 (80.18%) later in life (62 HAs, 7 HAm,7 HAl and 9 HBs, 2 HBm, 1HBl). In 58 (36 HAs, 5 HAm, 3 HAl and 10 HBs, 3 HBm, 1 HBl) of the episodes, CNS bleeding was spontaneous.

Results: Neurosurgery was performed in 27 patients: 20 (74%) with HA (18 HAs, 1 HAm, 1HAl) and 6 (22.2%) with HB (5 HBs, 1 HBm), in association with factor replacement therapy. Four (1%) patients presented seizures. Psychomotor impairment were seen in 9(2.4%) patients. Thirty nine deaths were recorded. Sixteen events occur in patients that presented a discontinuation in prophylaxis.

Conclusion: Prophylaxis with clotting factor concentrates is considered optimal care for patients with severe haemophilia A or B.

In our experience, CNS is the first cause of mortality .According with the high proportion of patients (around 20%) that had, recurrence of CNS bleeding, mostly patients with severe hemophilia. It would be wise to optimize the indication of prophylaxis and intensive education of patients and family in order to prevent CNS bleeding.

PO 104

Primary prophylaxis in Venezuelan cohort: 5-year experience

Boadas A, Mijares ME, Hernandez L, Echenagucia M, Fernandez N and Ruiz-Saez A
Banco Municipal de Sangre, Caracas, Venezuela

Introduction: Primary prophylaxis (PP) has been used with the purpose of preventing recurrent hemarthroses and serious bleeding. In Venezuela, once we achieved safe treatment of all people with hemophilia (PWH) we started PP in children.

Patients and Methods: We enrolled boys with severe or moderate hemophilia (FVIII or FIX $\leq$ 2.5UI/dL) and without inhibitors (< 0.65Bethesda Units). The inhibitors were detected every 3 months, an annual musculoskeletal evaluation in HJHS scale was done and education regarding prophylaxis was given to parents. We used modified Canadian dose-escalating protocol, making the following changes: lower dosage in < 1 year and skipping to the next phase when one spontaneous hemarthroses appeared.

Results: Fifty-seven patients (severe HA: 43, moderate HA: 9, severe HB: 4, moderate HB: 1) since January 2007 to December 2012. Average age of initiation in PP: 19 months (7–39), average duration: 25 months (2–60), average IU/kg/day:33.7(17–56), average hemarthroses in last year: 1.7 (1–5), average soft-tissue bleeding episodes in last year: 2.3 (1–7). Twelve children were dismissed because of high-response inhibitor development and 3 were dismissed for lack of

adherence. No serious bleeding happened during the period under analysis. One boy had one target joint, clinically evaluated.
Conclusions: It is key to keep educating parents continuously, explaining the importance of complying with instructions and recording the treatment in written form.

PO 105
Incidence of reduced bone mineral density among patients with hemophilia

Boban A, Zupancic Salek S, Kaštelan D and Nemet D
University Hospital Center Zagreb, Zagreb, Croatia

Background: Osteoporotic fractures bear a high morbidity and mortality rate, particularly in hemophilia patients. Reduced bone mineral density (BMD) has been recently recognized in hemophilia patients, but the pathology of bone metabolism is still unclear.
Aim: The aim of our study was to evaluate the impact of severity of hemophilia, number of target joints and presence of inhibitors and hepatitis C infection on bone mineral density in hemophilia patients.
Methods: We evaluated BMD in 58 patient with hemophilia A and hemophilia B. Thirty-eight patients had severe hemophilia, defined by FVIII of FIX activity < 1%, and 19 patients had mild and moderate hemophilia, defined by activity of FVIII or FIX < 5%. Among patients with severe hemophilia nine patients (23%) had positive inhibitors to FVIII. Eighty-five patients were hepatitis C positive. Number of target joints was higher in patients with severe hemophilia when compared to patients with mild and moderate hemophilia, median 3.82 and 1.70 respectively. Lumbar spine and hip BMD was determined by dual-energy X-ray absorptiometry. Osteoporosis was considered when T-value was < -2.0 and osteopenia when T-value was < -1.0.
Results: Out of 58 patients with hemophilia 43% had normal bone mineral density, 48% osteopenia and 9% osteoporosis. BMD was significantly lower in hemophilia patients than in controls. The severity of osteoporosis correlated with severity of hemophilia, but not with number of target joints. There was no difference between groups regarding presence of inhibitors or infection with hepatitis C.
Conclusion: Our results showed that patients with hemophilia have high risk of developing osteoporosis and osteopenia, which is dependent on severity of hemophilia, but not on presence of FVIII inhibitors or hepatitis C infection.

PO 106
Feasibility study of a randomized control trial to evaluate an internet-based self-management program for adolescents with hemophilia: preliminary results and observations

Breakey VR[1], Ignas DM[2], Warias A[1], White M[2], Blanchette VS[2] and Stinson JN[2]
[1]McMaster University, Hamilton; [2]The Hospital for Sick Children, Toronto, Canada

Background: As adolescents with hemophilia approach adulthood, they must assume responsibility for their disease management. An innovative bilingual (English and French) Internet-based self-management program, 'Teens Taking Charge: Managing Hemophilia Online', was developed to support adolescents during this transition.
Aim: To determine the feasibility of an 8-week online educational program using a randomized control trial design in terms of study accrual and attrition rates; participants' willingness to be randomized, compliance with program and completion of outcome measures, and satisfaction; as well as preliminary estimates of treatment effectiveness.
Methods: A non-blind pilot randomized control trial (NCT01477437) was designed to test the feasibility the planned study of 'Teens Taking Charge: Managing Hemophilia Online'. Adolescents ($N = 31$), ages 12–18, were selected from three tertiary care centres in Canada. After a research assistant (RA) had explained the study in detail and obtained informed consent, adolescents were randomized to the intervention ($n = 15$) or the control arm ($n = 16$). Adolescents in both arms of the study were asked to complete pre- and post-outcome measures online and received weekly telephone support from a trained RA. Following completion of the 8-week program, one-on-one semi-structured interviews were conducted to assess user satisfaction with the intervention. This study was approved by research ethics boards at each site.
Results: At present, nine participants in the intervention arm have completed the study in an average of 14.4 weeks (SD = 5.8) and three are active in the program. Among those randomized to the intervention, two participants dropped out of the study and 2 were lost to follow-up, resulting in an attrition rate of 25% (4/16). Six participants in the control group have completed the study. Despite the plan to give the control participants access to the website after the study's completion, the control arm has a higher attrition rate with five participants being lost to follow-up and four participants dropping out or a rate of 56% (9/16). Reasons for dropping out included: disappointment in not being assigned to the intervention, a lack of interest and being 'too busy' to complete the program. Post-intervention interviews are ongoing, with three participants interviewed to date. Overall, these teens found the website to be informative, comprehensive and easy to use and were satisfied with the program.
Summary: This pilot randomized control trial is ongoing. Interim findings indicate an acceptable attrition rate in the intervention group as compared to other online interventions. Higher than expected attrition rate in the control group, suggests the need to improve the strategies for maintaining participant engagement in the design of this web-based intervention prior to a larger randomized control trial to assess efficacy. Collection of qualitative interview data is ongoing and further analysis is needed to assess study feasibility and alter design, if deemed necessary.

PO 107
Ischemic stroke and haemophilia A: what therapy?

Campello E[1], Luca S[1], Barbara B[2], Renzo M[3] and Ezio Z[2]
[1]Department of Cardiologic, Throcacic and Vascular Science, University of Padua; [2]Department of Cardiothoracic and Vascular Sciences, SS Hemophilia Center; [3]Neuroradiology, Department of Neuroscience, University of Padua, Padova, Italy

Background: Advances in haemophilia care have led to an increase in the overall life expectancy of patients with haemophilia such that it is approaching that of the general male population. Although data on the protective effect of haemophilia on cardiovascular diseases are conflicting, their longevity exposes this group of patients to the same cardiovascular risk factors (hypertension, smoking, diabetes mellitus, hyperlipidemia, obesity) as the general population. There are limited data on the prevalence and management of such risk factors in patients with haemophilia when compared to the general population. In addition, evidence-based guidelines on management of patients with cardiovascular diseases are lacking.
Aim: The purpose of our report was to describe three cases brought to our attention from our adult haemophilia population. We also looked at outcomes of our management of haemophilia patients with overt cerebral ischemic events.
Methods/Methods: A 45 years patient, with severe haemophilia A treated on-demand, high blood pressure, HBV-HCV hepatitis, is hospitalized for subjective vertigo, postural instability, nausea, vomiting and diplopia, right ptosis, right emivolto hypoesthesia. The TSA and transcranial Doppler showed right vertebral artery with dissection of the wall and occlusion of intracranial tract of left vertebral artery. The Cerebral MRI showed ischemic lesion in the left lateral medulla and inferior cerebellar peduncle (in the Posterior Inferior Cerebellar Artery

territory); dissection of both vertebral arteries and left vertebral artery occlusion; intramural hematoma along the course of the cervical right vertebral artery. At follow up, the MRI described complete resumption of the hematoma, persistence of left vertebral artery occlusion. To date (44 months of follow-up) are not described further ischemic events. A 53 years patient, with moderate haemophilia A treated on-demand, HCV hepatitis, smoker, is hospitalized for right hemisoma weakness. The Cerebral MRI showed acute ischemic lesion in the right corona radiata in the territory of the perforating branches of middle cerebral artery. He had a progressive recovery and to date (48 months of follow-up) did not relapse. A 77 years patient, with moderate haemophilia A treated on-demand, overweight, hypertension, diabetes mellitus, smoker, is hospitalized for diplopia, dysarthria, and instability in the standing. The cerebral TC highlighted some areola of clear hypo-density bilaterally in nucleus-capsular as recent vascular outcomes. All symptoms progressively regressed. To date (24 months of follow-up) did not relapse. The antiplatelet therapy has not been administered to any patient because of the protective effect of the haemophilia. In the first patient it was administrated prophilaxis dose of FVIII, because of the intramural hematoma along the right vertebral artery. In all cases we have acted in the correction of cardiovascular risk factors.

Conclusions: The cases are among the first described in the literature and confirm the management difficulties and the uncertainty on the correct treatment. Given the increased risk, haemophilia patients should be screened regularly for hypertension, tobacco use, diabetes, cholesterol, obesity especially during their periodic haemophilia evaluation, and managed appropriately.

PO 108

Physical and mental quality-of-life in patients with haemophilia in Belgium: the impact of financial issues and of patients' understanding of their condition

Carvalhosa AM, Henrard S and Hermans C

St-Luc University Hospital, Brussels, Belgium

Background: Haemophilia affects 988 people in Belgium. However, there are very few studies evaluating patients' quality of life (QoL) in the country.

Aim: This project aimed to collect such data and assess the influence of both well-identified factors (eg. arthropathies) on QoL, and of other less studied, modifiable variables (eg. patients' understanding of haemophilia-related issues, financial concerns).

Methods: This study involved adult haemophilia A (HA) and B (HB) patients, without current inhibitors, on replacement therapy, regularly followed-up at our comprehensive treatment centre. After Ethics Committee approval, patients meeting the inclusion criteria (n = 84) were informed and invited to complete a questionnaire, including the SF36v2 QoL forms. Seventy one (n = 59 HA, n = 12 HB) responded. Analysed variables included factors known to have an impact on QoL (age, haemophilia type, treatment type [secondary prophylaxis vs. on-demand], severity, number of arthropathies, sport activities, HCV/HIV status) and others (occupation, self-assessed compliance, concerns about haemophilia-related personal/public financial issues, understanding of general haemophilia-related issues [transmission, identifying emergencies, holiday planning, identifying sources of information, latest treatments available, insurance coverage, meaning of 'inhibitor']). Data analysis was performed using the QualityMetric® software for SF36v2 data, and a regression tree-based model (RT) to evaluate the relative impact of the aforementioned variables on QoL scores (norm-based). RT-based models are non-linear, non-parametric alternatives to linear models for regression problems. All significant variables appearing in the trees are clearly mentioned.

Results: QoL scores in our population (mean ± SD age: 45.2 ± 14.7 years old) were similar to those of other countries: the physical QoL score (Physical Component Summary, PCS) was lower compared to the healthy population (PCS = 46.3), whereas the mental QoL score (Mental Component Summary, MCS) was within normal values (MCS = 51.1). Scores did not depend on haemophilia type.

The PCS was primarily influenced by the number of arthropathies (RT showed a PCS = 55.4 without arthropathies vs. 42.1 with ≥ 1 arthropathy, $P < 0.001$), followed by the patients' understanding of inhibitors, haemophilia severity, and eventually patients' compliance.

The MCS was primarily affected by patients' concern regarding personal financial issues (spending) related to haemophilia (RT showed a MCS = 54.2 when not concerned vs. 37.9 when concerned. Within this last group, those with poor knowledge of insurance coverage had lower MCS scores than their peers, $P < 0.001$). Age was the second factor in the whole population, closely followed by patients' understanding of insurance coverage, ability to identify sources of information, haemophilia severity, HIV status, and ability to plan for holiday. All other variables had little or no impact on these scores.

Summary/Conclusion: Haemophilia patients' QoL in Belgium is comparable to that of other countries. Originally, our study highlights modifiable variables influencing QoL, such as patients' compliance and their understanding of haemophilia-related issues, including financial issues. Indeed, these played a major role in mental QoL – a most interesting finding in a time where the cost of clotting factor use challenges most countries' healthcare systems.

We believe that addressing these questions by providing patients with better focused information could significantly improve their QoL.

PO 109

Treatment of acute abdomen resulting from hematoma of the jejunum in severe Haemophilia A

Chalkling AG, Pias SN and Perera F

Hospital Escuela del Litoral, Paysandu, Uruguay

Background: Adequate haemophilia care requires well-coordinated specialist input when diagnosing and treating bleeding episodes.

Aims: We illustrate this with a case presenting with a bleeding episode in an unusual location, easily diagnostically mistaken.

Methods: Presentation: A male patient, 55 years old, weight 54 kg, with a history of tuberculosis with family and personal history of severe Hemophilia A without inhibitors to Factor VIII, and previous episodes of hematuria, hemoptysis and multiple episodes of bleeding in both hip joints leading to musculoskeletal grade IV hemophilic arthropathy, uninfected with blood borne viruses. The patient was admitted to the Emergency Service with epigastric pain conformant with diagnosis of gastritis for which he was treated. Readmitted 12 h after the patient complaining of burning epigastric pain, anorexia, nausea, vomiting, signs of peritoneal irritation and intestinal bleeding. At this stage a Transfusion Medicine specialist consultation was requested. A history of an episode of hematoma of the jejunum, confirmed by imaging studies 2 years previously, was revealed a presumptive clinical diagnosis of hematoma of the bowel loop was subject to confirmation by investigation.

Investigations: Ultrasound revealed a thickened mass in the small bowel loop, with diffuse and regular contours, approximately 11 cm by 3 cm longitudinal axis cross, suggesting a hypogastrium hematoma and moderate amount free fluid in pelvis. Coagulation Tests: APTT: 79. 8 s (VR 24–35) Prothrombin Time Activity 86%, Fibrinogen 816 mg/dl. Complete Blood Count: Hb 14.6 g/dl, Hematocrit 48.6%, WBC 15,000 per mm^3, platelets 213 000 per mm^3.

Treatment: Commercial Factor VIII (Octanate®, Octapharma) loading dose 1000 IU IV bolus and 2000 IU/given by continuous infusion (CI) in the first day was followed by 2000 IU on the second day and 1000 IU every 24 h for a further 5 days.

Results: Clinical remission and CT scan resolution of hematoma. Evolution:

The patient was readmitted with the same symptoms after a week. The treatment course outlined above was repeated with full resolution. He was discharged for further complete investigation of intestinal tract and was kept on a prophylaxis regimen of 1000 IU every 2 days to

minimize the risk of bleeding until perform the invasive study that revealed no evidence of underlying lesions and confirm full resolution. The patient has had no recurrence since 2 years.
Conclusions: Specialist input for haemophilia is crucial if misdiagnosis with possible negative effects is to be avoided. The interface between the admitting ward and the Transfusion Medicine specialist requires improvement and formalization. Although a rare manifestation of hemophilia, jejuminal hematoma has been described (Int J Hematol. 2006 Aug;84(2):166–9, Arch Klin Chir 1908;87: 542 -551) and should be suspected with cases running a course similar to our report.

PO 110

Hemophilia children receiving immune tolerance induction with adjuvant rituximab: 5-year long-term follow-up

Chuansumrit AV[1], Sirachainan N[1], Wongwerawattanakoon P[2], Songdej D[1], Kadegasem P[1] and Sasanakul W[1]
[1]Department of Pediatrics, Faculty of Medicine; [2]Department of Nursing, Faculty of Medicine, Ramathibodi Hospital, Bangkok, Thailand

Background: Immune tolerance induction (ITI) is essentially required for hemophilia patients with inhibitor.
Aims: To evaluate the long-term outcome of hemophilia children receiving low dose ITI.
Methods: Four hemophilia boys with inversion of intron 22 (A 2 cases), large deletion (A 1 case) and stop codon at exon 2 (B 1 case) exhibiting inhibitors were enrolled in the study. Inhibitor was found at 1 year of age in three patients except for one hemophilia A was referred to us at 10 years of age. All patients had high inhibitor titer ranging from 30 to 3400 Bethesda units (BU). The hemophilia B patient had anaphylaxis to prothrombin complex concentrate and factor IX concentrate. ITI was initiated at 10 years of age except for one hemophilia A at 2 years and 10 months. The levels of inhibitor at initiating ITI were 4.5, 16, 17 and 336 BU. Rituximab at the dose of 375 mg/m^2/week for 4–6 doses were given simultaneously with factor concentrate. For hemophilia A patients, factor VIII concentrate at the dose of 100 unit/kg three times per week was given for 6 months followed by 50 unit/kg three times per week for 6 months and then tapered to 50 unit/kg twice per week continuously. For hemophilia B patient, he initially received desensitization to factor IX concentrate in the intensive care unit. However, factor IX concentrate at the dose of 40 unit/kg three times per week was given for 1 month followed by 40 unit/kg twice per week continuously. All patients were monitored for 5 years.
Results: At the first year of ITI, the occurrence of spontaneous bleeding episodes were seldom found. They were responsive to the administration of recombinant activated factor VII (rFVIIa). The anamnestic response of inhibitor was found during the first 4–6 weeks of ITI ranging from 164 to 3000 BU. Three hemophilia A and B patients' inhibitors were gradually decreased to 3, 25 and 20 BU after completing ITI for 1 year. During the follow-up, they exhibited 6.1, 8.5 and 2.7 BU in the second year; 0.3, 0.9 and 9.6 BU in the third year; 0.87, 0 and 6.8 BU in the fourth year; and 0.1, 0 and 7.2 BU in the fifth year of ITI. Although the success of ITI was achieved in two hemophilia A patients with inversion of intron 22 at 3 and 4 years, respectively, the episodes of bleeding were infrequent and additional rFVIIa was seldom required. The hemophilia B patient did not have nephrotic syndrome. One hemophilia A patient with large deletion failed to ITI since he exhibited high inhibitor of 1040 BU at 6 months of ITI. Therefore, ITI was stopped and he was switched to prophylaxis treatment of rFVIIa at the dose of 90 mcg/kg three times per week for 1 year and two times per week for the subsequent 4 years. He tolerated well with prophylaxis and seldom exhibited spontaneous bleeding episodes.
Conclusion: Low dose ITI with the simultaneous adjuvant rituximab administration was helpful in hemophilia children with inhibitor.

PO 111

Challenging diagnosis of haemophilia

De luca M[1], Calò Carducci FI[1], Bicocchi MP[2], Acquila M[2], Coletti V[1], Persano G[1], Cirillo M[1], Soldati M[1], D'Argenio P[1] and Luciani M[1]
[1]Bambino Gesù Children's Hospital, Rome; [2]Giannina Gaslini Children's Hospital, Genoa, Italy

Background: Haemophilia A (HA) is a rare X-linked recessive bleeding disorder caused by deficiency or functional defects in coagulation factor VIII (FVIII).
Aims: Here we report two cases of challenging diagnosis of HA because of unusual presentation.
Results: The first case is a 10-month-old female, admitted to our hospital because of a neck mass appeared within the previous 24 h, who had a past medical history consistent with recurrent spontaneous haematomas but no family history of bleeding disorders. During hospitalization, blood tests revealed aPTT prolongation (61.5 s) and a FVIII level below 1%. The levels of von Willebrand factor antigen and ristocetin cofactor activity were within the normal range. Further laboratory tests showed absence of FVIII inhibitors and lupus anticoagulant antibodies. Ultrasonography and contrast enhanced computer tomography were performed to investigate the neck mass and revealed a solid lesion (approximately 44 × 47 × 23 mm) extended to the infraclavicular and pectoral regions. In the suspicion of a lymphoproliferative disease, the patient underwent surgical excision of the lesion. Histology of the lesion surprisingly revealed a haematoma. Chromosomal analysis showed a normal female karyotype and a mutation into the FVIII intron 22 associated with a skewed X chromosome inactivation. This mutation, present in the proposita and undetected in the peripheral blood DNA of her mother and her father, could be the result of a *de novo* mutation. The patient started prophylactic treatment with intravenous recombinant factor VIII, with progressive normalisation of aPTT.
The second case is a male neonate, born by vacuum-assisted vaginal delivery, whose mother had a thrombophilic condition and was prophylactically treated during pregnancy with antiplatelet agents and low molecular weight heparin. Family history was otherwise non significant. On the first day of life, the child presented with petechiae and gastric bleeding and received plasma and platelet transfusion. On the third day, he developed generalized seizures. The brain ultrasonography was suspicious of an aneurysm of vein of Galen and hydrocephalus. Brain MRI showed an anomaly, suspicious of a vascular malformation, localised on the quadrigeminal cistern that caused compression of the cerebellum, anterior displacement of the brainstem and consequent hydrocephalus. Blood tests revealed severe anaemia and prolonged aPTT. Due to worsening neurological symptoms, diagnostic imaging was repeated and showed initial herniation of the cerebellar tonsils into the foramen magnum. The dosage of coagulation factors revealed a severe deficiency of FVIII. Given the suspicion of haemorrhagic diathesis, radiological images were re-evaluated; vascular anomalies were excluded and the diagnosis of haematoma was made. Molecular studies were performed as described before, and showed a rearrangement of the FVIII gene involving intron 22. Because of the obstructive hydrocephalus, the child underwent surgical placement of a ventriculo-peritoneal shunt and replacement therapy with intravenous recombinant factor VIII was started. In the following days, his general and neurological conditions have significantly improved.
Conclusion: The HA diagnosis can be challenging. Lack of family history, difficulties in detecting haematomas by imaging techniques, female gender and neonatal age represent misleading factors that can delay the diagnosis.

PO 112

Management of dental invasive procedures in hemophilia A/B (HA/HB) and von willebrand disease (VWD) outpatients: experience of a single center

De Padua V[1], Santoro C[2], Gaglioti D[1], Bosco R[1], Riva F[1], Baldacci E[2], Mercanti C[2], Parlanti L[2] and Mazzucconi MG[2]
[1]George Eastman Hospital Rome; [2]Hematology Sapienza University of Rome, Rome, Italy

Background: Dental procedures in Hereditary Bleeding Disorders (HBD) patients can be complicated by excessive bleeding. Replacement prophylactic therapy, and local measures, dramatically reduce the risk of complications in these surgeries. Moreover, self-infusion and home-treatment reduce therapy cost. Aim. To describe the dental procedures performed in a group of HA/B and VWD outpatients utilizing systemic prophylactic therapy and local measures.
